Since there is no surface or zone to identify the channel inlet or outlet, the inlet flow direction of the group is used to determine the channel inlet. Therefore, It is very important to specify the flow direction correctly.

- c. Select the wall boundary zones which correspond to the reacting channels in the group under **Channel Walls in Group**.
 - d. Select the group material from the **Material** drop-down list. You can choose any mixture material available in the case as a group material.
 - e. You can import a CHEMKIN mechanism using the **Import CHEMKIN Mechanism...** button. For details see *Importing a Volumetric Kinetic Mechanism in CHEMKIN Format* (p. 883).
 - f. Under **Group Inputs**, specify the **Inlet Temperature** and **Inlet Flow Rate** for each channel and the **Inlet Pressure** of the channels in the group.
 - g. After selecting the group material, input the inlet mass fractions of the group under **Inlet Composition of Group**.
3. Click the **Apply** button to set the channel boundary conditions for all the channels selected.
 4. Under the **Plots** tab, click the **Display Reacting Channel Variables** button to open the **Reacting channel 2D Curves** dialog box (*Figure 16.17* (p. 899)). For information about the plotting of reacting channel model variables, see *Postprocessing for Reacting Channel Model Calculations* (p. 899).

Modeling Curvilinear Reacting Channels

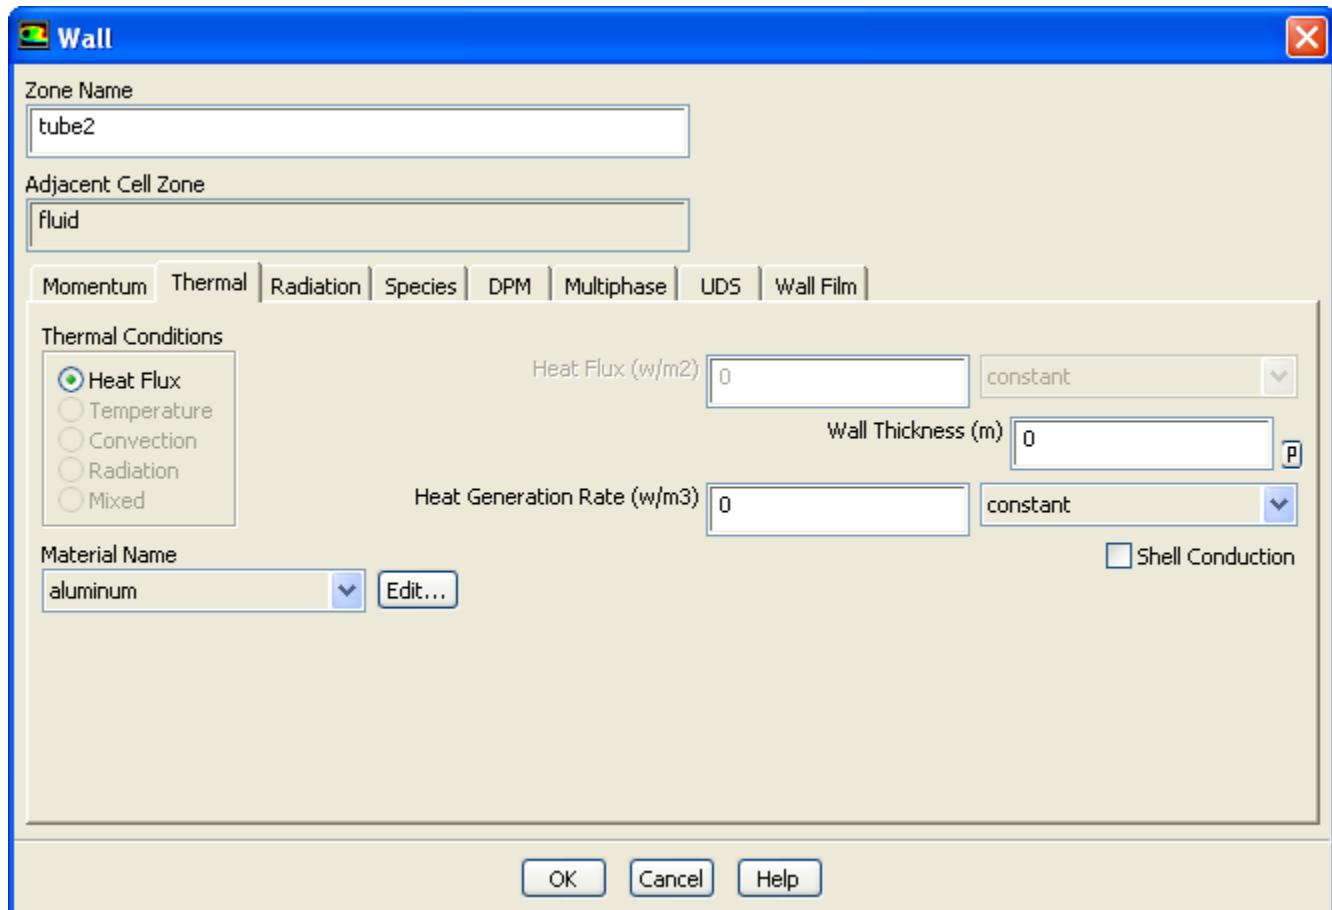

In the reacting channel model, the two ends of a channel are identified as the inlet and the outlet based on the inputs provided for the inlet flow direction of the group. However, for some special channel configurations, such as U-tubes, it is not possible to identify the inlet/outlet of the channel based on the information of the inlet flow direction. For such cases, an additional input is required to differentiate between the end points of the channel as inlet or outlet. The additional input is to provide the centroid coordinates of the inlet of the U shaped channel. Therefore, for U-tube configurations, after setting up the reacting channel model following the earlier steps in this section, it is required to use the following text user interface commands to set the inlet and outlets correctly:

```
/define/models/species> reacting-channel-model-options  
Are any of the channels a U-tube configuration? [no] yes  
Is wall tube1 a U-tube configuration? [no] yes  
Enter the coordinates of the center of the inlet for wall tube1  
X coordinate [0] 0.01  
Y coordinate [0] 0  
Z coordinate [0] 0
```

Where tube1 is a reacting channel wall having a U shape. You will be asked the same questions for each of the existing reacting channel walls.

16.5.3. Boundary Conditions for Channel Walls

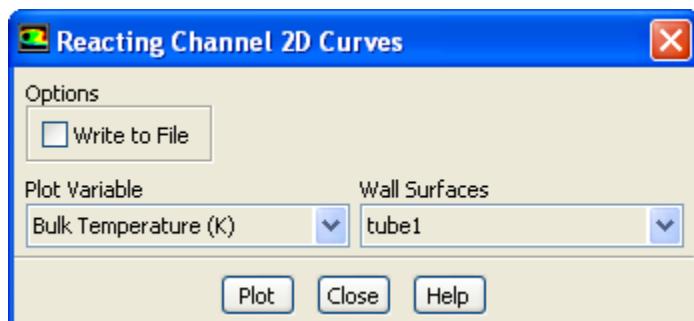

In the ANSYS FLUENT wall boundary conditions dialog box, the wall surfaces that you selected as channel walls in the **Reacting Channel Model** dialog box will have zero heat flux boundary conditions, which are disabled as shown in *Wall Surface Reactions and Chemical Vapor Deposition* (p. 886).

Figure 16.16 The Wall Boundary Condition Dialog Box for the Reacting Channel Model

The heat flux at the channel walls is calculated internally through the coupling of the reacting channel model with the outer flow as described in [Reacting Channel Model](#) in the [Theory Guide](#). For all other wall surfaces, which are not channel walls, all boundary conditions as described in [Wall Boundary Conditions](#) (p. 313) are applicable.

16.5.4. Postprocessing for Reacting Channel Model Calculations

You can generate the X-Y plot of the channel variables using the **Reacting Channel 2D Curves** dialog box. Select the **Plot Variable** and the **Wall Surface** you would like to plot or write to a file (when the **Write to File** option is enabled).

Figure 16.17 Reacting Channel 2D Curves Dialog Box

You can create X-Y plots for the following reacting channel variables:

- Bulk mean temperature of the channel
- Wall temperature of the channel
- Nusselt Number (for the channel wall on the channel side)
- Wall heat flux through the channel walls
- Velocity inside the channel
- Mass fraction of the species inside the channel

Chapter 17: Modeling Non-Premixed Combustion

In non-premixed combustion, fuel and oxidizer enter the reaction zone in distinct streams. This is in contrast to premixed systems, in which reactants are mixed at the molecular level before burning. Examples of non-premixed combustion include pulverized coal furnaces, diesel internal-combustion engines and pool fires.

Under certain assumptions, the thermochemistry can be reduced to a single parameter: the mixture fraction. The mixture fraction, denoted by f , is the mass fraction that originated from the fuel stream. In other words, it is the local mass fraction of burnt and unburnt fuel stream elements (C, H, etc.) in all the species (CO_2 , H_2O , O_2 , etc.). The approach is elegant because atomic elements are conserved in chemical reactions. In turn, the mixture fraction is a conserved scalar quantity, and therefore its governing transport equation does not have a source term. Combustion is simplified to a mixing problem, and the difficulties associated with closing non-linear mean reaction rates are avoided. Once mixed, the chemistry can be modeled as being in chemical equilibrium with the Equilibrium model, being near chemical equilibrium with the Steady Laminar Flamelet model, or significantly departing from chemical equilibrium with the Unsteady Laminar Flamelet model.

The non-premixed combustion model is presented in the following sections:

- 17.1. Steps in Using the Non-Premixed Model
- 17.2. Setting Up the Equilibrium Chemistry Model
- 17.3. Setting Up the Steady and Unsteady Laminar Flamelet Models
- 17.4. Defining the Stream Compositions
- 17.5. Setting Up Control Parameters
- 17.6. Calculating the Flamelets
- 17.7. Calculating the Look-Up Tables
- 17.8. Defining Non-Premixed Boundary Conditions
- 17.9. Defining Non-Premixed Physical Properties
- 17.10. Solution Strategies for Non-Premixed Modeling
- 17.11. Postprocessing the Non-Premixed Model Results

For theoretical background on the non-premixed combustion model, see "Non-Premixed Combustion" in the [Theory Guide](#).

17.1. Steps in Using the Non-Premixed Model

A description of the user inputs for the non-premixed model is provided in the sections that follow.

- 17.1.1. Preliminaries
- 17.1.2. Defining the Problem Type
- 17.1.3. Overview of the Problem Setup Procedure

17.1.1. Preliminaries

Before turning on the non-premixed combustion model, you must enable turbulence calculations in the [Viscous Model Dialog Box](#) (p. 1778).

◆ Models →  Viscous → Edit...

If your model is non-adiabatic, you should also enable heat transfer (and radiation, if required).

◆ Models →  Energy → Edit...

◆ Models →  Radiation → Edit...

Figure 8.7: "Reacting Systems Requiring Non-Adiabatic Non-Premixed Model Approach" in the Theory Guide illustrates the types of problems that must be treated as non-adiabatic.

17.1.2. Defining the Problem Type

Your first task is to define the type of reaction system and reaction model that you intend to use. This includes selection of the following options:

- Non-premixed or partially premixed model option (see [Modeling Partially Premixed Combustion \(p. 969\)](#)).
- Equilibrium chemistry model, steady laminar flamelet model, unsteady laminar flamelet model, or diesel unsteady flamelet.
- Adiabatic or non-adiabatic modeling options (see [Non-Adiabatic Extensions of the Non-Premixed Model](#) in the [Theory Guide](#)).
- Addition of a secondary stream (equilibrium model only).
- Empirically defined fuel and/or secondary stream composition (equilibrium model only).

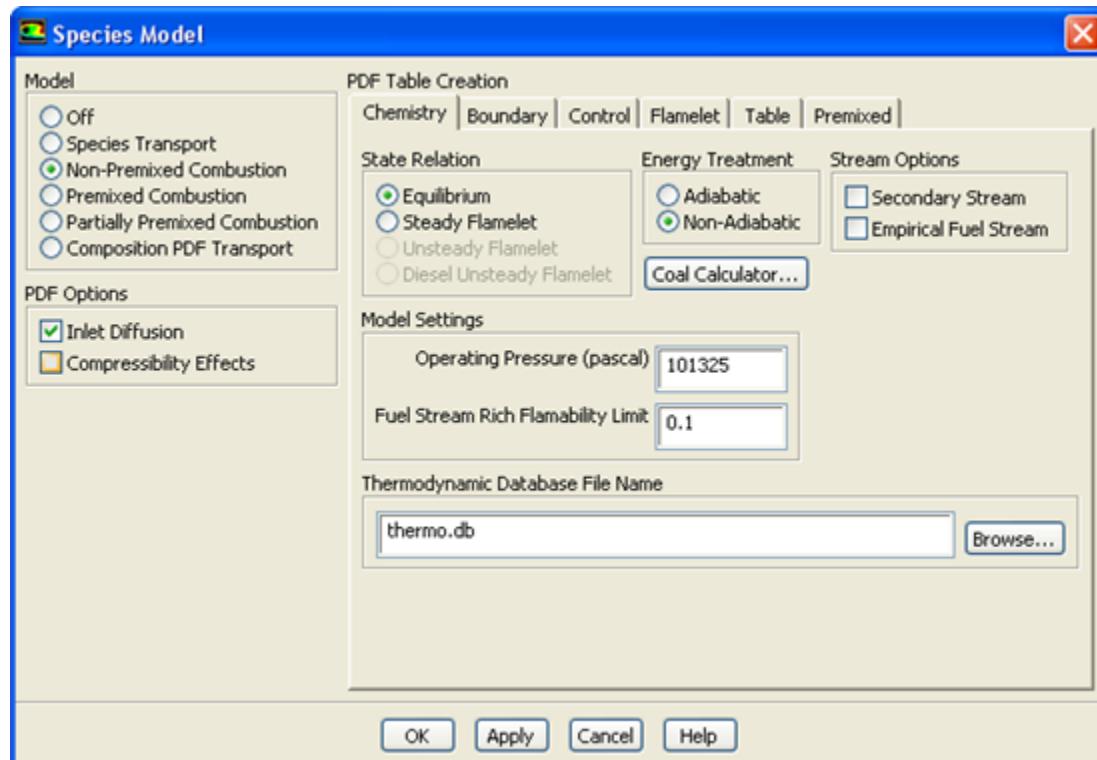

You can make these model selections using the **Species Model** dialog box ([Figure 17.6 \(p. 906\)](#)).

◆ Models →  Species → Edit...

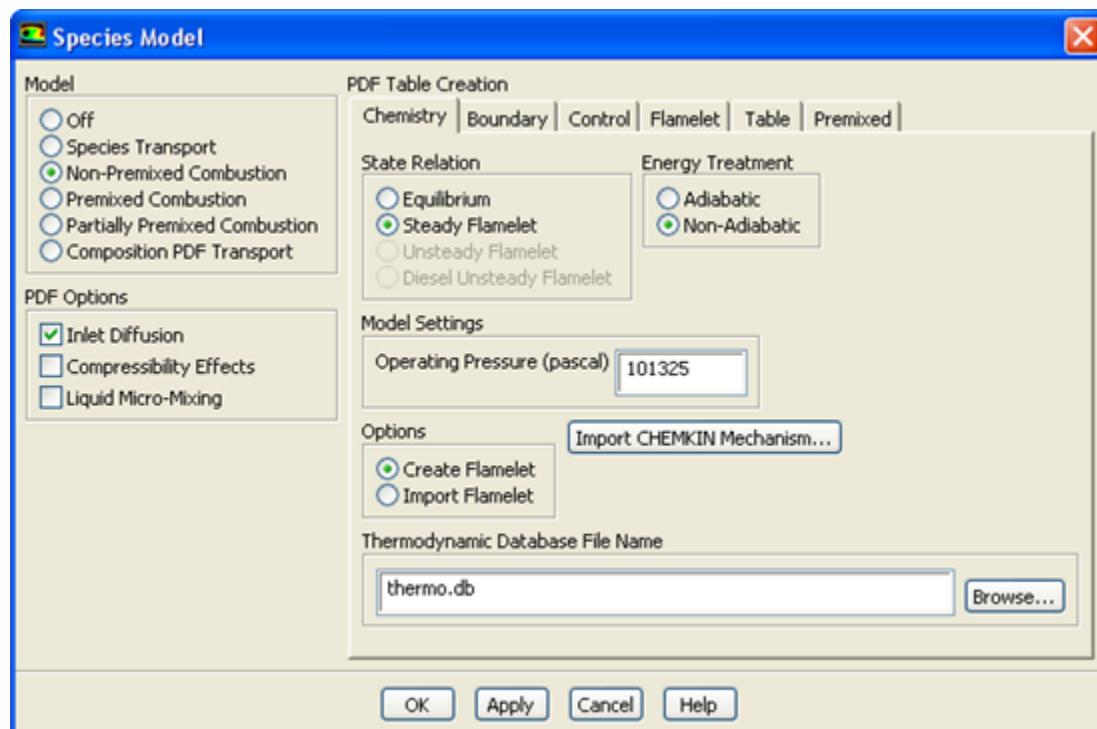

17.1.3. Overview of the Problem Setup Procedure

For a single-mixture-fraction problem, you will perform the following steps:

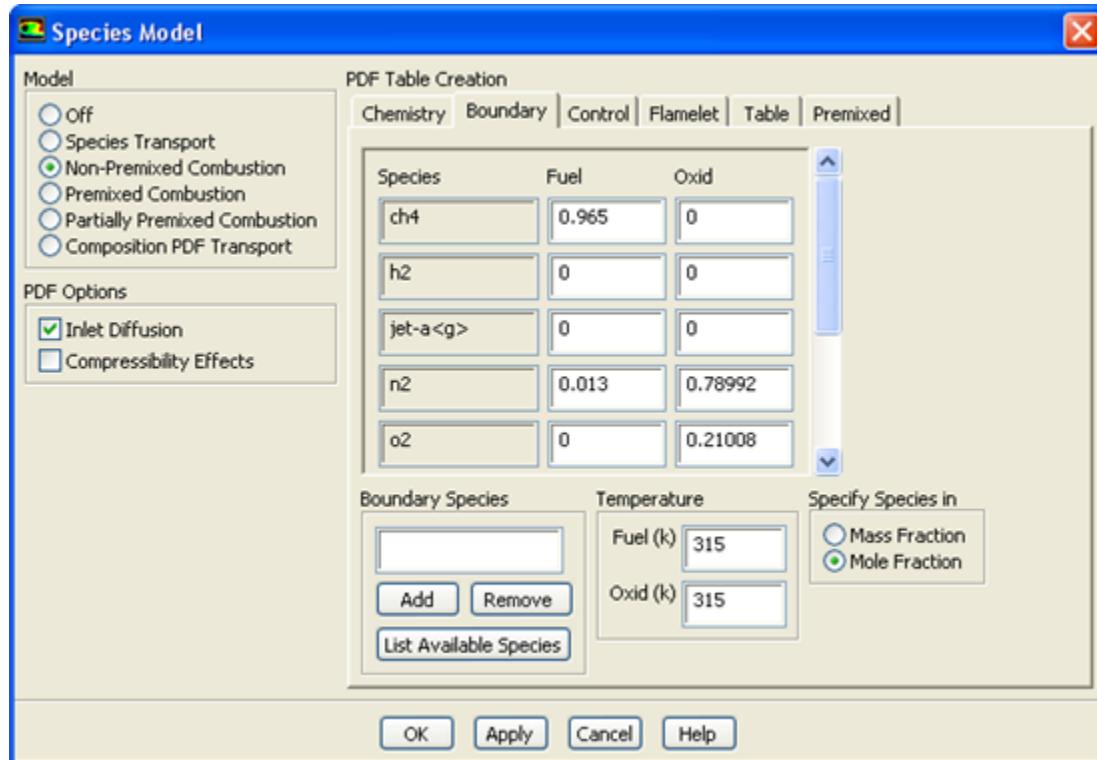

1. Choose the chemical description of the system: equilibrium, steady flamelet, unsteady flamelet, or diesel unsteady flamelet ([Figure 17.1 \(p. 903\)](#)).
2. Indicate whether the problem is adiabatic or non-adiabatic.

Figure 17.1 Defining Equilibrium Chemistry

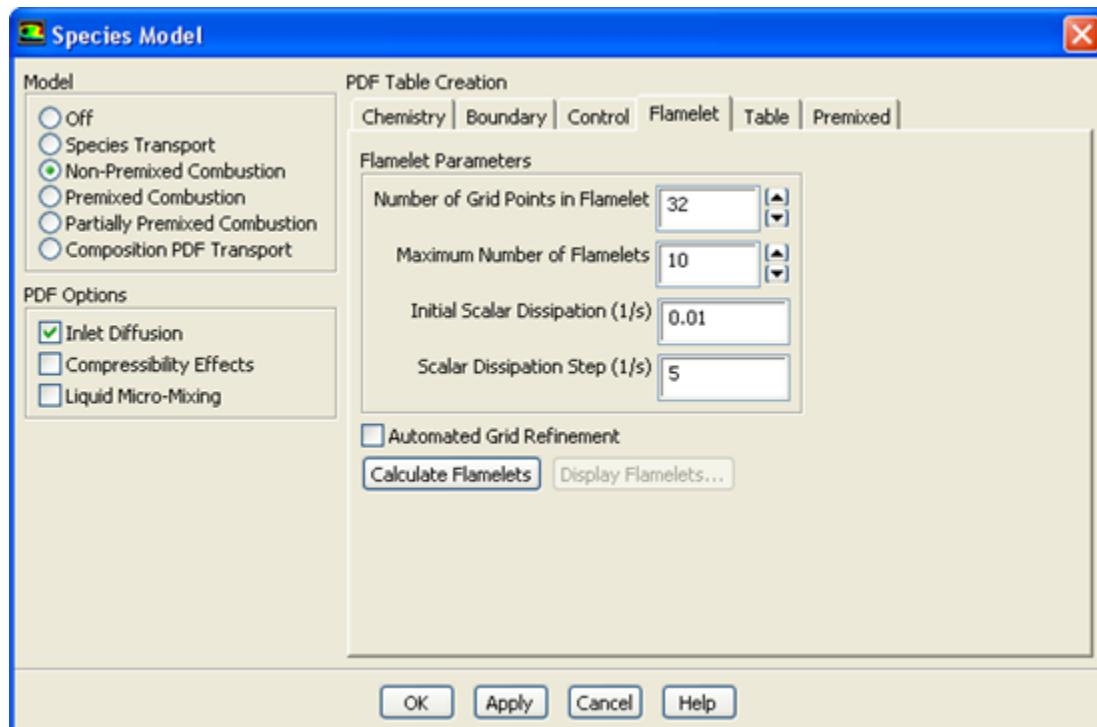

3. (steady laminar flamelet model only) Import a flamelet file or appropriate CHEMKIN mechanism file if generating flamelets ([Figure 17.2 \(p. 903\)](#)).

Figure 17.2 Defining Steady Laminar Flamelet Chemistry

4. Define the chemical boundary species to be considered for the streams in the reacting system model. Note that this step is not relevant in the case of flamelet import ([Figure 17.3 \(p. 904\)](#)).

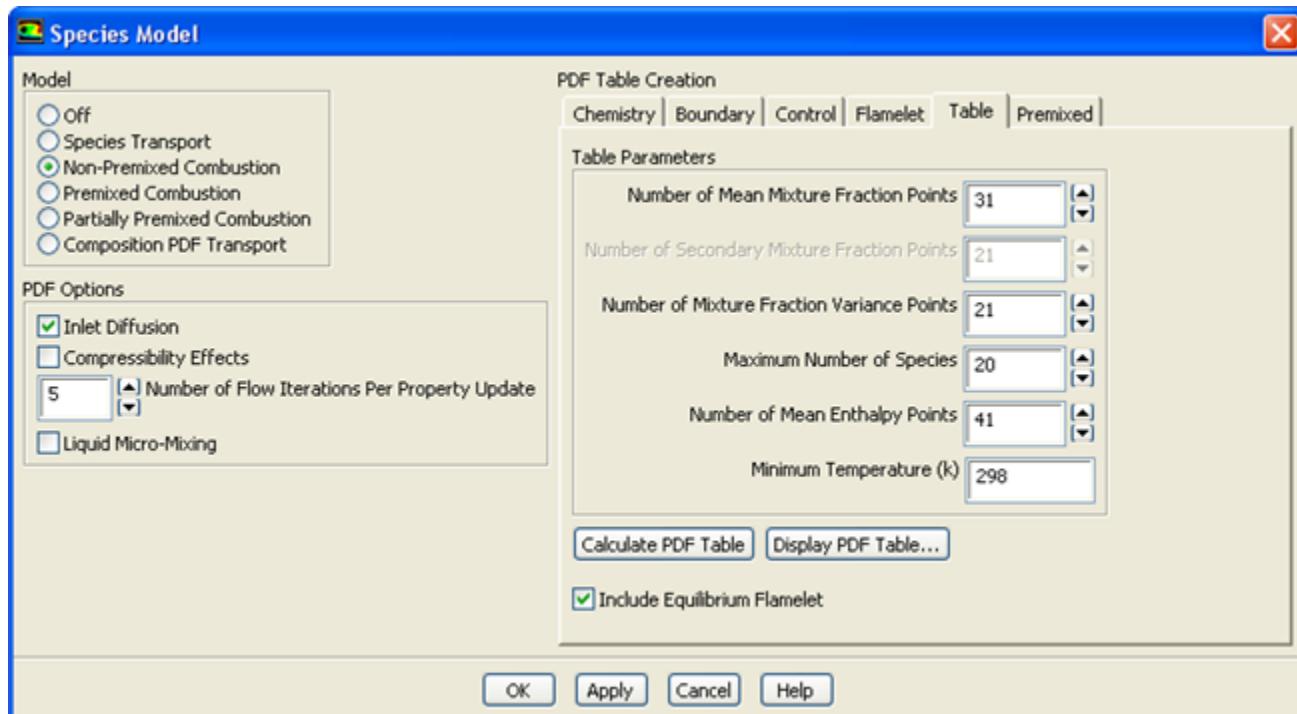

Figure 17.3 Defining Chemical Boundary Species

5. (steady laminar flamelet model only) If you are generating flamelets, compute the flamelet state relationships of species mass fractions, density, and temperature as a function of mixture fraction and scalar dissipation ([Figure 17.4 \(p. 904\)](#)).

Figure 17.4 Calculating Steady Flamelets

- Compute the final chemistry look-up table, containing mean values of species fractions, density, and temperature as a function of mean mixture fraction, mixture fraction variance, and possibly enthalpy and scalar dissipation. The contents of this look-up table will reflect your preceding inputs describing the turbulent reacting system ([Figure 17.5 \(p. 905\)](#)).

Figure 17.5 Calculating the Chemistry Look-Up Table

The look-up table is the stored result of the integration of [Equation 8–16](#) (or [Equation 8–24](#)) and [Equation 8–18](#) (in the [Theory Guide](#)). The look-up table will be used in ANSYS FLUENT to determine mean species mass fractions, density, and temperature from the values of mean mixture fraction (\bar{f}), mixture fraction variance (\bar{f}^2), and possibly mean enthalpy (\bar{H}) and mean scalar dissipation ($\bar{\chi}$) as they are computed during the ANSYS FLUENT calculation of the reacting flow. See [Look-Up Tables for Adiabatic Systems](#) and [Figure 8.8: "Visual Representation of a Look-Up Table for the Scalar \(Mean Value of Mass Fractions, Density, or Temperature \) as a Function of Mean Mixture Fraction and Mixture Fraction Variance in Adiabatic Single-Mixture-Fraction Systems"](#) and [Figure 8.10: "Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems"](#) in the [Theory Guide](#).

For a problem that includes a secondary stream (and, therefore, a second mixture fraction), you will perform the first two steps listed above for the single-mixture-fraction approach and then prepare a look-up table of instantaneous properties using [Equation 8–12](#) or [Equation 8–14](#) in the [Theory Guide](#).

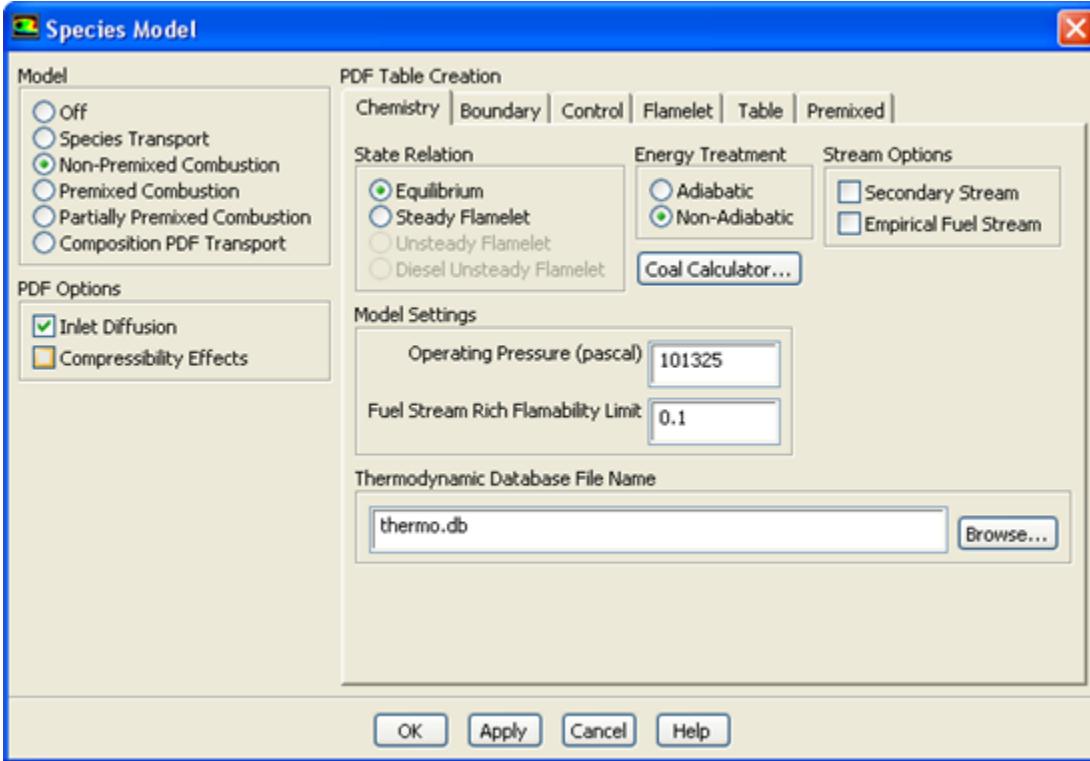

17.2. Setting Up the Equilibrium Chemistry Model

In the equilibrium chemistry model, the concentrations of species of interest are determined from the mixture fraction using the assumption of chemical equilibrium (see [Non-Premixed Combustion and Mixture Fraction Theory](#) in the [Theory Guide](#)). With this model, you can include the effects of intermediate species and dissociation reactions, producing more realistic predictions of flame temperatures than the Eddy-Dissipation model. When you choose the equilibrium chemistry option, you will have the opportunity to use the rich flammability limit (RFL) option.

To enable the equilibrium chemistry model

1. Select **Non-Premixed Combustion** in the **Species Model** dialog box.
2. Select **Equilibrium** in the **Chemistry** tab of the **Species Model** dialog box.

Figure 17.6 The Species Model Dialog Box (Chemistry Tab)

For additional information, please see the following sections:

- 17.2.1. Choosing Adiabatic or Non-Adiabatic Options
- 17.2.2. Specifying the Operating Pressure for the System
- 17.2.3. Enabling a Secondary Inlet Stream
- 17.2.4. Choosing to Define the Fuel Stream(s) Empirically
- 17.2.5. Enabling the Rich Flammability Limit (RFL) Option

17.2.1. Choosing Adiabatic or Non-Adiabatic Options

You should use the non-adiabatic modeling option if your problem definition in ANSYS FLUENT will include one or more of the following:

- radiation or wall heat transfer
- multiple fuel inlets at different temperatures
- multiple oxidant inlets at different temperatures
- liquid fuel, coal particles, and/or heat transfer to inert particles

Note that the adiabatic model is a simpler model involving a two-dimensional look-up table in which scalars depend only on \overline{f} and $\overline{f'^2}$ (or on f_{fuel} and p_{sec}). If your model is defined as adiabatic, you will not need to solve the energy equation in ANSYS FLUENT and the system temperature will be determined directly from the mixture fraction and the fuel and oxidant inlet temperatures. The non-adiabatic

batic case will be more complex and more time-consuming to compute, requiring the generation of three-dimensional look-up tables. However, the non-adiabatic model option allows you to include the types of reacting systems described above.

Select **Adiabatic** or **Non-Adiabatic** in the **Chemistry** tab of the **Species Model** dialog box.

17.2.2. Specifying the Operating Pressure for the System

The system **Operating Pressure** is used to calculate density using the ideal gas law. For non-adiabatic simulations, the **Compressibility Effects** under **PDF Options** can be enabled to account for cases where substantial pressure changes occur in time and/or space. In such cases it is assumed that the species mass fractions do not change with pressure, and the density is calculated as

$$\bar{\rho} = \rho_{op} \frac{\bar{p}}{p_{op}} \quad (17-1)$$

where ρ_{op} is the density at the specified **Operating Pressure** (p_{op}), and \bar{p} is the local mean pressure in an ANSYS FLUENT cell.

When the **Compressibility Effects** option is enabled, the flow operating pressure (set in the **Operating Conditions** dialog box) can differ from the Non-Premixed model operating pressure. To distinguish this difference, the **Operating Pressure** name tag in the **Species Model** dialog box changes to **Equilibrium Operating Pressure** when the compressibility effects option is enabled.

See *Solution Strategies for Non-Premixed Modeling* (p. 949) for details about enabling compressibility effects.

17.2.3. Enabling a Secondary Inlet Stream

If you are modeling a system consisting of a single fuel and a single oxidizer stream, you do not need to enable a secondary stream in your PDF calculation. As discussed in [Definition of the Mixture Fraction](#) in the [Theory Guide](#), a secondary stream should be enabled if your PDF reaction model will include any of the following:

- two dissimilar gaseous fuel streams
 - In these simulations, the fuel stream defines one of the fuels and the secondary stream defines the second fuel.
- mixed fuel systems of dissimilar gaseous and liquid fuel
 - In these simulations, the fuel stream defines the gaseous fuel and the secondary stream defines the liquid fuel (or vice versa).
- mixed fuel systems of dissimilar gaseous and coal fuels
 - In these simulations, you can use the fuel stream or the secondary stream to define either the coal or the gaseous fuel. See [Modeling Coal Combustion Using the Non-Premixed Model](#) (p. 917) regarding coal combustion simulations with the non-premixed combustion model.
- mixed fuel systems of coal and liquid fuel
 - In these simulations, you can use the fuel stream or the secondary stream to define either the coal or the liquid fuel. See [Modeling Coal Combustion Using the Non-Premixed Model](#) (p. 917) regarding coal combustion simulations with the non-premixed combustion model.
- coal combustion

- Coal combustion can be more accurately modeled by using a secondary stream to track the distinct volatile and char off-gases. The fuel stream must define the char and the secondary stream must define the volatile components of the coal. See [Modeling Coal Combustion Using the Non-Premixed Model](#) (p. 917) regarding coal combustion simulations with the non-premixed combustion model.
- a single fuel with two dissimilar oxidizer streams
 - In these simulations, the fuel stream defines the fuel, the oxidizer stream defines one of the oxidizers, and the secondary stream defines the second oxidizer.

To include a secondary stream in your model, turn on the **Secondary Stream** option under **Stream Options** in the **Chemistry** tab.

Important

Using a secondary stream can substantially increase the calculation time for your simulation since the multi-dimensional PDF integrations are performed at run-time. Alternatively, ANSYS FLUENT can perform a full tabulation of the PDF integrations, as detailed in [Full Tabulation of the Two-Mixture-Fraction Model](#) (p. 936).

17.2.4. Choosing to Define the Fuel Stream(s) Empirically

The empirical fuel option provides an alternative method for defining the composition of the fuel or secondary stream when the individual species components of the fuel are unknown. In other words, you will define the elemental fraction *not* the individual species. When this option is disabled, you will define the chemical species which are present in each stream and the mass or mole fraction of each species, as described in [Defining the Stream Compositions](#) (p. 913). The option for defining an empirical fuel stream is particularly useful for coal combustion simulations (see [Modeling Coal Combustion Using the Non-Premixed Model](#) (p. 917)) or for simulations involving other complex hydrocarbon mixtures.

To define a fuel or secondary stream empirically

1. Turn on the **Empirical Fuel Stream** option under **Stream Options** in the **Chemistry** tab of the **Species Model** dialog box. If you have a secondary stream, enable the **Empirical Secondary Stream** option, or both as appropriate.
2. Specify the appropriate lower heating value (e.g. **Empirical Fuel Lower Caloric Value**, **Empirical Secondary Lower Caloric Value**), specific heat (**Empirical Fuel Specific Heat**, **Empirical Secondary Specific Heat**), and molecular weight (**Empirical Fuel Molecular Weight**, **Empirical Secondary Molecular Weight**) for each empirically defined stream.

Important

The empirical definition option is available only with the full equilibrium chemistry model. It cannot be used with the rich flammability limit (RFL) option or the steady and unsteady laminar flamelet models, since equilibrium calculations are required for the determination of the fuel composition.

Important

The empirical fuel and secondary molecular weights are only required if your empirical streams are entering the domain via an inlet boundary, or if you are using the partially premixed model. If you are using the non-premixed model and the empirically defined streams originate from the dispersed phase (for example, if you are modeling coal or liquid fuel combustion) the molecular weights are not required for the computation.

17.2.5. Enabling the Rich Flammability Limit (RFL) Option

You can define a rich limit on the mixture fraction when the equilibrium chemistry option is used. Input of the rich limit is accomplished by specifying a value of the **Rich Flammability Limit** for the appropriate **Fuel Stream**, **Secondary Stream**, or both. You will not be allowed to specify the **Rich Flammability Limit** if you have used the empirical definition option for fuel composition.

ANSYS FLUENT will compute the composition at the rich limit using equilibrium. For mixture fraction values above this limit, ANSYS FLUENT will suspend the equilibrium chemistry calculation and will compute the composition based on mixing, but not burning, of the fuel with the composition at the rich limit. A value of 1.0 for the rich limit implies that equilibrium calculations will be performed over the full range of mixture fraction. When you use a rich limit that is less than 1.0, equilibrium calculations are suspended whenever f_fuel or f_{sec} exceeds the limit. This RFL model is often more accurate than the assumption of chemical equilibrium for rich mixtures, and also avoids complex equilibrium calculations, speeding up the preparation of the look-up tables. An RFL value of approximately twice the stoichiometric mixture fraction is appropriate.

For the **Secondary Stream**, the rich flammability limit controls the equilibrium calculation for the secondary mixture fraction. If your secondary stream is not a fuel, you should use an RFL value of 1. A value of 1.0 for the rich limit implies that equilibrium calculations will be performed over the full range of mixture fraction. When you input a rich limit that is less than 1.0, equilibrium calculations are suspended whenever f_{sec} exceeds the limit. (Note that it is the secondary mixture fraction f_{sec} and not the partial fraction p_{sec} that is used here.)

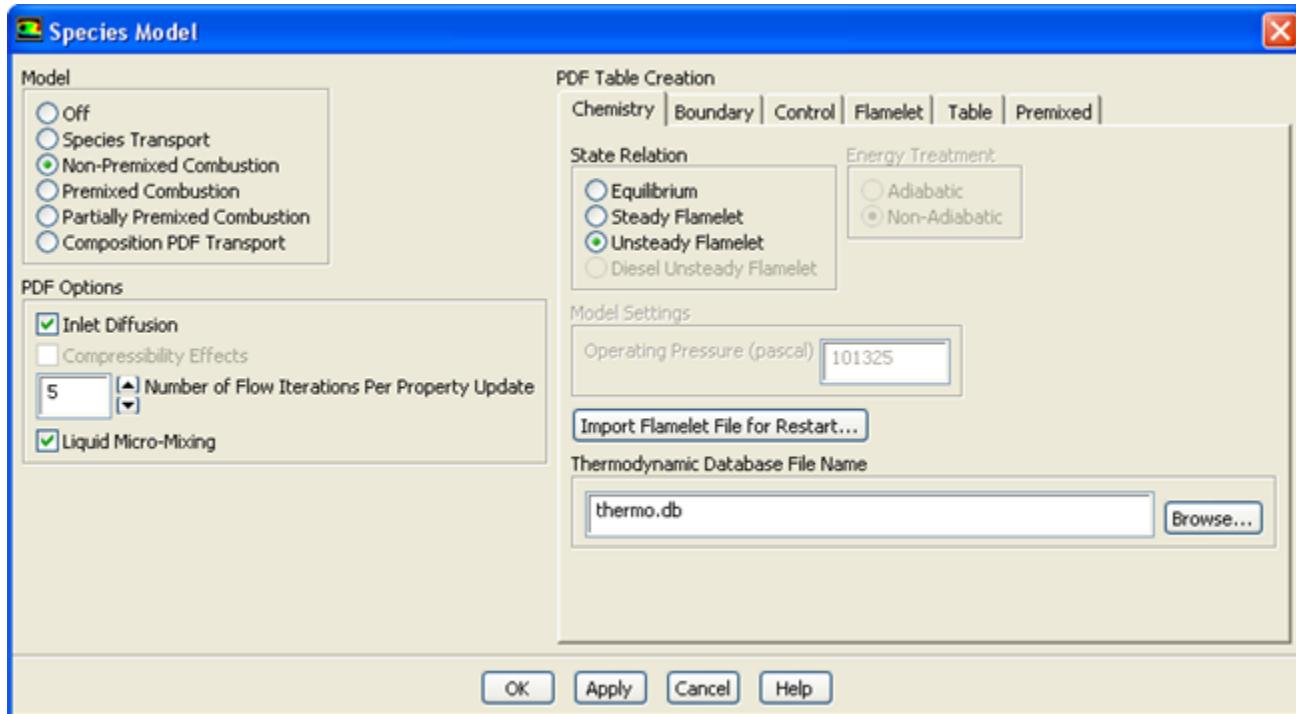

Important

Experimental studies and reviews [11] (p. 2367), [80] (p. 2371) have shown that although the fuel-lean flame region approximates thermodynamic equilibrium, non-equilibrium kinetics will prevail under fuel-rich conditions. Therefore, for non-empirically defined fuels, the RFL model is strongly recommended.

17.3. Setting Up the Steady and Unsteady Laminar Flamelet Models

To enable the laminar flamelet models

1. Select **Non-Premixed Combustion** in the **Species Model** dialog box.
2. Select **Steady Flamelet** or **Unsteady Flamelet** in the **Chemistry** tab of the **Species Model** dialog box. See [Using the Unsteady Laminar Flamelet Model](#) (p. 912).

Figure 17.7 The Chemistry Tab for the Unsteady Flamelet Model

For additional information, please see the following sections:

- 17.3.1. Choosing Adiabatic or Non-Adiabatic Options
- 17.3.2. Specifying the Operating Pressure for the System
- 17.3.3. Specifying a Chemical Mechanism File for Flamelet Generation
- 17.3.4. Importing a Flamelet
- 17.3.5. Using the Unsteady Laminar Flamelet Model
- 17.3.6. Using the Diesel Unsteady Laminar Flamelet Model

17.3.1. Choosing Adiabatic or Non-Adiabatic Options

Select **Adiabatic** or **Non-Adiabatic** in the **Chemistry** tab of the **Species Model** dialog box. See the discussion in [Choosing Adiabatic or Non-Adiabatic Options \(p. 906\)](#) about the two options.

17.3.2. Specifying the Operating Pressure for the System

The system **Operating Pressure** is used to calculate density using the ideal gas law. When the **Compressibility Effects** option is enabled, the name **Operating Pressure** is changed to **Equilibrium Operating Pressure** since the non-premixed combustion model operating pressure can differ from the flow operating pressure. [Specifying the Operating Pressure for the System \(p. 907\)](#) provides more information about this value.

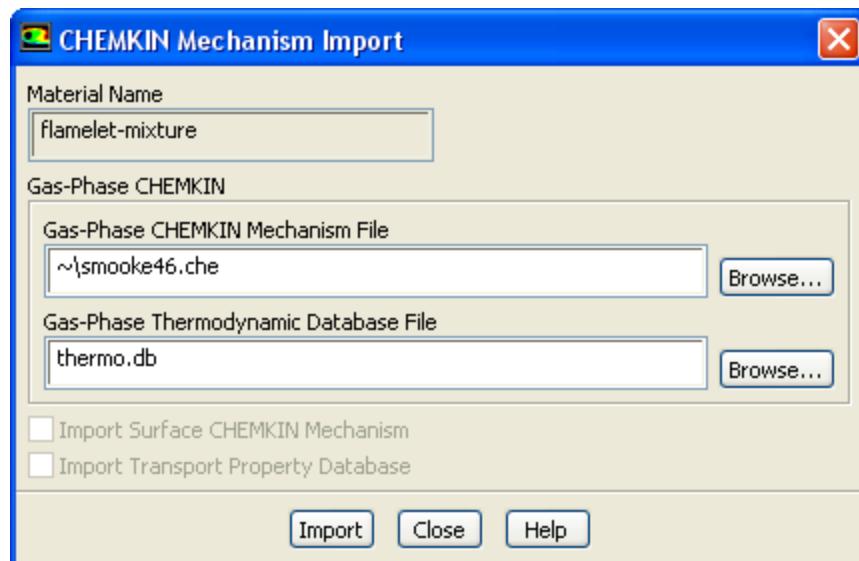

You can use the steady or unsteady laminar flamelet model for reactions in liquid systems. To do so, enable **Liquid Micro-Mixing** under **PDF Options**. The **Liquid Micro-Mixing** option is discussed in detail in [Liquid Reactions in the Theory Guide](#).

17.3.3. Specifying a Chemical Mechanism File for Flamelet Generation

If you are generating a flamelet file yourself, you will need to read in the chemical kinetic mechanism and thermodynamic data. The mechanism and thermodynamic data must be in CHEMKIN format [41] (p. 2369).

To read in a CHEMKIN mechanism, select the **Create Flamelet** option in the **Chemistry** tab of the **Species Model** dialog box and click the **Import CHEMKIN Mechanism...** button. When you click this button, the **CHEMKIN Mechanism Import** dialog box (*Figure 17.8 (p. 911)*) will open. In the **CHEMKIN Mechanism Import** dialog box, enter the path to the CHEMKIN file to be read under **Gas-Phase CHEMKIN Mechanism File** and specify the location of the thermodynamic database under **Gas-Phase Thermodynamic Database File**. Alternatively, you can click the appropriate **Browse...** button to open *The Select File Dialog Box* (p. 33), or simply use the default thermo.db which is already provided.

Figure 17.8 The Laminar Flamelet CHEMKIN Mechanism Import Dialog Box

Click **Import** in the **CHEMKIN Mechanism Import** dialog box to read the specified files into ANSYS FLUENT. Note that the import is limited to mechanisms with 300 or fewer species and 1500 or fewer reactions.

17.3.4. Importing a Flamelet

To import an existing flamelet file

1. Select the **Import Flamelet** option in the **Chemistry** tab of the **Species Model** dialog box.
2. (steady flamelet only) Select either **Standard**, **Oppdif** or **CFX-RIF** format under **File Type**.
3. (steady flamelet only) If you selected **Oppdif** as the **File Type**, choose a **Mixture Fraction Method**. Select **Drake** if you want to calculate the mixture fraction using carbon and hydrogen elements. Select **Bilger** to calculate the mixture fraction using hydrocarbon formula. Select **Nitrogen** to calculate the mixture fraction in terms of nitrogen species.
4. (steady flamelet only) If you selected the **Oppdif File Type**, you have a choice of importing **Single** or **Multiple** OPPDIF files under **Oppdif Flamelet Type**.
5. Click the **Import Flamelet File...** button. In *The Select File Dialog Box* (p. 33), select the file (for a single flamelet) or files (for multiple flamelets) to be read in to ANSYS FLUENT.

After you have completed this step, you can skip ahead to the **Table** tab of the **Species Model** dialog box (see [Calculating the Look-Up Tables \(p. 933\)](#)).

17.3.5. Using the Unsteady Laminar Flamelet Model

The unsteady laminar flamelet model can only be enabled from a valid steady-state, steady laminar flamelet solution. When enabled, the unsteady laminar flamelet model will change this case to unsteady and post-process a marker probability equation on the frozen flow field. You should hence ensure that the starting steady-state, steady laminar flamelet solution is fully converged.

When the **Unsteady Flamelet** is enabled in the **Chemistry** tab, the **Import Flamelet File for Restart...** button appears in the dialog box, allowing you to run the simulation from a previously saved case, data and unsteady flamelet file.

The Unsteady Laminar Flamelet Model requires four user inputs in the **Flamelet** tab:

- The **Number of Grid Points in Flamelet**.
- The **Mixture Fraction Lower Limit for Initial Probability**. The initial condition of the marker probability field is unity for all mean mixture fractions above the **Mixture Fraction Lower Limit for Initial Probability**, and zero for mean mixture fractions below it. Note that this should be specified to be greater than the stoichiometric mixture fraction.
- **Maximum Scalar Dissipation**. Laminar flamelets may extinguish at high scalar dissipations because diffusion in the flamelet overwhelms reaction. It is possible to have unrealistically high modeled scalar dissipation in the 2D or 3D ANSYS FLUENT simulations, which gets transferred to the 1D unsteady flamelet. In order to avoid excessive diffusion in the 1D unsteady flamelet, the instantaneous scalar dissipation in the 1D flamelet is limited to the specified **Maximum Scalar Dissipation**.
- **Courant Number**. The time step for the unsteady probability marker equation is calculated automatically by ANSYS FLUENT based on the **Courant Number**. Larger values imply fewer time steps to convect/diffuse the marker probability out of the domain, but also results in a larger numerical error. The **Courant Number** should be small enough so that the unsteady flamelet mean mass fractions are unchanged with any smaller **Courant Number**. The default value of 1 should be sufficient for most applications.

When these inputs have been set, clicking the **Initialize Unsteady Flamelet Probability** button initializes the marker probability equation, automatically enabling the **Unsteady** solver, while disabling all equations except the **Unsteady Flamelet Probability** equation in the **Solution Controls** task page. This initialization in the **Flamelet** tab also sets the **Time Step Size** in the **Run Calculation** task page.

Important

Do not initialize your solution using the **Solution Initialization** task page. Note that you are postprocessing a probability field on the frozen steady-state flow field, and by clicking the **Initialize Unsteady Flamelet Probability** button, you have already initialized the probability marker field.

Important

If you disable the **Unsteady Laminar Flamelet** model and you want to revert to solving a steady laminar flamelet simulation, make sure you enable **Steady** in the **General** task page and enable all the equations in the **Solution Controls** task page.

17.3.6. Using the Diesel Unsteady Laminar Flamelet Model

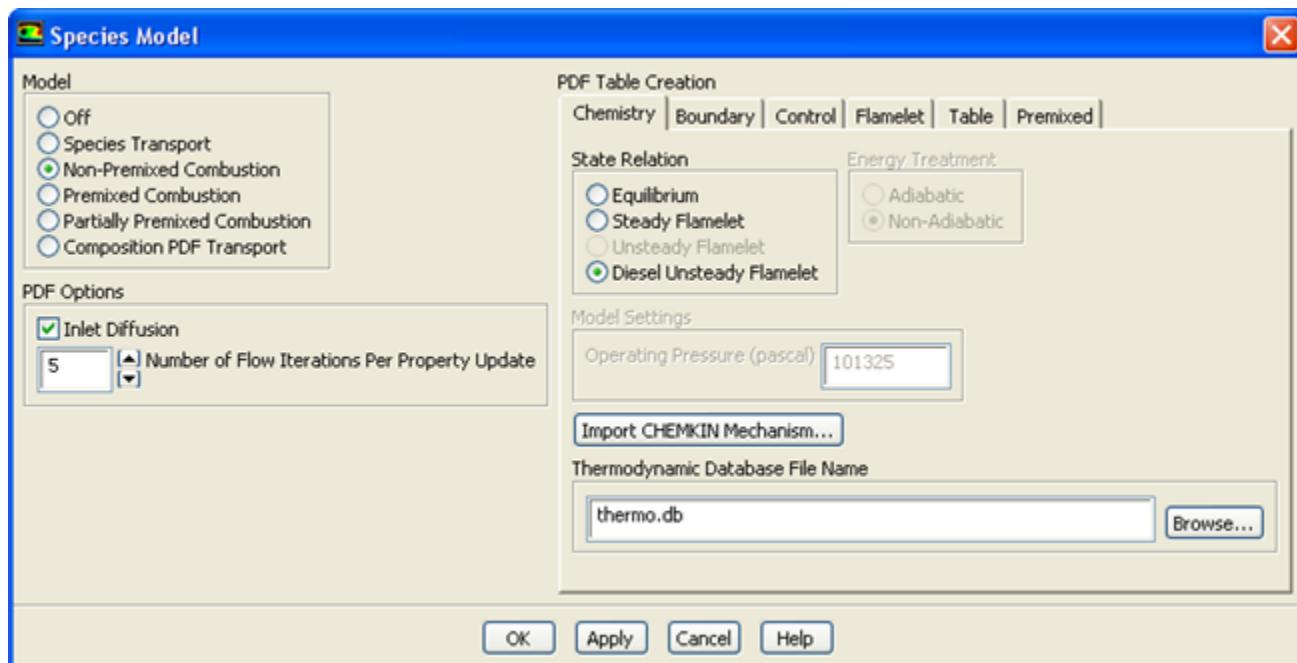

The diesel unsteady laminar flamelet model can only be enabled when conditions for compression-ignition are met:

- The **Transient** solver is selected in the **General** task page.
- The **In-Cylinder** dynamic mesh is enabled.
- The Discrete Phase model option **Interaction with Continuous Phase** is on.

A detailed chemical mechanism is required which should contain kinetic reactions appropriate for compression ignition. The mechanism can include pollutant formation reactions as well if you are interested in modeling emissions.

In the **Chemistry** tab, select **Diesel Unsteady Flamelet**.

Figure 17.9 The Enabled Diesel Unsteady Flamelet Model

With the **Diesel Unsteady Flamelet** model enabled, you can define the stream compositions ([Defining the Stream Compositions \(p. 913\)](#)) and the flamelet controls ([Defining the Flamelet Controls \(p. 925\)](#)). Note that while you can enter the **Number of Grid Points in Flamelet** in the **Flamelet** tab ([Unsteady Flamelet \(p. 929\)](#)), you will not be able to calculate the flamelet or PDF table ([Calculating the Look-Up Tables \(p. 933\)](#)). The reason for this is because the table creation and the flamelet calculation are performed at every time step of the ANSYS FLUENT simulation, and not just in a pre-processing step as in other non-premixed combustion models. However, you can set the table parameters in the **Table** tab.

17.4. Defining the Stream Compositions

In ANSYS FLUENT, you will input only the boundary species (i.e., the fuel, oxidizer, and if necessary, secondary stream species). The intermediate and product species will be determined automatically.

ANSYS FLUENT provides you with an initial list of common boundary species (ch4, h2, jet-a<g>, n2 and o2). If your fuel and/or oxidizer is composed of different species, you can add them to the

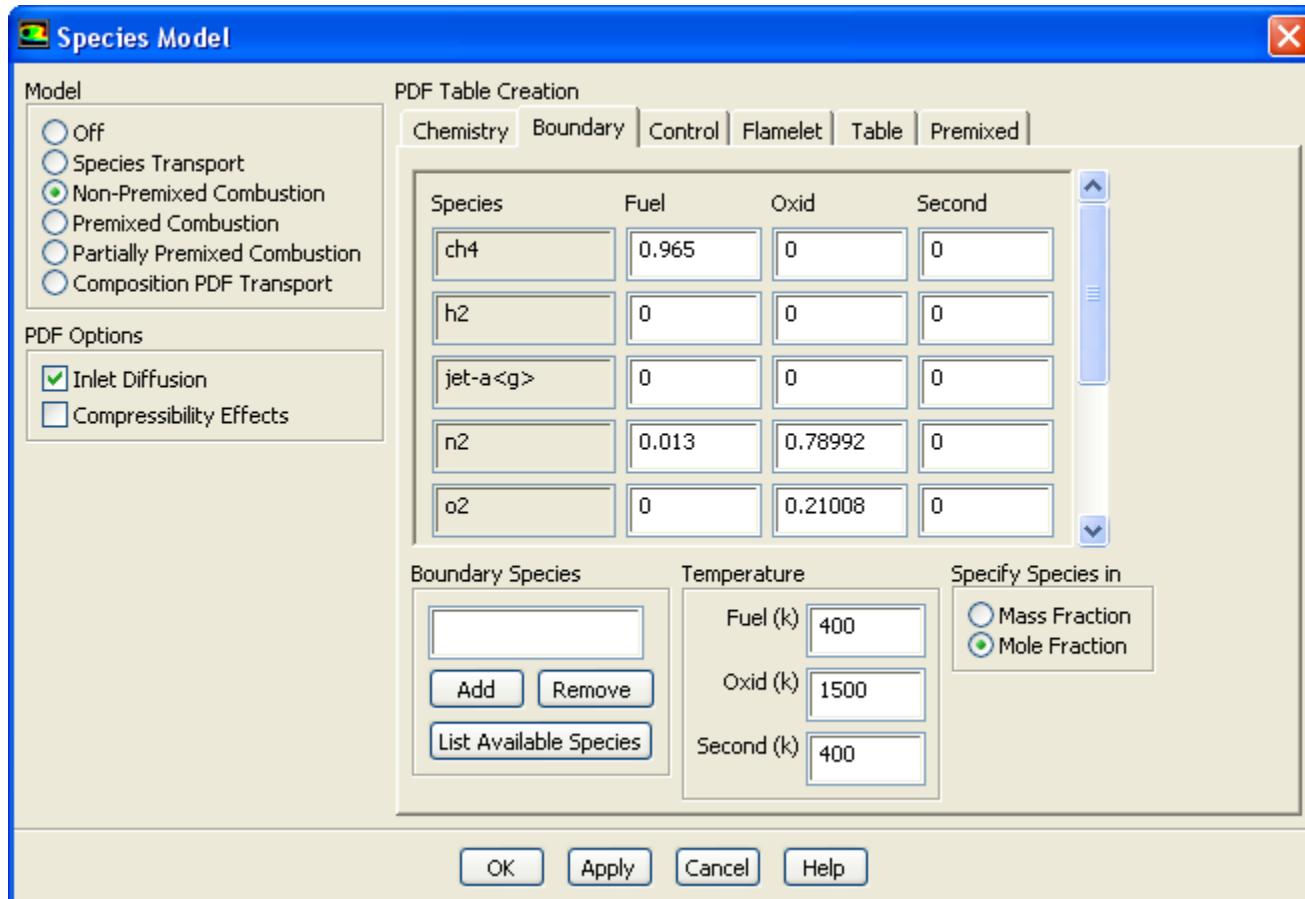

boundary **Species** list. All boundary species must exist in the chemical database and you must enter their names in the same format used in the database, otherwise an error message will be issued.

After defining the boundary species that will be considered in the reaction system, you must define their mole or mass fractions at the fuel and oxidizer inlets and at the secondary inlet, if one exists. (If you choose to define the fuel or secondary stream composition empirically, you will instead enter the parameters described at the end of this section.) For the example shown in [Figure 8.12: "Chemical Systems That Can Be Modeled Using a Single Mixture Fraction" in the Theory Guide](#), for example, the fuel inlet consists of 60% CH₄, 20% CO, 10% CO₂, and 10% C₃H₈.

Finally, the inlet stream temperatures of your reacting system are required for construction of the look-up table and computation of the equilibrium chemistry model.

For the equilibrium chemistry model, the species names are entered using the **Boundary** tab in the **Species Model** dialog box ([Figure 17.10 \(p. 914\)](#)). If you are generating a steady or unsteady laminar flamelet, the list of boundary species will be automatically filled as all the species in the CHEMKIN mechanism, and you will be unable to change these.

Figure 17.10 The Species Model Dialog Box (Boundary Tab)

The steps for adding new species and defining their compositions is as follows:

- (equilibrium chemistry model only) If your fuel, oxidizer, or secondary streams are composed of species other than the default species list, type the chemical formula (e.g., so2 or SO₂ for SO₂) under **Boundary Species** and click **Add**. The species will be added to the **Species** list. Continue in this manner until all of the boundary species you want to include are shown in the **Species** list.

To remove a species from the list, type the chemical formula under **Boundary Species** and click **Remove**. To print a list of all species in the thermodynamic database file (thermo.db) in the console window, click **List Available Species**.

2. Under **Species Unit**, specify whether you want to enter the **Mass Fraction** or **Mole Fraction**. **Mass Fraction** is the default.
3. For each relevant species in the **Species** list, specify its mass or mole fraction for each stream (**Fuel**, **Oxid**, or **Second** as appropriate) by entering values in the table. Note that if you change from **Mass Fraction** to **Mole Fraction** (or vice versa), all values will be automatically converted if they sum to 0 or 1, so be sure that you are entering either all mass fractions or all mole fractions as appropriate. If the values do not sum to 0 or 1, an error will be issued.
4. Under **Temperature**, specify the following inputs:

Fuel

is the temperature of the fuel inlet in your model. In adiabatic simulations, this input (together with the oxidizer inlet temperature) determines the inlet stream temperatures that will be used by ANSYS FLUENT. In non-adiabatic systems, this input should match the inlet thermal boundary condition that you will use in ANSYS FLUENT (although you will enter this boundary condition again in the ANSYS FLUENT session). If your ANSYS FLUENT model will use liquid fuel or coal combustion, define the inlet fuel temperature as the temperature at which vaporization/devolatilization begins (i.e., the **Vaporization Temperature** specified for the discrete-phase material—see *Setting Material Properties for the Discrete Phase* (p. 1128)). For such non-adiabatic systems, the inlet temperature will be used only to adjust the look-up table grid (e.g., the discrete enthalpy values for which the look-up table is computed). Note that if you have more than one fuel inlet, and these inlets are not at the same temperature, you must define your system as non-adiabatic. In this case, you should enter the fuel inlet temperature as the value at the dominant fuel inlet.

Oxid

is the temperature of the oxidizer inlet in your model. The issues raised in the discussion of the input of the fuel inlet temperature (directly above) pertain to this input as well.

Second

is the temperature of the secondary stream inlet in your model. (This item will appear only when you have defined a secondary inlet.) The issues raised in the discussion of the input of the fuel inlet temperature (directly above) pertain to this input as well.

For additional information, please see the following sections:

- [17.4.1. Setting Boundary Stream Species](#)
- [17.4.2. Modifying the Database](#)
- [17.4.3. Composition Inputs for Empirically-Defined Fuel Streams](#)
- [17.4.4. Modeling Liquid Fuel Combustion Using the Non-Premixed Model](#)
- [17.4.5. Modeling Coal Combustion Using the Non-Premixed Model](#)

17.4.1. Setting Boundary Stream Species

In combustion, a large number of intermediate and product species may be produced from a small number of initial boundary species. In ANSYS FLUENT you need to input only the species composition of your boundary species in the fuel, oxidizer, and (if appropriate) secondary streams. ANSYS FLUENT will calculate all intermediate and product species automatically. The following suggestions may be helpful in the definition of the system chemistry:

- For coal combustion, char in the coal should be represented by C(s).

Important

Care should be taken to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should be selected only if you are using the empirically-defined input method.

- If your fuel composition is known empirically (e.g., $C_{0.9}H_{3.0}O_{0.2}$), use the option for an empirically-defined stream (see below).
- If you wish to include the sulfur that may be present in a hydrocarbon fuel, note that this may hinder the convergence of the equilibrium solver, especially if the concentration of sulfur is small. It is therefore recommended that you include sulfur in the calculation only if it is present in considerable quantities.

17.4.1.1. Including Condensed Species

In addition to gaseous species, liquid and solid species can be included in the chemistry calculations. They are often indicated by an "l" or an "s" in parentheses after the species name. If you add a condensed species to the equilibrium chemical system, its density will be retrieved from ANSYS FLUENT's chemical property database file `propdb.scm` if you are using the thermodynamic database file `thermo.db` that is also supplied with ANSYS FLUENT. If you are using a custom thermodynamic database file and want to include a condensed species in the equilibrium system that does not exist in `propdb.scm`, a density of 1000 kg/m^3 will be assumed. The condensed species density can be changed in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) after the PDF table has been calculated. If you modify the condensed species density in this manner, you will then need to recalculate the PDF table.

17.4.2. Modifying the Database

If you want to include a new species in your reacting system that is not available in the chemical database, you can add it to the database file, `thermo.db`. The format for `thermo.db` is detailed in [\[41\] \(p. 2369\)](#). If you choose to modify the standard database file, you should create copies of the original file.

17.4.3. Composition Inputs for Empirically-Defined Fuel Streams

As mentioned in [Defining the Problem Type \(p. 902\)](#), you can define the composition of a fuel stream (i.e., the standard fuel or a secondary fuel) empirically. For an empirically-defined stream, you will need to enter the atomic mass or mole fractions in addition to the inputs for lower calorific (heating) value of the fuel and the mean specific heat of the fuel that were described previously.

The heat of formation of an empirically defined stream is calculated from the heating value and the atomic composition. The fuel inlet temperature and fuel specific heat are used to calculate the sensible enthalpy. The molecular weight is used for the computation of the unburnt stream density. Note that the unburnt density is only required if the stream enters via an inlet boundary, or if you are using the partially-premixed model.

When an empirically-defined fuel or secondary stream is specified in the **Chemistry** tab (equilibrium chemistry model only) of the **Species Model** dialog box, you must specify the atom fractions of C, H, O, N, and S in that stream instead of the species mass or mole fractions. To avoid confusion, the species fraction inputs for an empirically-defined stream will be grayed out in the table within the **Boundary** tab, leaving only the fields for atom fractions (i.e., **c**, **h**, **o**, **n**, and **s**).

17.4.4. Modeling Liquid Fuel Combustion Using the Non-Premixed Model

Liquid fuel combustion can be modeled with the discrete phase and non-premixed models. In ANSYS FLUENT, the fuel vapor, which is produced by evaporation of the liquid fuel, is defined as the fuel stream. (See [Defining the Stream Compositions \(p. 913\)](#).) The liquid fuel that evaporates within the domain appears as a source of the mean fuel mixture fraction.

Within ANSYS FLUENT, you define the liquid fuel discrete-phase model in the usual way. The gas phase (oxidizer) flow inlet is modeled using an inlet mixture fraction of zero and the fuel droplets are introduced as discrete phase injections (see [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#)). The property inputs for the liquid fuel droplets are unaltered by the non-premixed model (see [Setting Material Properties for the Discrete Phase \(p. 1128\)](#)). Note that when you are requested to input the gas phase species destination for the evaporating liquid, you should input the species that comprises the evaporating stream.

If the fuel stream was defined as a mixture of components, you should select the largest of these components as the “evaporating species”. ANSYS FLUENT will ensure that the mass evaporated from the liquid droplet enters the gas phase as a source of the fuel mixture that you defined. The evaporating species you select here is used only to compute the diffusion controlled driving force in the evaporation rate.

17.4.5. Modeling Coal Combustion Using the Non-Premixed Model

If your model involves coal combustion, the fuel and secondary stream compositions can be input in one of several ways. You can use a single mixture fraction (fuel stream) to represent the coal, defining the fuel composition as a mixture of volatiles and char (solid carbon). Alternatively, you can use two mixture fractions (fuel and secondary streams), defining the volatiles and char separately. In two-mixture-fraction models for coal combustion, the fuel stream represents the char and the secondary stream represents volatiles. This section describes the modeling options and special input procedures for coal combustion models using the non-premixed approach.

There are three options for coal combustion:

- When coal is the only fuel in the system, you can model the coal using two mixture fractions, where the primary stream represents the char and the secondary stream represents the volatiles. Generally, the char stream composition is defined as 100% C(s). The volatile stream composition is defined by selecting appropriate species and setting their mole or mass fractions. Alternatively, you can use the empirical method (input of atom fractions) for defining these compositions.

Important

Using two mixture fractions to model coal combustion is more accurate than using one mixture fraction as the volatile and char streams are modeled separately. However, the two-mixture-fraction model incurs significant additional computational expense since the multi-dimensional PDF integrations are performed at run-time.

- When coal is the only fuel in the system, you can choose to model the coal using a single mixture fraction (the fuel stream). When this approach is adopted, the fuel composition you define includes both volatile species and char. Char is typically represented by including C(s) in the species list. You can define the fuel stream composition by selecting appropriate species and setting their mole fractions, or by using the empirical method (input of atom fractions). Definition of the composition is described in detail below.

Important

Using a single mixture fraction for coal combustion is less accurate than using two mixture fractions. However, convergence in ANSYS FLUENT should be substantially faster than the two-mixture-fraction model.

- When coal is used with another (gaseous or liquid) fuel of different composition, you must model the coal with one mixture fraction and use a second mixture fraction to represent the second (gaseous or liquid) fuel. The stream associated with the coal composition is defined as detailed below for single-mixture-fraction models.

17.4.5.1. Defining the Coal Composition: Single-Mixture-Fraction Models

When coal is modeled using a single mixture fraction (the fuel stream), the fuel stream composition can be input using the conventional approach or the empirical fuel approach.

- Conventional approach:

To use the conventional approach, you will need to define the mixture of species in the coal and their mole or mass fractions in the fuel stream. Use the **Boundary** tab in the **Species Model** dialog box to input the list of species (e.g., C₃H₈, CH₄, CO, CO₂, C(s)) that approximate the coal composition, and their mole or mass fractions.

Note that C(s) is used to represent the char content of the coal. For example, consider a coal that has a molar composition of 40% volatiles and 60% char on a dry ash free (DAF) basis. Assuming the volatiles can be represented by an equimolar mixture of C₃H₈ and CO, the fuel stream composition defined in the **Boundary** tab would be C₃H₈=0.2, CO = 0.2, and C(s)=0.60. Note that the coal composition should always be defined on an ash-free basis, even if ash will be considered in the ANSYS FLUENT calculation.

To define ash properties, go to the **Create/Edit Materials** dialog box and select **combusting-particle** as the **Material Type**.

The following table illustrates the conversion from a typical mass-based proximate analysis to the species fraction inputs required by ANSYS FLUENT. Note that the conversion requires that you make an assumption regarding the species representing the volatiles. Here, the volatiles are assumed to exist as an equimolar mix of propane and carbon monoxide.

Proximate Analysis	Weight %	Mass Fraction (DAF)	Moles (DAF)	Mole Fraction (DAF)
Volatiles	30			
- C ₃ H ₈		0.2035	0.004625	0.07134
- CO		0.1295	0.004625	0.07134
Fixed Carbon (C(s))	60	0.667	0.05558	0.85732
Ash	10	-	-	-
(Total)			0.06483	1.0

Moisture in the coal can be considered by adding it in the fuel composition as liquid water, H₂O(l). The moisture can also be defined as water vapor, H₂O, provided that the corresponding latent heat is included in the discrete phase material inputs in ANSYS FLUENT. If the liquid water is used

as a boundary species, it should be removed from the list of excluded species (see *Forcing the Exclusion and Inclusion of Equilibrium Species* (p. 924)).

Important

Note that if water is included in the coal, the water release is not modeled as evaporation, which is typically the case in the wet combustion model, described in *Particle Types* (p. 1099).

- Empirical fuel approach:

To use the empirical approach, enable the **Empirical Fuel Stream** option in the **Chemistry** tab. This method is ideal if you have an elemental analysis of the coal.

In the **Chemistry** tab, input the lower heating value and mean specific heat of the coal. ANSYS FLUENT will use these inputs to determine the mole fractions of the chemical species you have included in the system. Then, in the **Boundary** tab, define the atom fractions of C, H, N, S, and O in the fuel stream.

Note that for both of these composition input methods, you should take care to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should only be selected if you are using the empirical fuel input method.

See *Additional Coal Modeling Inputs in ANSYS FLUENT* (p. 921) for details about further inputs for modeling coal combustion.

17.4.5.2. Defining the Coal Composition: Two-Mixture-Fraction Models

You can model coal using the two mixture fractions model, where the primary stream represents the char and the secondary stream represents the volatiles.

As in single-mixture-fraction cases, the fuel stream and secondary stream compositions in a two-mixture-fraction case can be input using either the conventional approach or the empirical fuel approach.

- Conventional approach:

To use the conventional approach, you will need to define the mixture of species in the coal and their mole or mass fractions in the fuel and secondary streams.

Use the **Boundary** tab of **Species Model** dialog box to define the mole or mass fractions of volatile species in the secondary stream (e.g., C_3H_8 , CH_4 , CO, CO_2 , C(s)). Next, define the mole or mass fractions of species used to represent the char. Generally, you will input 100% C(s) for the fuel stream.

- Empirical fuel approach:

To use the empirical fuel approach, enable the **Empirical Secondary Stream** option in the **Chemistry** tab for the volatile (secondary) stream. This method is ideal if you have an elemental analysis of the coal.

In the **Chemistry** tab, input the lower heating value and mean specific heat of the coal. Then, in the **Boundary** tab, define the mole or mass fractions of species used to represent the char. Generally, you will input 100% C(s) for the fuel stream. Finally, define the atom fractions of C, H, N, S, and O in the volatiles. ANSYS FLUENT will use these inputs to determine the mole fractions of the chem-

ical species you have included in the system. For example, consider coal with the following DAF (dry ash free) data and elemental analysis:

Proximate Analysis	Wt % (dry)	Wt % (DAF)
Volatiles	28	30.4
Char (C(s))	64	69.6
Ash	8	-

Element	Wt % (DAF)	Wt % (DAF)
C	89.3	89.3
H	5.0	5.0
O	3.4	3.4
N	1.5	2.3
S	0.8	-

(Note that in the final column, for modeling simplicity, the sulfur content of the coal has been combined into the nitrogen mass fraction.)

You can combine the proximate and ultimate analysis data to yield the following elemental composition of the volatile stream:

Element	Mass	Mass Fraction	Moles	Mole Fraction
C	(89.3 - 69.6)	0.65	5.4	0.24
H	5.0	0.16	16	0.70
O	3.4	0.11	0.7	0.03
N	2.3	0.08	0.6	0.03
Total	30.4		22.7	

This adjusted composition is used to define the secondary stream (volatile) composition.

The lower heating value of the volatiles can be computed from the known heating value of the coal and the char (DAF):

- $LCV_{coal, DAF} = 35.3 \text{ MJ/kg}$
- $LCV_{char, DAF} = 32.9 \text{ MJ/kg}$

You can compute the heating value of the volatiles as

$$LCV_{vol} = \frac{35.3 \text{ MJ/kg} - 0.696 \times 32.9 \text{ MJ/kg}}{0.304} \quad (17-2)$$

or

$$LCV_{vol} = 40.795 MJ/kg \quad (17-3)$$

Note that for both of these composition input methods, you should take care to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should only be selected if you are using the empirical fuel input method.

17.4.5.3. Additional Coal Modeling Inputs in ANSYS FLUENT

Within ANSYS FLUENT, the DPM coal combustion simulation is defined as usual when the non-premixed combustion model is selected. The air (oxidizer) inlets are defined as having a mixture fraction value of zero. No gas phase fuel inlets will be included and the sole source of fuel will come from the coal devolatilization and char burnout. The coal particles are defined as injections using the **Set Injection Properties** dialog box in the usual way, and physical properties for the coal material are specified as described in *Setting Material Properties for the Discrete Phase* (p. 1128). You should keep in mind the following issues when defining injections and discrete-phase material properties for coal materials:

- In the **Set Injection Properties** dialog box, you will specify for the **Oxidizing Species** one of the components of the oxidizer stream. This species concentration field will be used to calculate the diffusion-controlled driving force in the char burnout law (if applicable), and is O_2 by default.

The specification of the char and volatile streams differs depending on the type of model you are defining:

- If coal is modeled using a single mixture fraction, the gas phase species representing the volatiles and the char combustion are represented by the mixture fraction used by the non-premixed combustion model.
- If coal is modeled using two mixture fractions, rather than specifying a destination species for the volatiles and char, you will instead specify the **Devolatilizing Stream** (as secondary) and the **Char Stream** (as primary).
- If coal is modeled using one mixture fraction, and another fuel is modeled using a second mixture fraction, you should specify the stream representing the coal as both the **Devolatilizing Stream** and the **Char Stream**.
- In the **Create/Edit Materials** dialog box, **Vaporization Temperature** should be set equal to the fuel inlet temperature. This temperature controls the onset of the devolatilization process. The fuel inlet temperature that you define in the **Boundary** tab of the **Species Model** dialog box should be set to the temperature at which you want to initiate devolatilization. This way, the look-up tables will include the appropriate temperature range for your process.
- In the **Create/Edit Materials** dialog box, **Volatile Component Fraction** and **Combustible Fraction** should be set to values that are consistent with the coal composition used to define the fuel (and secondary) stream composition.
- Also in the **Create/Edit Materials** dialog box, you will be prompted for the **Burnout Stoichiometric Ratio** and for the **Latent Heat**. The **Burnout Stoichiometric Ratio** is used in the calculation of the diffusion controlled burnout rate but has no other impact on the system chemistry when the non-premixed combustion model is used. The **Burnout Stoichiometric Ratio** is the mass of oxidant required per mass of char. The default value of 1.33 assumes that C(s) is oxidized by O_2 to yield CO. The **Latent Heat** input determines the heat required to generate the vapor phase volatiles defined in the non-premixed system chemistry. You can usually set this value to zero when the non-premixed model is used, since your definition of volatile species will have been based on the overall heating value of the coal. However, if the coal composition includes the water content, the latent heat should be set as follows:

- Set the latent heat to zero if the water content of the coal has been defined as **H₂O(L)**. In this case, the system chemistry will include the latent heat required to vaporize the liquid water.
- Set the latent heat to the value for water (2.25×10^6 J/kg), adjusted by the mass loading of water in the volatiles, if the water content of the coal has been defined using water vapor, **H₂O**. In this case, the water content you defined will be evolved along with the other species in the coal but the system chemistry does not include the latent heat effect.
- The **Density** you define for the coal in the **Create/Edit Materials** dialog box should be the apparent density, including ash content.
- You will not be asked to define the **Heat of Reaction for Burnout** for the char combustion.

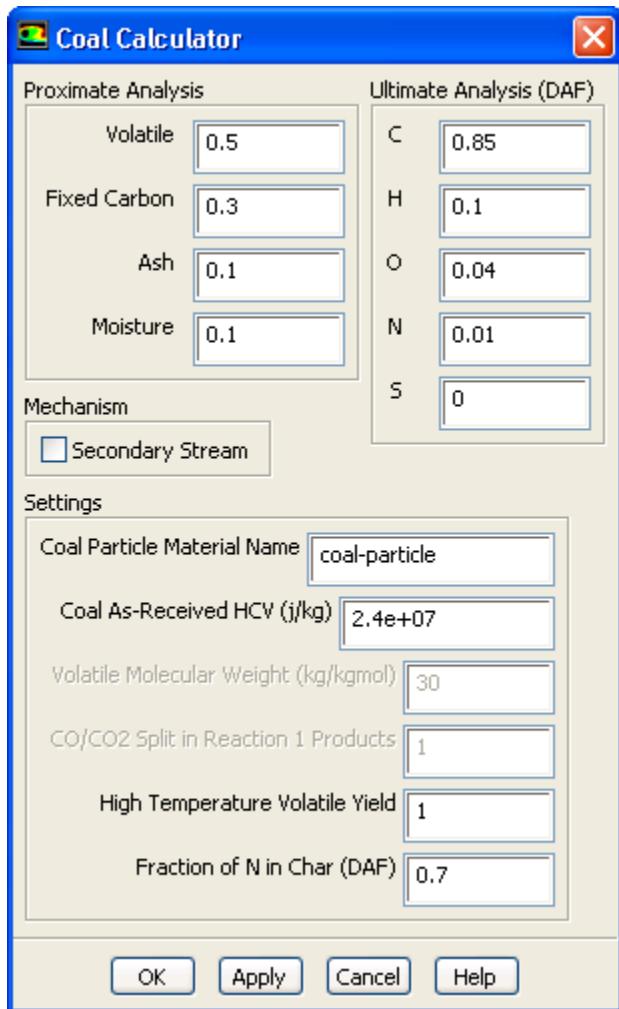

17.4.5.4. Postprocessing Non-Premixed Models of Coal Combustion

ANSYS FLUENT reports the rate of volatile release from the coal using the **DPM Evaporation/Devolatilization** postprocessing variable. The rate of char burnout is reported in the **DPM Burnout** variable.

17.4.5.5. The Coal Calculator

The **Coal Calculator** dialog box automates the calculations described above for setting up a coal case from the proximate and ultimate analyses.

Figure 17.11 The Coal Calculator Dialog Box

The inputs to the **Coal Calculator** dialog box are:

1. Coal **Proximate Analysis**, which is the mass fraction of **Volatile**, **Fixed Carbon**, **Ash** and **Moisture** in the coal.
2. Coal **Ultimate Analysis**, which is the mass fraction of atomic **C**, **H**, **O**, **N** and optionally **S**, in the Dry-Ash-Free (DAF) coal.
3. The option to use a **Secondary Stream**. If enabled, the two mixture fraction model will be set with the primary stream representing char as $C < s >$, and an empirical secondary stream representing the volatiles.
4. The **Coal Particle Material Name**. A DPM Combusting Particle Material will be created with this name. The default name is *coal-particle*.
5. The **Coal As-Received HCV** (Higher Calorific Value).
6. The **High Temperature Volatile Yield**. Enhanced devolatilization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction. To model this, the actual volatile fraction used is calculated as that specified in the **Proximate Analysis** input multiplied by the **High Temperature Volatile Yield**. The actual **Fixed Carbon** fraction is then calculated as one minus the sum of the actual **Volatile**, **Ash**, and **Moisture** fractions.
7. **Fraction of N in Char (DAF)**. This input is used in calculating the split of atomic nitrogen for the Fuel NOx model.

When the **OK** button is clicked, ANSYS FLUENT makes the following changes:

- a. The empirical fuel atomic compositions in the **Boundary** tab are set, and the **Non-Adiabatic** model is enabled as required for DPM. The empirical fuel (DAF volatile) Lower Calorific Value (LCV_{vol}) is calculated as follows. First the DAF LCV of the coal is computed as,

$$LCV_{coal}^{DAF} = \frac{HCV_{coal}^{ar} - h_{H_2O}^{latent} Moisture}{1 - Moisture - Ash} - \frac{H_{ar} W_{H_2O}}{2 W_H} h_{H_2O}^{latent} \quad (17-4)$$

where *Moisture* and *Ash* are the proximate moisture and ash fractions, H_{ar} is the ultimate *H* fraction, W_{H_2O} and W_H are the molecular weight of water and atomic hydrogen, respectively, and $h_{H_2O}^{latent}$ is the latent heat of water.

LCV_{vol} is calculated from LCV_{coal}^{DAF} using,

$$LCV_{vol} = \frac{LCV_{coal}^{DAF} (1 - Moisture - Ash) - LCV_{char} FixedCarbon}{Volatile} \quad (17-5)$$

where *FixedCarbon* and *Volatile* are the proximate fixed carbon and volatile fractions, respectively.

- b. A combusting particle material is created with **Volatile Component Fraction** and **Combustible Fraction** calculated from the ultimate and proximate analyses. The Discrete Phase Model (DPM) is enabled.

- c. For the Fuel NOx model, the char N conversion is set to *NO*, and the Fuel NOx **Volatile** and **Char** mass fractions are set according to the ultimate and proximate compositions. Note that even though some of the Fuel NOx parameters are changed, the Fuel NOx model itself is not enabled.

After the **Coal Calculator** has set up the relevant models, you must build the PDF Table by clicking **Calculate PDF Table** in the **Table** tab. You will also need to create injections if you have not done this yet. After converging your coal combustion case, you may want to enable the NOx model for post-processing nitrogen-oxide pollutants.

17.5. Setting Up Control Parameters

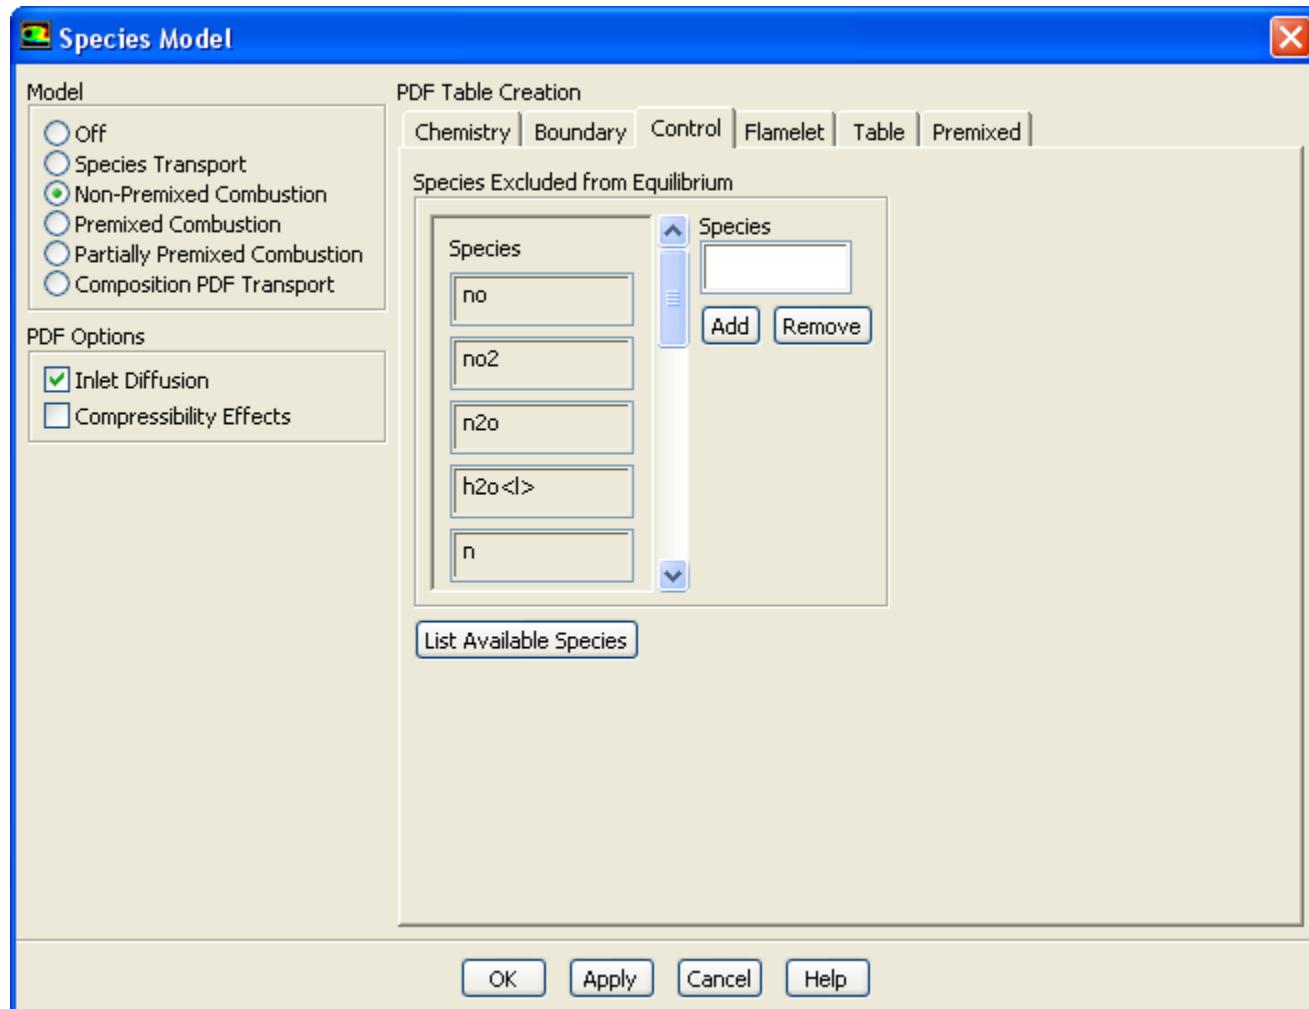

For information about setting up control parameters, please see the following sections:

- 17.5.1. Forcing the Exclusion and Inclusion of Equilibrium Species
- 17.5.2. Defining the Flamelet Controls
- 17.5.3. Zeroing Species in the Initial Unsteady Flamelet

17.5.1. Forcing the Exclusion and Inclusion of Equilibrium Species

Because ANSYS FLUENT calculates all intermediate and product species automatically during the equilibrium calculation, certain species will be included that are generally not in chemical equilibrium. Principal among these are the NOx species. Specifically, the NOx reaction rates are slow and should not be treated using an equilibrium assumption. Instead, the NOx concentration is predicted most accurately using the ANSYS FLUENT NOx postprocessor, where finite-rate kinetics are included (see [NOx Formation \(p. 1009\)](#)). The NOx species can be safely excluded from the equilibrium calculation since they are present at low concentrations and have little impact on the density, temperature, and other species.

To force the exclusion of a species from the equilibrium calculation, click the **Control** tab in the **Species Model** dialog box (*Figure 17.12 (p. 925)*).

Figure 17.12 The Species Model Dialog Box (Control Tab)

Under **Species Excluded From Equilibrium**, enter the chemical formula for the desired species in the **Add/Remove Species** field. Next, click **Add** to add the species to the **Species** list or **Remove** to remove an existing species from the **Species** list.

If there are species that you want to include in your PDF table that would be ignored by ANSYS FLUENT due to their low concentration (e.g., CH, CH₂, CH₃ for the NOx calculation), you can force ANSYS FLUENT to include them using the text interface:

```
define → models → species → non-premixed-combustion
```

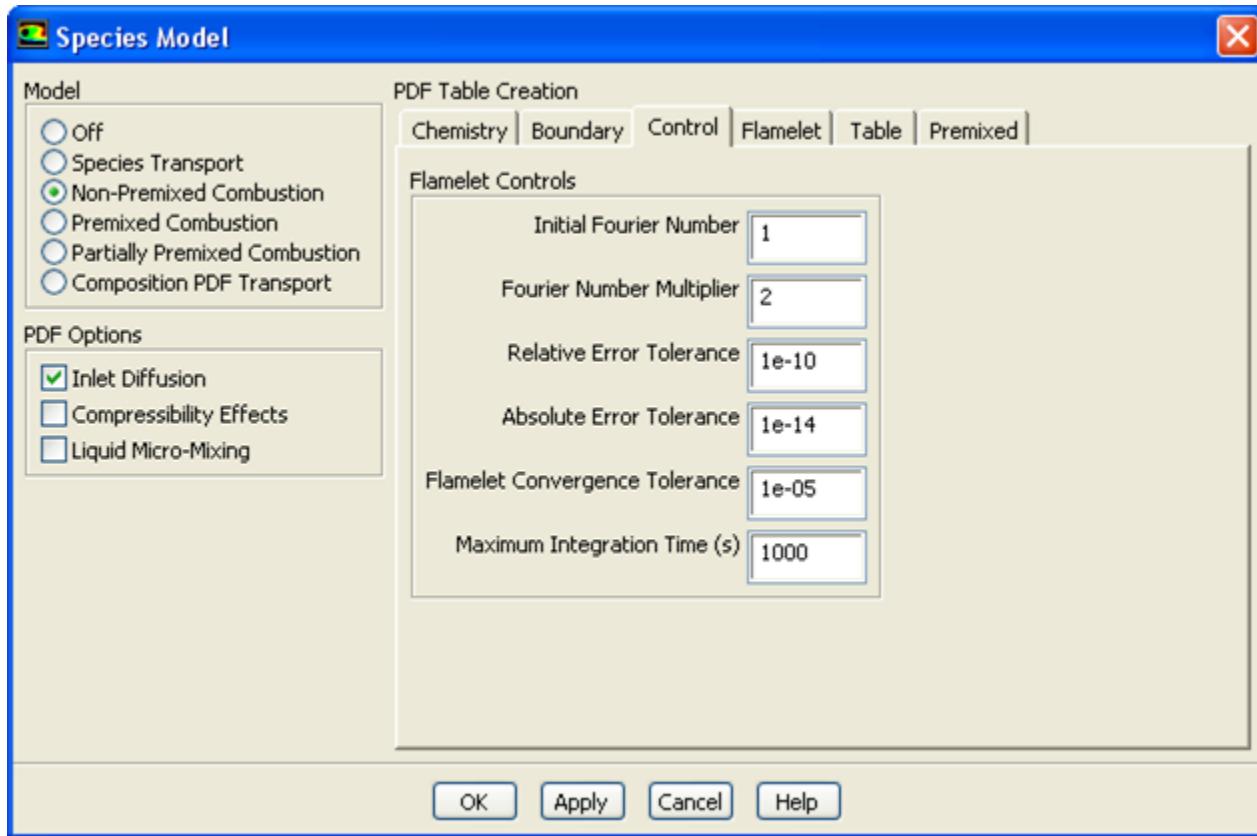

When the console window prompts you with **Force Equilibrium Species to Include...**, specify the appropriate species by entering the chemical formula(s) in double quotes (e.g., "ch", "ch2").

Note that you will have to first set up the inputs for the fuel and oxidizer before you are given the option to include the species.

17.5.2. Defining the Flamelet Controls

When the steady laminar flamelet model is selected, and you have created or imported a flamelet, you can adjust the controls for the flamelet solution in the **Control** tab of the **Species Model** dialog box ([Figure 17.13 \(p. 926\)](#)).

Figure 17.13 The Species Model Dialog Box (Control Tab) for the Steady Laminar Flamelet Model

The **Initial Fourier Number** sets the first time step for the solution of the flamelet equations (Equation 8–43 and Equation 8–44 in the [Theory Guide](#)). This first time step is calculated as the explicit stability-limited diffusion time step multiplied by this value. If the solution diverges before the first time step is complete, the value should be lowered.

The **Fourier Number Multiplier** increases the time step at subsequent times. Every time step after the first is multiplied by this value. If the solution diverges after the first time step, this value should be reduced.

During the numerical integration of the flamelet equations, the local error is controlled to be less than

$$\text{error}_{\text{loc},i} = \varepsilon_{\text{rel}}\phi_i + \varepsilon_{\text{abs}} \quad (17-6)$$

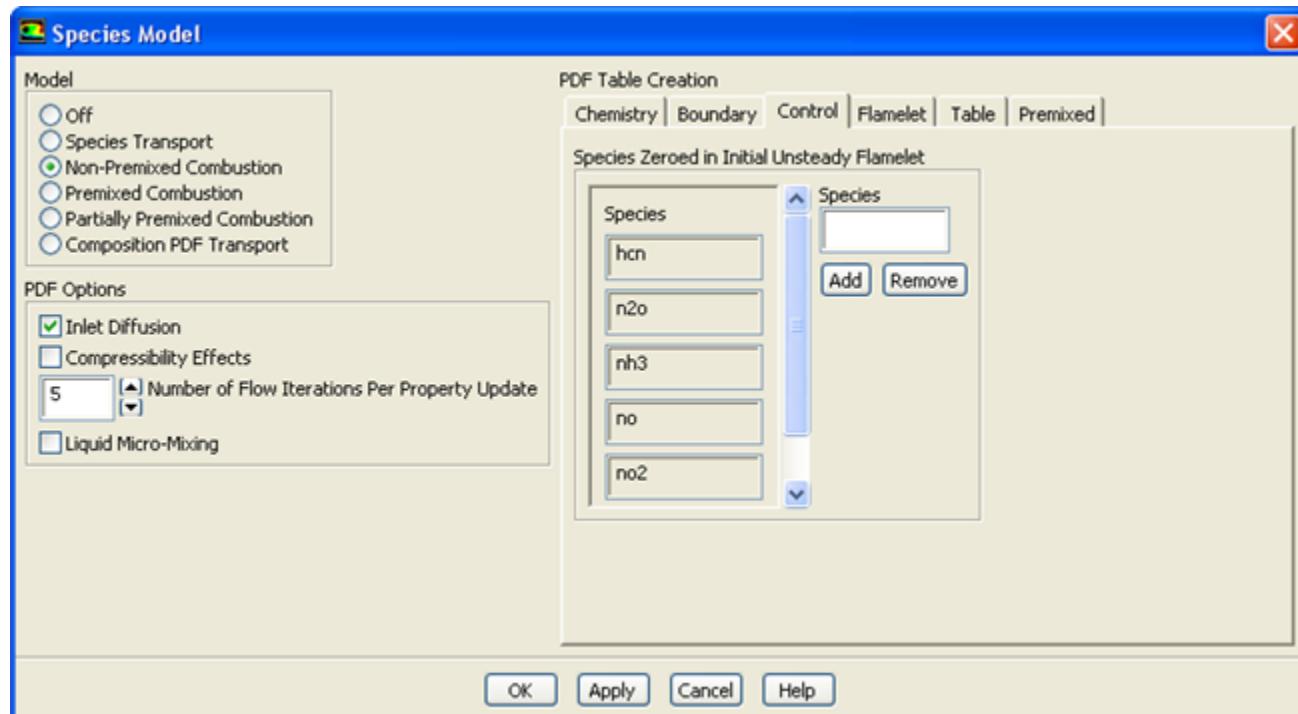

where ϕ_i represents the species mass fractions and temperature at point i in the 1D flamelet. ε_{rel} is the value of the **Relative Error Tolerance** and ε_{abs} is the value of the **Absolute Error Tolerance**, both of which you can specify.

Because steady laminar flamelets are obtained by time-stepping, they are considered converged only when the maximum absolute change in species fraction or temperature at any discrete mixture-fraction point is less than the specified **Flamelet Convergence Tolerance**. Between time steps, the flamelet species fractions and temperature will sometimes oscillate, which causes absolute changes that are always greater than the flamelet convergence tolerance. In such cases, ANSYS FLUENT will stop the flamelet calculation after the total elapsed time has exceeded the **Maximum Integration Time**.

17.5.3. Zeroing Species in the Initial Unsteady Flamelet

When modeling gas-phase combustion using the Eulerian unsteady laminar flamelet model, the flamelet fields are initialized to a burning, steady-flamelet solution in order to model ignition. However, assuming steady-flamelet profiles for slow-forming species is inaccurate. A better approximation is to identify the slow species and to set them to zero, which is done in the **Control** tab. By default, ANSYS FLUENT selects some NOx species (NO , NO_2 , N_2O , N , NH , NH_2 , NH_3 , NNH , HCN , HNO , CN , H_2CN , $HCNN$, $HCNO$, $HOCN$, $HNCO$, HCO), as well as liquid water $H_2O < l >$ and solid carbon $C < s >$ to be zeroed. See [Figure 17.14 \(p. 927\)](#).

Figure 17.14 Method to Zero Out the Slow Chemistry Species

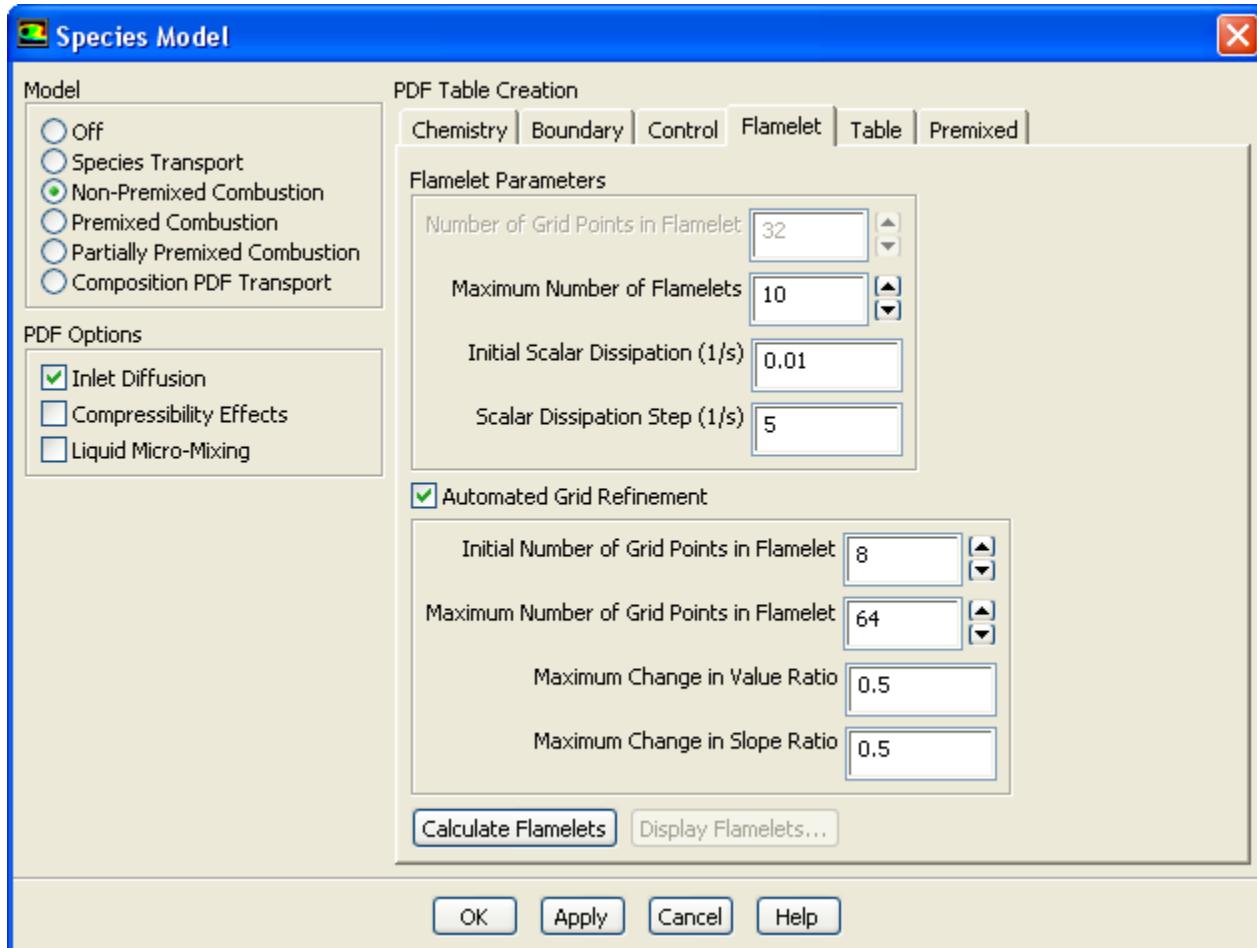

17.6. Calculating the Flamelets

For information about calculating flamelets, please see the following sections:

- 17.6.1. Steady Flamelet
- 17.6.2. Unsteady Flamelet
- 17.6.3. Saving the Flamelet Data
- 17.6.4. Postprocessing the Flamelet Data

17.6.1. Steady Flamelet

In the **Flamelet** tab of the **Species Model** dialog box ([Figure 17.15 \(p. 928\)](#)), you will enter values for parameters of the flamelet(s).

Figure 17.15 The Species Model Dialog Box (Flamelet Tab)

The **Flamelet Parameters** are as follows:

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f = 0$) and the fuel ($f = 1$). Increased resolution will provide greater accuracy, but since the flamelet species and temperature are solved coupled and implicit in f space, the solution time and memory requirements increase greatly with the number of f grid points.

Maximum Number of Flamelets

specifies the maximum number of laminar flamelet profiles to be calculated. If the flamelet extinguishes before this number is reached, flamelet generation is halted and the actual number of flamelets in the flamelet library will be less than this value.

Initial Scalar Dissipation

is the scalar dissipation of the first flamelet in the library. This corresponds to χ_0 in [Equation 8-49](#) in the [Theory Guide](#).

Scalar Dissipation Step

specifies the interval between scalar dissipation values (in s^{-1}) for which multiple flamelets will be calculated. This corresponds to $\Delta\chi$ in [Equation 8-49](#) in the [Theory Guide](#).

Automated Grid Refinement employs an adaptive algorithm, which inserts grid points so that the change of values, as well as the change of slopes, between successive grid points is less than user specified tolerances. For information about this option, refer to [Steady Laminar Flamelet Automated Grid Refinement](#) in the [Theory Guide](#).

Initial Number of Grid Points in Flamelet

calculates a steady solution on a coarse grid, with a default of 8. See [Equation 8–50](#) in the [Theory Guide](#).

Maximum Number of Grid Points in Flamelet

has a default of 64.

Maximum Change in Value Ratio

has a default of 0.5 and is ε_v in [Equation 8–50](#) in the [Theory Guide](#).

Maximum Change in Slope Ratio

has a default of 0.5 and is ε_s in [Equation 8–50](#) in the [Theory Guide](#).

Click **Calculate Flamelets** to begin the laminar flamelet calculation. Sample output for a flamelet calculation is shown below.

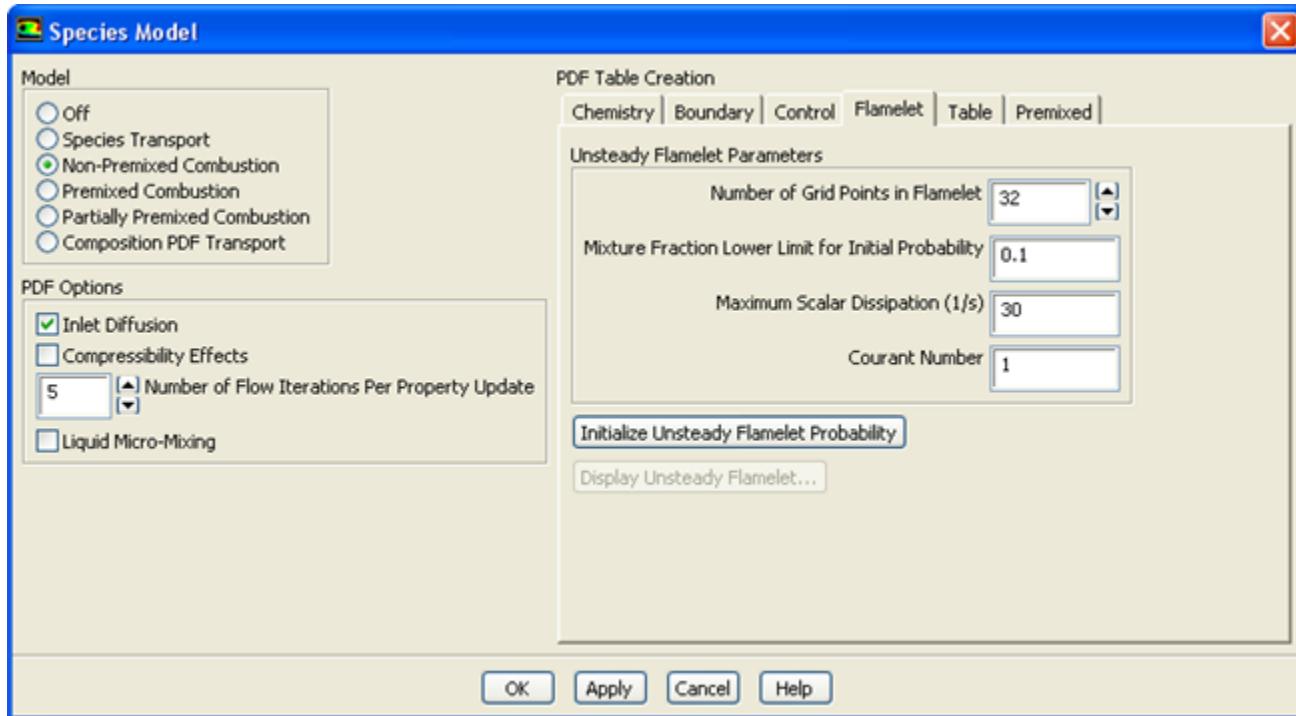

```

17.6.2. Unsteady Flamelet

In the **Flamelet** tab of the **Species Model** dialog box ([Figure 17.16 \(p. 930\)](#)), you will enter values for parameters of the flamelet.

Figure 17.16 The Flamelet Tab for the Unsteady Laminar Flamelet Model

The **Unsteady Flamelet Parameters** are as follows:

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f = 0$) and the fuel ($f = 1$). Increased resolution will provide greater accuracy, but since the flamelet species and temperature are solved coupled and implicit in f space, the solution time and memory requirements increase with the number of f grid points.

Mixture Fraction Lower Limit for Initial Probability

is the mixture fraction above which the marker probability will be initialized to 1, and below which the marker probability will be initialized to 0. In general, it should be set greater than the stoichiometric mixture fraction.

Maximum Scalar Dissipation

is where flamelets extinguish at large scalar dissipation (mixing) rates. To prevent excessive mixing in the flamelet, ANSYS FLUENT allows you to specify a **Maximum Scalar Dissipation** rate for the 1D flamelet equations. A reasonable value for this is the steady flamelet extinction scalar dissipation. The default value of 30/s is near the steady extinction scalar dissipation of a methane-air flame at standard temperature and pressure.

Courant Number

is the number at which ANSYS FLUENT automatically selects the time step for the probability equation based on this convective Courant number.

Click **Initialize Unsteady Flamelet Probability** to initialize the unsteady flamelet and its probability marker equation. ANSYS FLUENT is now ready for postprocessing the 1D unsteady flamelet and the 2D/3D unsteady marker probability equation.

17.6.3. Saving the Flamelet Data

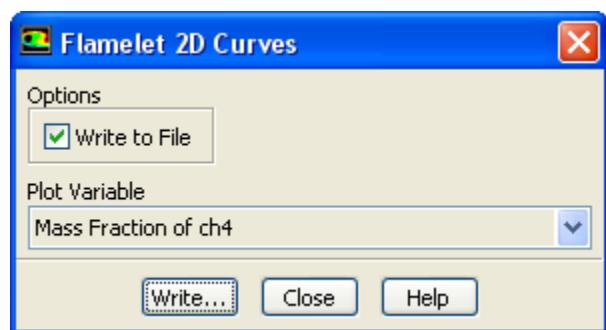

The flamelet tables may be written to file for import into later sessions of ANSYS FLUENT. You may want to do this, for example, to change the number of discretization points in the PDF table, or to plot the flamelet profiles in ANSYS FLUENT. The flamelet tables should be saved before you create the PDF table:

File → Write → Flamelet...

17.6.4. Postprocessing the Flamelet Data

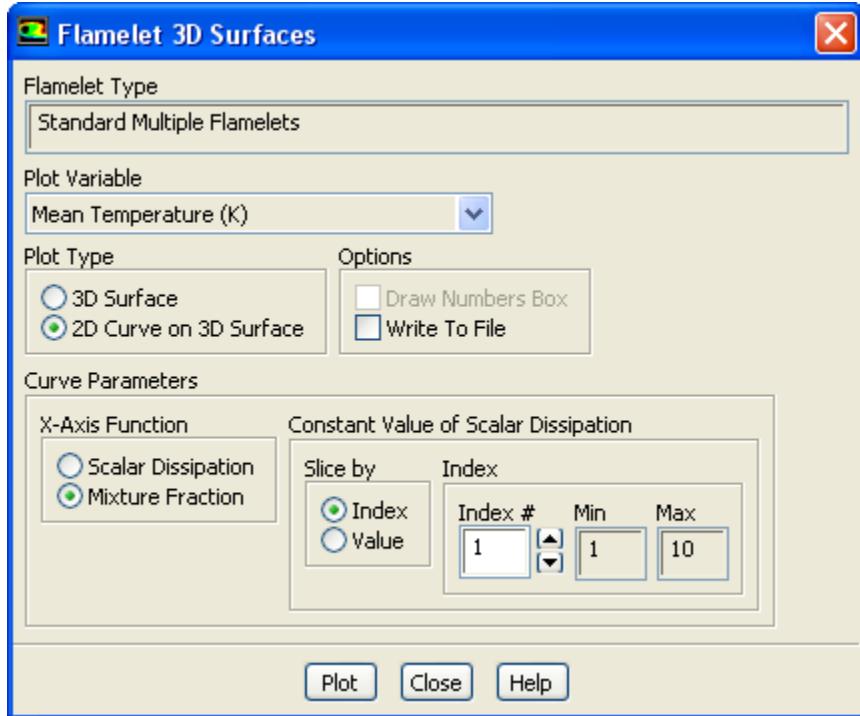

For the flamelet model, you can display or write flamelet curves. Click the **Display Flamelets...** or **Display Unsteady Flamelet...** button. If you have a single flamelet, as for the unsteady flamelet model, you can access the **Flamelet 2D Curves** dialog box (*Figure 17.17* (p. 931)).

Figure 17.17 The Flamelet 2D curves Dialog Box

For the steady flamelet model with more than one flamelet, you can display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation using the **Flamelet 3D Surfaces** dialog box (e.g., *Figure 17.18* (p. 932)).

To access this dialog box, click the **Display Flamelets...** button in the **Flamelet** tab of the **Species Model** dialog box, as shown in *Figure 17.15* (p. 928).

Figure 17.18 The Flamelet 3D Surfaces Dialog Box

To display the flamelet tables graphically, use the following procedure:

1. In the **Flamelet 3D Surfaces**
2. Specify the **Plot Type** as either **3D Surface** or **2D Curve on 3D Surface**.
 - For a 3D surface, enable or disable **Draw Numbers Box** under **Options**. When this option is turned on, the display will include a wireframe box with the numerical limits in each coordinate direction.
 - For a 2D curve on a 3D surface:
 - a. Specify whether you want to write the plot data to a file by toggling **Write To File** under **Options**.
 - b. Specify the **X-Axis Function** against which the plot variable will be displayed by selecting **Scalar Dissipation (χ)**, or **Mixture Fraction (f)**. The variable that is not selected will be held constant.
 - c. Specify the type of discretization (i.e., how the flamelet data will be sliced) for the variable that is being held constant (under **Constant Value of Mixture Fraction** or **Constant Value of Scalar Dissipation**).
 - If you selected **Index** under **Slice by**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Flamelet** tab of the **Species Model** dialog box (see *Calculating the Flamelets (p. 927)*).
 - If you selected **Value** under **Slice by**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.

3. Write or display the flamelet table results. If you have turned on the **Write To File** option for a 2D plot, click **Write** and specify a name for the file in *The Select File Dialog Box (p. 33)*. Otherwise, click **Plot** or **Display** as appropriate to display a 2D plot or 3D surface in the graphics window.

Figure 17.19 (p. 933) and *Figure 17.20 (p. 933)* show examples of a 2D curve plot and 3D surface plot of a flamelet table.

Figure 17.19 Example 2D Plot of Flamelet Data

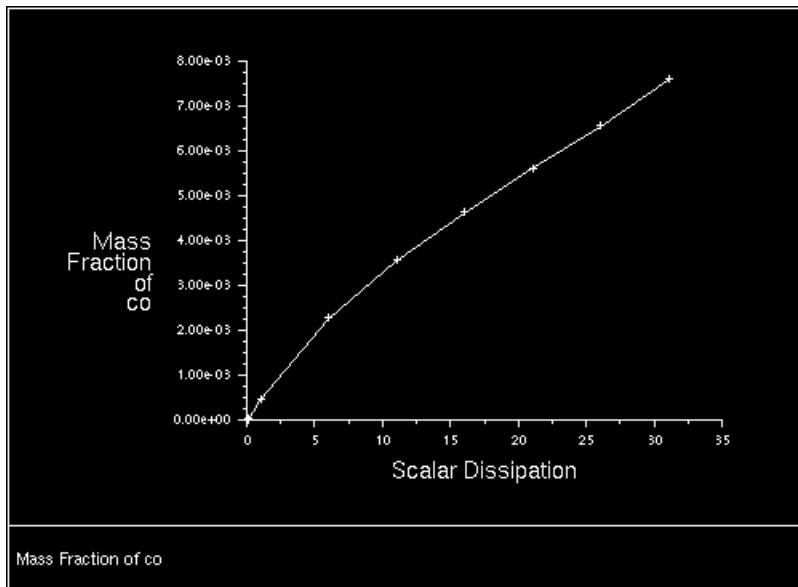

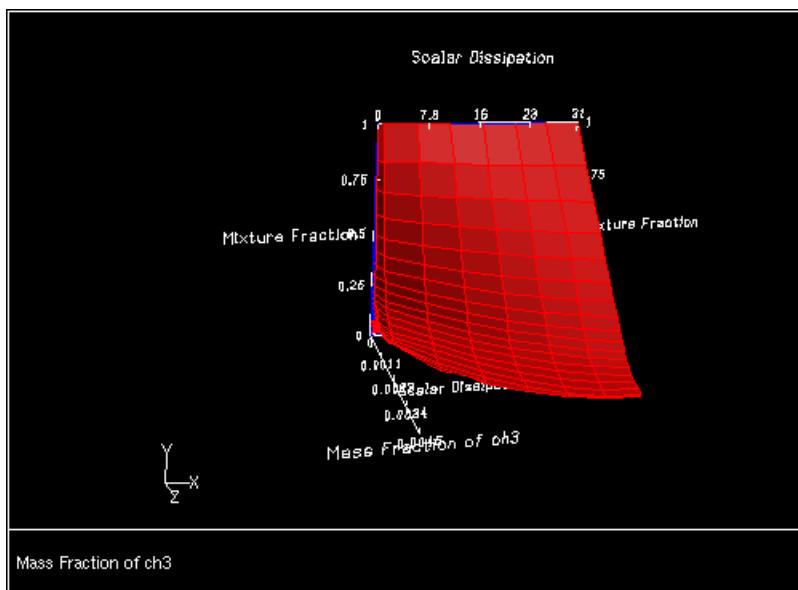

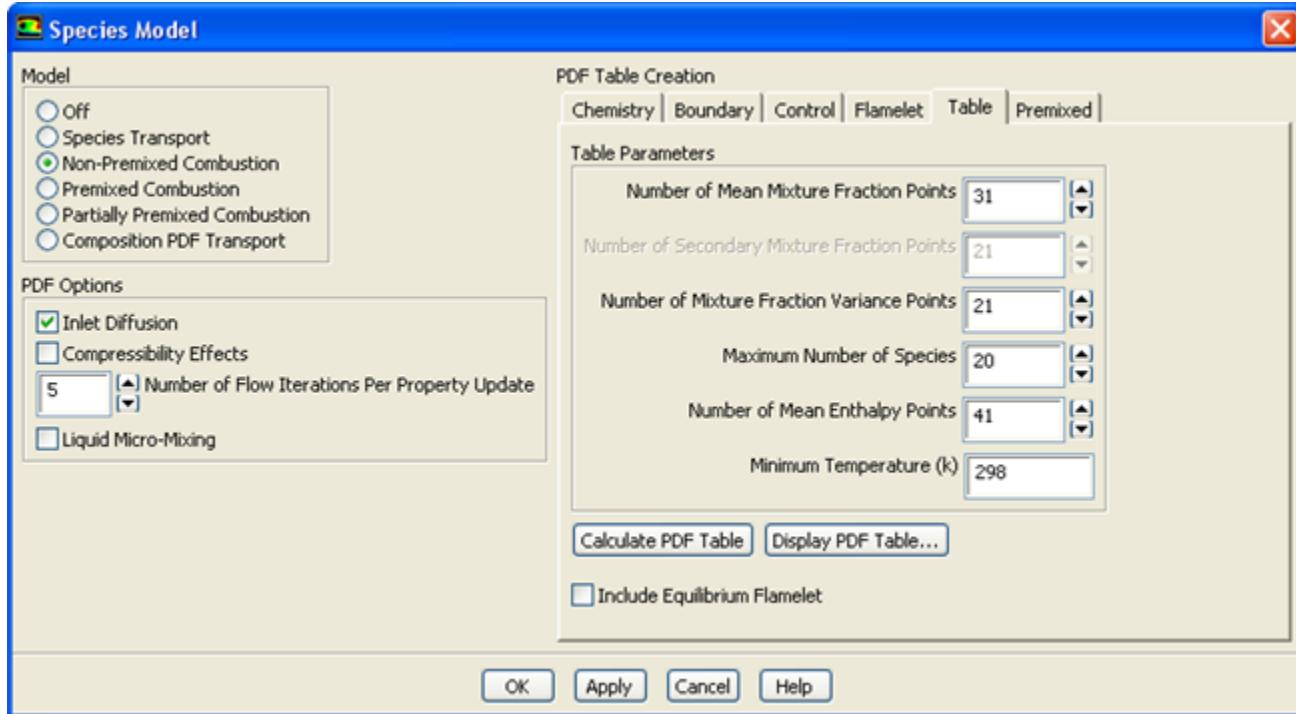

Figure 17.20 Example 3D Plot of Flamelet Data

17.7. Calculating the Look-Up Tables

ANSYS FLUENT requires additional inputs that are used in the creation of the look-up tables. Several of these inputs control the number of discrete values for which the look-up tables will be computed. These parameters are input in the **Table** tab of the **Species Model** dialog box (e.g., *Figure 17.21 (p. 934)*).

Figure 17.21 The Species Model Dialog Box (Table) Tab

The look-up table parameters are as follows:

Number of Mean Mixture Fraction Points

is the number of discrete values of \bar{f} at which the look-up tables will be computed. For a two-mixture-fraction model, this value is the number of points in the instantaneous state profile used to compute the PDF if you choose the β PDF model (see [Tuning the PDF Parameters for Two-Mixture-Fraction Calculations \(p. 951\)](#)). Increasing the number of points will yield a more accurate PDF shape, but the calculation will take longer. The mean mixture fraction points will be automatically clustered around the stoichiometric mixture fraction value.

Number of Mixture Fraction Variance Points

is the number of discrete values of \bar{f}^2 at which the look-up tables will be computed. Lower resolution is acceptable because the variation along the \bar{f}^2 axis is, in general, slower than the variation along the \bar{f} axis of the look-up tables. This option is available only when no secondary stream has been defined.

Number of Secondary Mixture Fraction Points

is the number of discrete values of p_{sec} at which the look-up tables will be computed. Like the **Number of Mean Mixture Fraction Points**, ANSYS FLUENT will use the **Number of Secondary Mixture Fraction Points** to compute the equilibrium state-relation if you choose the β PDF option (see [Tuning the PDF Parameters for Two-Mixture-Fraction Calculations \(p. 951\)](#)) for a two-mixture-fraction model. A larger number of points will give a more accurate shape for the PDF, but with a longer calculation time. This option is available only when a secondary stream has been defined.

Maximum Number of Species

is the maximum number of species that will be included in the look-up tables. The maximum number of species that can be included is 100. Note that the maximum number of species for the equilibrium computations is 500, and the maximum number of species for the flamelet generation and importing

is 300. ANSYS FLUENT will automatically select the species with the largest mole fractions to include in the PDF table.

Number of Mean Enthalpy Points

is the number of discrete values of enthalpy at which the look-up tables will be computed. This input is required only if you are modeling a non-adiabatic system. The number of points required will depend on the chemical system that you are considering, with more points required in high heat release systems (e.g., hydrogen/oxygen flames). This option is not available with the unsteady flamelet model.

Minimum Temperature

is used to determine the lowest temperature for which the look-up tables are generated. Your input should correspond to the minimum temperature expected in the domain (e.g., an inlet or wall temperature). The minimum temperature should be set 10–20 K below the minimum system temperature. This option is available only if you are modeling a non-adiabatic system. This option is not available with the unsteady flamelet model.

Include Equilibrium Flamelet

specifies that an equilibrium flamelet (i.e., $\chi = 0$) will be generated in ANSYS FLUENT and appended to the flamelet library before the PDF table is calculated. This option is available when generating or importing multiple flamelets, as well as when a single flamelet is considered. In the latter case, the PDF table will consist of two scalar dissipation slices, namely the equilibrium slice at $\chi = 0$, and the flamelet slice. This option is not available with the equilibrium chemistry model or the unsteady flamelet model.

When you are satisfied with your inputs, click **Calculate PDF Table** to generate the look-up tables.

The computations performed for a single-mixture-fraction calculation culminate in the discrete integration of [Equation 8–16](#) (or [Equation 8–24](#) in the [Theory Guide](#)) as represented in [Figure 8.5: "Logical Dependence of Averaged Scalars on Mean Mixture Fraction, the Mixture Fraction Variance, and the Chemistry Model \(Adiabatic, Single-Mixture-Fraction Systems\)"](#) (or [Figure 8.6: "Logical Dependence of Averaged Scalars on Mean Mixture Fraction, the Mixture Fraction Variance, Mean Enthalpy, and the Chemistry Model \(Non-Adiabatic, Single-Mixture-Fraction Systems\)"](#) in the [Theory Guide](#)). For a two-mixture-fraction calculation, ANSYS FLUENT will calculate the physical properties using [Equation 8–14](#) or its adiabatic equivalent. The computation time will be shortest for adiabatic single-mixture-fraction equilibrium calculations and longest for non-adiabatic calculations involving multiple flamelet generation. Below, sample outputs are shown for an adiabatic single-mixture-fraction equilibrium calculation and a non-adiabatic calculation with laminar flamelets:

```

Generating PDF lookup table
Type of the PDF Table: Adiabatic Table (Two Streams)
Calculating table ......

1271 points calculated
22 species added
PDF Table successfully generated!

Generating PDF lookup table
Type of the PDF Table: Nonadiabatic Table with Strained Flamelet Model (Two Streams)
Calculating table .....
calculating temperature limits .....
calculating temperature limits .....
calculating scalar dissipation slices .....
- scalar dissipation slice 9
calculating equilibrium slice .....
Performing PDF integrations.....

16810 points calculated
17 species added
PDF Table successfully generated!
Initializing PDF table arrays and structures.

```

Important

Note that there is a significant difference in run-time between the one-mixture fraction model and the two-mixture fraction model. In the one-mixture fraction model, the PDF table contains the mean data of density, temperature, and specific heats, and is three-dimensional for an equilibrium nonadiabatic case (mean mixture fraction, mixture fraction variance, and mean heat loss). For this case, ANSYS FLUENT updates properties every flow iteration. In the case of the two-mixture fraction model, only the instantaneous state relationships are stored and mean properties are calculated from these by performing PDF integrations in every cell of the ANSYS FLUENT simulation. Since this is computationally expensive, ANSYS FLUENT provides the option of only updating properties after a specified number of iterations.

After completing the calculation at the specified number of mixture fraction points, ANSYS FLUENT reports that the calculation succeeded. In a single-mixture-fraction case, the resulting look-up tables take the form illustrated in [Figure 8.8: "Visual Representation of a Look-Up Table for the Scalar \(Mean Value of Mass Fractions, Density, or Temperature \) as a Function of Mean Mixture Fraction and Mixture Fraction Variance in Adiabatic Single-Mixture-Fraction Systems"](#) in the Theory Guide (or [Figure 8.10: "Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems"](#), for non-adiabatic systems). These look-up tables can be plotted using the available graphics tools, as described in [Postprocessing the Look-Up Table Data](#) (p. 937).

Note that in non-adiabatic calculations, the console window will report that the temperature limits and enthalpy slices have been calculated.

For a two-mixture-fraction case, the resulting look-up tables take the form illustrated in [Figure 8.9: "Visual Representation of a Look-Up Table for the Scalar \$\phi_I\$ as a Function of Fuel Mixture Fraction and Secondary Partial Fraction in Adiabatic Two-Mixture-Fraction Systems"](#) in the Theory Guide (or [Figure 8.11: "Visual Representation of a Look-Up Table for the Scalar \$\phi_I\$ as a Function of Fuel Mixture Fraction and Secondary Partial Fraction, and Normalized Heat Loss/Gain in Non-Adiabatic Two-Mixture-Fraction Systems"](#), for non-adiabatic systems).

17.7.1. Full Tabulation of the Two-Mixture-Fraction Model

The default algorithm for the two-mixture-fraction model is to perform PDF integrations of the equilibrium state relationships at run-time. Since these are multi-dimensional integrals, the default two-mixture-fraction model can be computationally demanding.

Alternatively, you may want to pre-compute these integrations and create 4D look-up tables for adiabatic simulations, or 5D tables for non-adiabatic simulations. Such high-dimensional tables are computationally expensive to build, and may require large memory and disk storage, but can offer substantial improvement in run-time speed.

The option to create a fully-tabulated two-mixture-fraction table is available in cases with the two-mixture-fraction model enabled, via the text command:

```
define/models/species/full-tabulation?
```

If you are modeling pollutant formation, please note that the full tabulation option is not compatible with the **mixture-fraction** option for **PDF Mode** in the **Turbulence Interaction Mode** tab settings. See [Setting Turbulence Parameters](#) (p. 1022) for details on Turbulence Interaction options for pollutant modeling.

17.7.2. Stability Issues in Calculating Chemical Equilibrium Look-Up Tables

Complex chemistry and non-adiabatic effects may make the equilibrium calculation more time-consuming and difficult. In some instances the equilibrium calculation may even fail. You may be able to eliminate any difficulties that you encounter by trying the calculation as an adiabatic system. Adiabatic system calculations are generally quite straightforward and can provide valuable insight into the optimal inputs to the non-adiabatic calculation.

Additional stability issues may arise for solid or heavy liquid fuels that have been defined using the empirical fuel approach. You may find that, for rich fuel mixtures, the equilibrium calculation produces very low temperatures and eventually fails. This indicates that strong endothermic reactions are taking place and the mixture is not able to sustain them. In this situation, you may need to raise the heating value of the fuel until ANSYS FLUENT produces acceptable results. Provided that your fuel will be treated as a liquid or solid (coal) fuel, you can maintain the desired heating value in your ANSYS FLUENT simulation. This is accomplished by defining the difference between the desired and the adjusted heating values as latent heat (in the case of combusting solid fuel) or heat of pyrolysis (in the case of liquid fuel).

17.7.3. Saving the Look-Up Tables

The look-up tables may be stored in a file that you can read back into later sessions of ANSYS FLUENT. The look-up tables should be saved before you exit from the current ANSYS FLUENT session.

File → Write → PDF...

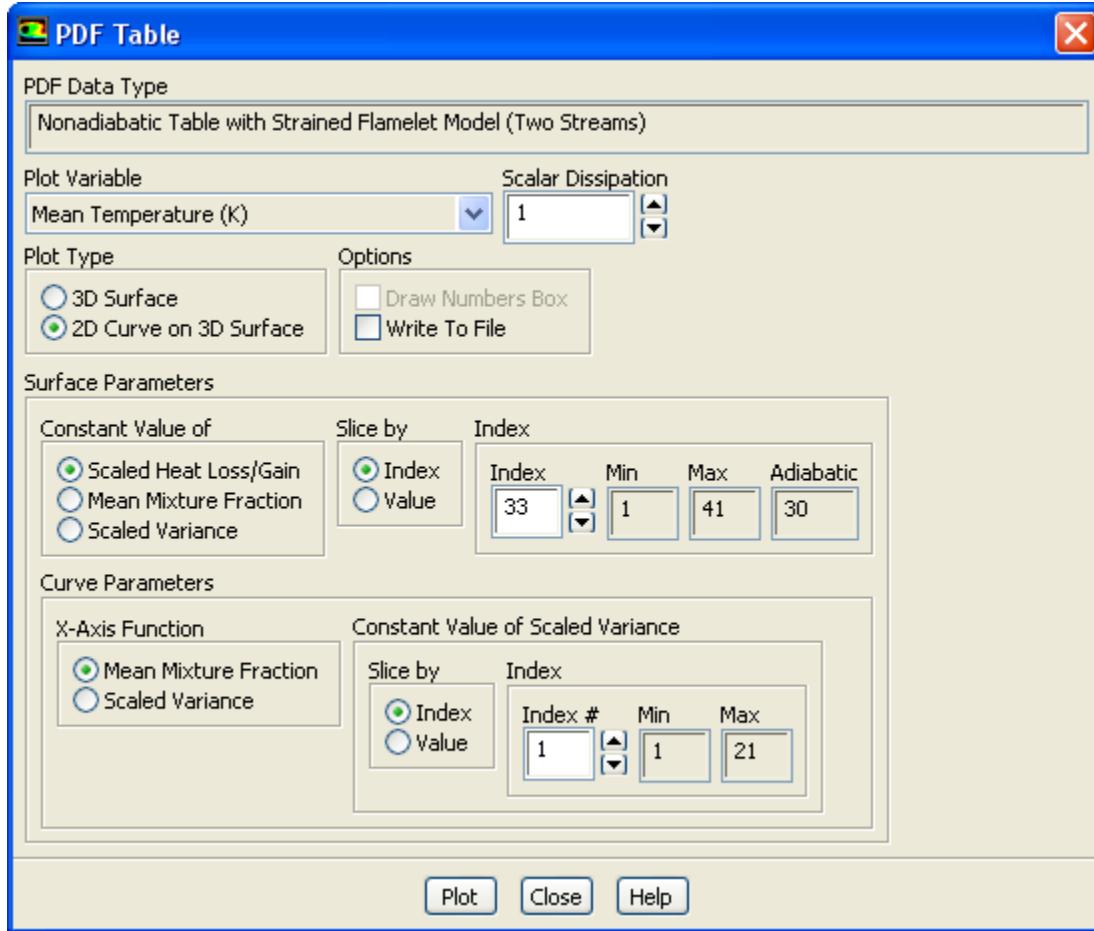

By default, the file will be saved as formatted (ASCII, or text). To save a binary (unformatted) file, turn on the **Write Binary Files** option in the **Select File** dialog box.

17.7.4. Postprocessing the Look-Up Table Data

It is important for you to view your temperature and species tables to ensure that they are adequately but not excessively resolved. Inadequate resolution will lead to inaccuracies, and excessive resolution will lead to unnecessarily slow calculation times.

After a PDF table has been generated or read into ANSYS FLUENT, you can display 2D plots and 3D surfaces showing the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy using the **PDF Table** dialog box (e.g., *Figure 17.22 (p. 938)*). The **PDF Table** dialog box can be accessed in one of two ways: you can click the **Display PDF Table...** button in the **Table** tab of the **Species Model** dialog box (as shown in *Figure 17.21 (p. 934)*) or you can use the path

Display → PDF Tables/Curves...

Figure 17.22 The PDF Table Dialog Box (Non-Adiabatic Case With Flamelets)

To display the look-up tables graphically, use the following procedure:

1. In the **PDF Table** dialog box, in the **Plot Variable** drop-down list you can select temperature, density, or species fraction as the variable to be plotted.
2. (multiple flamelets only) Specify the value of the **Scalar Dissipation**. In the case of non-adiabatic flamelets, there is the additional parameter of mean enthalpy. In addition to varying the mean enthalpy and mean mixture fraction, you can vary the display of the PDF table by changing the value of the scalar dissipation, which gives the table a fourth “dimension”.
3. Specify the **Plot Type** as either **3D Surface** or **2D Curve on 3D Surface**. In the equilibrium model, a 2D curve is a slice of a 3D surface, and thus some options selected for a 3D surface may impact the display of a 2D curve.
 - For a 3D surface:
 - a. Enable or disable **Draw Numbers Box** under **Options**. When this option is turned on, the display will include a wireframe box with the numerical limits in each coordinate direction.
 - b. (non-adiabatic cases only) Under **Surface Parameters**, specify the discrete independent variable to be held constant in the look-up table (**Constant Value of**).
 - For a single-mixture-fraction case, select **Scaled Heat Loss/Gain** (\bar{H}), **Mean Mixture Fraction** (\bar{f}), or **Scaled Variance** (\bar{f}''^2). For any mean mixture fraction \bar{f} , the variance varies between a minimum of 0 and a maximum of $\bar{f}(1 - \bar{f})$. In order to view the

mixture fraction variance, it is normalized by [Equation 17-7 \(p. 939\)](#) so that for any mean mixture fraction the scaled variance ranges from 0 to 0.25.

$$\overline{f_s'^2} = 0.25 \frac{\overline{f'^2}}{\overline{f} (1 - \overline{f})} \quad (17-7)$$

- For a two-mixture-fraction case, the **Scaled Heat Loss/Gain** is the only available option.
- c. (non-adiabatic cases only) Specify whether the 3D array of data points available in the look-up table will be sliced by **Index** or **Value** under **Slice by**.
 - If you selected **Index**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Table** tab of the **Species Model** dialog box (see [Calculating the Look-Up Tables \(p. 933\)](#)). If you specified to hold the enthalpy (**Scaled Heat Loss/Gain**) constant, the enthalpy slice index corresponding to the adiabatic case will be displayed in the **Adiabatic** field.
 - If you selected **Value**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.
- For a 2D curve on a 3D surface:
 - a. Specify whether you want to write the plot data to a file by toggling **Write To File** under **Options**.
 - b. Under **Curve Parameters**, specify the **X-Axis Function** against which the plot variable will be displayed.
 - For an adiabatic single-mixture-fraction case, select **Mean Mixture Fraction** (\overline{f}), or **Scaled Variance** ($\overline{f'^2}$).
 - For a non-adiabatic single-mixture-fraction case, the options will depend on what was selected under **Constant Value of** under **Surface Parameters**, but will include two of the following: **Scaled Heat Loss/Gain** (\overline{H}), **Mean Mixture Fraction**, and **Scaled Variance**.
 - For a two-mixture-fraction case, select **Fuel Mixture Fraction** (f_{fuel}) or **Secondary Partial Fraction** (p_{sec}).
 - c. Specify the type of discretization (i.e., how the look-up table data will be sliced) for the variable that is being held constant (under **Constant Value of Mean Mixture Fraction**, **Constant Value of Scaled Variance**, etc.). Note that for non-adiabatic cases, each 3D surface slice contains a full set of 2D slices.
 - If you selected **Index** under **Slice by**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Table** tab of the **Species Model** dialog box (see [Calculating the Look-Up Tables \(p. 933\)](#)).
 - If you selected **Value** under **Slice by**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.

4. Write or display the look-up table results. If you have turned on the **Write To File** option for a 2D plot, click **Write** and specify a name for the file in *The Select File Dialog Box* (p. 33). Otherwise, click **Plot** or **Display** as appropriate to display a 2D plot or 3D surface in the graphics window.

Figure 17.23 (p. 940) and *Figure 17.24* (p. 940) show examples of 2D plots derived for a very simple hydrocarbon system.

Figure 17.23 Mean Species Fraction Derived From an Equilibrium Chemistry Calculation

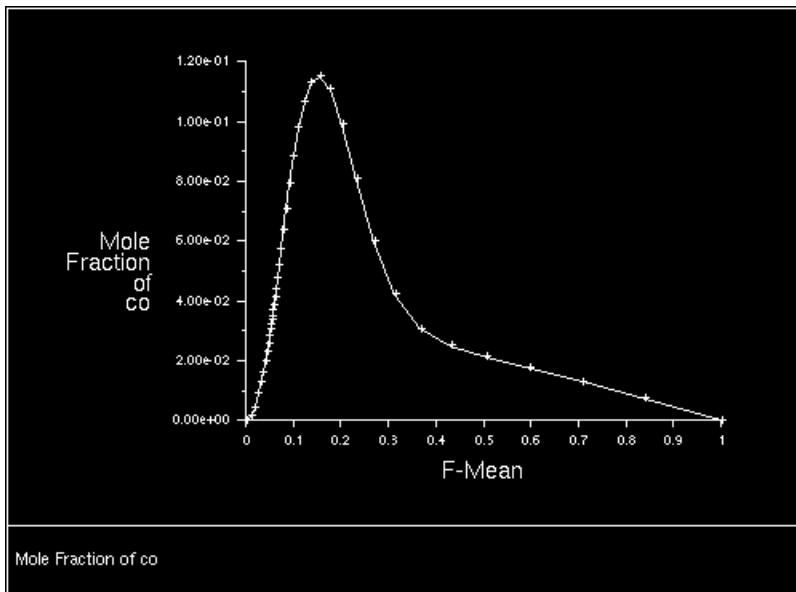

Figure 17.24 Mean Temperature Derived From an Equilibrium Chemistry Calculation

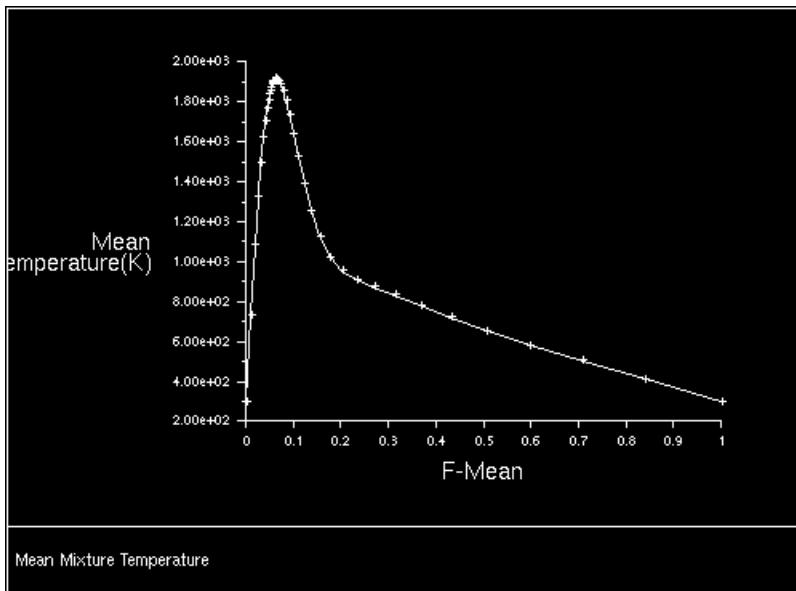

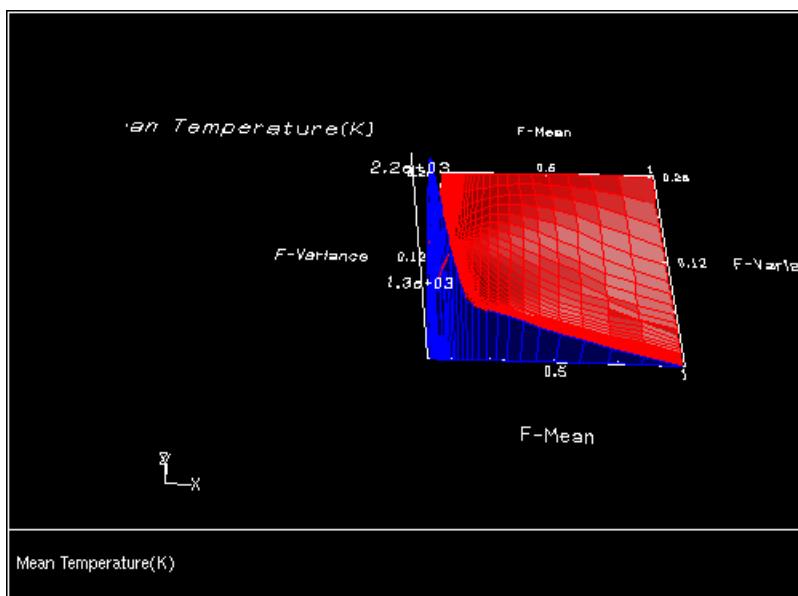

Figure 17.25 (p. 941) shows an example of a 3D surface derived for the same system.

Figure 17.25 3D Plot of Look-Up Table for Temperature Generated for a Simple Hydrocarbon System

17.7.4.1. Files for Flamelet Modeling

In this section, information is provided about the standard flamelet files used for flamelet generation and import.

17.7.4.1.1. Standard Flamelet Files

The data structure for the standard flamelet file format is based on keywords that precede each data section. If any of the keywords in your flamelet data file do not match the supported keywords, you will have to manually edit the file and change the keywords to one of the supported types. (The ANSYS FLUENT flamelet filter is case-insensitive, so you need not worry about capitalization within the keywords.)

The following keywords are supported by the ANSYS FLUENT filter:

- Header section: HEADER
- Main body section: BODY
- Number of species: NUMOFSPECIES
- Number of grid points: GRIDPOINTS
- Pressure: PRESSURE
- Strain rate: STRAINRATE
- Scalar dissipation: CHI
- Temperature: TEMPERATURE and TEMP
- Mass fraction: MASSFRACTION-
- Mixture fraction: Z

17.7.4.1.1.1. Sample File

A sample flamelet file in the standard format is provided below. Note that not all species are listed in this file.

```

17.7.4.1.1.2. Missing Species

ANSYS FLUENT will check whether all species in the flamelet data file exist in the thermodynamic properties databases thermo.db. If any of the species in the flamelet file do not exist, ANSYS FLUENT will issue an error message and halt the flamelet import. If this occurs, you can either add the missing species to the database, or remove the species from the flamelet file.

You should not remove a species from the flamelet data file unless its species concentration is very small (10^{-3} or less) throughout the flamelet profile. If you remove a low-concentration species, you will not have the species concentrations available for viewing in the ANSYS FLUENT calculation, but the accuracy of the ANSYS FLUENT calculation will otherwise be unaffected.

Important

If you choose to remove any species, be sure to also update the number of species (keyword NUMOFSPECIES) in the flamelet data file, to reflect the loss of any species you have removed from the file.

If a species with relatively large concentration is missing from the ANSYS FLUENT thermodynamic databases, you will have to add it. Removing a high-concentration species from the flamelet file is not recommended.

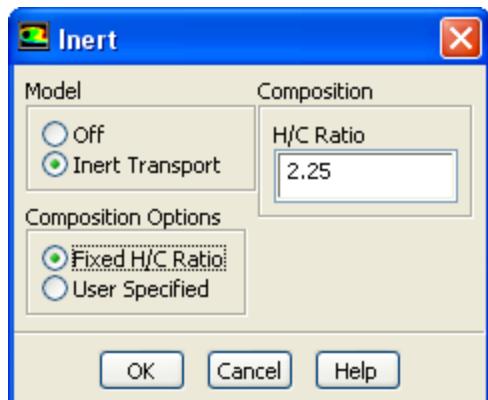

17.7.5. Setting Up the Inert Model

This section describes how to set up and apply the inert model. For a discussion about the theory, refer to [Using the Non-Premixed Model with the Inert Model](#) in the [Theory Guide](#).

To enable the inert model, make sure that the non-premixed or partially premixed model is selected in the **Species Model** dialog box, or that a PDF file is read. Refer to [Steps in Using the Non-Premixed Model \(p. 901\)](#) and [Modeling Partially Premixed Combustion \(p. 969\)](#) to learn more about these models.

◆ **Models** → **Inert** → **Edit...**

Figure 17.26 The Inert Model Dialog Box

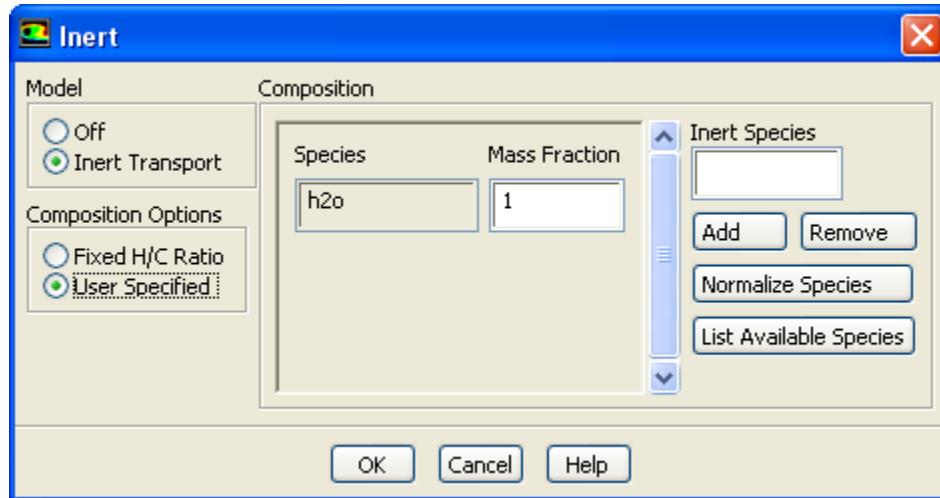

The **Inert** dialog box will be displayed ([Figure 17.26 \(p. 943\)](#)). To enable this model, select **Inert Transport**. The following steps will walk you through setting up the inert model:

1. Select **Fixed H/C Ratio** as the **Composition Option** if the hydrogen to carbon ratio is known. For example, for methane (CH_4) enter 4 for **H/C Ratio**.

Setting the H/C ratio assumes that the burned gas resulted from the complete, stoichiometric combustion of that hydrocarbon fuel with air, and the only products of the combustion are CO_2 , H_2O and N_2 .

2. Select **User Specified** as the **Composition Option** if you want to specify an arbitrary composition for the inert stream, as shown in [Figure 17.27 \(p. 944\)](#).

Figure 17.27 The Inert Model Dialog Box

You can specify your composition stream by adding or removing species if your stream is composed of species other than the default species list.

- To add species to the **Species** list, type the chemical formula under **Inert Species** and click **Add**.
- Enter the **Mass Fraction** of the newly added species. Continue in this manner until all of the inert species you want to include are shown in the **Species** list.
- Make sure the sum of the mass fractions add up to 1. ANSYS FLUENT will normalize the species mass fractions for you when you click **Normalize Species**.
- To remove a species from the list, type the chemical formula under **Inert Species** and click **Remove**.
- To print a list of all species in the thermodynamic database file (thermo.db) in the console window, click **List Available Species**.

17.7.5.1. Setting Boundary Conditions for Inert Transport

You will need to set appropriate boundary conditions at flow inlets and exits for the inert tracer mass fraction, Y_I . The tracer species mass fraction must be between zero and one, with the value of one meaning that all of the material entering the domain comes from the inert stream. The values for flow boundaries are set in the **Inert Stream** field of the inlet boundary condition dialog boxes, under the **Species** tab.

17.7.5.2. Initializing the Inert Stream

The main assumption of the inert model is that the composition of the inert stream does not change with combustion. For some dilutants, this is a very reasonable assumption, however, it is not valid for rich combustion where there is fuel in the exhaust stream. For cases where there is fuel or oxidizer left in the exhaust gas, accurate results will depend upon the user taking the fuel or oxidizer species into account when setting initial conditions.

17.7.5.2.1. Inert Fraction

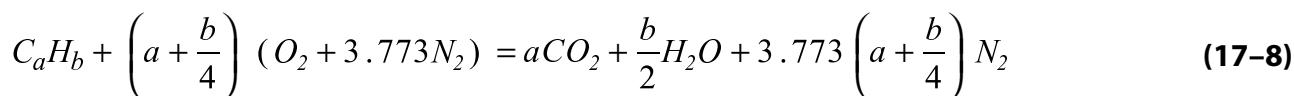

Initialization of the inert mass fraction Y_I is done in the same way as other variables: by entering in the appropriate value in the **Solution Initialization** task page. Another option for initialization is to patch the value of Y_I in a region of the domain. When the value of Y_I is patched in this way, ANSYS FLU-

ENT automatically recalculates the enthalpy field for the current temperature field in order to account for the change in composition.

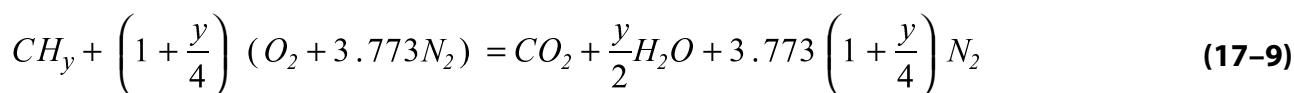

See [Patching Values in Selected Cells \(p. 1351\)](#) for details about patching values of solution variables.

17.7.5.2.2. Inert Composition

For combustion calculations which burn a hydrocarbon fuel, ANSYS FLUENT provides a straightforward way of setting the initial composition of the inert stream. The inert composition can be set by assuming a ratio of hydrogen to carbon in the following overall oxidation reaction (from Heywood [32] (p. 2368)):

which can be rewritten in terms of the ratio of hydrogen to carbon atoms ($y = b/a$) in the fuel as

If [Equation 17-9 \(p. 945\)](#) is solved for the mass fractions of CO_2 , H_2O and N_2 , the following relations are obtained:

$$\begin{aligned} Y_{CO_2} &= \frac{44.01}{y_{tot}} \\ Y_{H_2O} &= \frac{9.01y}{y_{tot}} \\ Y_{N_2} &= \frac{26.56192y + 106.24768}{y_{tot}} \end{aligned} \quad (17-10)$$

where

$$y_{tot} = 35.57192y + 150.25768$$

Setting the H/C ratio assumes that the burned gas resulted from the complete, stoichiometric combustion of that hydrocarbon fuel, and the only products of the combustion are CO_2 , H_2O and N_2 . An arbitrary composition for the inert stream can also be specified in the interface.

17.7.5.3. Resetting Inert EGR

ANSYS FLUENT allows burned gases to be converted to an inert gas. This has been designed with in-cylinder combustion modeling in mind to aid the simulation of multiple cycles of such engines and of exhaust gas recirculation (EGR). This facility is accessed via the **Dynamic Mesh Events** dialog box, as described in [Resetting Inert EGR \(p. 645\)](#). There, you will need to set the crank angle at which the event occurs (usually shortly before the inlet valves open) and the outlet zones from which the inert composition is to be calculated. The inert composition is then calculated as a progress variable weighted average of the composition across these zones. The use of progress variable weighting reduces the impact on

the inert composition of small amounts of unburned gases remaining at these zones. However, if significant proportions of unburned gases are present at the chosen outlet zones, it may be inappropriate to treat them as inert gases during subsequent time steps. Therefore, you should consider setting the inert composition manually as detailed in [Initializing the Inert Stream \(p. 944\)](#).

Having calculated the inert composition, burned gases throughout the model are converted to inert gases and the combustion reset. This entails:

- Setting the inert mass fraction to be:

$$Y_{inert,new} = Y_{inert} + (1.0 - Y_{inert}) \cdot \tilde{c} \quad (17-11)$$

- Setting the progress variable \tilde{c} to zero everywhere
- Resetting other partially premixed combustion model equations appropriately:
 - For the ECFM model, flame area density is set to zero
 - For the G-Equation model, G (the mean distance from the flame front) is set to a negative value everywhere

Note

The reverse flow value of the inert stream at the chosen outlets is set to be 1.0.

Important

You should be aware that a possible error inherent in this process is that if you choose to perform this reset when combustion is still taking place then that combustion will be stopped.

17.8. Defining Non-Premixed Boundary Conditions

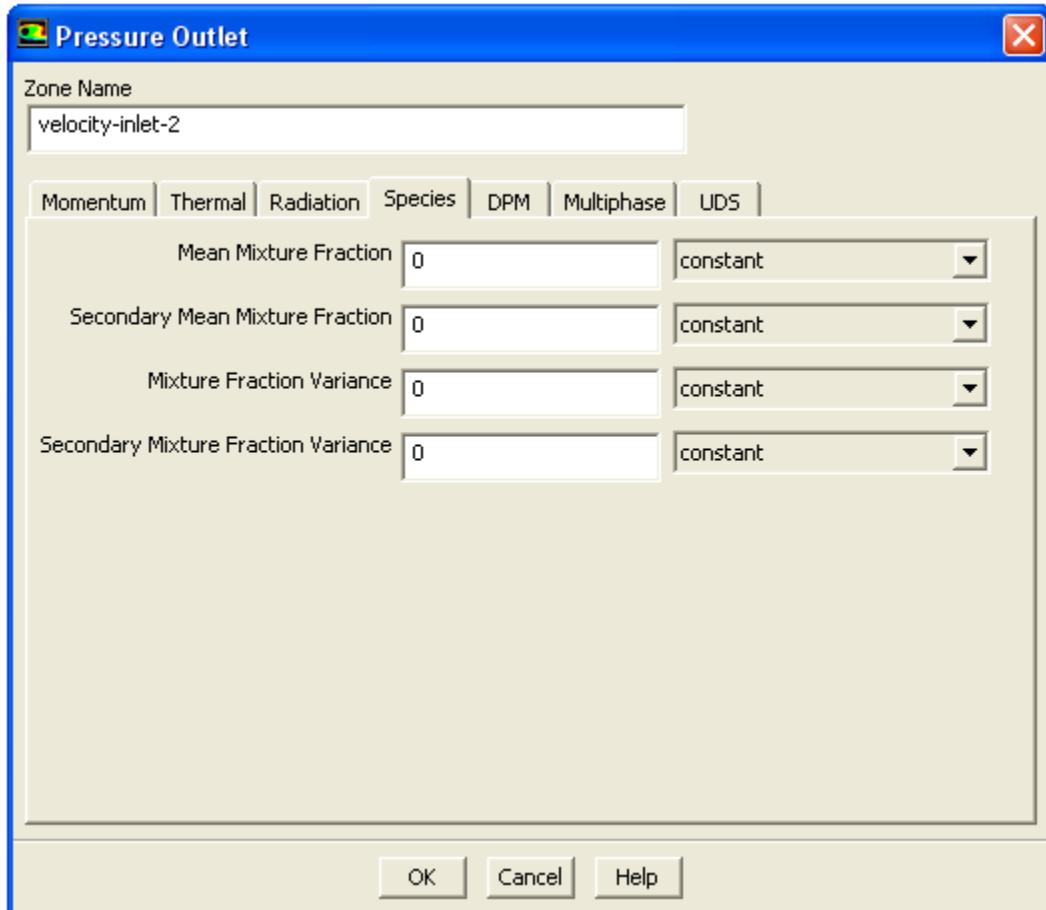

For information about defining non-premixed boundary conditions, please see the following sections:

- [17.8.1. Input of Mixture Fraction Boundary Conditions](#)
- [17.8.2. Diffusion at Inlets](#)
- [17.8.3. Input of Thermal Boundary Conditions and Fuel Inlet Velocities](#)

17.8.1. Input of Mixture Fraction Boundary Conditions

When the non-premixed combustion model is used, flow boundary conditions at inlets and exits (i.e., velocity or pressure, turbulence intensity) are defined in the usual way. Species mass fractions at inlets are not required. Instead, you define values for the mean mixture fraction, \bar{f} , and the mixture fraction variance, $\bar{f''}$, at inlet boundaries. (For problems that include a secondary stream, you will define boundary conditions for the mean secondary partial fraction and its variance as well as the mean fuel mixture fraction and its variance.) These inputs provide boundary conditions for the conservation equations you will solve for these quantities. The inlet values are supplied in the boundary conditions task page, under the available tabs, for the selected inlet boundary (e.g., [Figure 17.28 \(p. 947\)](#)).

Boundary Conditions

Figure 17.28 The Velocity Inlet Dialog Box Showing Mixture Fraction Boundary Conditions

Click the **Species** tab and input the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions). In general, the inlet value of the mean fractions will be 1.0 or 0.0 at flow inlets: the mean fuel mixture fraction will be 1.0 at fuel stream inlets and 0.0 at oxidizer or secondary stream inlets; the mean secondary mixture fraction will be 1.0 at secondary stream inlets and 0.0 at fuel or oxidizer inlets. The fuel or secondary mixture fraction will lie between 0.0 and 1.0 only if you are modeling flue gas recycle, as illustrated in [Figure 8.15: "Using the Non-Premixed Model with Flue Gas Recycle"](#) and discussed in [Definition of the Mixture Fraction](#) in the [Theory Guide](#). The fuel or secondary mixture fraction variance can usually be taken as zero at inlet boundaries.

17.8.2. Diffusion at Inlets

In some cases, you may wish to include the diffusive transport of mixture fraction through the inlets of your domain. You can do this by enabling inlet mixture-fraction diffusion. By default, ANSYS FLUENT excludes the diffusion flux of mixture fraction at inlets. To enable inlet diffusion, use either the

```
define/models/species/inlet-diffusion?
```

text command, or the **Species Model** dialog box ([Figure 17.1 \(p. 903\)](#))

◆ **Models** → **Species** → **Edit...**

and enable the **Inlet Diffusion** option.

17.8.3. Input of Thermal Boundary Conditions and Fuel Inlet Velocities

If your model is non-adiabatic, you should input the **Temperature** at the flow inlets. Recall that the inlet temperatures were requested during the table construction in the **Chemistry** tab of the **Species Model** dialog box, and were used in the construction of the look-up tables. The inlet temperatures for each fuel, oxidizer, and secondary inlet in your non-adiabatic model should be defined, in addition, as boundary conditions in ANSYS FLUENT. It is acceptable for the inlet temperature boundary conditions to differ slightly from those you input for the look-up table calculations. If the inlet temperatures differ significantly from those in the **Chemistry** tab, however, your look-up tables may provide inaccurate interpolation. This is because the discrete points in the look-up tables were clustered around a finite range of the temperatures defined in the **Chemistry** tab, and your input in the ANSYS FLUENT inlet boundary condition may fall outside this range.

Wall thermal boundary conditions should also be defined for non-adiabatic non-premixed combustion calculations. You can use any of the standard conditions available in ANSYS FLUENT, including specified wall temperature, heat flux, external heat transfer coefficient, or external radiation. If radiation is to be included within the domain, the wall emissivity should be defined as well. See *Thermal Boundary Conditions at Walls* (p. 322) for details about thermal boundary conditions at walls.

17.9. Defining Non-Premixed Physical Properties

When you use the non-premixed combustion model, the material used for all fluid zones is automatically set to **pdf-mixture**. This material is a special case of the mixture material concept discussed in *Mixture Materials* (p. 856). The constituent species of this mixture are the species that were calculated in the PDF look-up table creation; you cannot change them directly. When the non-premixed model is used, heat capacities, molecular weights, and enthalpies of formation for each species considered are extracted from the chemical database, so you will not modify any properties for the constituent species in the PDF mixture. For the PDF mixture itself, the mean density and mean specific heat are determined from the look-up tables.

The physical property inputs for a non-premixed combustion problem are therefore only the transport properties (viscosity, thermal conductivity, etc.) for the PDF mixture. To set these in the *Create/Edit Materials Dialog Box* (p. 1882), choose **mixture** as the **Material Type**, **pdf-mixture** (the default, and only choice) in the **Mixture Materials** list, and set the desired values for the transport properties.

Materials

See *Physical Properties* (p. 403) for details about setting physical properties. The transport properties in a non-premixed combustion problem can be defined as functions of temperature, if desired, but not as functions of composition. In practice, since turbulence effects will dominate, it will be of little benefit to include even the temperature dependence of the laminar transport properties.

If you are modeling radiation heat transfer, you will also input radiation properties, as described in *Radiation Properties* (p. 454). Composition-dependent absorption coefficients (using the WSGGM) are allowed.

The non-premixed model can also be used with real gas models in ANSYS FLUENT, if the **Compressibility Effects** option is enabled in the **Species Model** dialog box. In this case, the density method is based on one of the four real gas models, discussed in *Equation of State* (p. 475) and *Using the Cubic Equation of State Real Gas Models* (p. 482).

17.10. Solution Strategies for Non-Premixed Modeling

The non-premixed model setup and solution procedure in ANSYS FLUENT differs slightly for single- and two-mixture-fraction problems. Below, an overview of each approach is provided. Note that your ANSYS FLUENT case file must always meet the restrictions listed for the non-premixed modeling approach in [Restrictions on the Mixture Fraction Approach](#) in the [Theory Guide](#). In this section, details are provided regarding the problem definition and calculation procedures you follow in ANSYS FLUENT.

For additional information, please see the following sections:

- 17.10.1. Single-Mixture-Fraction Approach
- 17.10.2. Two-Mixture-Fraction Approach
- 17.10.3. Starting a Non-Premixed Calculation From a Previous Case File
- 17.10.4. Solving the Flow Problem

17.10.1. Single-Mixture-Fraction Approach

For a single-mixture-fraction system, when you have completed the calculation of the PDF look-up tables, you are ready to begin your reacting flow simulation. In ANSYS FLUENT, you will solve the flow field and predict the spatial distribution of \bar{f} and $\bar{f}^{'2}$ (and \bar{H} if the system is non-adiabatic or $\bar{\chi}$ if the system is based on laminar flamelets). ANSYS FLUENT will obtain the corresponding values of temperature and individual chemical species mass fractions from the look-up tables.

17.10.2. Two-Mixture-Fraction Approach

When a secondary stream is included, ANSYS FLUENT will solve transport equations for the mean secondary partial fraction (p_{sec}) and its variance in addition to the mean fuel mixture fraction and its variance. ANSYS FLUENT will then look up the instantaneous values for temperature, density, and individual chemical species in the look-up tables, compute the PDFs for the fuel and secondary streams, and calculate the mean values for temperature, density, and species.

Note that in order to avoid both inaccuracies and unnecessarily slow calculation times, it is important for you to view your temperature and species tables in ANSYS FLUENT to ensure that they are adequately but not excessively resolved.

17.10.3. Starting a Non-Premixed Calculation From a Previous Case File

You can read a previously defined ANSYS FLUENT case file as a starting point for your non-premixed combustion modeling. If this case file contains inputs that are incompatible with the current non-premixed combustion model, ANSYS FLUENT will alert you when the non-premixed model is turned on and it will turn off those incompatible models. For example, if the case file includes species that differ from those included in the PDF file created by ANSYS FLUENT, these species will be disabled. If the case file contains property descriptions that conflict with the property data in the chemical database, these property inputs will be ignored.

Important

PDF files created by prePDF 2 or older are not supported by this version of ANSYS FLUENT. The files generated by PrePDF version 3 or newer, are fully compatible.

In the **Species Model** dialog box, select **Non-Premixed Combustion** under the **Model** heading. When you click **OK** in the **Species Model** dialog box, *The Select File Dialog Box (p. 33)* will immediately appear,

prompting you for the name of the PDF file containing the look-up tables created in a previous ANSYS FLUENT session. (The PDF file is the file you saved using the **File/Write/PDF...** menu item after computing the look-up tables.) ANSYS FLUENT will indicate that it has successfully read the specified PDF file:

```
Reading "/home/mydirectory/adiabatic.pdf"...
read 5 species (binary c, adiabatic fluent)
pdf file successfully read.
Done.
```

After you read in the PDF file, ANSYS FLUENT will inform you that some material properties have changed. You can accept this information; you will be updating properties later on.

You can read in an altered PDF file at any time by using the **File/Read/PDF...** menu item.

Important

Recall that the non-premixed combustion model is available only when you used the pressure-based solver; it cannot be used with the density-based solvers. Also, the non-premixed combustion model is available only when turbulence modeling is active.

If you are modeling a non-adiabatic system and you wish to include the effects of compressibility, re-open the **Species Model** dialog box and turn on **Compressibility Effects** under **PDF Options**. This option tells ANSYS FLUENT to update the density according to [Equation 17-1 \(p. 907\)](#). When the non-premixed combustion model is active, you can enable compressibility effects only in the **Species Model** dialog box. For other models, you will specify compressible flow (**ideal-gas**, **boussinesq**, etc.) in the **Create/Edit Materials** dialog box. See [Specifying the Operating Pressure for the System \(p. 907\)](#) and [Tuning the PDF Parameters for Two-Mixture-Fraction Calculations \(p. 951\)](#) for more information about compressibility effects.

17.10.3.1. Retrieving the PDF File During Case File Reads

The PDF filename is specified to ANSYS FLUENT only once. Thereafter, the filename is stored in your ANSYS FLUENT case file and the PDF file will be automatically read into ANSYS FLUENT whenever the case file is read. ANSYS FLUENT will remind you that it is reading the PDF file after it finishes reading the rest of the case file by reporting its progress in the text (console) window.

Note that the PDF filename stored in your case file may not contain the full name of the directory in which the PDF file exists. The full directory name will be stored in the case file only if you initially read the PDF file through the GUI (or if you typed in the directory name along with the filename when using the text interface). In the event that the full directory name is absent, the automatic reading of the PDF file may fail (since ANSYS FLUENT does not know which directory to look in for the file), and you will need to manually specify the PDF file. The safest approaches are to use the GUI when you first read the PDF file or to supply the full directory name when using the text interface.

17.10.4. Solving the Flow Problem

The next step in the non-premixed combustion modeling process in ANSYS FLUENT is the solution of the mixture fraction and flow equations. First, initialize the flow. By default, the mixture fraction and its variance have initial values of zero, which is the recommended value; you should generally not set non-zero initial values for these variables. See [Initializing the Solution \(p. 1348\)](#) for details about solution initialization.

Solution Initialization

Next, begin calculations in the usual manner.

Run Calculation

During the calculation process, ANSYS FLUENT reports residuals for the mixture fraction and its variance in the `fmean` and `fvar` columns of the residual report:

iter	cont	x-vel	y-vel	k	epsilon	fmean	fvar
28	1.57e-3	4.92e-4	4.80e-4	2.68e-2	2.59e-3	9.09e-1	1.17e+0
29	1.42e-3	4.43e-4	4.23e-4	2.48e-2	2.30e-3	8.89e-1	1.15e+0
30	1.28e-3	3.98e-4	3.75e-4	2.29e-2	2.04e-3	8.88e-1	1.14e+0

(For two-mixture-fraction calculations, columns for `psec` and `pvar` will also appear.)

17.10.4.1. Under-Relaxation Factors for PDF Equations

The transport equations for the mean mixture fraction and mixture fraction variance are quite stable and high, under-relaxation can be used when solving them. By default, an under-relaxation factor of 1 is used for the mean mixture fraction (and secondary partial fraction) and 0.9 for the mixture fraction variance (and secondary partial fraction variance). If the residuals for these equations are increasing, you should consider decreasing these under-relaxation factors, as discussed in [Setting Under-Relaxation Factors \(p. 1323\)](#).

17.10.4.2. Density Under-Relaxation

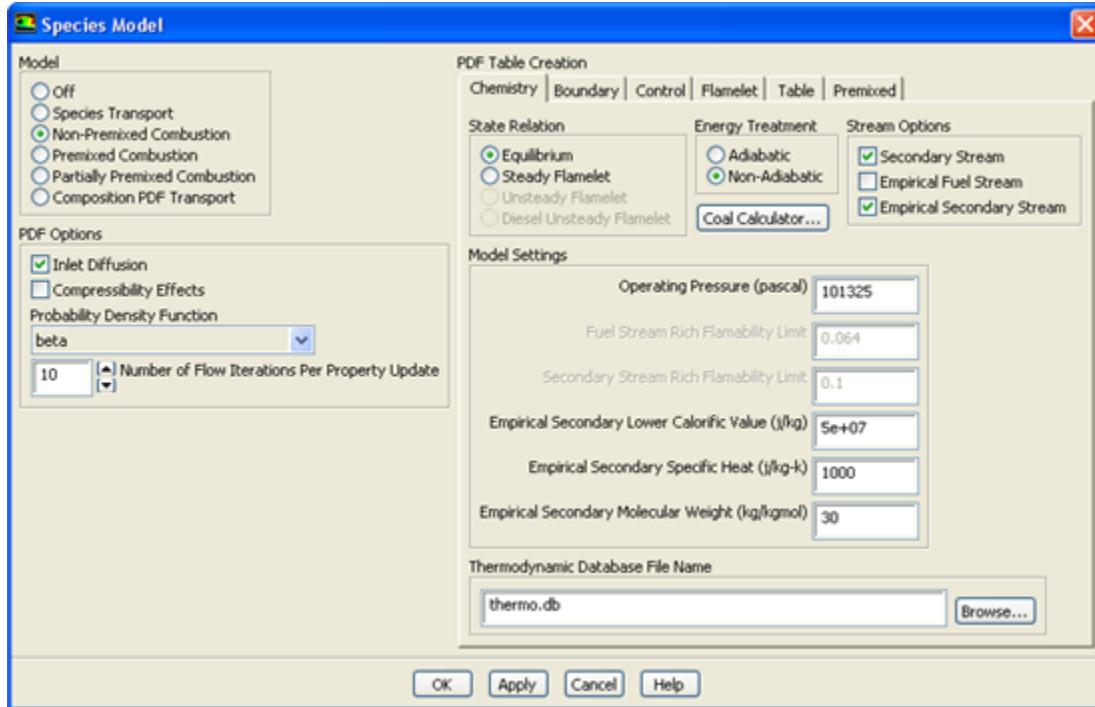

One of the main reasons a combustion calculation can have difficulty converging is that large changes in temperature cause large changes in density, which can, in turn, cause instabilities in the flow solution. ANSYS FLUENT allows you to under-relax the change in density to alleviate this difficulty. The default value for density under-relaxation is 1, but if you encounter convergence trouble you may wish to reduce this to a value between 0.5 and 1 (in the **Solution Controls** task page).

17.10.4.3. Tuning the PDF Parameters for Two-Mixture-Fraction Calculations

For cases that include a secondary stream, the PDF integrations are performed inside ANSYS FLUENT.

The parameters for these integrations are defined in the [Species Model Dialog Box \(p. 1814\)](#) (*Figure 17.29 (p. 952)*).

  Models → Species → Edit...

Figure 17.29 The Species Model Dialog Box for a Two-Mixture-Fraction Calculation

The parameters are as follows:

Compressibility Effects

(non-adiabatic systems only) tells ANSYS FLUENT to update the density, temperature, species mass fraction, and enthalpy from the PDF tables to account for the varying pressure of the system.

Probability Density Function

specifies which type of PDF should be used. You can pick either **double delta** or **beta** in the drop-down list. The **double delta** PDF has the advantage of being faster than the **beta** PDF, but is theoretically less accurate.

Number of Flow Iterations Per Property Update

specifies how often the flow properties (density, temperature, etc.) are updated from the look-up table. Remember that when you are calculating two mixture fractions, the updating of properties includes computation of the PDFs and can be CPU-intensive.

For simulations involving non-adiabatic multiple strained flamelets, looking up the four-dimensional PDF tables can be CPU-intensive. In such cases, the **Number of Flow Iterations Per Property Update** controls the updating of flow properties such as density.

For the Eulerian unsteady laminar flamelet model, a marker probability equation is solved in an unsteady mode. Residuals for ufla-prob will be displayed.

17.11. Postprocessing the Non-Premixed Model Results

The final step in the non-premixed combustion modeling process is the postprocessing of species concentrations and temperature data from the mixture fraction and flow-field solution data. The following variables are of particular interest:

- **Mean Mixture Fraction** (in the **Pdf...** category)
- **Secondary Mean Mixture Fraction** (in the **Pdf...** category)

- **Mixture Fraction Variance** (in the **Pdf...** category)
- **Secondary Mixture Fraction Variance** (in the **Pdf...** category)
- **Fvar Prod** (in the **Pdf...** category, which is the production term in the mixture fraction variance transport equation)
- **Fvar2 Prod** (in the **Pdf...** category)
- **Scalar Dissipation** (in the **Pdf...** category)
- **PDF Table Adiabatic Enthalpy** (in the **Pdf...** category)
- **PDF Table Heat Loss/Gain** (in the **Pdf...** category)
- **Mass fraction of (species-n)** (in the **Species...** category)
- **Mole fraction of (species-n)** (in the **Species...** category)
- **Molar Concentration of (species-n)** (in the **Species...** category)
- **RMS (species-n) Mass Fraction** (in the **Species...** category)
- **Static Temperature** (in the **Temperature...** category)
- **RMS Temperature** (in the **Temperature...** category)
- **Enthalpy** (in the **Temperature...** category)
- **Mean Probability** (in the **Unsteady Flamelet...** category)
- **Mean Temperature** (in the **Unsteady Flamelet...** category)
- **Mean Mass Fraction of (species-n)** (in the **Unsteady Flamelet...** category)

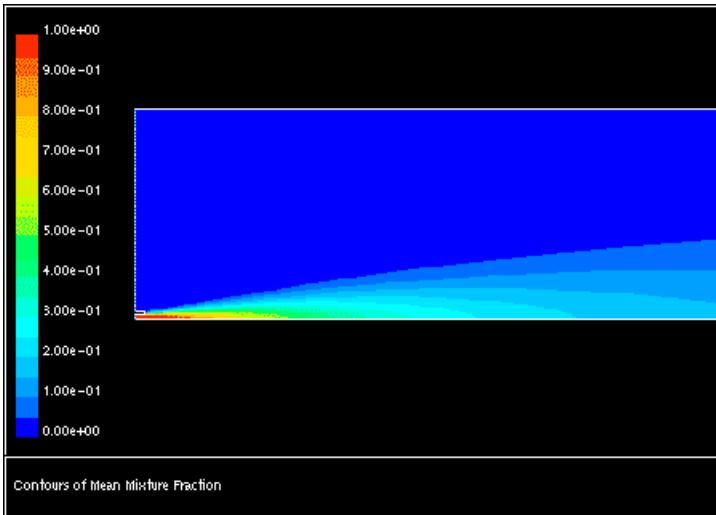

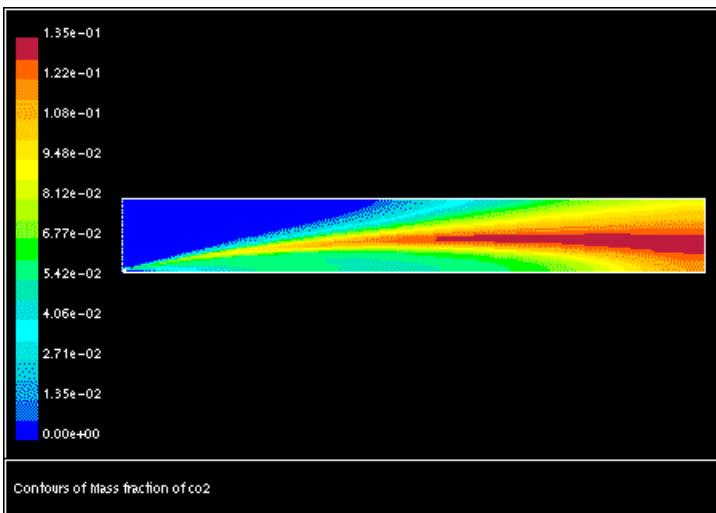

Important

For the unsteady laminar flamelet model, mean species mass fractions are displayed for the first fifty species in the flamelet kinetic mechanism.

These quantities can be selected for display in the indicated category of the variable-selection drop-down list that appears in postprocessing dialog boxes. See *Field Function Definitions* (p. 1653) for their definitions.

In all cases, the species concentrations are derived from the mixture fraction/variance field using the look-up tables. Note that temperature and enthalpy can be postprocessed even when your ANSYS FLUENT model is an adiabatic non-premixed combustion simulation in which you have not solved the energy equation. In both the adiabatic and non-adiabatic cases, the temperature is derived from the look-up table.

Figure 17.30 (p. 954) and *Figure 17.31* (p. 954) illustrate typical results for a methane diffusion flame modeled using the non-premixed approach.

Figure 17.30 Predicted Contours of Mixture Fraction in a Methane Diffusion Flame**Figure 17.31 Predicted Contours of CO₂ Mass Fraction Using the Non-Premixed Combustion Model**

For additional information, please see the following section:

[17.11.1. Postprocessing for Inert Calculations](#)

ANSYS FLUENT provides several additional reporting options for post processing calculations with the inert model. You can generate graphical plots or alphanumeric reports of the same items that are available with the non premixed or partially premixed models, and in addition the following variables are available:

- **Inert Mass Fraction**
- **Inert Specific Heat**
- **Inert Density**
- **Inert Enthalpy**

- **Pdf Enthalpy**
- **Pdf Fmean**
- **Pdf Fvar**
- **Mass Fraction of Inert Y_i**

where the mass fraction of the i th inert species, Y_i , is calculated as

$$Y_i = Y_I Y_i^I$$

where Y_I is the inert tracer and Y_i^I is the mass fraction of the i th inert species defined in the **Inert** dialog box.

Note these variables appear in the **Inert...** category.

Chapter 18: Modeling Premixed Combustion

ANSYS FLUENT has several models to simulate premixed turbulent combustion. For theoretical background on this model, see "Premixed Combustion" in the [Theory Guide](#). Information about using this model is provided in the following sections:

- 18.1. Overview and Limitations
- 18.2. Using the Premixed Combustion Model
- 18.3. Setting Up the C-Equation and G-Equation Models
- 18.4. Setting Up the Extended Coherent Flame Model
- 18.5. Postprocessing for Premixed Combustion Calculations

18.1. Overview and Limitations

In premixed combustion, fuel and oxidizer are mixed at the molecular level prior to ignition. Combustion occurs as a flame front propagating into the unburnt reactants. Examples of premixed combustion include aspirated internal combustion engines, lean-premixed gas turbine combustors, and gas-leak explosions.

Premixed combustion is much more difficult to model than non-premixed combustion. The reason for this is that premixed combustion usually occurs as a thin, propagating flame that is stretched and contorted by turbulence. For subsonic flows, the overall rate of propagation of the flame is determined by both the laminar flame speed and the turbulent eddies. The laminar flame speed is determined by the rate that species and heat diffuse upstream into the reactants and burn. To capture the laminar flame speed, the internal flame structure would need to be resolved, as well as the detailed chemical kinetics and molecular diffusion processes. Because practical laminar flame thicknesses are of the order of millimeters or smaller, resolution requirements are usually unaffordable.

The effect of turbulence is to wrinkle and stretch the propagating laminar flame sheet, increasing the sheet area and, in turn, the effective flame speed. The large turbulent eddies tend to wrinkle and corrugate the flame sheet, while the small turbulent eddies, if they are smaller than the laminar flame thickness, may penetrate the flame sheet and modify the laminar flame structure.

Non-premixed combustion, in comparison, can be greatly simplified to a mixing problem (see the mixture fraction approach in [Introduction](#) in the [Theory Guide](#)). The essence of premixed combustion modeling lies in capturing the turbulent flame speed, which is influenced by both the laminar flame speed and the turbulence.

In premixed flames, the fuel and oxidizer are intimately mixed before they enter the combustion device. Reaction then takes place in a combustion zone that separates unburnt reactants and burnt combustion products. Partially premixed flames exhibit the properties of both premixed and diffusion flames. They occur when an additional oxidizer or fuel stream enters a premixed system, or when a diffusion flame becomes lifted off the burner so that some premixing takes place prior to combustion.

Premixed and partially premixed flames can be modeled using ANSYS FLUENT's finite-rate/eddy-dissipation formulation (see [Modeling Species Transport and Finite-Rate Chemistry](#) (p. 855)). If finite-rate chemical kinetic effects are important, the Laminar Finite-Rate model (see [The Laminar Finite-Rate Model](#) in the [Theory Guide](#)), the EDC model (see [The Eddy-Dissipation-Concept \(EDC\) Model](#) in the [Theory Guide](#)) or the composition PDF transport model (see [Modeling a Composition PDF Transport Problem](#) (p. 975))

can be used. For information about ANSYS FLUENT's partially premixed combustion model, see [Modeling Partially Premixed Combustion \(p. 969\)](#). If the flame is perfectly premixed, so only one stream at one equivalence ratio enters the combustor, it is possible to use the premixed combustion model, as described in this chapter.

18.1.1. Limitations of the Premixed Combustion Model

The following limitations apply to the premixed combustion model:

- You must use the pressure-based solver. The premixed combustion model is not available with the density-based solver.
- The premixed combustion model is valid only for turbulent, subsonic flows. These types of flames are called deflagrations. Explosions, also called detonations, where the combustible mixture is ignited by the heat behind a shock wave, can be modeled with the finite-rate model using the density-based solver. See [Modeling Species Transport and Finite-Rate Chemistry \(p. 855\)](#) for information about the finite-rate model.
- The premixed combustion model cannot be used in conjunction with the pollutant (that is, soot and NO_x) models. However, a perfectly premixed system can be modeled with the partially premixed model (see [Modeling Partially Premixed Combustion \(p. 969\)](#)), which can be used with the pollutant models.
- You cannot use the premixed combustion model to simulate reacting discrete-phase particles, because these would result in a partially premixed system. Only inert particles can be used with the premixed combustion model.
- The G-Equation model can be used only with the unsteady solver because it tracks the flame front in time. However, RANS solutions, which tend to a steady-state, can be modeled by evolving them in time until the solution is stationary.

18.2. Using the Premixed Combustion Model

The procedure for setting up and solving a premixed combustion model is outlined below, and then described in detail. Remember that only the steps that are pertinent to premixed combustion modeling are shown here. For information about inputs related to other models that you are using in conjunction with the premixed combustion model, see the appropriate sections for those models.

1. Enable the premixed turbulent combustion model and set the related parameters.

Note

Make sure a turbulence model (other than the Spalart-Allmaras model) is selected before selecting a combustion model.

2. Define the physical properties for the unburnt and burnt material in the domain.

3. Set the value of the progress variable c at flow inlets and exits.

4. Initialize the value of the progress variable.

 **Solution Initialization → Patch...**

5. Solve the problem and perform postprocessing.
-

Important

If you are interested in computing the concentrations of individual species in the domain, you can use the partially premixed model described in [Modeling Partially Premixed Combustion \(p. 969\)](#). Alternatively, compositions of the unburnt and burnt mixtures can be obtained from external analyses using equilibrium or kinetic calculations.

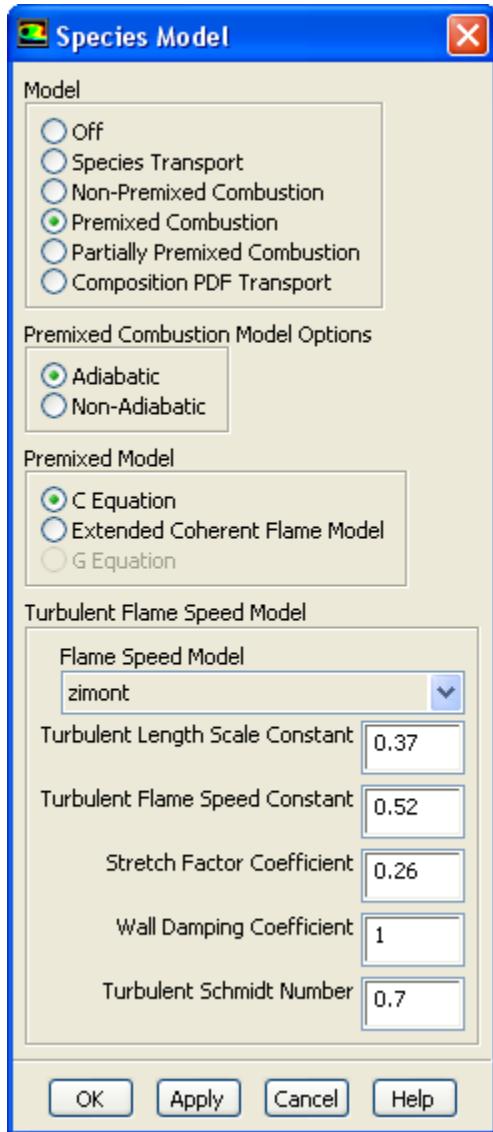

For additional information, see the following sections:

- [18.2.1. Enabling the Premixed Combustion Model](#)
- [18.2.2. Choosing an Adiabatic or Non-Adiabatic Model](#)

18.2.1. Enabling the Premixed Combustion Model

To enable the premixed combustion model, select **Premixed Combustion** under **Model** in the [Species Model Dialog Box \(p. 1814\)](#) ([Figure 18.1 \(p. 960\)](#)).

 **Models → Species → Edit...**

Figure 18.1 The Species Model Dialog Box for Premixed Combustion

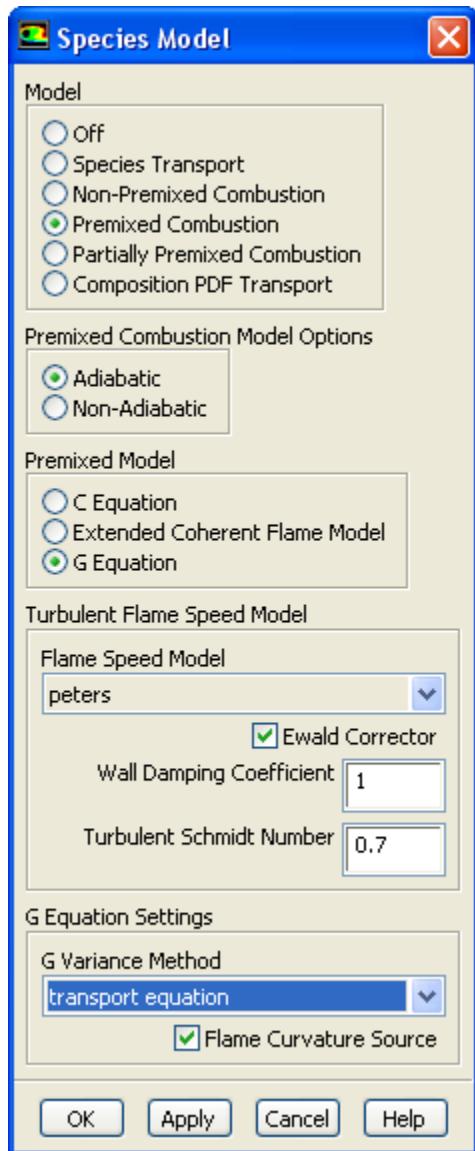

When you enable **Premixed Combustion**, the dialog box expands to show the relevant inputs.

18.2.2. Choosing an Adiabatic or Non-Adiabatic Model

Under **Premixed Combustion Model Options** in the *Species Model Dialog Box* (p. 1814), choose either **Adiabatic** (the default) or **Non-Adiabatic**. This choice affects only the calculation method used to determine the temperature (either Equation 9–64 or Equation 9–65 in the *Theory Guide*).

18.3. Setting Up the C-Equation and G-Equation Models

When **C Equation** or **G Equation** is selected as the **Premixed Model**, you can then choose to use the **zimont** or **peters Flame Speed Model** (described in *Turbulent Flame Speed Models*). You can also modify a number of model constants, as described in *Modifying the Constants for the Zimont Flame Speed Model* (p. 962) and *Modifying the Constants for the Peters Flame Speed Model* (p. 962).

Figure 18.2 The Species Model Dialog Box for the G-Equation Model

For a non-adiabatic premixed combustion model, note that the value you specify for the **Turbulent Schmidt Number** will also be used as the Prandtl number for energy. (The **Energy Prandtl Number** will therefore not appear in the **Viscous Model** dialog box for non-adiabatic premixed combustion models.) These parameters control the level of diffusion for the progress variable and for energy. The progress variable is closely related to energy (because the flame progress results in heat release), so it is important that the transport equations use the same level of diffusion.

For additional information, see the following sections:

- [18.3.1. Modifying the Constants for the Zimont Flame Speed Model](#)
- [18.3.2. Modifying the Constants for the Peters Flame Speed Model](#)
- [18.3.3. Additional Options for the G-Equation Model](#)
- [18.3.4. Defining Physical Properties for the Unburnt Mixture](#)
- [18.3.5. Setting Boundary Conditions for the Progress Variable](#)
- [18.3.6. Initializing the Progress Variable](#)

18.3.1. Modifying the Constants for the Zimont Flame Speed Model

In general, you will not need to modify the constants used in the equations presented in [C-Equation Model Theory](#) in the [Theory Guide](#). The default values are suitable for a wide range of premixed flames.

You can set the **Turbulent Length Scale Constant** (C_D in [Equation 9–11](#)), **Turbulent Flame Speed Constant** (A in [Equation 9–9](#)), the **Stretch Factor Coefficient** (μ_{str} in [Equation 9–16](#)), the **Turbulent Schmidt Number** (Sc_t in [Equation 9–1](#)), and the **Wall Damping Coefficient** (α_w in [Equation 9–19](#)).

18.3.2. Modifying the Constants for the Peters Flame Speed Model

The Peters turbulent flame speed model constants, as described in [Peters Flame Speed Model](#) in the [Theory Guide](#), are not available in the GUI because they are generally suitable for a wide range of premixed flames. They can, however, be accessed from the TUI.

The **Ewald Corrector** is enabled by default and described in [Peters Flame Speed Model](#). The **Turbulent Schmidt Number** (Sc_t in [Equation 9–1](#)), and the **Wall Damping Coefficient** (α_w in [Equation 9–19](#)) are the same as those described for the Zimont model.

18.3.3. Additional Options for the G-Equation Model

When the G-Equation model is enabled, the **G Equation Settings** group box appears. You can select either the **transport equation** or **algebraic** option for the calculation of the flame distance variance. Consult [Peters Flame Speed Model](#) in the [Theory Guide](#) for the variance transport and algebraic equation expressions ([Equation 9–6](#) and [Equation 9–7](#)). It is recommended to use the **transport equation** option for RANS and the **algebraic** option for LES.

When **Flame Curvature Source** is enabled, the curvature source term in the G-Equation, which is the last term in [Equation 9–4](#), is included. By default, this term is excluded.

18.3.4. Defining Physical Properties for the Unburnt Mixture

The fluid material in your domain should be assigned the properties of the unburnt mixture, including the molecular heat transfer coefficient (α in [Equation 9–9](#) in the [Theory Guide](#)), which is also referred to as the thermal diffusivity. α is defined as $k/\rho c_p$, and values at standard conditions can be found in combustion handbooks (for example, [42] (p. 2369)).

For both adiabatic and non-adiabatic combustion models, you will need to specify the **Laminar Flame Speed** (U_l in [Equation 9–9](#) in the [Theory Guide](#)) as a material property, in the **Create/Edit Materials** dialog box. ANSYS FLUENT will automatically select the **prepdf-polynomial** function for **Laminar Flame Speed**, indicating that the piecewise-linear polynomial function from the PDF look-up table will be used to compute the laminar flame speed. You may also choose to enter a **constant** value, use a **user-defined** function, or apply the **metghalchi-keck-law** instead of a piecewise-linear polynomial function. See [Laminar Flame Speed](#) in the [Theory Guide](#) and [Defining Physical Properties for the Unburnt Mixture](#) (p. 962) for information about setting the other properties for the unburnt material.

When using the Zimont turbulent flame speed model, if you want to include the flame stretch effect in your model, you will also need to specify a lower value than the default **Critical Rate of Strain** (g_{cr} in [Equation 9–17](#) in the [Theory Guide](#)). As discussed in [Flame Stretch Effect](#) in the [Theory Guide](#), g_{cr} is set to a very high value ($1 \times 10^8 \text{ s}^{-1}$) by default, so no flame stretching occurs. To include flame

stretching effects, you will need to adjust the **Critical Rate of Strain** based on experimental data for the burner. Because the flame stretching and flame extinction can influence the turbulent flame speed (as discussed in [Flame Stretch Effect](#) in the [Theory Guide](#)), a realistic value for the **Critical Rate of Strain** is required for accurate predictions. Typical values for CH_4 lean premixed combustion range from 3000 to 8000 s^{-1} [103] (p. 2372). Note that you can specify constant values or user-defined functions to define the **Laminar Flame Speed** and **Critical Rate of Strain**. See the [UDF Manual](#) for details about user-defined functions.

For adiabatic models, you will also specify the **Adiabatic Burnt Temperature** (T_{ad} in [Equation 9–64](#) in the [Theory Guide](#)), which is the temperature of the burnt products under adiabatic conditions. This temperature will be used to determine the linear variation of temperature in an adiabatic premixed combustion calculation. You can specify a constant value or use a user-defined function.

For non-adiabatic models, you will instead specify the **Heat of Combustion** per unit mass of fuel and the **Unburnt Fuel Mass Fraction** (H_{comb} and Y_{fuel} in [Equation 9–66](#) in the [Theory Guide](#)). ANSYS FLUENT will use these values to compute the heat losses or gains due to combustion, and include these losses/gains in the energy equation that it uses to calculate temperature. The **Heat of Combustion** can be specified only as a constant value, but you can specify a constant value or use a user-defined function for the **Unburnt Fuel Mass Fraction**.

To specify the density for a premixed combustion model, choose **premixed-combustion** in the **Density** drop-down list and set the **Adiabatic Unburnt Density** and **Adiabatic Unburnt Temperature** (T_u and ρ_u in [Equation 9–67](#) in the [Theory Guide](#)). For adiabatic premixed models, your input for **Adiabatic Unburnt Temperature** (T_u) will also be used in [Equation 9–64](#) in the [Theory Guide](#) to calculate the temperature.

The other properties specified for the unburnt mixture are viscosity, specific heat, thermal conductivity, and any other properties related to other models that are being used in conjunction with the premixed combustion model.

18.3.5. Setting Boundary Conditions for the Progress Variable

For premixed combustion models, you will need to set an additional boundary condition at flow inlets and exits: the progress variable, c . Valid inputs for the **Progress Variable** are as follows:

- $c = 0$: unburnt mixture
- $c = 1$: burnt mixture

18.3.6. Initializing the Progress Variable

Often, it is sufficient to initialize the progress variable c to 1 (burnt) everywhere and allow the unburnt ($c = 0$) mixture entering the domain from the inlets to blow the flame back to the stabilizer. A better initialization is to patch an initial value of 0 (unburnt) upstream of the flame holder and a value of 1 (burnt) in the downstream region (after initializing the flow field in the **Solution Initialization** task page).

Solution Initialization → Patch...

See [Patching Values in Selected Cells](#) (p. 1351) for details about patching values of solution variables.

18.4. Setting Up the Extended Coherent Flame Model

The Extended Coherent Flame Model (ECFM) solves a transport equation for the flame surface area density, denoted Σ , in addition to the reaction progress variable. Details about setting up the reaction progress variable boundary and initial conditions, and material properties, can be found in [Setting Up the C-Equation and G-Equation Models \(p. 960\)](#). To use the ECFM, select **Extended Coherent Flame Model** as the **Premixed Model**. A list of **Extended Coherent Flame Model Constants** will appear in the **Species Model** dialog box.

For additional information, see the following sections:

- [18.4.1. Modifying the ECFM Model Variant](#)
- [18.4.2. Modifying the Constants for the ECFM Flame Speed Closure](#)
- [18.4.3. Setting Boundary Conditions for the ECFM Transport](#)
- [18.4.4. Initializing the Flame Area Density](#)

18.4.1. Modifying the ECFM Model Variant

The source terms for [Equation 9–26](#) in the [Theory Guide](#) are determined by which ECFM model variant is used. There are four ECFM model variants available. The default Veynante scheme is the recommended scheme, because it provides the best accuracy in most situations. If you want access to a different model variant, you must use the following text command:

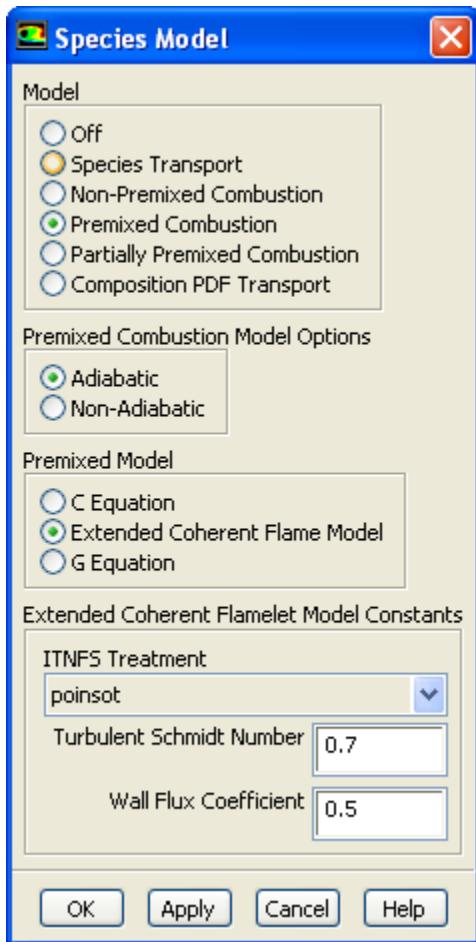

```
define → models → species → ecfm-controls
```

You can then revise the model constants as necessary. See [Closure for ECFM Source Terms](#) in the [Theory Guide](#) for further details. If you are using LES turbulence modeling, see [LES and ECFM](#) as well.

18.4.2. Modifying the Constants for the ECFM Flame Speed Closure

In the **Extended Coherent Flame Model Constants** group box of the **Species Model** dialog box, select the **ITNFS Treatment**. You have a choice of **constant-delta**, **meneveau**, **blint**, **poinsot**, or **constant**. The various ITNFS treatments are described in detail in [Closure for ECFM Source Terms](#) in the [Theory Guide](#).

The treatment you select will determine which constants you can set. In all cases, you need to define the **Turbulent Schmidt Number** (Sc_t) and the **Wall Flux Coefficient**. If you selected the **constant-delta** treatment, you can set the **ITNFS Flame Thickness** (δ_l^0 in [Equation 9–30](#) in the [Theory Guide](#)). If you selected the **constant** treatment, you can set the **ITNFS Value** (Γ_K in [Equation 9–28](#) in the [Theory Guide](#)). Note that, in general, you will not need to modify the constants available in the **Extended Coherent Flame Model Constants** group box because the default values are suitable for a wide range of premixed flames.

Figure 18.3 The Species Model Dialog Box for ECFM

18.4.3. Setting Boundary Conditions for the ECFM Transport

For the ECFM transport equation option for the premixed combustion models, you will need to set an additional boundary condition at flow inlets and exits: the flame area density, Σ . Valid inputs for the **Flame Area Density** are as follows:

- $\Sigma = 0$: no flame area (unburned)
- $\Sigma > 0$: burning with nonzero flame area

18.4.4. Initializing the Flame Area Density

Often, it is sufficient to initialize the flame area density Σ to 1 (laminar flame speed) everywhere and allow the unburnt mixture entering the domain from the inlets to develop. Another option for initialization is to patch an initial value of 0 (not burning) upstream of the flame holder and a value of 10 or higher (burning) in the downstream region (after initializing the flow field in the region).

See *Patching Values in Selected Cells* (p. 1351) for details about patching values of solution variables.

18.5. Postprocessing for Premixed Combustion Calculations

ANSYS FLUENT provides several additional reporting options for premixed combustion calculations. You can generate graphical plots or alphanumeric reports of the following items:

- **Progress Variable**
- **Damkohler Number**
- **Stretch Factor**
- **Turbulent Flame Speed**
- **Static Temperature**
- **Product Formation Rate**
- **Laminar Flame Speed**
- **Critical Strain Rate**
- **Unburnt Fuel Mass Fraction**
- **Adiabatic Flame Temperature**

These variables are contained in the **Premixed Combustion...** category of the variable selection dropdown list that appears in postprocessing dialog boxes. See *Field Function Definitions* (p. 1653) for a complete list of flow variables, field functions, and their definitions. *Displaying Graphics* (p. 1499) and *Reporting Alphanumeric Data* (p. 1633) explain how to generate graphics displays and reports of data.

Note that **Static Temperature** and **Adiabatic Flame Temperature** will appear in the **Premixed Combustion...** category only for adiabatic premixed combustion calculations; for non-adiabatic calculations, **Static Temperature** will appear in the **Temperature...** category. **Unburnt Fuel Mass Fraction** will appear only for non-adiabatic models.

ANSYS FLUENT also provides several additional reporting options for premixed combustion calculations with the ECFM model for flame speed closure. You can generate graphical plots or alphanumeric reports of the same items that are available with the premixed mode, and in addition:

- **Progress Variable Curvature**
- **Flame Area Density**
- **Net Flame Area Production**
- **Flame Area Production P1**
- **Flame Area Production P2**
- **Flame Area Production P3**
- **Flame Area Production P4**
- **Intermittent Turb Net Flame Stretch**
- **Flame Area Destruction**

These variables will also appear in the **Premixed Combustion...** category.

ANSYS FLUENT also provides two additional reporting options for premixed combustion calculations with the G-Equation model:

- **Mean Distance from Flame**
- **Variance of Distance from Flame**

The **Variance of Distance from Flame** is the variance of the distance of the instantaneous flame from the mean flame position. These variables appear in the **Premixed Combustion...** category.

For additional information, see the following section:

18.5.1. Computing Species Concentrations

18.5.1. Computing Species Concentrations

If you know the composition of the unburnt and burnt mixtures in your model (that is, if you have performed separate ANSYS FLUENT or external analyses of chemical equilibrium calculations or 1D premixed flames), you can compute the species concentrations in the domain using custom field functions:

- To determine the concentration of a species in the unburnt mixture, define the custom function $Y_u(1 - c)$, where Y_u is the mass fraction for the species in the unburnt mixture (specified by you) and c is the value of the progress variable (computed by ANSYS FLUENT).
- To determine the concentration of a species in the burnt mixture, define the custom function $Y_b c$, where Y_b is the mass fraction for the species in the burnt mixture (specified by you) and c is the value of the progress variable (computed by ANSYS FLUENT).

See [Custom Field Functions \(p. 1708\)](#) for details about defining and using custom field functions.

Chapter 19: Modeling Partially Premixed Combustion

ANSYS FLUENT provides a partially premixed combustion model that is based on the non-premixed combustion model described in [Modeling Non-Premixed Combustion \(p. 901\)](#) and the premixed combustion model described in [Modeling Premixed Combustion \(p. 957\)](#). For information about the theory behind the partially premixed combustion model, see "Partially Premixed Combustion" in the [Theory Guide](#). Information about using the partially premixed combustion model is presented in the following sections:

- 19.1. Overview and Limitations
- 19.2. Using the Partially Premixed Combustion Model

19.1. Overview and Limitations

For additional information, please see the following sections:

- 19.1.1. Overview
- 19.1.2. Limitations

19.1.1. Overview

Partially premixed combustion systems are premixed flames with non-uniform fuel-oxidizer mixtures (equivalence ratios). Such flames include premixed jets discharging into a quiescent atmosphere, lean premixed combustors with diffusion pilot flames and/or cooling air jets, and imperfectly mixed inlets.

The partially premixed model in ANSYS FLUENT is a combination of the non-premixed model ([Modeling Non-Premixed Combustion \(p. 901\)](#)) and the premixed model ([Modeling Premixed Combustion \(p. 957\)](#)). The premixed reaction-progress variable, c , determines the position of the flame front. Behind the flame front ($c = 1$), the mixture is burnt and the equilibrium or laminar flamelet mixture fraction solution is used. Ahead of the flame front ($c = 0$), the species mass fractions, temperature, and density are calculated from the mixed but unburnt mixture fraction. Within the flame ($0 < c < 1$), a linear combination of the unburnt and burnt mixtures is used.

19.1.2. Limitations

The underlying theory, assumptions, and limitations of the non-premixed and premixed models apply directly to the partially premixed model. In particular, the single-mixture-fraction approach is limited to two inlet streams, which may be pure fuel, pure oxidizer, or a mixture of fuel and oxidizer. The two-mixture-fraction model extends the number of inlet streams to three, but incurs a major computational overhead. See [Limitations of the Premixed Combustion Model \(p. 958\)](#) for additional limitations.

19.2. Using the Partially Premixed Combustion Model

The procedure for setting up and solving a partially premixed combustion problem combines parts of the non-premixed combustion setup and the premixed combustion setup. An outline of the procedure is provided in [Setup and Solution Procedure \(p. 970\)](#), along with information about where to look in the non-premixed and premixed combustion chapters for details. Inputs that are specific to the partially premixed combustion model are provided in [Setup and Solution Procedure \(p. 970\)](#) and [Modifying the Unburnt Mixture Property Polynomials \(p. 972\)](#).

For additional information, please see the following sections:

- 19.2.1. Setup and Solution Procedure
- 19.2.2. Modifying the Unburnt Mixture Property Polynomials
- 19.2.3. Modeling In Cylinder Combustion

19.2.1. Setup and Solution Procedure

1. Read your mesh file into ANSYS FLUENT and set up any other models you plan to use in conjunction with the partially premixed combustion model (turbulence, radiation, etc.).
2. Enable the partially premixed combustion model.
 - a. Turn on the **Partially Premixed Combustion** model in the **Species Model** dialog box.

Note

Make sure a turbulence model (other than the Spalart-Allmaras model) is selected before selecting a combustion model.

- b. If necessary, modify the model constants for the selected **Turbulent Flame Speed Model** in the **Species Model** dialog box. These are the same as the constants for the premixed combustion model and, in most cases, you will not need to change them from their default values. See [Modifying the Constants for the Zimont Flame Speed Model \(p. 962\)](#) for details. Similarly, you can modify the **Extended Coherent Flamelet Model Constants** if you selected the **Extended Coherent Flame Model**. See [Modifying the Constants for the ECFM Flame Speed Closure \(p. 964\)](#) for details.
3. Generate a PDF look-up table. You can follow the procedure for non-premixed combustion described in [Steps in Using the Non-Premixed Model \(p. 901\)](#).

Important

If ANSYS FLUENT warns you, during the partially premixed properties calculation, that any parameters are out of the range for the laminar flame speed function, you will need to modify the piecewise-linear points manually before saving the PDF file. See [Modifying the Unburnt Mixture Property Polynomials \(p. 972\)](#) for details. Also, the calculation of the thermal diffusivity uses the thermal conductivity in the **Create/Edit Materials** dialog box. More accurate thermal diffusivity polynomials can be obtained by editing the thermal conductivity in the **Create/Edit Materials** dialog box and then clicking **Recalculate Properties** in the **Premixed** tab.

4. Define the physical properties for the unburnt material in the domain.

ANSYS FLUENT will automatically select the **prepdf-polynomial** function for **Laminar Flame Speed**, indicating that the piecewise-linear polynomial function from the PDF look-up table will be used to compute the laminar flame speed. You may also choose to enter a **constant** value, use a **user-defined** function, or apply the **metghalchi-keck-law** instead of a piecewise-linear polynomial function. See [Laminar Flame Speed](#) in the [Theory Guide](#) and [Defining Physical Properties for the Unburnt Mixture \(p. 962\)](#) for information about setting the other properties for the unburnt material.

5. Set the values for the mean progress variable (\bar{c}) and the mean mixture fraction (\bar{f}) and its variance (\bar{f}^2) at flow inlets and exits. (For problems that include a secondary stream, you will define boundary conditions for the mean secondary partial fraction and its variance as well.)

Boundary Conditions

See [Defining Non-Premixed Boundary Conditions \(p. 946\)](#) for guidelines on setting mixture fraction and variance conditions, as well as thermal and velocity conditions at inlets.

Important

There are two ways to specify a premixed inlet boundary condition:

- a. If you defined the fuel composition in the **Boundary** tab to be the premixed inlet species, then you should set $\bar{f} = 1$ and $\bar{c} = 0$ in the boundary condition dialog boxes.
- b. If you set the fuel composition to pure fuel in the **Boundary** tab, you will need to set the correct equivalence ratio ($0 < \bar{f} < 1$) and $\bar{c} = 0$ at your premixed inlet boundary condition.

For example, if the premixed inlet of methane and air is at an equivalence ratio of 0.3, you can

- a. specify the mass fraction of the fuel composition of $Y_{CH_4} = 0.017$, $Y_{O_2} = 0.236$, and $Y_{N_2} = 0.747$ in the **Boundary** tab and $\bar{f} = 1$ and $\bar{c} = 0$ in the boundary condition dialog box.
- b. specify the mass fraction of the fuel composition of $Y_{CH_4} = 1.0$ in the **Boundary** tab and $\bar{f} = 0.017$ and $\bar{c} = 0$ in the boundary condition dialog box.

Method (a) is preferred since it will have more points in the flame zone than method (b).

Note

Cooling inlet air should be set to $\bar{c} = 0$ (unburnt) if it is injected ahead of the flame front, and to $\bar{c} = 1$ (burnt) if injected behind the flame front.

6. Initialize the value of the progress variable.

Solution Initialization → Patch...

See [Initializing the Progress Variable \(p. 963\)](#) for details.

7. Solve the problem and perform postprocessing.

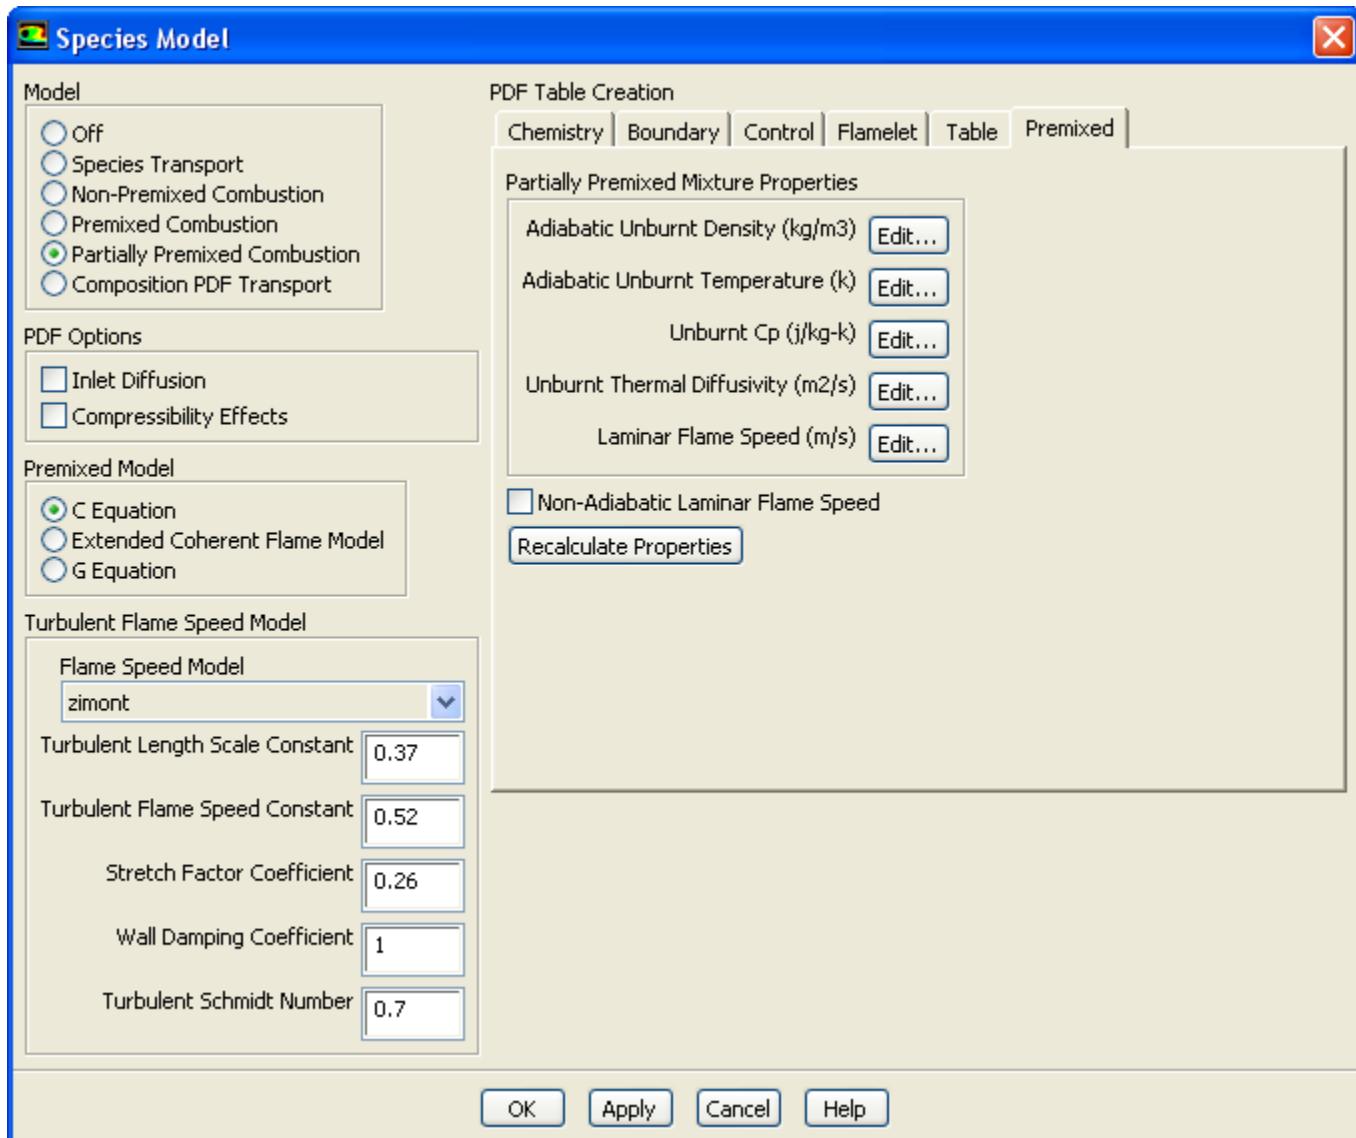

See [Solving the Flow Problem \(p. 950\)](#) for guidelines about setting solution parameters. (These guidelines are for non-premixed combustion calculations, but they are relevant for partially premixed as well.)

19.2.2. Modifying the Unburnt Mixture Property Polynomials

After building the PDF table, ANSYS FLUENT automatically calculates the temperature, density, heat capacity, and thermal diffusivity of the unburnt mixture as polynomial functions of the mean mixture fraction, \bar{f} (see [Equation 10–3](#) in the [Theory Guide](#)). The laminar flame speed is automatically calculated as a piecewise-linear polynomial function of \bar{f} .

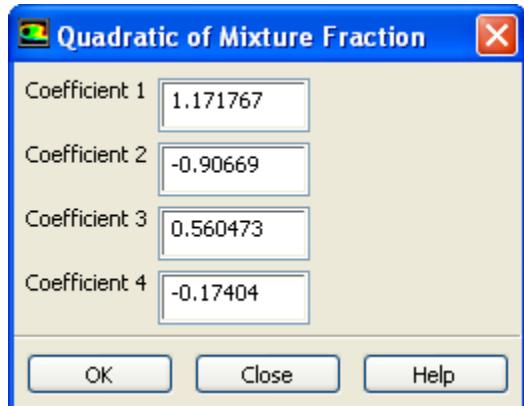

However, as outlined in [Partially Premixed Combustion Theory](#) in the [Theory Guide](#), the laminar flame speed depends on details of the chemical kinetics and molecular transport properties, and is not calculated directly. Instead, curve fits are made to flame speeds determined from detailed simulations [28] (p. 2368). These fits are limited to a range of fuels (H_2 , CH_4 , C_2H_2 , C_2H_4 , C_2H_6 , and C_3H_8), air as the oxidizer, equivalence ratios of the lean limit through unity, unburnt temperatures from 298 K to 800 K, and pressures from 1 bar to 40 bars. If your parameters fall outside this range, ANSYS FLUENT will warn you when it computes the look-up table. In this case, you will need to modify the piecewise-linear points in the **Premixed** tab of the **Species Model** dialog box ([Figure 19.1 \(p. 972\)](#)) before you save the PDF file.

Figure 19.1 The Species Model Dialog Box (Premixed Tab)

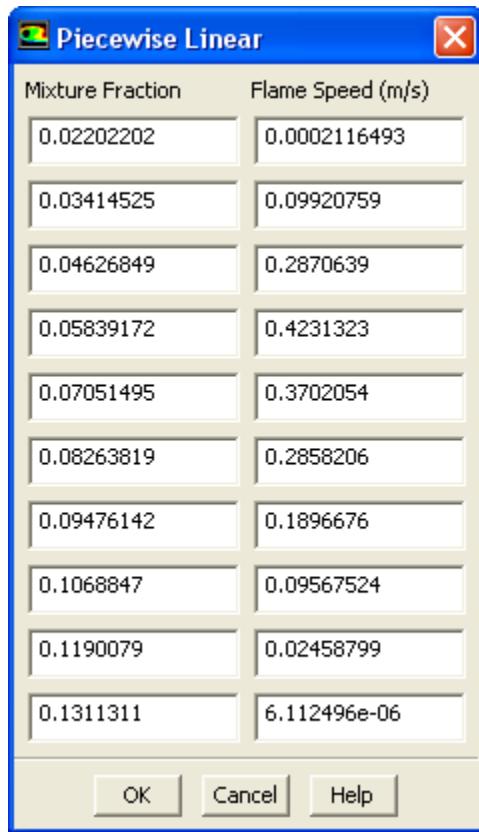

For each polynomial function of \bar{f} under **Partially Premixed Mixture Properties (Adiabatic Unburnt Density, Adiabatic Unburnt Temperature, Unburnt Cp, and Unburnt Thermal Diffusivity)**, you can specify values for **Coefficient 1**, **Coefficient 2**, **Coefficient 3**, and **Coefficient 4** (the polynomial coefficients in [Equation 10-3](#) in the [Theory Guide](#)) in the appropriate **Quadratic of Mixture Fraction** dialog box ([Figure 19.2 \(p. 973\)](#)). To open this dialog box, click the appropriate **Edit...** button in the **Premixed** tab.

Figure 19.2 The Quadratic of Mixture Fraction Dialog Box

You can also specify the piecewise-linear **Mixture Fraction** and its corresponding **Laminar Flame Speed** for 10 different points in the **Piecewise Linear** dialog box ([Figure 19.3 \(p. 974\)](#)). The first set of values is the lower limit and the last set of values is the upper limit. Outside of either limit, the laminar flame speed is constant and equal to that limit. To open this dialog box, click the **Edit...** button next to **Laminar Flame Speed** in the **Premixed** tab.

Figure 19.3 The Piecewise Linear Dialog Box**Important**

Note also that if you choose to use a user-defined function for the laminar flame speed in the [Create/Edit Materials Dialog Box \(p. 1882\)](#), the piecewise-linear fit becomes irrelevant.

If the secondary mixture fraction model is enabled, the unburnt properties are a function of both the mean and secondary mixture fractions. An additional column is added in the **Piecewise Linear** dialog box for the secondary mixture fraction unburnt polynomial coefficients.

19.2.3. Modeling In Cylinder Combustion

Each of the partially premixed combustion models may be used for modeling in cylinder combustion. When modeling more than one cycle of such engines, you may choose to model trapped combustion products and exhaust gas recirculation (EGR) using the inert species model (see [Setting Up the Inert Model \(p. 943\)](#)). A **Dynamic Mesh Event** has also been provided for calculating the inert composition, converting burned gases to inert and resetting the combustion process ready for the next cycle (see [Resetting Inert EGR \(p. 645\)](#) and [Resetting Inert EGR \(p. 945\)](#)).

In the case of the G-Equation model, this is the only way to automatically model multiple in cylinder combustion cycles and take into account trapped burned gases remaining in the cylinder from one cycle to the next.

Chapter 20: Modeling a Composition PDF Transport Problem

ANSYS FLUENT provides a composition PDF transport model for modeling finite-rate chemistry in turbulent flames. For information about the theory behind the composition PDF transport model, see "Composition PDF Transport" in the [Theory Guide](#). Information about using this model is presented in the following sections:

- 20.1. Overview and Limitations
- 20.2. Steps for Using the Composition PDF Transport Model
- 20.3. Enabling the Lagrangian Composition PDF Transport Model
- 20.4. Enabling the Eulerian Composition PDF Transport Model
- 20.5. Initializing the Solution
- 20.6. Monitoring the Solution
- 20.7. Postprocessing for Lagrangian PDF Transport Calculations
- 20.8. Postprocessing for Eulerian PDF Transport Calculations

20.1. Overview and Limitations

The composition PDF transport model, like the Laminar Finite-Rate (see [The Laminar Finite-Rate Model](#) in the [Theory Guide](#)) and EDC model (see [The Eddy-Dissipation-Concept \(EDC\) Model](#) in the [Theory Guide](#)), should be used when you are interested in simulating finite-rate chemical kinetic effects in turbulent reacting flows. With an appropriate chemical mechanism, kinetically-controlled species such as CO and NO_x, as well as flame extinction and ignition, can be predicted. PDF transport simulations are computationally expensive, and it is recommended that you start your modeling with small meshes, and preferably in 2D.

A limitation that applies to the composition PDF transport model is that you must use the pressure-based solver as the model is not available with the density-based solver.

ANSYS FLUENT has two different discretizations of the composition PDF transport equation, namely Lagrangian and Eulerian. The Lagrangian method is strictly more accurate than the Eulerian method, but requires significantly longer run time to converge.

20.2. Steps for Using the Composition PDF Transport Model

The procedure for setting up and solving a composition PDF transport problem is outlined below, and then described in detail. Remember that only steps that are pertinent to composition PDF transport modeling are shown here. For information about inputs related to other models that you are using in conjunction with the composition PDF transport model, see the appropriate sections for those models.

1. Read a CHEMKIN-formatted gas-phase mechanism file and the associated thermodynamic data file in the **CHEMKIN Mechanism** dialog box (see [Importing a Volumetric Kinetic Mechanism in CHEMKIN Format](#) (p. 883)).

File → Import → CHEMKIN Mechanism...

Important

If your chemical mechanism is not in CHEMKIN format, you will have to enter the mechanism into ANSYS FLUENT as described in *Overview of User Inputs for Modeling Species Transport and Reactions* (p. 855).

2. Enable a turbulence model.

 **Models** →  **Viscous** → **Edit...**

3. Enable the **Composition PDF Transport** model and set the related parameters. Refer to *Enabling the Lagrangian Composition PDF Transport Model* (p. 977) and *Enabling the Eulerian Composition PDF Transport Model* (p. 979) for further details.

 **Models** →  **Species** → **Edit...**

4. Check the material properties in the **Create/Edit Materials** dialog box and the reaction parameters in the **Reactions** dialog box. The default settings should be sufficient.

 **Materials**

5. Set the operating conditions, cell zone conditions, and boundary conditions.

 **Cell Zone Conditions** → **Operating Conditions...**

 **Boundary Conditions**

6. Check the solver settings.

 **Solution Methods**

 **Solution Controls**

The default settings should be sufficient, although it is recommended to change the discretization to second-order once the solution has converged.

7. Initialize the solution. You may need to patch a high-temperature region to ignite the flame.

 **Solution Initialization** → **Initialize**

 **Solution Initialization** → **Patch...**

8. Run the solution.

 **Run Calculation**

9. Solve the problem and perform postprocessing.

Important

A good initial condition can reduce the solution time substantially. It is recommended to start from an existing solution calculated using the Laminar Finite-Rate, EDC model, non-premixed combustion model, or partially premixed combustion model. See *Modeling Species Transport and Finite-Rate Chemistry* (p. 855), *Modeling Non-Premixed Combustion* (p. 901), and *Modeling Partially Premixed Combustion* (p. 969) for further information on such simulations.

20.3. Enabling the Lagrangian Composition PDF Transport Model

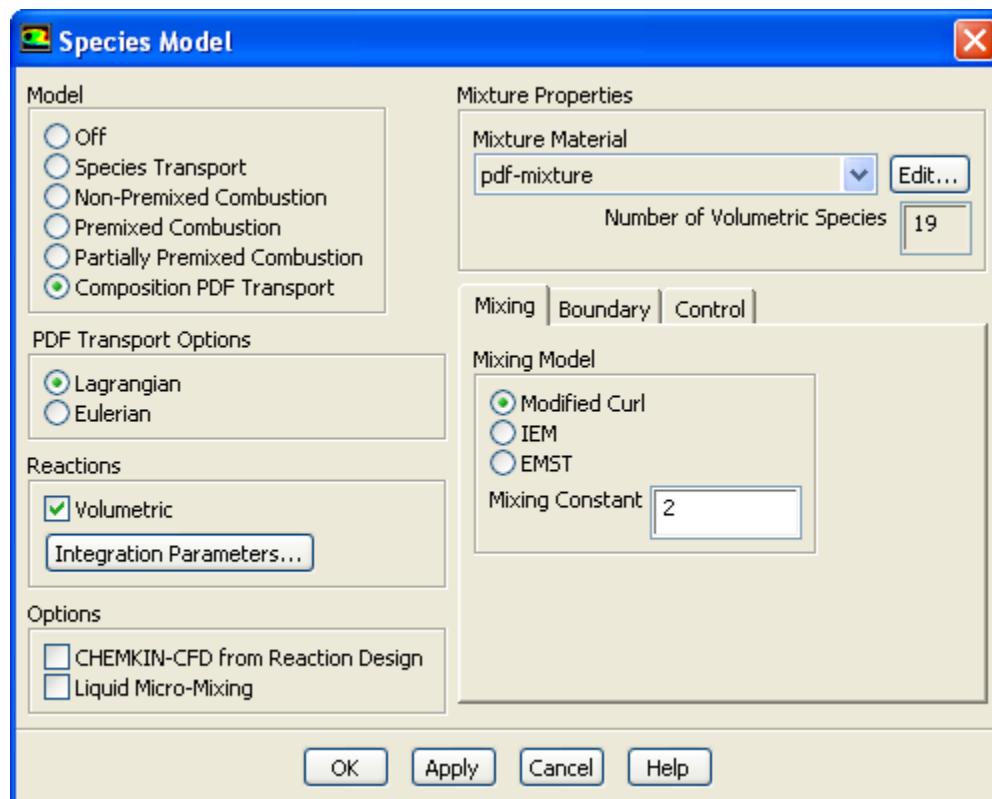

To enable the composition PDF transport model, select **Composition PDF Transport** in the **Species Model** dialog box (*Figure 20.1 (p. 977)*).

◆ Models → Species → Edit...

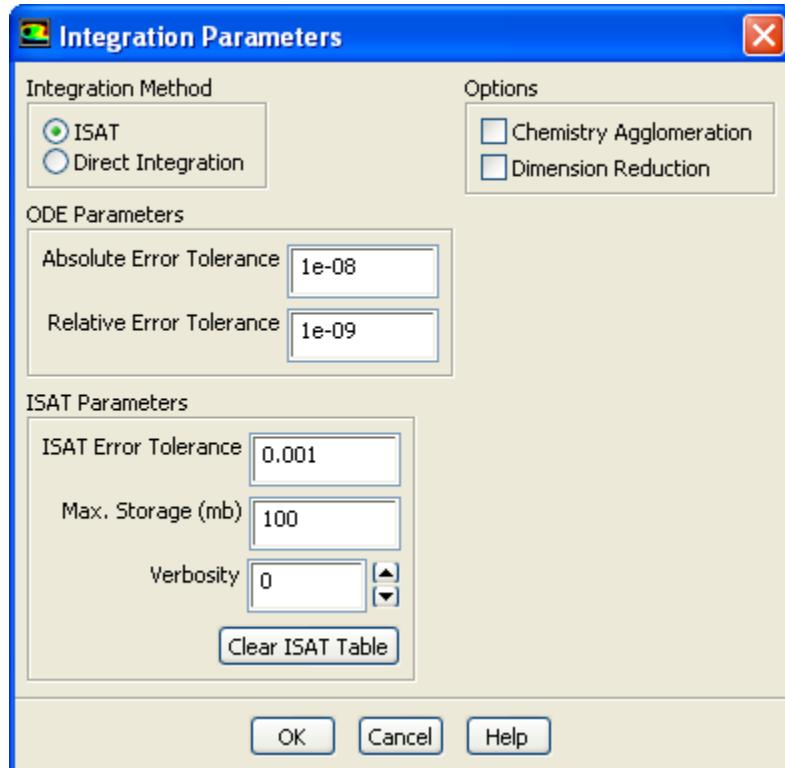

When you enable **Composition PDF Transport**, the dialog box will expand to show the relevant inputs.

1. Select **Lagrangian** under **PDF Transport Options**.

Figure 20.1 The Species Model Dialog Box for Lagrangian Composition PDF Transport

2. Enable **Volumetric** under **Reactions**.
3. Click the **Integration Parameters...** button to open the *Integration Parameters Dialog Box* (p. 1828) (*Figure 20.2 (p. 978)*). For additional information, see *Using ISAT* (p. 988).

Figure 20.2 The Integration Parameters Dialog Box

4. Enable **CHEMKIN-CFD from Reaction Design** to allow you to use reaction rates from Reaction Design's CHEMKIN module, instead of the default ANSYS FLUENT reaction rates. ANSYS FLUENT's ISAT algorithm is employed to integrate these rates. Please refer to the manual [2] (p. 2367) from Reaction Design for details on the chemistry formulation options. For more information, or to obtain a license to use the FLUENT/CHEMKIN module, please contact Reaction Design at info@reactiondesign.com or +1 858-550-1920, or go to www.reactiondesign.com.
5. Enable **Liquid Micro-Mixing** to interpolate C_ϕ from turbulence models and scalar spectra, as noted in **Liquid Reactions** in the **Theory Guide**. This is applied to cases where reactions in liquids occur at low turbulence levels, among reactants with low diffusivities. Therefore, a default value of $C_\phi = 2$ may not be desirable, as it over-estimates the mixing rate.
6. In the **Mixing** tab, select **Modified Curl, IEM, or EMST** under **Mixing Model** and specify the value of the **Mixing Constant** (C_ϕ in [Equation 11-6](#) in the **Theory Guide**). For more information about particle diffusion, see **Particle Mixing** in the **Theory Guide**.

Important

If the **Liquid Micro-Mixing** option is enabled, you cannot set the **Mixing Constant**.

7. You will not be specifying species boundary conditions in the **Boundary** tab. This is only applicable to the **Eulerian PDF Transport Option**.
8. In the **Control** tab, you will specify the Lagrangian PDF transport control parameters.

Particles Per Cell

sets the number of PDF particles per cell. Higher values of this parameter will reduce statistical error, but increase computational time.

Local Time Stepping

is available for steady-state simulations and can increase the convergence rate by taking maximum allowable time-steps on a cell-by-cell basis. (see [Equation 11–4](#) of the [Theory Guide](#)). If **Local Time Stepping** is enabled, then you can specify the following parameters:

Convection #

specifies the particle convection number (see Δt_{conv} in [Equation 11–4](#) in the [Theory Guide](#)).

Diffusion #

specifies the particle diffusion number (see Δt_{diff} in [Equation 11–4](#)).

Mixing #

specifies the particle mixing number (see Δt_{mix} in [Equation 11–4](#)).

20.4. Enabling the Eulerian Composition PDF Transport Model

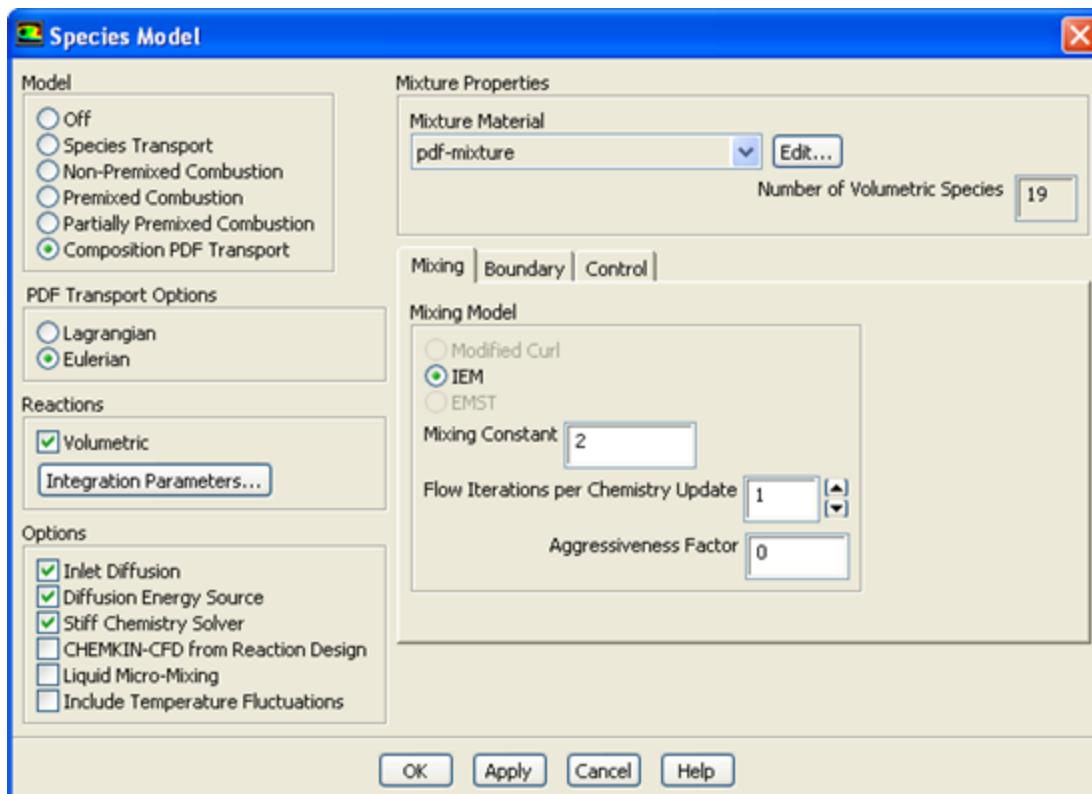

To enable the composition PDF transport model, select **Composition PDF Transport** in the **Species Model** dialog box ([Figure 20.1 \(p. 977\)](#)).

◀ Models → Species → Edit...

When you enable **Composition PDF Transport**, the dialog box will expand to show the relevant inputs.

1. Select **Eulerian** under **PDF Transport Options**.

Figure 20.3 The Species Model Dialog Box for Eulerian Composition PDF Transport

2. Enable **Volumetric** under **Reactions**. The **Stiff Chemistry Solver** is disabled by default and should be enabled if the kinetic mechanism is numerically stiff.

3. Click the **Integration Parameters...** button to open the *Integration Parameters Dialog Box* (p. 1828) (*Figure 20.2* (p. 978)). See *Using ISAT* (p. 988) for detailed information about this dialog box.
4. Enable **Inlet Diffusion** to include the diffusive transport of species through the inlets of your domain. Disable this option if the convective flux at one of the inlets is very small, resulting in mass loss by diffusion through that inlet.
5. Make sure that **Diffusion Energy Source** is enabled if you want to include species diffusion effects in the energy equation.
6. Enable **Liquid Micro-Mixing** if the fuel and oxidizer are liquids with low diffusivities (high Schmidt numbers). In this case, The **Mixing Constant** will be calculated per *Equation 11–13* in the *Theory Guide*.
7. By default, the Laminar (one mode) energy equation is solved, where temperature fluctuations are ignored. By enabling **Include Temperature Fluctuations**, the multi-mode energy equation will be solved as done for species.
8. In the **Mixing** tab, only the **IEM** mixing model is available for Eulerian PDF transport.
 - a. Specify the value of the **Mixing Constant**. The default value is 2 for gas phase species.

Important

If the **Liquid Micro-Mixing** option is enabled, you cannot set the **Mixing Constant**.

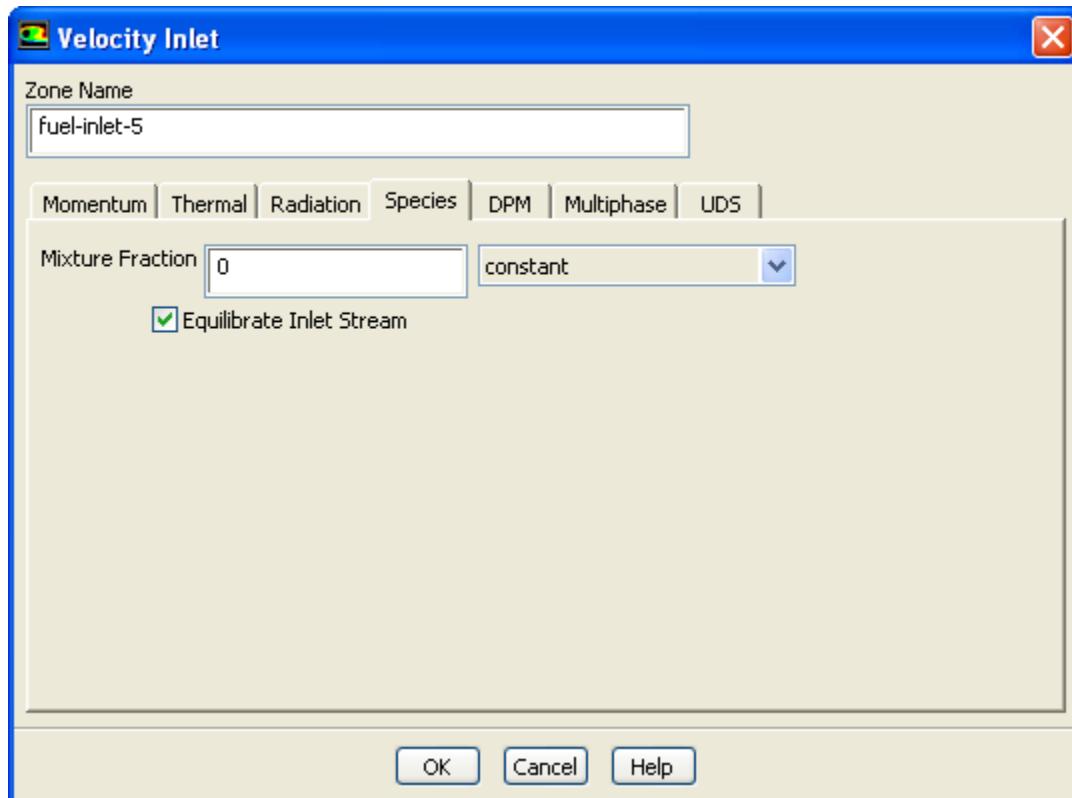

- b. Enter the number of **Flow Iterations per Chemistry Update**. This is the frequency at which ANSYS FLUENT will update the chemistry during the calculation. Increasing the number can reduce the computational expense of the chemistry calculations.
 - c. Enter the **Aggressiveness Factor**. This is a numerical factor which controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 (the default) is the most robust, but results in the slowest convergence.
9. In the **Boundary** tab, define the compositions of the fuel and oxidizer.

For additional information, please see the following sections:

[20.4.1. Defining Species Boundary Conditions](#)

20.4.1. Defining Species Boundary Conditions

At flow inlets, specify the **Mixture Fraction** in the **Species** tab of the boundary condition inlet dialog boxes, as shown in *Figure 20.4* (p. 981). At outlet boundaries, similarly specify the **Backflow Mixture Fraction**. ANSYS FLUENT always applies zero flux boundary conditions at walls for all species.

Figure 20.4 The Velocity Inlet Dialog Box for Eulerian Composition PDF Transport

20.4.1.1. Equilibrating Inlet Streams

The **Equilibrate Inlet Stream** option in the **Species** tab of the boundary conditions dialog boxes will set the inlet compositions to their chemical equilibrium values. This option can be used to model pilot flames and exhaust gas recirculation.

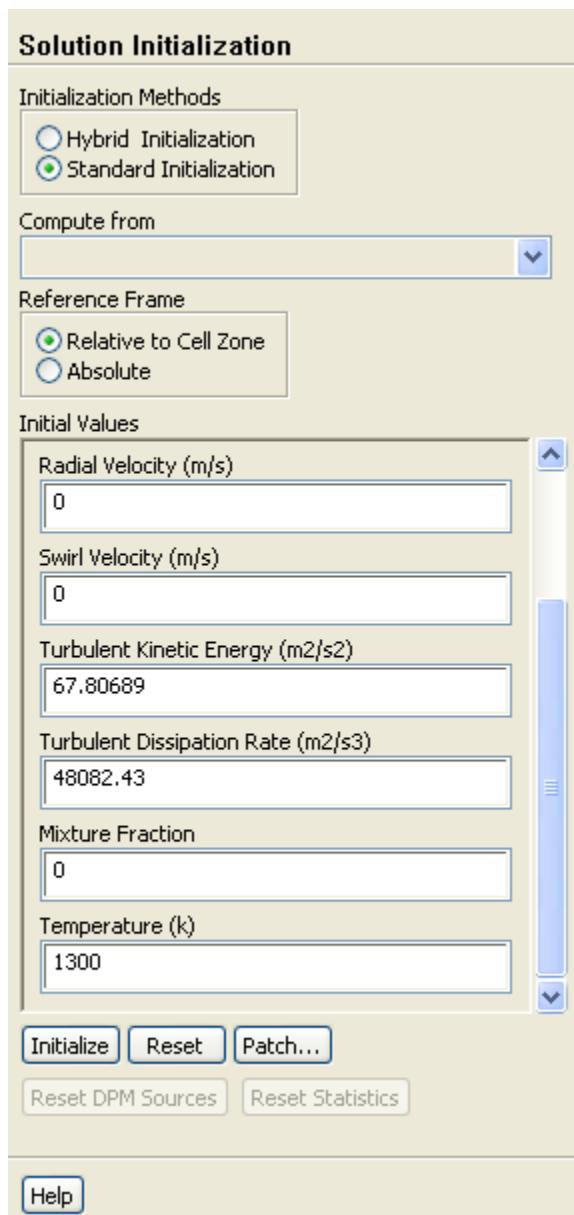

Important

This option should not be enabled for pure fuel or oxidizer inlets.

If you are using the Eulerian PDF transport model, specify the discretization and under-relaxation for the **Eulerian PDF** composition transport in the **Solution Controls** and **Solution Methods** task page.

20.5. Initializing the Solution

For the Eulerian PDF Transport model, the initialization variables are the mixture fraction and the temperature. The species mass fractions and enthalpy are calculated based on the fuel and oxidizer composition (specified in the **Species** dialog box) and the initialized mixture fraction and temperature.

Figure 20.5 The Solution Initialization Task Page for Eulerian Composition PDF Transport

20.6. Monitoring the Solution

At low speeds, combustion couples to the fluid flow through density. The Lagrangian PDF transport algorithm has random fluctuations in the density field, which in turn causes fluctuations in the flow field. For steady-state flows, statistical fluctuations are decreased by averaging over a number of previous iterations in the **Run Calculation** task page ([Figure 20.6 \(p. 983\)](#)).

Figure 20.6 The Run Calculation Task Page for Composition PDF Transport

Averaging reduces statistical fluctuations and stabilizes the solution. However, ANSYS FLUENT often indicates convergence of the flow field before the composition fields (temperatures and species) are converged. You should lower the default convergence criteria in the [Residual Monitors Dialog Box \(p. 2065\)](#), and always check that the **Total Heat Transfer Rate** in the [Flux Reports Dialog Box \(p. 2184\)](#) is balanced. It is also recommended that you monitor temperature/species on outlet boundaries and ensure that these are steady.

The Lagrangian PDF method has the additional solution controls: **Iterations in Average** and **Iteration Increment**. By increasing the **Iterations in Average**, fluctuations are smoothed out and residuals level off at smaller values. However, the composition PDF method requires a larger number of iterations to reach steady-state. It is recommended that you use the default of 50 **Iterations in Average** until the steady-state solution is obtained. Then, to gradually decrease the residuals, increase the **Iterations in Average** by setting a **Iteration Increment** to a value from 0 to 1 (the value 0.2 is recommended). Subsequent iterations will increase the **Iterations in Average** by the **Iteration Increment**.

For additional information, please see the following sections:

- [20.6.1. Running Unsteady Composition PDF Transport Simulations](#)
- [20.6.2. Running Compressible Lagrangian PDF Transport Simulations](#)
- [20.6.3. Running Lagrangian PDF Transport Simulations with Conjugate Heat Transfer](#)

20.6.1. Running Unsteady Composition PDF Transport Simulations

For unsteady Lagrangian composition PDF transport simulations, a fractional step scheme is employed where the PDF particles are advanced over the time step, and then the flow is advanced over the time step. Unlike steady-state simulations, composition statistics are not averaged over iterations, and to reduce statistical error you should increase the number of particles per cell in the **Solution Monitors** dialog box.

For low speed flows, the thermo-chemistry couples to the flow through density. Statistical errors in the calculation of density may cause convergence difficulties between time step iterations. If you experience this, increase the number of PDF particles per cell, or decrease the density under-relaxation.

20.6.2. Running Compressible Lagrangian PDF Transport Simulations

Compressibility is included when **ideal-gas** is selected as the density method in the *Create/Edit Materials Dialog Box* (p. 1882). For such flows, particle internal energy is increased by $p \Delta v$ over the time step Δt , where p is the cell pressure and Δv is the change in the particle specific volume over the time step.

20.6.3. Running Lagrangian PDF Transport Simulations with Conjugate Heat Transfer

When solid zones are present in the simulation, ANSYS FLUENT solves the energy equation in the turbulent flow zones by the Lagrangian Monte Carlo particle method, and the energy equation in the solid zones by the finite-volume method.

20.7. Postprocessing for Lagrangian PDF Transport Calculations

For additional information, please see the following sections:

[20.7.1. Reporting Options](#)

[20.7.2. Particle Tracking Options](#)

20.7.1. Reporting Options

ANSYS FLUENT provides several reporting options for the Lagrangian composition PDF transport calculations. You can generate graphical plots or alphanumeric reports of the following items:

- **Static Temperature**
- **Mean Static Temperature**
- **RMS Static Temperature**
- **Mass fraction of species-n**
- **Mean species-n Mass Fraction**
- **RMS species-n Mass Fraction**

The instantaneous composition (**Static Temperature** and **Mass fraction of species-n**) in a cell are calculated as,

$$\phi_{instant} = \frac{\sum_{i=1}^{N_c} \phi_p m_p}{\sum_{i=1}^{N_c} m_p} \quad (20-1)$$

where

$\phi_{instant}$ = instantaneous cell species mass fraction or temperature at the present iteration

N_c = number of particles in the cell

T_p = particle mass fraction or temperature

m_p = particle mass

Mean and root-mean-square (RMS) temperatures are calculated in ANSYS FLUENT by averaging instantaneous temperatures over a user-specified number of previous iterations (see [Monitoring the Solution \(p. 982\)](#)).

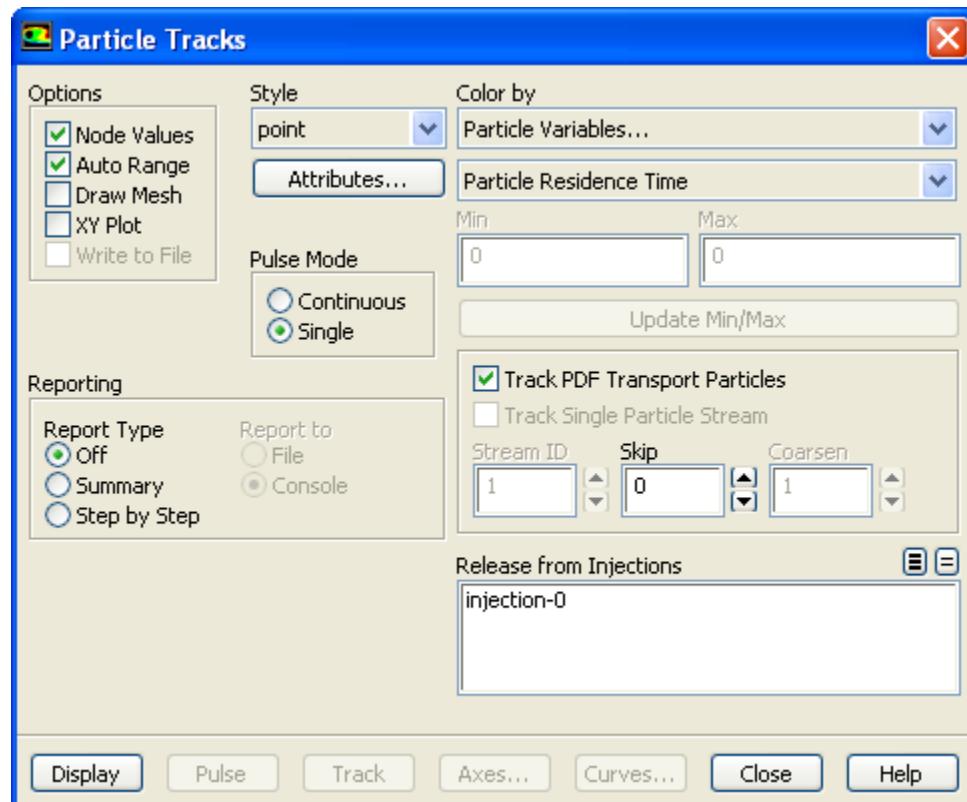

Note that for steady-state simulations, instantaneous temperatures and species represent a Monte Carlo realization and are as such unphysical. Mean and RMS quantities are much more useful.

20.7.2. Particle Tracking Options

When you have enabled the Lagrangian composition PDF transport model, you can display the trajectories of the PDF particles using the [Particle Tracks Dialog Box \(p. 2133\)](#) ([Figure 20.7 \(p. 985\)](#)).

◆ **Graphics and Animation** → **Particle Tracks** → **Set Up...**

Figure 20.7 The Particle Tracks Dialog Box for Tracking PDF Particles

Select the **Track PDF Transport Particles** option to enable PDF particle tracking. To speed up the plotting process, you can specify a value n for **Skip**, which will plot only every n th particle. For details about setting other parameters in the **Particle Tracks** dialog box, see [Displaying of Trajectories \(p. 1143\)](#).

When you have finished setting parameters, click **Display** to display the particle trajectories in the graphics window.

20.8. Postprocessing for Eulerian PDF Transport Calculations

For additional information, please see the following sections:

20.8.1. Reporting Options

To postprocess the Eulerian composition PDF transport model, the following variables are available for each mode:

- **Mixture fraction**
- **Mass fraction of species in mode n**
- **Temperature of mode n**
- **Sensible Enthalpy of mode n**

Chapter 21: Using Chemistry Acceleration

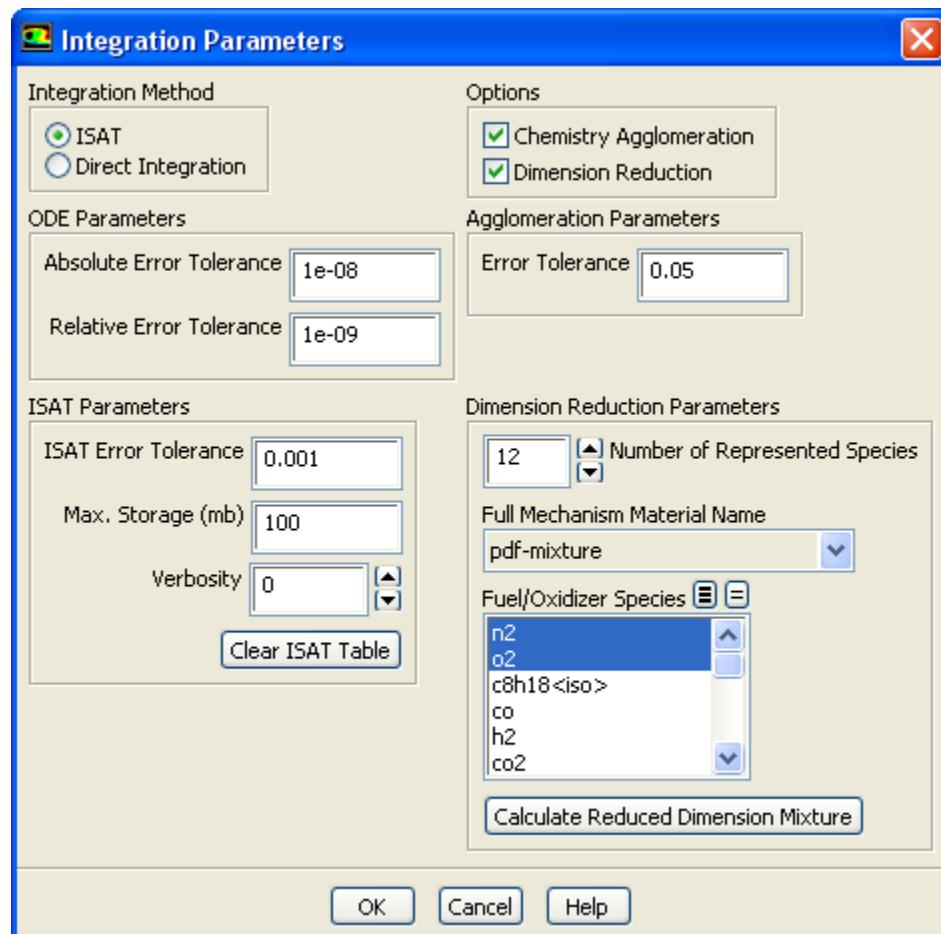

ANSYS FLUENT can model detailed chemical kinetics in laminar and turbulent flames. Laminar flames are modeled with the **Laminar Finite-Rate** option, while four turbulence-chemistry interaction models are available for turbulent flames (**Laminar Finite-Rate**, **Eddy-Dissipation Concept**, **Lagrangian PDF Transport**, and **Eulerian PDF Transport**). Detailed chemical mechanisms are invariably numerically stiff and compute-intensive. ANSYS FLUENT provides three methods to accelerate these computations:

- ISAT
- Chemistry Agglomeration
- Dimension Reduction

All three methods are enabled or disabled in the **Integration Parameters** dialog box, accessed from the **Species Model** dialog box:

◆ Models → Species → Edit...

Figure 21.1 The Integration Parameters Dialog Box Displaying Dimension Reduction

All three acceleration methods induce some accuracy loss, and the controlling parameters should be carefully adjusted to ensure that this inaccuracy is acceptable, see "[Chemistry Acceleration](#)". Further information about using the three chemistry acceleration models is presented in the following sections:

- [21.1. Using ISAT](#)
- [21.2. Using Chemistry Agglomeration](#)
- [21.3. Dimension Reduction](#)

21.1. Using ISAT

In-Situ Adaptive Tabulation (ISAT) is a storage-retrieval method that constructs a chemistry table at run-time (in-situ) with a user-specified interpolation accuracy (adaptive tabulation). ANSYS FLUENT uses an ODE solver to integrate the stiff chemical kinetics.

The stiff ODE integrator has two error tolerances: the **Absolute Error Tolerance** and the **Relative Error Tolerance** under **ODE Parameters**, that are set to default values of 10^{-8} and 10^{-9} respectively. These should be sufficient for most applications, although these tolerances may need to be decreased for some cases such as ignition. For problems in which the accuracy of the chemistry integrations is crucial, it may be useful to test the accuracy of the error tolerances in simple zero-dimensional and one-dimensional test simulations with parameters comparable to those in the full simulation.

For additional information, please see the following sections:

- [21.1.1. ISAT Parameters](#)
- [21.1.2. Monitoring ISAT](#)
- [21.1.3. Using ISAT Efficiently](#)
- [21.1.4. Reading and Writing ISAT Tables](#)

21.1.1. ISAT Parameters

If you have selected **ISAT** under **Integration Method**, you will then be able to set additional ISAT parameters. The numerical error in the ISAT table is controlled by the **ISAT Error Tolerance** under **ISAT Parameters**. The default **ISAT Error Tolerance** of 0.001 may be sufficiently accurate for temperature and major species, but will most likely need to be decreased to get accurate minor species and pollutant predictions. For steady-state simulations, it may help to start with a high error tolerance during the initial iterations towards a converged solution. A larger error tolerance results in smaller tables and quicker run times, but greater error.

Important

After your steady simulation is converged, you should always decrease the **ISAT Error Tolerance** and perform further iterations until the species that you are interested in are unchanged.

The **Max. Storage** is the maximum RAM used by the ISAT table, and has a default value of 100 MB. It is recommended that you set this parameter to a large fraction of the available memory on your computer. The value of **Verbosity** allows you to monitor ISAT performance in different levels of detail. See [Monitoring ISAT \(p. 989\)](#) for details about this parameter.

Chemistry agglomeration is available for all models that use ISAT. Enable **Chemistry Agglomeration** in the **Integration Parameters** dialog box. The chemistry agglomeration **Error Tolerance** (ε_{tol}) can be set in the **Integration Parameters** dialog box. Larger values of ε_{tol} result in a larger number of cells agglomerated, fewer calls to the reaction integrator, increased run-time speed, but greater error. More information can be found in [Chemistry Agglomeration](#) in the [Theory Guide](#).

To purge the ISAT table, click the **Clear ISAT Table** button. See [Using ISAT Efficiently \(p. 989\)](#) for more details.

21.1.2. Monitoring ISAT

You can monitor ISAT performance by setting the **Verbosity** in the **Integration Parameters** dialog box. For a **Verbosity** of 1 or 2, ANSYS FLUENT writes the following information periodically to a file named `case-file-name_stats.out`:

- total number of *queries*
- total number of queries resulting in *retrieves*
- total number of queries resulting in *grows*
- total number of queries resulting in *adds*
- total number of queries resulting in *direct integrations*
- cumulative CPU seconds in ISAT
- cumulative CPU seconds outside ISAT
- cumulative wall-clock time in seconds (i.e., total CPU time in ISAT plus total CPU time out of ISAT plus CPU idle time)

The ISAT **Verbosity** option of 2 is for expert users who are familiar with ISATAB v5.0 [68] (p. 2370). ANSYS FLUENT writes out the following files for **Verbosity** = 2:

- `tablename_stats.out`, as described above
- `tablename_ODE_accuracy.out` reports the accuracy of the ODE integrations. For every new ISAT table entry, if the maximum absolute error in temperature or species is greater than any previous error, a line is written to this file. This line consists of the total number of ODE integrations performed up to this time, the maximum absolute species error, the absolute temperature error, the initial temperature and the time step.
- `tablename_ODE_diagnostic.out` prints diagnostics from the ODE solver
- `tablename_ODE_warning.out` prints warnings from the ODE solver

Initially, the table name is equal by default to the current case name, and is changed as the table is written or read.

In parallel, each processor builds its own ISAT table. If **Verbosity** is enabled in parallel, each compute node writes out the **Verbosity** file(s) with the node ID number appended to the file name.

21.1.3. Using ISAT Efficiently

Efficient use of ISAT requires thoughtful control. What follows are some detailed recommendations concerning the achievement of this goal.

Important

The numerical error in the ISAT table is controlled by the **ISAT Error Tolerance**, which has a default value of 0.001. This value is relatively large, which allows faster convergence times for steady-state simulations. However, once the solution has converged, it is important to reduce this **ISAT Error Tolerance** and re-converge. This process should be repeated until the species that you are interested in modeling are unchanged. Unsteady simulations should be run with a sufficiently small **ISAT Error Tolerance** so that the species of interest are unaffected by this parameter. Note that as the error tolerance is decreased, the memory and time requirements to build the ISAT table will increase substantially. There is a large performance penalty in specifying an error tolerance smaller than is needed to achieve acceptable accuracy, and the error tolerance should be decreased gradually and judiciously.

Important

Once the ISAT table is full, all queries that cannot be retrieved are directly integrated. Since retrieves are much quicker than direct integrations, larger ISAT tables are faster. Hence, you should set the ISAT **Max. Storage** to a large fraction of the available memory on your computer.

During the initial iterations, before a steady-state solution is attained, transient composition states occur that are not present in the steady-state solution. For example, you might patch a high temperature region in a cold fuel-air mixing zone to ignite the flame, whereas the converged solution never has hot reactants without products. Since all states that are realized in the simulation are tabulated in ISAT, these initial mappings are wasteful of memory, and can degrade ISAT performance. If the table fills the allocated memory and contains entries from an initial transient that are no longer accessed, it may be beneficial to purge the ISAT table. This is achieved by either clearing it in the **Integration Parameters** dialog box, or saving your case and data files, exiting ANSYS FLUENT, then restarting ANSYS FLUENT and reading in the case and data.

From experience, ISAT performs very well on premixed turbulent flames, where the range of composition states are smaller than in non-premixed flames. ISAT performance degrades in flames with large residence times, where more work is required in the ODE integrator.

21.1.4. Reading and Writing ISAT Tables

ANSYS FLUENT can write and subsequently read ISAT tables. However, it is in general not recommended to write and read ISAT tables for the following reason: ISAT tabulates chemical states that are specific to a single simulation. The ISAT tabulated composition states are determined by the geometry, boundary conditions, physics models such as turbulence and radiation, thermodynamic and transport properties, as well the chemical mechanism. If any of these parameters change, the realized composition space changes, and significant parts of the existing ISAT table are no longer accessed. These un-accessed ISAT table entries slow interpolation and decrease the number of useful accessed table entries that can be added. Since the time consumed building the ISAT table (hours) is typically much smaller than simulation run-times (days), it is advised to re-build the table when restarting.

When ANSYS FLUENT is run in parallel, each partition builds its own ISAT table and does not exchange information with ISAT tables on other compute nodes. You can save the ISAT tables on all compute nodes:

File → Write → ISAT Table...

Each compute node writes out its ISAT table to the specified file name, with the node ID number appended to the file name. For example, a specified file name of `my_name` on a two compute node run will write two files called `my_name-0.isat` and `my_name-1.isat`.

Subsequent runs can start from existing ISAT tables by reading them into memory.

File → Read → ISAT Table...

Files can be read in two ways:

- Parallel nodes can read in corresponding ISAT tables saved from a previous parallel simulation. The appended node ID should not be removed from the input file name.

Note

You should never read ISAT tables generated from a parallel simulation with a different number of parallel nodes.

- All nodes can read one unique ISAT table. You might use this approach if you have a large table from a serial simulation. ANSYS FLUENT first checks to see if the exact file name that you specified exists, and if it does, all nodes will read this one file.

21.2. Using Chemistry Agglomeration

The Chemistry Agglomeration method reduces the number of calls to the computationally expensive ODE integrator by clustering cells with similar compositions. The size of these clusters is determined by the **Agglomeration Parameters Error Tolerance** (ε_{tol}) in the **Integration Parameters** dialog box.

Larger values of ε_{tol} result in a larger number of agglomerated cells, fewer calls to the reaction integrator, increased run-time speed, but greater error. More information can be found in [Chemistry Agglomeration](#) in the [Theory Guide](#).

Important

The default **Error Tolerance** of 0.05 is relatively large. This enables faster convergence times for steady-state simulations. However, once the solution has converged, it is important to reduce this agglomeration **Error Tolerance** and re-converge. This process should be repeated until the species that you are interested in modeling are unchanged. Unsteady simulations should be run with a sufficiently small **Error Tolerance** so that the species of interest are unaffected by this parameter. However, since performance can decrease substantially when the **Error Tolerance** is decreased, care should be taken to ensure that this parameter is not smaller than is needed to achieve acceptable accuracy.

21.3. Dimension Reduction

Detailed kinetic mechanisms typically contain a multitude of intermediate species that far exceed the number of major fuel, oxidizer, and product species. Chemical mechanism **Dimension Reduction** reduces the number of intermediate species transport equations (called representative species) that are solved, and reconstructs the ‘unrepresented’ species using chemical equilibrium assumptions.

Important

Since ANSYS FLUENT is limited to a maximum of 50 transported species, the main use of **Dimension Reduction** is to enable simulation with chemical mechanisms containing more than 50 species.

Follow these steps to use **Dimension Reduction**:

- Import your CHEMKIN mechanism. Note that you can import CHEMKIN mechanisms which contain more than 50 species.
- Click the **Integration Parameters** button in the **Species Model** dialog box, and enable **Dimension Reduction**.
- Set the **Number of Represented Species**. This must be greater than 10 and less than the number of species in the full mechanism. The **Number of Represented Species** must also be less than 50 minus the number of unrepresented elements (the number of chemical elements in the unrepresented species). A larger **Number of Represented Species** will increase accuracy, but also increase computational expense. The default of 12 has been chosen to provide a good compromise between accuracy and speed.
- Select the **Full Mechanism Material Name**, which is typically the name of the CHEMKIN mechanism that you imported. ANSYS FLUENT can store several imported CHEMKIN mechanisms in different mixture materials whose mechanisms you are not using. However, since mechanisms are typically large, it is recommended to delete unused mixtures to reduce memory requirements.
- Set the boundary and initial fuel and oxidizer, as well as product species, as represented species. These are input in the **Fuel/Oxidizer Species** list. Note that you can force other species to be represented by selecting them here. Species of interest, especially species that are not near chemical equilibrium, such as pollutants, and their associated intermediate species in the mechanism should also be included. Intermediate species that occur in large mass fractions relative to the fuel and oxidizer species should be included, as well as species important in the chemical pathway. For example, for methane combustion in air, CH_3 should be included as a represented species since CH_4 pyrolyzes to CH_3 first.
- Click **Calculate Reduced Dimension Mixture**. This will create a new mixture material called `reduced-dimension-mixture`, which contains the represented species as well as proxy 'species' for the unrepresented elements. These unrepresented elements have "u" prepended to the element name. You should never rename the reduced-dimension-mixture mixture material, or select another mixture as the active material, while **Dimension Reduction** is enabled.
- Continue with the setup, solution, and postprocessing as for other detailed chemistry cases. Note that the boundary and initial mass fraction of unrepresented elements should always be zero. The entries for the unrepresented element mass fractions are disabled in the ANSYS FLUENT GUI.

For postprocessing, the unrepresented elements are available in the **Species** list as the element name with "u" prepended. All species in the full mechanism, consisting of both represented and unrepresented species, are available in the **Full Mechanism Species...** category of the postprocessing dialog boxes.

After you obtain a preliminary solution with **Dimension Reduction**, it is recommended that you check the magnitude of all unrepresented species, which are available in the **Full Mechanism Species...** option in the **Contours** dialog box. If the mass fraction of any unrepresented species is larger than other represented species, you should repeat the simulation with this species included in the represented species list. In turn, the mass fraction of all unrepresented elements should decrease.

Note

Note that **Dimension Reduction** is only available with ISAT. **Dimension Reduction** is initially comparable in speed to a simulation with the full mechanism, but iterations become significantly faster at later times when the ISAT table is populated.

For information about the theory of this option, see [Chemical Mechanism Dimension Reduction](#).

Chapter 22: Modeling Engine Ignition

This chapter discusses how to use the engine ignition models available in ANSYS FLUENT in the following sections. For information about the theory behind these ignition models, see "Engine Ignition" in the Theory Guide.

- 22.1. Spark Model
- 22.2. Autoignition Models
- 22.3. Crevice Model

22.1. Spark Model

The spark model in ANSYS FLUENT will be described in the context of the premixed turbulent combustion model. For information regarding the theory of this model, see [Spark Model](#) in the [Theory Guide](#). Information regarding the use of this model is detailed in the following sections:

- 22.1.1. Using the Spark Model
- 22.1.2. Using the ECFM Spark Model

22.1.1. Using the Spark Model

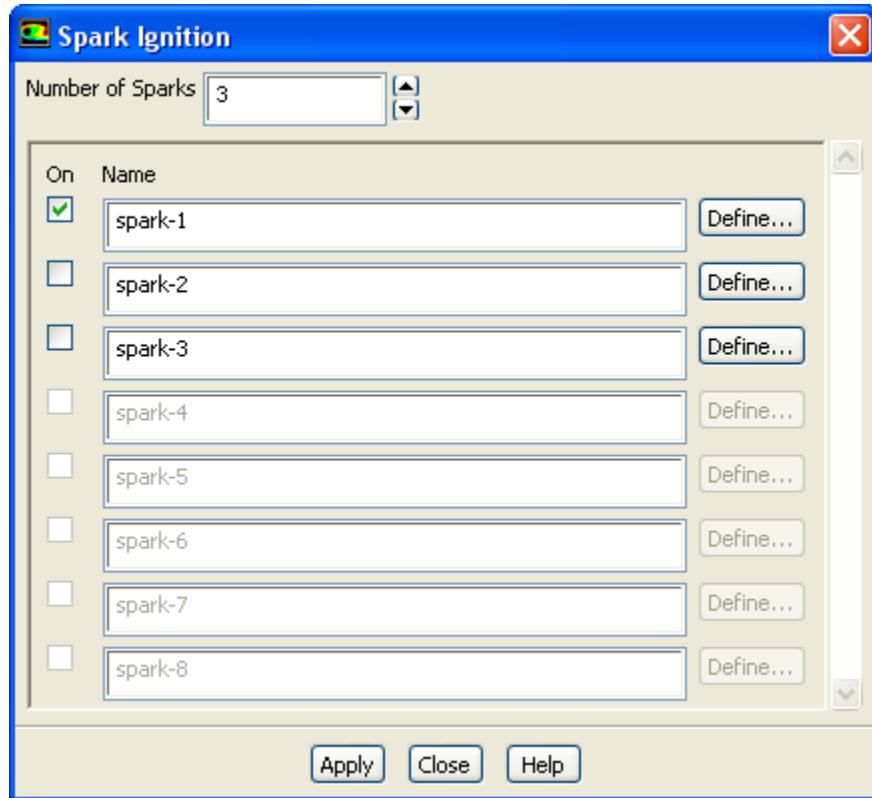

You can model a single spark or multiple sparks. To activate the spark model, perform the following steps:

1. Select **Transient** from the **Time** list in the **General** task page.
2. Select an appropriate reaction model in the **Species Model** dialog box.

Models → **Species** → **Edit...**

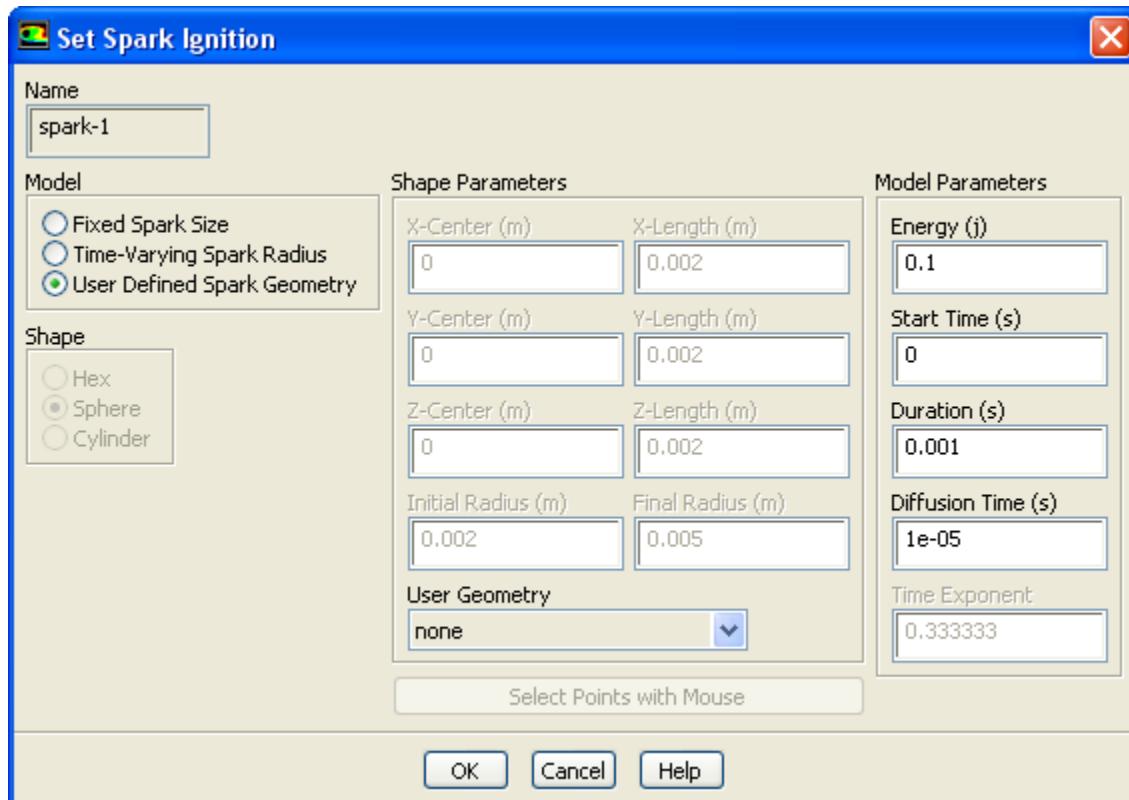

3. Select **Species Transport** under **Model** in the **Species Model** dialog box and enable **Volumetric** under **Reactions**. Or you can select the **Premixed Model** with the **C Equation** or **G Equation** model enabled. See [Setting Up the C-Equation and G-Equation Models](#) (p. 960) for more information.
4. The **Spark Ignition** model will now appear in the **Models** task page. Select **Spark Ignition** and click **Edit....** This will open the **Spark Ignition** dialog box , as shown in [Figure 22.1](#) (p. 996).

Models → **Spark Ignition** → **Edit...**

Figure 22.1 The Spark Ignition Dialog Box

5. Specify the **Number of Sparks** you would like to include in your simulation. You can define up to 16 sparks.
6. While you can define several sparks, you can choose which ones to activate using the **On** option.
7. Enter the **Name** of the spark, or simply keep the default name.
8. Click the **Define...** button to open the **Set Spark Ignition** dialog box ([Figure 22.2 \(p. 997\)](#)), where you will set the parameters of the selected spark ignition models.

Figure 22.2 The Set Spark Ignition Dialog Box

- Define the spark model as **Fixed Spark Size**, **Time-Varying Spark Radius**, or **User Defined Spark Geometry**.

When the **Fixed Spark Size** is enabled (*Figure 22.2 (p. 997)*), you can select the shape of the spark to be spherical, cylindrical, or hexahedral in three dimensional simulations, or circular or quadrilateral in two dimensional simulations. Depending on the shape selected, appropriate inputs are highlighted or grayed out.

- To define a spherical spark, the shape parameters can be selected by clicking the **Select Points with Mouse** button at the bottom of the dialog box, and highlighting the center and radius of the spark kernel.
- Enter **Energy**, **Start Time**, **Duration**, and **Diffusion Time** in the **Set Spark Ignition** dialog box.

Important

When the in-cylinder model is turned on, the **Start Time** is entered in crank angle degrees instead of seconds, while the spark **Duration** is still in seconds.

- While the **Energy** input is in Joules by default, you can redefine the units as needed. The rate of energy input into the domain is constant so that the total energy will be evenly distributed over the duration that you set. The **Energy** input in the spark model should result in an appropriate temperature rise in the cell that is high enough to initiate combustion. The **Energy** input is only a model parameter and does not reflect energy input in actual automotive ignition systems, which typically range between 50 and 150 millijoules.

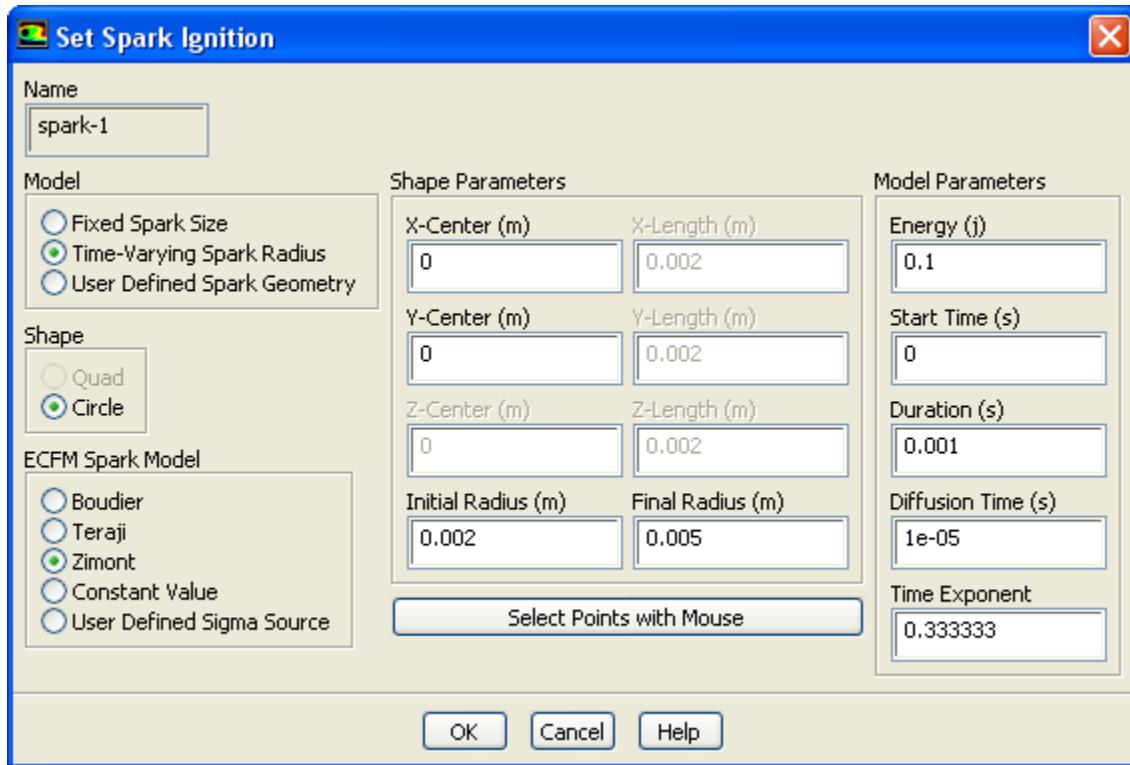

If you select the **Time-Varying Spark Radius** model, you will need to specify the **Energy**, **Start Time**, **Duration**, **Diffusion Time**, and **Time Exponent**. The spark is assumed spherical (in 3D and circular in 2D) and will grow from an **Initial Radius**, r_0 , to a **Final Radius**, r_f , over the spark **Duration**, with a cube root dependence on time so that the radius will grow faster at the beginning and more slowly near the end. This time-dependent behavior is consistent with experimental findings [32] (p. 2368). The **Time-Varying Spark Radius** option is recommended as it has been found to be less sensitive to model parameters.

If you select **User Defined Spark Geometry** model, you can hook a user-defined function to define custom spark kernel volume shapes, which becomes selectable from the **User Geometry** drop-down list. For details about this user-defined function, please refer to **DEFINE_SPARK_GEOM** in the **UDF Manual**. In addition, you will need to specify the model parameters, such as **Energy**, **Start Time**, **Duration**, and **Diffusion Time**.

22.1.2. Using the ECFM Spark Model

When the **Extended Coherent Flamelet Model** (see *Setting Up the Extended Coherent Flame Model* (p. 964)) is selected in the **Species Model** dialog box, the **Set Spark Ignition** dialog box will exhibit additional **ECFM Spark Model** options, as shown in *Figure 22.3* (p. 998). These options are described in detail in **ECFM Spark Model Variants** in the **Theory Guide**.

Figure 22.3 The Set Spark Ignition Dialog Box Displaying the ECFM Spark Model Options

In addition to specifying the variables mentioned in *Using the Spark Model* (p. 995), you can

- Select the **Fixed Spark Size** model and select one of the three available **ECFM Spark Model** options:
 - **Zimont**: Specify the **Energy**, **Start Time**, **Duration**, and **Diffusion Time**.
 - **Constant Value**: Specify the **Energy**, **Start Time**, **Duration**, **Diffusion Time**, and the **Flame Surface Density**.

- **User Defined Sigma Source:** Select the hooked UDF from the **User Sigma Source** drop-down list to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, please refer to [Hooking DEFINE_ECFM_SPARK_SOURCE UDFs](#) in the [UDF Manual](#).
- Select the **Time-Varying Spark Radius** model and select one of the five available **ECFM Spark Model** options:
 - **Boudier:** Specify the **Energy, Start Time, Duration, Diffusion Time**, and **Time Exponent**.
 - **Teraji:** Specify the **Energy, Start Time, Duration**, and **Diffusion Time**.
 - **Zimont:** Specify the **Energy, Start Time, Duration, Diffusion Time**, and **Time Exponent**.
 - **Constant Value:** Specify the **Energy, Start Time, Duration, Diffusion Time, Time Exponent**, and the **Flame Surface Density**.
 - **User Defined Sigma Source:** Select the hooked UDF from the **User Sigma Source** drop-down list to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, please refer to [Hooking DEFINE_ECFM_SPARK_SOURCE UDFs](#) in the [UDF Manual](#).
- Select the **User Defined Spark Geometry** model and select one of the two available **ECFM Spark Model** options:
 - **Constant Value:** Specify the **Energy, Start Time, Duration, Diffusion Time**, and the **Flame Surface Density**.
 - **User Defined Sigma Source:** Select the hooked UDF from the **User Sigma Source** drop-down list to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, please refer to [Hooking DEFINE_ECFM_SPARK_SOURCE UDFs](#) in the [UDF Manual](#).

22.2. Autoignition Models

Autoignition phenomena in engines are due to the effects of chemical kinetics of the reacting flow inside the cylinder. There are two types of autoignition models considered in ANSYS FLUENT:

- knock model in spark-ignited (SI) engines
- ignition delay model in diesel engines

For information regarding the theory behind autoignition models, see [Autoignition Models](#) in the [Theory Guide](#). [Using the Autoignition Models \(p. 999\)](#) describes how to use the autoignition models in ANSYS FLUENT.

22.2.1. Using the Autoignition Models

To activate the autoignition model, perform the following steps:

1. Select **Transient** from the **Time** list in the **General** task page.
2. Select an appropriate reaction model in the **Species Model** dialog box.

3. The models in the **Species Model** dialog box that are compatible with the autoignition model are **Species Transport**, **Premixed Combustion**, and **Partially Premixed Combustion**.

Important

If you select **Species Transport**, you must also enable the **Volumetric** option in the **Reactions** group box.

Important

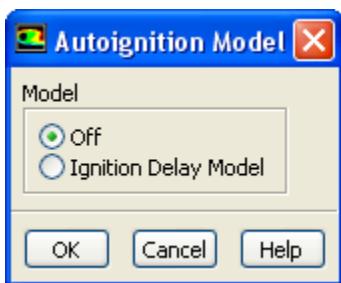

The **Premixed Combustion** and **Partially Premixed Combustion** models are only available for turbulent flows using the pressure-based solver.

4. The **Autoignition** model will now appear in the **Models** task page.

↳ **Models** → **Autoignition** → **Edit...**

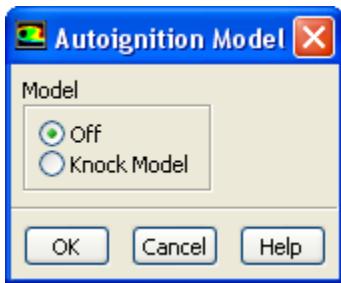

- If **Species Transport** is selected in the **Species Model** dialog box, you can only select the **Ignition Delay Model**.

Figure 22.4 The Ignition Delay Model in the Autoignition Model Dialog Box

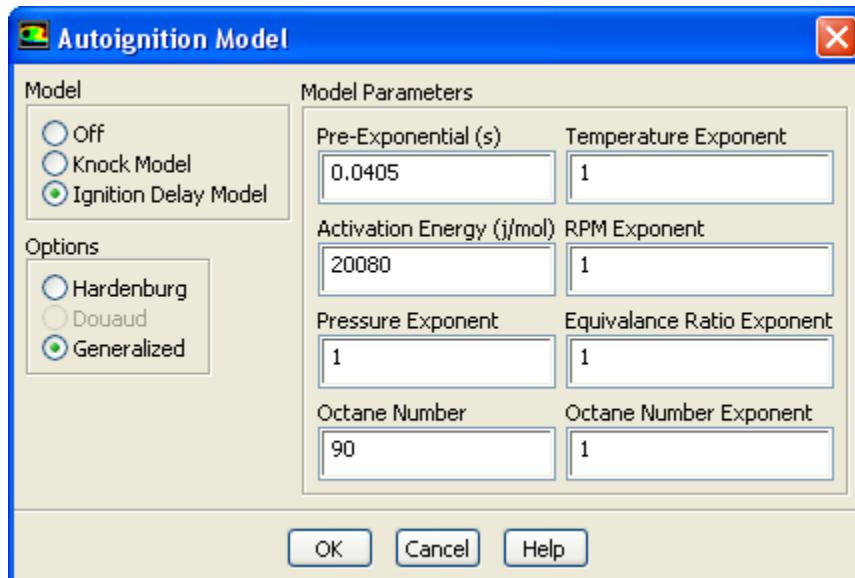

- If **Premixed Combustion** is selected in the **Species Model** dialog box, you can only select the **Knock Model**.

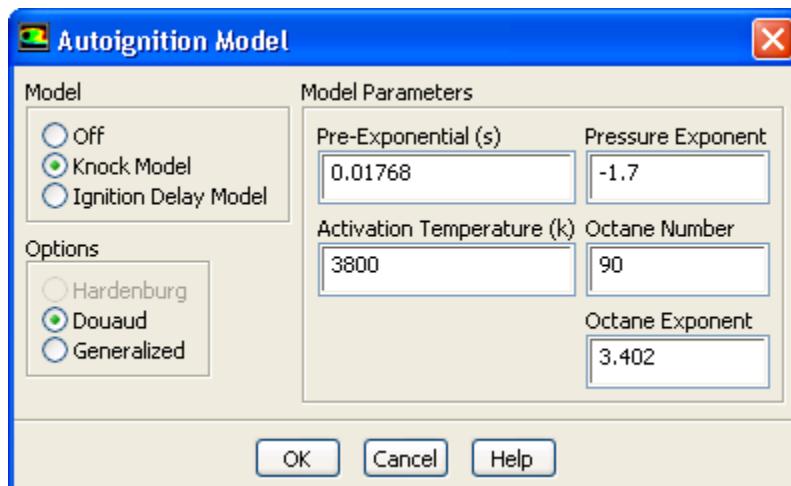

Figure 22.5 The Knock Model in the Autoignition Model Dialog Box

- If **Partially Premixed Combustion** is selected in the **Species Model** dialog box, you can select either the **Knock Model** or the **Ignition Delay Model**.
5. When the **Ignition Delay Model** is enabled, the dialog box expands to include the modeling parameters for this model (*Figure 22.6 (p. 1001)*). The two correlation options that exist with this model are **Hardenburg** and **Generalized**. Depending on which correlation option is selected, the appropriate modeling parameters will appear in the dialog box.

Figure 22.6 The Ignition Delay Model for the Partially Premixed Combustion Model

- The **Hardenburg** option is typically used for heavy duty diesel engines. A **Fuel Species** is selected from the drop-down list and the **Pre-Exponential, Pressure Exponent, Activation Energy**, and **Cetane Number** are entered using the GUI. Default values of these parameters can be found in Table 13.1: "Default Values of the Variables in the Hardenburg Correlation" in the Theory Guide.
 - The **Generalized** option is described by [Equation 13–13](#) in the Theory Guide. Similarly to the **Hardenburg** option, a **Fuel Species** is selected from the drop-down list and the **Pre-Exponential, Temperature Exponent, Activation Energy, RPM Exponent, Pressure Exponent, Equivalence Ratio Exponent, Octane Number**, and **Octane Number Exponent** are entered using the GUI.
6. When the **Knock Model** is enabled, the dialog box expands to include modeling parameters for this model ([Figure 22.7 \(p. 1001\)](#)). The two correlation options that exist with this model are **Douaud** and **Generalized**. Depending on which correlation option is selected, the appropriate modeling parameters will appear in the dialog box.

Figure 22.7 The Knock Model with the Partially Premixed Combustion Model Enabled

- The **Douaud** option is used for knock in SI engines. The modeling parameters that are specified in the GUI for this option are the **Pre-Exponential, Pressure Exponent, Activation Temperature, Octane Number**, and **Octane Exponent** ([Equation 13–12](#) in the Theory Guide).

- The **Generalized** option ([Equation 13–13](#) in the [Theory Guide](#)) in the knock model requires the same parameters as in the ignition delay model.

22.3. Crevice Model

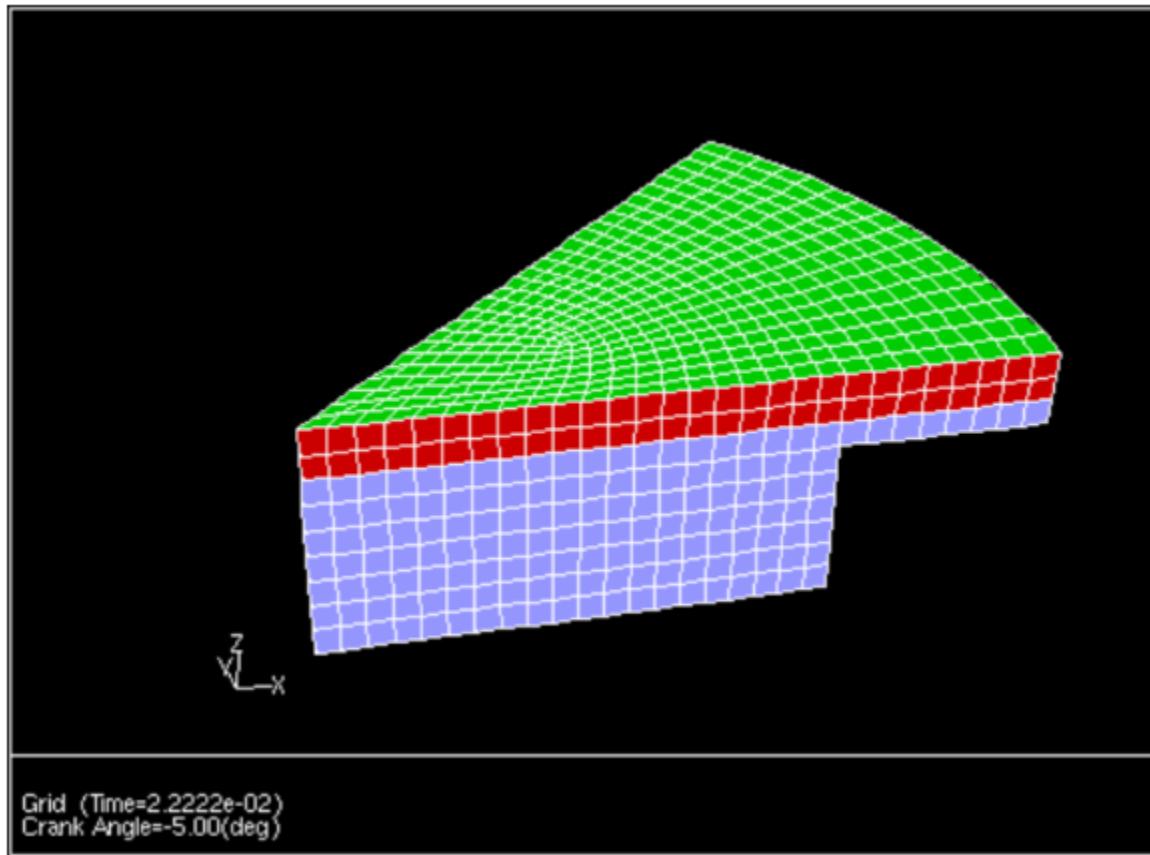

For information regarding the theory behind the crevice model, see [Crevice Model](#) in the [Theory Guide](#). Using the crevice models in ANSYS FLUENT are described in the following sections:

- [22.3.1. Using the Crevice Model](#)
- [22.3.2. Crevice Model Solution Details](#)
- [22.3.3. Postprocessing for the Crevice Model](#)

22.3.1. Using the Crevice Model

An optical experimental engine [19] (p. 2368) is used below to show a working example of how to use the crevice model as it is implemented in ANSYS FLUENT. The mesh at ten crank angle degrees before top center is shown in [Figure 22.8](#) (p. 1002).

Figure 22.8 Experimental Engine Mesh

The following example shows the necessary steps to enable the crevice model for a typical in-cylinder flow.

- From the > prompt, enter the define/models menu by using the following text command:

```
define → models
```

- Enable the crevice model, as follows:

```
/define/models  crevice-model?

Enable crevice model? [no] yes
/define/models
acoustics/           multiphase/           species/
addon-module         noniterative-time-advance? steady?
axisymmetric?        nox?                 unsteady-1st-order?
crevice-model-controls/ radiation/           unsteady-2nd-order?
crevice-model?       solidification-melting? viscous/
dpm/                solver/              soot?
energy?              soot?               sox?
```

3. Enter the ring pack geometry:

```
/define/models  crevice-model-controls

Cylinder bore (m) [0.1] 0.1397
Piston to bore clearance (m) [3.0e-5] 5.08e-05
Piston crevice temperature (K) [400] 433
Piston sector angle (deg) [360] 45
Ring discharge coefficient [0.8] 0.7
Pressure in crankcase (exit pressure) (Pa) [101325]
Write out crevice data to a file? [no] yes

output file name ["crev.out"]

Available wall threads are: (wall.1 wall wall-8)
Leaking wall [] wall.1

Shared boundary [] wall-8
Selected boundary threads : (wall.1 wall-8)
Use these zones? [yes] yes

Solve crevice model ? [no] yes
Number of rings [3]
Width of ring number 0 is: [0.00375]
Thickness of ring number 0 is: [0.0015]
Spacing of ring number 0 is: [0.008]
Land Length for ring number 0 is: [0.00391]
Top Gap of ring number 0 is: [6e-05]
Middle Gap of ring number 0 is: [4e-05]
Bottom Gap of ring number 0 is: [6e-05]

Width of ring number 1 is: [0.00375]
Thickness of ring number 1 is: [0.0015]
Spacing of ring number 1 is: [0.008]
Land Length for ring number 1 is: [0.00391]
Top Gap of ring number 1 is: [6e-05]
Middle Gap of ring number 1 is: [4e-05]
Bottom Gap of ring number 1 is: [6e-05]

Width of ring number 2 is: [0.00375]
Thickness of ring number 2 is: [0.0015]
Spacing of ring number 2 is: [0.00391]
Land Length for ring number 2 is: [0.00391]
Top Gap of ring number 2 is: [6e-05]
Middle Gap of ring number 2 is: [4e-05]
Bottom Gap of ring number 2 is: [6e-05]

Initial conditions in ring pack
Pressure 1 is: [4600623.5]
Pressure 2 is: [4173522.5]
Pressure 3 is: [3689110.5]
Pressure 4 is: [3130620]
Pressure 5 is: [2214841.8]
```

A fast way to set up multiple rings in the ring pack is to specify only one ring and enter the geometry. Once the ring geometry is entered, invoke the crevice-model-controls menu a

second time and specify the number of rings desired. When the number of rings changes, the geometry from the first ring is copied to all subsequent rings. Default values can be taken for the rest of the way through the menu structure.

A summary of the crevice model is printed out by entering the (`crevice-summary`) command at the command prompt:

```
>(crevice-summary)
      crevice/n-rings   : 3
      crevice/ring-width : (0.00375 0.00375 0.00375)

      crevice/pressures      : (4600623.5 4173522.5 3689110.5 3130620 2214841)
```

22.3.2. Crevice Model Solution Details

The under-relaxation factor for the crevice model source terms can be found in the **Solution Controls** task page. The default value for **Crevice Model Sources** is 0.8, which has been found to work well for motored engine simulations. Once the crevice model is enabled, the solution proceeds normally.

 **Solution Controls**

 **Solution Initialization**

 **Run Calculation**

22.3.3. Postprocessing for the Crevice Model

A plot of cylinder mass with and without the crevice model during the motored engine simulation is shown in [Figure 22.9 \(p. 1005\)](#). The rate of mass loss from the crevice is proportional to the pressure difference between the cylinder and the crankcase pressure defined in the text interface.

Figure 22.9 Cylinder Mass vs. Crank Angle

A plot of cylinder pressure with and without the crevice model for the same engine simulation is shown in [Figure 22.10 \(p. 1006\)](#). The effect of the mass loss from the crevice is to lower the peak pressure in proportion to the total mass loss from the cylinder.

Figure 22.10 Cylinder Pressure vs. Crank Angle

22.3.3.1. Using the Crevice Output File

The pressure in the top ring land is defined as the cylinder pressure (i.e., the pressure in the cells defining the ring landing). Intermediate pressures are available at any point during the ANSYS FLUENT session through the (crevice-summary) command as previously shown. If the optional data file output is chosen in the crevice-model-controls, the intermediate pressures in the defined crevices are printed to the file `crev.out` at the start of each new time step. The format of the file is as follows:

```
# crank (deg) data-press[0...1...2...3...4...5...6] total_mdot
1.95500e+02 2.16650e+05 1.01325e+05 1.01325e+05 1.01325e+05 1.01325e+05 1.01325e+05 0.0
1.96000e+02 2.09945e+05 1.06794e+05 1.81553e+05 1.04111e+05 1.48582e+05 1.02202e+05 1.01325e+05 -1.6
1.96500e+02 2.17787e+05 1.13070e+05 1.88242e+05 1.07960e+05 1.53544e+05 1.03526e+05 1.01325e+05 -1.6
1.97000e+02 2.17434e+05 1.19065e+05 1.88060e+05 1.11705e+05 1.53475e+05 1.04830e+05 1.01325e+05 -1.6
1.97500e+02 2.17652e+05 1.24777e+05 1.88299e+05 1.15286e+05 1.53668e+05 1.06081e+05 1.01325e+05 -1.6
1.98000e+02 2.17937e+05 1.30215e+05 1.88594e+05 1.18711e+05 1.53900e+05 1.07283e+05 1.01325e+05 -1.6
```

where the first column is the current flow time (or crank angle), and the next $n_{cv} + 2$ columns are the ring pressures (where n_{cv} is the number of crevice volumes, or $2n_r - 1$), including the face pressure on the crevice cell, and the defined pressure at the crevice exit. The final column is the mass flow past the top ring. This file is currently formatted so that it can be read into the free **Gnuplot** plotting package, which is available at www.gnuplot.info.

To read the crevice output file into ANSYS FLUENT as a data file, you will need to put each column of the crevice output file in its own individual file. The first three lines of each column of the data file should be of the following form:

```
"Title"
"X-Label" "Y-Label"
0 0 0 0
```

where the title, *x*-label, and *y*-label strings are enclosed by double quotes and the third line of the file contains four zeros. The lines following the first three lines of the file are the columns you wish to plot. For example, to plot column 1 versus column 3 of the crevice model output file in ANSYS FLUENT, you would enter the following commands in a Linux terminal:

```
cat > crev_col_1_3.dat
"Column 1 vs Column 3"
"Crank Angle (deg)" "Pressure behind ring 1 (Pa)"
0 0 0
ctrl-d
```

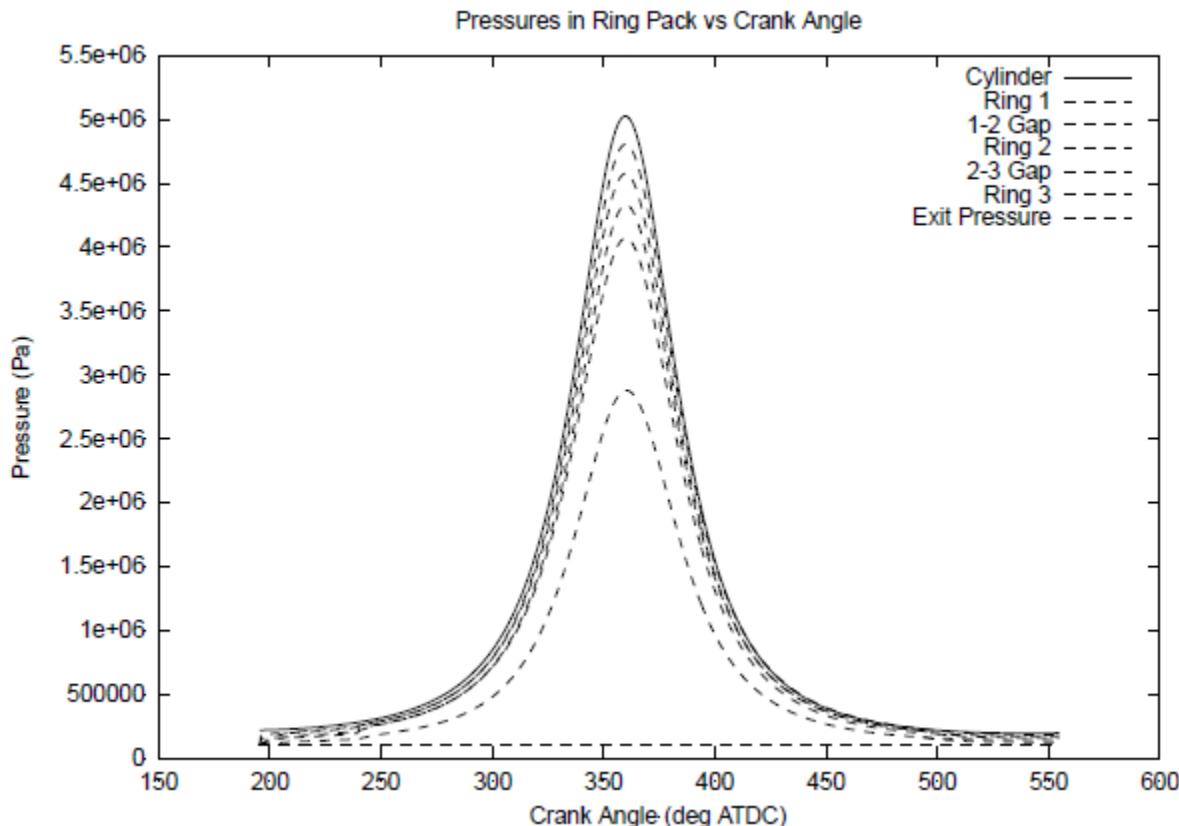

where *ctrl-d* is the end-of-file character made holding down the *<Ctrl>* key and pressing *d*. To append columns 1 and 3 to this file, enter the following:

```
tail +2 crev.out | awk '{print $1, $3}' >> crev_col_1_3.dat
```

The file *crev_col_1_3.dat* can now be read into ANSYS FLUENT using the *File XY Plot Dialog Box* (p. 2173). See *XY Plots of File Data* (p. 1593) for details about creating *x*- *y* plots. For Windows users, the file *crev.out* can be imported into Excel for plotting purposes without any modification.

A **Gnuplot** plot of the pressure in the ring pack crevices for the above engine simulation is shown in *Figure 22.11* (p. 1007). After an initial transient period where the flows in the network settle down, *Figure 22.11* (p. 1007) shows that the pressure in the ring crevices follows the cylinder pressure in form, though with pressure magnitudes that are controlled by the ring pack geometry.

Figure 22.11 Crevice Pressures

Chapter 23: Modeling Pollutant Formation

This chapter discusses how to use the models available in ANSYS FLUENT for modeling pollutant formation. For information about the theory behind the models in ANSYS FLUENT, see "[Pollutant Formation](#)" in the [Theory Guide](#).

Information is presented in the following sections:

- 23.1. NOx Formation
- 23.2. SOx Formation
- 23.3. Soot Formation
- 23.4. Using the Decoupled Detailed Chemistry Model

23.1. NOx Formation

The following sections describe how to use the NO_x models in ANSYS FLUENT. For information about the theory behind the NO_x models in ANSYS FLUENT, see [NOx Formation](#) in the [Theory Guide](#).

- 23.1.1. Using the NOx Model
- 23.1.2. Solution Strategies
- 23.1.3. Postprocessing

23.1.1. Using the NOx Model

23.1.1.1. Decoupled Analysis: Overview

NO_x concentrations generated in combustion systems are generally low. As a result, NO_x chemistry has negligible influence on the predicted flow field, temperature, and major combustion product concentrations. It follows that the most efficient way to use the NO_x model is as a postprocessor to the main combustion calculation.

The recommended procedure is as follows:

1. Calculate your combustion problem using ANSYS FLUENT as usual.

Important

The premixed combustion model is not compatible with the NO_x model.

Important

If you plan to use the ANSYS FLUENT SNCR model for NO_x reduction, you will first need to include ammonia or urea (depending upon which reagent is employed) as a fluid species in the main combustion calculation and define appropriate ammonia injections, as described later in this section. See [Defining the Species in the Mixture \(p. 862\)](#) for details about adding species to your model and [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#) for details about creating injections.

2. Enable the desired NO_x models (thermal, prompt, fuel, and/or N_2O intermediate NO_x , with or without reburn), define the fuel streams (for prompt NO_x and fuel NO_x only), and set the appropriate parameters, as described in this section.

 **Models** →  **NOx** → **Edit...**

3. Define the boundary conditions for NO (and HCN, NH_3 , or N_2O , if necessary) at flow inlets.

 **Boundary Conditions**

4. In the [Equations Dialog Box \(p. 2054\)](#), turn off the solution of all variables except species NO (and HCN, NH_3 , or N_2O , based on the model selected).

 **Solution Controls** → **Equations...**

5. Perform calculations until convergence (i.e., until the NO—and HCN, NH_3 , or N_2O , if solved—species residuals are below 10^{-6}) to ensure that the NO and HCN or NH_3 concentration fields are no longer evolving.

 **Run Calculation**

6. Review the mass fractions of NO (and HCN, NH_3 , or N_2O) by generating graphical plots or alphanumeric reports in the usual way.
7. Save a new set of case and data files, if desired.

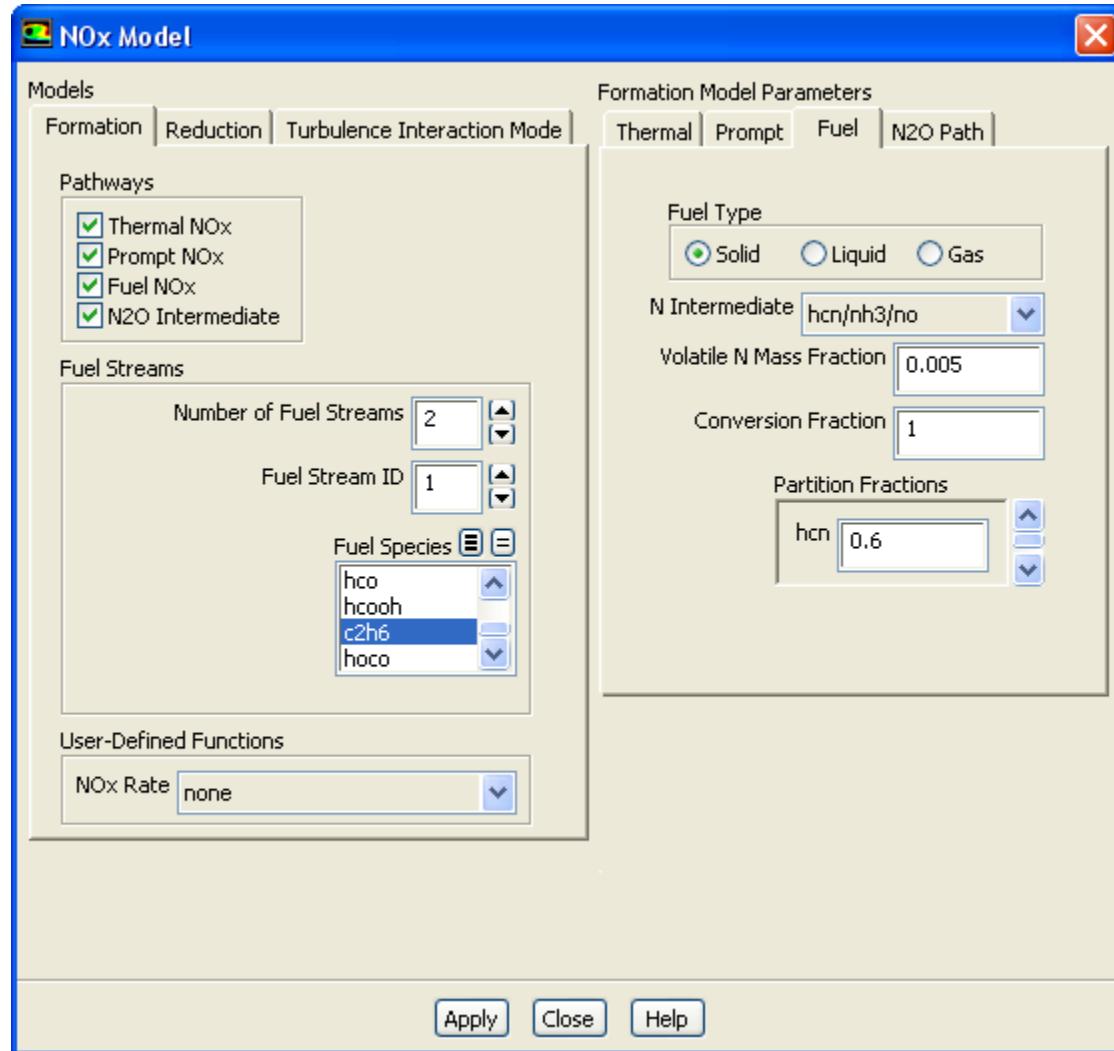

File → **Write** → **Case & Data...**

Inputs specific to the calculation of NO_x formation are explained in the remainder of this section.

23.1.1.2. Enabling the NOx Models

To enable the NO_x models and set related parameters, you will use the [NOx Model Dialog Box \(p. 1839\)](#) (e.g., [Figure 23.1 \(p. 1011\)](#)).

 **Models** →  **NOx** → **Edit...**

Figure 23.1 The NOx Model Dialog Box

In the **Formation** tab, select the NO_x models under **Pathways** to be used in the calculation of the NO and HCN, NH_3 , or N_2O concentrations:

- To enable thermal NO_x , turn on the **Thermal NOx** option.
- To enable prompt NO_x , turn on the **Prompt NOx** option.
- To enable fuel NO_x , turn on the **Fuel NOx** option.

Important

When using the non-premixed combustion model, the **Fuel NOx** option is only available if the DPM model is also enabled.

- To enable the formation of NO_x through an N_2O intermediate, turn on the **N2O Intermediate** option. (Note that the **N2O Intermediate** option will not appear until you have activated one of the other NO models listed above.)

Your selection(s) under **Pathways** will activate the calculation of thermal, prompt, fuel, and/or N₂O-intermediate NO_x in accordance with the chemical kinetic models described in [Thermal NOx Formation through NOx Formation from Intermediate N2O](#) in the [Theory Guide](#). Mean NO formation rates will be computed directly from mean concentrations and temperature in the flow field.

23.1.1.3. Defining the Fuel Streams

ANSYS FLUENT allows you to define multiple fuel streams when you are modeling prompt or fuel NO_x formation. If either **Prompt NOx** or **Fuel NOx** is enabled in the **Pathways** group box in the **Formation** tab, perform the following steps:

1. Specify the **Number of Fuel Streams** in the **Fuel Streams** group box. You are allowed up to three separate fuel streams.
2. Define the first fuel stream.
 - a. Select the fuel stream to be defined by using the arrow keys of the **Fuel Stream ID** text box.
 - b. When modeling fuel NO_x formation in conjunction with the non-premixed combustion model (which requires that the discrete phase model be enabled as well), make a selection from the **PDF Stream** drop-down list ([Figure 23.2 \(p. 1013\)](#)) to define the species for this stream. You can select either the **primary** or **secondary** fuel stream species, as defined in the PDF table.

Important

Note that the **PDF Stream** drop-down list defines the species for the fuel NO_x calculations only.

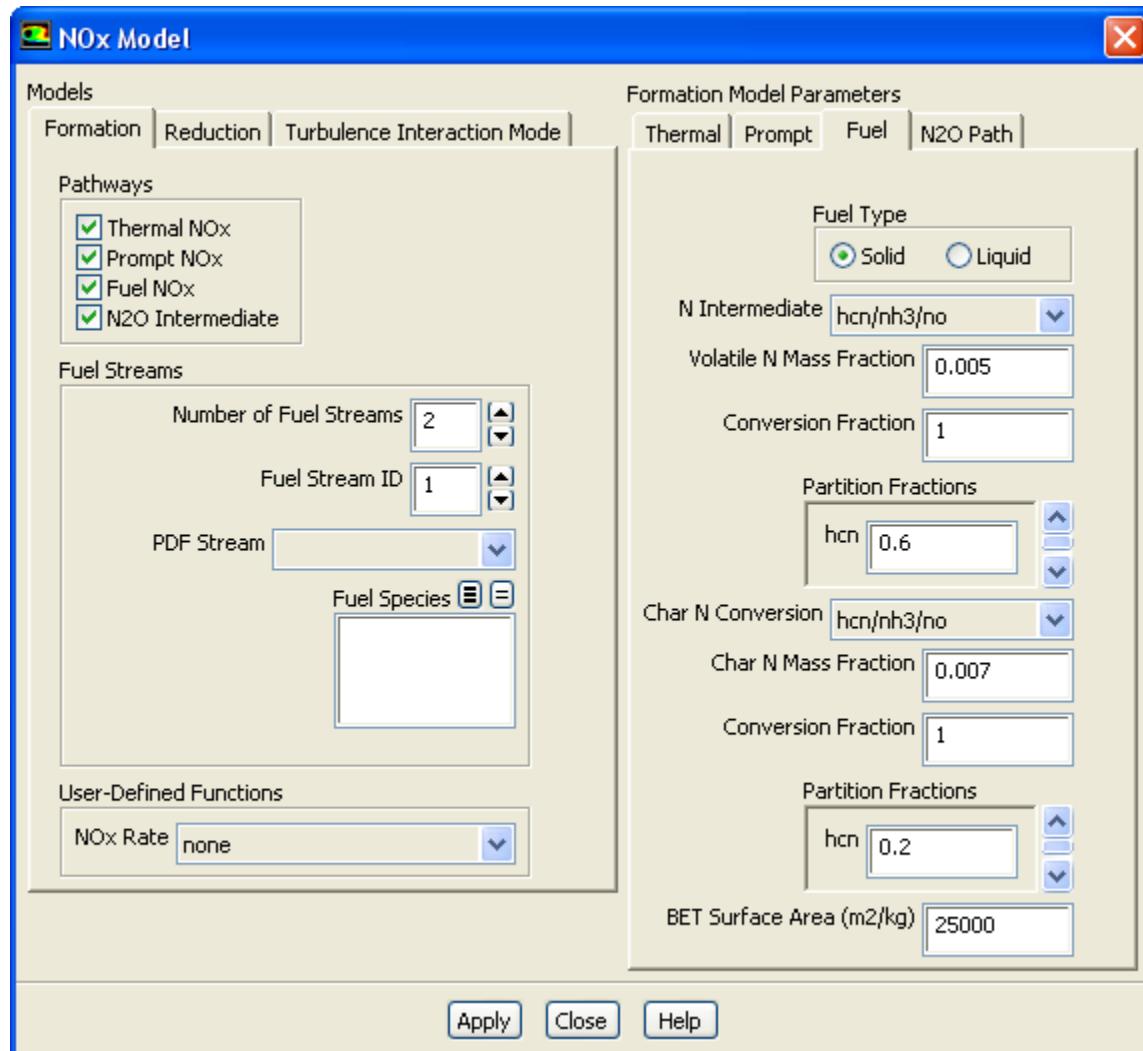

- c. When modeling prompt NO_x formation or when using a combustion model other than non-premixed combustion, select the fuel species from the **Fuel Species** list. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10.

Important

Note that the **Fuel Species** selections define the species for the prompt NO_x calculations only when modeling non-premixed combustion.

- d. Set the other parameters associated with your selected pathway(s) in the **Prompt** and/or **Fuel** tabs under **Formation Model Parameters**. See [Setting Prompt NOx Parameters \(p. 1015\)](#) and [Setting Fuel NOx Parameters \(p. 1015\)](#) for details.
3. Repeat steps 2.(a)–2.(d) for each additional fuel stream.

Figure 23.2 The NOx Model Dialog Box with Non-Premixed Combustion

Note that the following limitations apply when you are modeling fuel NO_x formation with multiple fuel streams, if more than one fuel stream has the same fuel type (as defined in the **Fuel Type** group box in the **Fuel** tab):

- You should only use multiple liquid fuel streams or multiple solid (coal) fuel streams when you have streams that have different destination species. Therefore, you must make sure that the injectors associated with the fuel streams specify these unique destination species correctly, as defined in the **Devolatilizing Species** drop-down list in the *Set Injection Properties Dialog Box* (p. 2255) (see *Defining Injection Properties* (p. 1114) for details).
- For multiple solid (coal) fuel streams, the fuel streams should have the same char-related parameter values in the **Fuel** tab — i.e., the **Char N Mass Fraction**, the **Partition Fractions** (for char N), and the **BET Surface Area** values. Note that even if different values are set for these char-related parameters, ANSYS FLUENT will only recognize those specified for the solid fuel stream with the lowest ID number, and then apply them to all of the other solid fuel streams.

For more information about the limitations associated with multiple fuel streams with the same fuel type, contact your ANSYS FLUENT support engineer.

Important

Note that if you read a case file with NO_x settings that was set up in a version of ANSYS FLUENT previous to 12, you may need to make a selection for the fuel species. This step is only necessary when all of the following conditions are met:

- **Fuel NOx** is enabled in the **Pathways** group box.
- **Prompt NOx** is not enabled in the **Pathways** group box.
- **Solid** or **Liquid** is selected for **Fuel Type** in the **Fuel** tab.

Your fuel species selection should be made either in the **PDF Stream** drop-down list for non-premixed combustion, or in the **Fuel Species** list for all other combustion models.

23.1.1.4. Specifying a User-Defined Function for the NO_x Rate

You can choose to specify a user-defined function for the rate of NO_x production. By default, the rate returned from the UDF is added to the rate returned from the standard NO_x production options, if any are selected. You also have the option of replacing any or all of ANSYS FLUENT's NO_x rate calculations with your own user-defined NO_x rate.

In addition to or instead of using the UDF to specify the NO_x rate, you can use it to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

To use a UDF to add a rate to ANSYS FLUENT's NO_x rate calculations, you must compile and load the desired function, and then select it from the **NOx Rate** drop-down list in the **User-Defined Functions** group box in the **Formation** tab. After you have selected the UDF, you have the following options:

- You can specify that your custom rate is added to the ANSYS FLUENT NO_x rate calculations, by retaining the default selection of **Add to FLUENT Rate** in the **UDF Rate** group box for the appropriate NO_x formation pathway(s) (e.g., in the **Fuel** tab).
- You can replace the ANSYS FLUENT NO_x rate calculations with your custom rate, by selecting **Replace FLUENT Rate** in the **UDF Rate** group box for the appropriate NO_x formation pathway(s) (e.g., in the **Fuel** tab).
- You can specify custom values for T_{max} , by selecting **user-defined** from the **Tmax Option** drop-down list in the **Turbulence Interaction Mode** tab.

See the [UDF Manual](#) for details about user-defined functions.

23.1.1.5. Setting Thermal NO_x Parameters

The NO_x routines employ three methods for calculation of thermal NO_x (as described in [Method 1: Equilibrium Approach](#) in the [Theory Guide](#)). You will specify the method to be used in the **Thermal** tab, under **Formation Model Parameters** in the [NOx Model Dialog Box](#) (p. 1839):

- To choose the equilibrium method, select **equilibrium** in the **[O] Model** drop-down list.
- To choose the partial equilibrium method, select **partial-equilibrium** in the **[O] Model** or **[OH] Model** drop-down list.

- To use the predicted O and/or OH concentration, select **instantaneous** in the [O] **Model** or [OH] **Model** drop-down list.

Important

Note that the urea model uses the [OH] model.

If you hooked a UDF in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace FLUENT Rate** to replace ANSYS FLUENT's thermal NO_x rate calculations with the custom NO_x rate produced by your UDF.
- Select **Add to FLUENT Rate** to add the custom NO_x rate produced by your UDF to ANSYS FLUENT's thermal NO_x rate calculations.

23.1.1.6. Setting Prompt NOx Parameters

Prompt NO_x formation is predicted using [Equation 14–26](#) and [Equation 14–28](#) in the [Theory Guide](#). For each fuel stream specified in the **Fuel Stream ID** text box in the **Formation** tab, set the parameters in the **Prompt** tab under **Formation Model Parameters** in the [NOx Model Dialog Box](#) (p. 1839) in the following manner:

- Set the **Fuel Carbon Number** to specify the number of carbon atoms per fuel molecule.
- Set the **Equivalence Ratio** as follows:

$$\text{Equivalence Ratio} = \frac{\text{actual fuel-to-air ratio}}{\text{stoichiometric fuel-to-air ratio}} \quad (23-1)$$

If you hooked a UDF in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace FLUENT Rate** to replace ANSYS FLUENT's prompt NO_x rate calculations with the custom NO_x rate produced by your UDF.
- Select **Add to FLUENT Rate** to add the custom NO_x rate produced by your UDF to ANSYS FLUENT's prompt NO_x rate calculations.

23.1.1.7. Setting Fuel NOx Parameters

When using the fuel NO_x model, you must set the parameters in the **Fuel** tab under **Formation Model Parameters** for each fuel stream specified in the **Fuel Stream ID** text box in the **Formation** tab.

If you hooked a UDF in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace FLUENT Rate** to replace ANSYS FLUENT's fuel NO_x rate calculations with the custom NO_x rate produced by your UDF.

- Select **Add to FLUENT Rate** to add the custom NO_x rate produced by your UDF to ANSYS FLUENT's fuel NO_x rate calculations.

If there is no NO_x rate UDF or if you selected **Add to FLUENT Rate**, you must define fuel parameters.

To begin, specify the fuel type in the following manner:

- For solid fuel NO_x , select **Solid** under **Fuel Type**.
- For liquid fuel NO_x , select **Liquid** under **Fuel Type**.
- For gaseous fuel NO_x , select **Gas** under **Fuel Type**.

Note that you can use only one of the fuel types for a given fuel stream. The **Gas** option is available only when the **Species Transport** model is enabled (see *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857)).

23.1.1.7.1. Setting Gaseous and Liquid Fuel NO_x Parameters

If you have selected **Gas** or **Liquid** as the **Fuel Type**, you will also need to specify the following:

- Select the intermediate species (**hcn**, **nh3**, or **hcn/nh3/no**) in the **N Intermediate** drop-down list.
- Set the correct mass fraction of nitrogen in the fuel (kg nitrogen per kg fuel) in the **Fuel N Mass Fraction** field.
- Specify the overall fraction of the fuel N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field. The **Conversion Fraction** for the **N Intermediate** has a default value of 1. Thus, any remaining N will not contribute to NO_x formation. This is based on the assumption that the remaining volatile N will convert to gas phase nitrogen. However, this has very little effect on the overall mass fraction of gas phase nitrogen. Therefore, you do not have to solve for nitrogen species when solving pollutant transport equations.
- If you selected **hcn/nh3/no** as the intermediate, specify the fraction of the converted fuel N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of fuel N that will become NO will be calculated by the remainder.

Note that setting a partition fraction of 0 for both HCN and NH_3 is equivalent to assuming that all fuel N is converted to the final product NO, whereas a partition fraction of 0 for HCN and 1 for NH_3 is the same as selecting **nh3** as the intermediate.

ANSYS FLUENT will use [Equation 14–31](#) and [Equation 14–32](#) in the [Theory Guide](#) (for HCN) or [Equation 14–42](#) and [Equation 14–43](#) in the [Theory Guide](#) (for NH_3) to predict NO formation for a gaseous or liquid fuel.

Important

Note that there is a limitation that must be considered when defining more than one liquid fuel stream. See [Defining the Fuel Streams](#) (p. 1012) for details.

23.1.1.7.2. Setting Solid (Coal) Fuel NOx Parameters

For solid (coal) fuel, ANSYS FLUENT will use [Equation 14–55](#) and [Equation 14–56](#) in the [Theory Guide](#) (for HCN) or [Equation 14–62](#) and [Equation 14–63](#) in the [Theory Guide](#) (for NH₃) to predict NO formation. Several inputs are required for the coal fuel NO_x model as follows:

- Select the intermediate species (**hcn**, **nh3**, or **hcn/nh3/no**) in the **N Intermediate** drop-down list.
- Specify the mass fraction of nitrogen in the volatiles in the **Volatile N Mass Fraction** field.
- Specify the overall fraction of the volatile N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field.
- If you selected **hcn/nh3/no** as the volatile N intermediate, specify the fraction of the converted volatile N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of volatile N that will become NO will be calculated by the remainder.
- Select the char N conversion path from the **Char N Conversion** drop-down list as **no**, **hcn**, **nh3**, or **hcn/nh3/no**. Note that **hcn** or **nh3** can be selected only if the same species has been selected as the intermediate species in the **N Intermediate** drop-down list.
- Specify the mass fraction of nitrogen in the char in the **Char N Mass Fraction** field.
- Specify the overall fraction of the char N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field.
- If you selected **hcn/nh3/no** as the char N conversion, specify the fraction of the converted char N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of char N that will become NO will be calculated by the remainder.
- Define the BET internal pore surface area (see [BET Surface Area](#) in the Theory Guide for details) of the particles in the **BET Surface Area** field.

Important

Note that there are limitations that must be considered when defining more than one solid fuel stream. See [Defining the Fuel Streams \(p. 1012\)](#) for details.

The following equations are used to determine the mass fraction of nitrogen in the volatiles and char:

$$\dot{m}_{N_{v/c}} = \dot{m}_{v/c} * mf_{N_{v/c}} \quad (23-2)$$

where

$\dot{m}_{N_{v/c}}$ = rate of release of fuel nitrogen in kg/s

$\dot{m}_{v/c}$ = rate of release of volatiles (v) or char (c) in kg/s

$mf_{N_{v/c}}$ = mass fraction of nitrogen in volatiles or char

Let

TN_{fuel} = total nitrogen mass fraction in daf coal (i.e., from daf ultimate analysis)

N_{split} = char nitrogen as a fraction of total nitrogen

F_{vol} = mass fraction of volatiles in daf coal

F_{char} = mass fraction of char in daf coal

Then the following should hold:

$$F_{vol} + F_{char} = 1 \quad (23-3)$$

$$\frac{F_{char} * mf_{N_c}}{TN_{fuel}} = N_{split} \quad (23-4)$$

$$F_{vol} * mf_{N_v} + F_{char} * mf_{N_c} = TN_{fuel} \quad (23-5)$$

$$mf_{N_v} = (1 - N_{split}) * \frac{TN_{fuel}}{F_{vol}} \quad (23-6)$$

$$mf_{N_c} = N_{split} * \frac{TN_{fuel}}{F_{char}} \quad (23-7)$$

23.1.1.8. Setting N₂O Pathway Parameters

The formation of NO through an N₂O intermediate can be predicted by two methods. You will specify the method to be used in the **N₂O Path** tab.

- To choose the quasi-steady state method, select **quasi-steady** in the **N₂O Model** drop-down list.

Important

The transport equation for the species N₂O will not be solved for N₂O. However, N₂O will be updated at every iteration. Therefore, the residual values that appear for N₂O are always zero. Do not be alarmed if the solver keeps printing zero at each iteration.

- To choose the simplified form of the N₂O-intermediate mechanism, select **transported-simple** in the **N₂O Model** drop-down list. Here, the species N₂O is added to the list of pollutant species, and its mass fraction is solved via a transport equation.

The atomic O concentration will be calculated according to the thermal NO_x [O] **Model** that you have specified previously. If you have not selected the **Thermal NOx** pathway, then you will be given the option to specify an **[O] Model** for the N₂O pathway calculation. The same three options for the thermal NO_x [O] **Model** will be the available options.

If you hooked a UDF in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace FLUENT Rate** to replace the NO_x rate calculated by ANSYS FLUENT using N_2O intermediates with the custom NO_x rate produced by your UDF.
- Select **Add to FLUENT Rate** to add the custom NO_x rate produced by your UDF to the NO_x rate calculated by ANSYS FLUENT using N_2O intermediates.

23.1.1.9. Setting Parameters for NOx Reburn

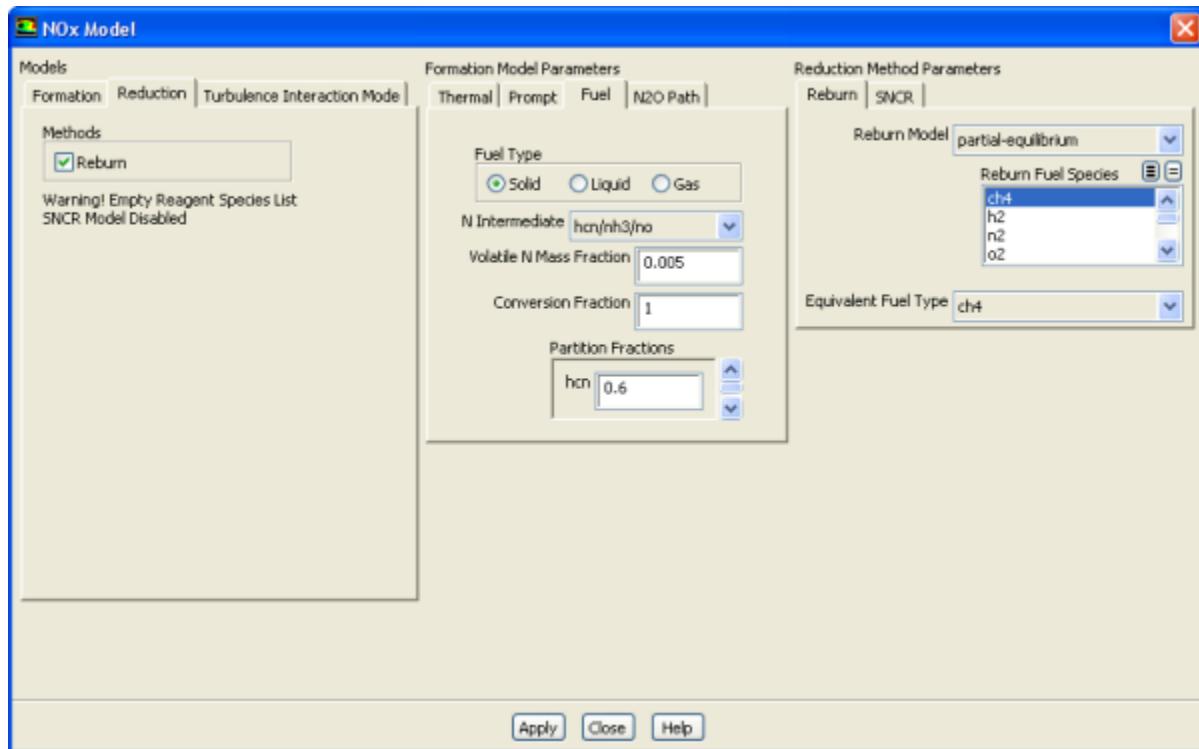

To enable NO_x reduction by reburning, click the **Reduction** tab in the [NOx Model Dialog Box \(p. 1839\)](#) and enable the **Reburn** option under **Methods**. In the expanded portion of the dialog box, as shown in [Figure 23.3 \(p. 1020\)](#), click the **Reburn** tab under **Reduction Method Parameters**, where you can choose from the following options:

- To choose the instantaneous method, select **instantaneous [CH]** in the **Reburn Model** drop-down list.

Important

When you use this method, you must be sure to include the species CH , CH_2 , and CH_3 in your problem definition. See [NOx Reduction by Reburning](#) in the [Theory Guide](#) for details.

- To choose the partial equilibrium method, select **partial-equilibrium** in the **Reburn Model** drop-down list. You will then need to select the **Reburn Fuel Species** from the list of available species. ANSYS FLUENT will allow you select up to 5 reburn fuel species. Specify the **Equivalent Fuel Type (ch4, ch3, ch2, or ch)**. For example, if you choose methane as the reburn fuel, then the **Equivalent Fuel Type** would be **ch4**. If you choose a reburn fuel such as **hv_vol** (a volatile component of coal), then you must specify the most appropriate equivalent hydrocarbon fuel type so that the partial equilibrium model will be activated correctly.
- Due to coal volatiles behaving very differently, it is important to select the correct equivalent fuel type. You must first consider the volatile fuel composition, then check the C/H ratio to find the fuel which most closely matches CH , CH_2 , CH_3 , or CH_4 [\[45\] \(p. 2369\)](#). While the method for best determining the equivalent fuel is debatable, considering the C/H ratio of the fuel itself is a reasonable indicator.

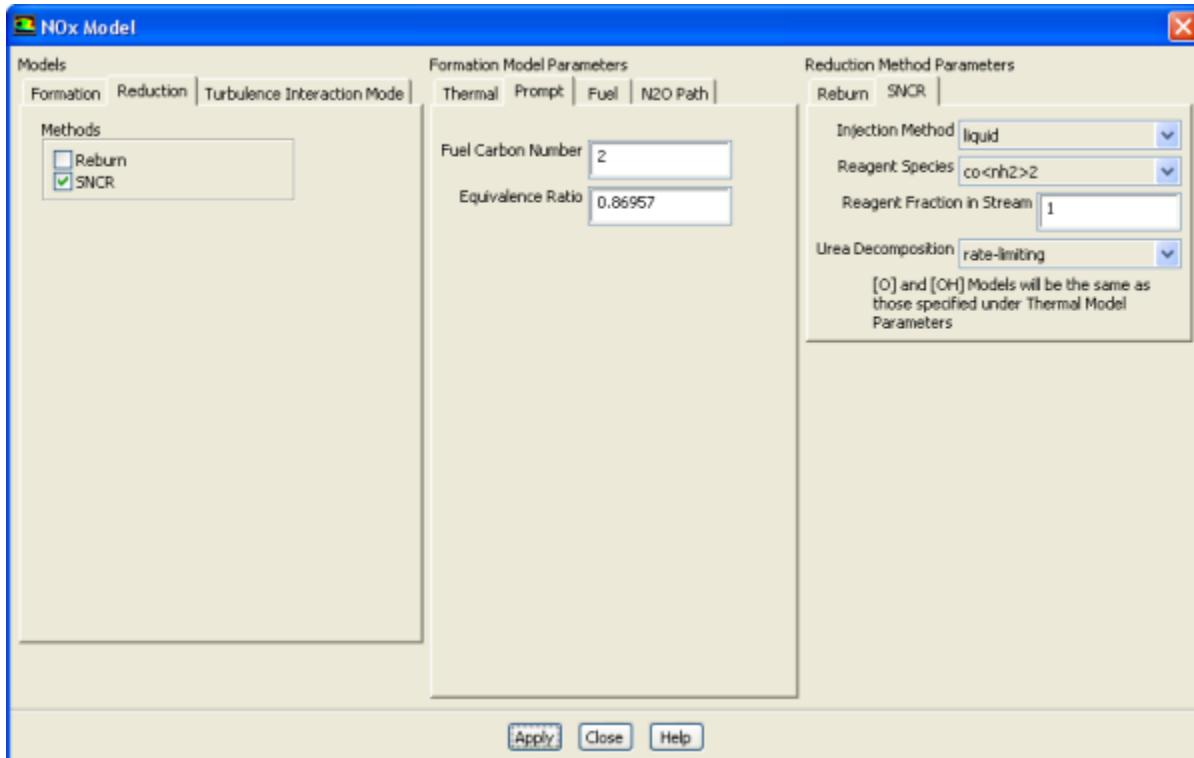

Figure 23.3 The NOx Dialog Box Displaying the Reburn Reduction Method

23.1.1.10. Setting SNCR Parameters

Prior to enabling reduction by SNCR, make sure that you have included in the species list **nh3** (for reduction by ammonia injection) and **co<nh2>2** (for reduction by urea injection). See [NOx Reduction by SNCR](#) in the [Theory Guide](#) for detailed information about SNCR theory.

To enable NO_x reduction by SNCR, click the **Reduction** tab in the [NOx Model Dialog Box](#) (p. 1839) and enable the **SNCR** option under **Methods**, as shown in [Figure 23.4](#) (p. 1021).

Figure 23.4 The NOx Dialog Box Displaying the SNCR Reduction Method

Then click the **SNCR** tab under **Reduction Method Parameters**, where you can choose from the following options:

- To have ammonia or urea included as a gas-phase pollutant species from the injection locations, select **gaseous** in the **Injection Method** drop-down list.

If you plan to select this option for NO_x postprocessing, then you must also include ammonia or urea as a gas-phase species. Additionally, you will need to specify the mass fraction of ammonia or urea at the respective inlet for the SNCR injection. You must include this set of inputs prior to the main ANSYS FLUENT combustion calculation.

- To have ammonia included as a liquid-phase pollutant species from the injection locations, select **liquid** in the **Injection Method** drop-down list. If urea is injected as a liquid solution, then select **liquid** in the **Injection Method** drop-down list. Note that you must activate the DPM model with urea or ammonia included as a material.

If you plan to select this option for NO_x postprocessing, then you must include NH_3 as both a gas-phase and liquid-phase species. Additionally, you will need to specify injection locations for liquid droplet ammonia particles and set gaseous ammonia as the evaporation species. You need to include this set of inputs in conjunction with the main ANSYS FLUENT combustion calculation.

Since urea is a subliming solid, and usually is injected as a solution, mixed in water, you have to define solid properties for urea under the [Create/Edit Materials Dialog Box \(p. 1882\)](#). It is assumed that the water evaporates before urea begins its subliming process. The sublimation process is modeled similar to the single rate devolatilization model of coal. You will supply the value for the sublimation rate (s^{-1}). You must specify the water content while defining the injection properties.

- Specify the SNCR **Reagent Species** as **nh3** (ammonia) or **co<nh2>2** (urea) in the drop-down list.

- When using the non-premixed combustion model with a liquid-phase reagent injection, enter a value in the **Reagent Fraction in Stream** to specify the mass fraction of the reagent in the reagent stream. The remaining mass fraction is assumed to be water. If you enabled a secondary stream in your PDF calculation, by default the secondary stream will act as the reagent stream. You can assign the primary stream as the reagent stream by using the text command that follows (enter 0 in response to the PDF Stream ID prompt that follows the Injection Method prompt):

```
define/models/nox-parameters/nox-chemistry
```

- If the **Reagent Species** selected is **co <nh2> 2**, then you will either accept the **rate-limiting** option for **Urea Decomposition**, or specify the **NH₃ Conversion** value when selecting a **user-specified Urea Decomposition**.

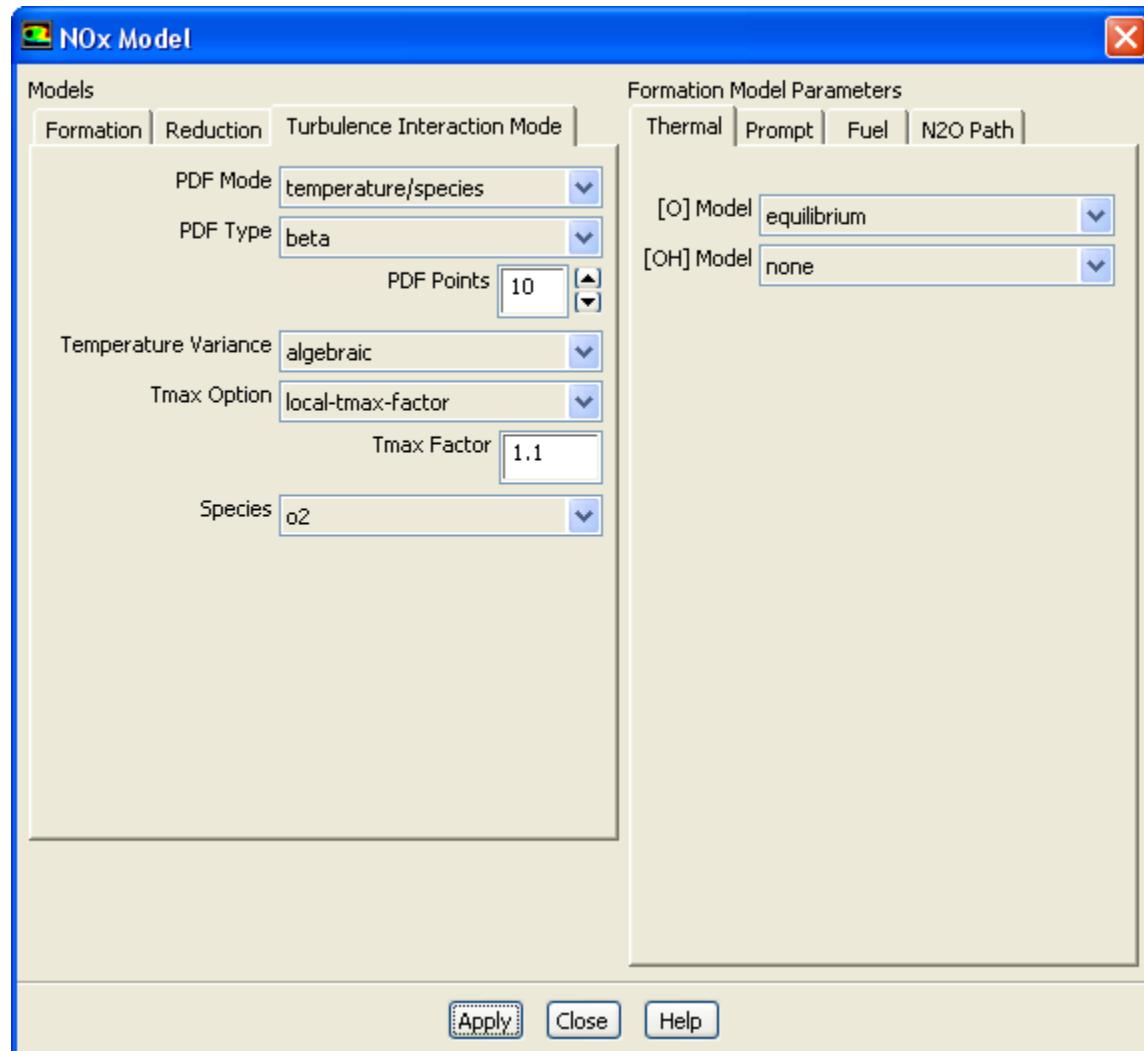

You will use the urea decomposition under the **SNCR** tab to define which of the two decomposition models is to be used. The first model (which is the default) is the rate-limiting decomposition model, as given in [Table 14.3: "Two-Step Urea Breakdown Process"](#) in the [Theory Guide](#). ANSYS FLUENT will then calculate the source terms according to the rates given in [Table 14.3: "Two-Step Urea Breakdown Process"](#) in the [Theory Guide](#). The second model is for when you assume that the urea decomposes instantly into ammonia and HNCO at a given proportion. In this case, you will specify the molar conversion fraction for ammonia, assuming that the rest of the urea is converted to HNCO. An example value is given above.

The value for **user-specified** NH₃ conversion is the mole fraction of NH₃ in the mixture of NH₃ and HNCO that is instantly created from the reagent injection. In this case, there is no urea source because all of reagent is assumed to convert to both NH₃ and HNCO, instantly.

23.1.1.11. Setting Turbulence Parameters

If you want to take into account turbulent fluctuations (as described in [NO_x Formation in Turbulent Flows](#) in the [Theory Guide](#)) when you compute the specified NO_x formation (thermal, prompt, and/or fuel, with or without reburn), define the turbulence parameters in the **Turbulence Interaction Mode** tab.

Figure 23.5 The NOx Model Dialog Box and the Turbulence Interaction Mode Tab

Select one of the options in the **PDF Mode** drop-down list in the **Turbulence Interaction Mode** tab:

- Select **temperature** to take into account fluctuations of temperature.
- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s).

Important

When modeling the formation of other pollutants along with NO_x , you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** group boxes of the *NOx Model Dialog Box* (p. 1839) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially premixed combustion model to model the reacting system. If you use the **mixture fraction** option, the

instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous NO_x rates are calculated at each cell. The PDF used for convoluting the instantaneous NO_x rates is the same as the one used to compute the mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF for mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous NO_x rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** tab:

PDF Type

allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using [Equation 14–108](#) in the [Theory Guide](#). If you select **gaussian**, the PDF will be modeled using [Equation 14–111](#) in the [Theory Guide](#).

PDF Points

allows you to specify the number of points used to integrate the beta or Gaussian function in [Equation 14–105](#) or [Equation 14–106](#) in the [Theory Guide](#) on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (e.g., 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see [Equation 14–114](#) of the [Theory Guide](#)). You have the option of selecting **transported** to instead solve [Equation 14–113](#) in the [Theory Guide](#). Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature:

- The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field.
- You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.
- You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**.
- If you have selected a user-defined function in the **NO_x Rate** drop-down list in the **Formation** tab, then you can select **user-defined** so that the temperature limit is specified by a UDF. See the [UDF Manual](#) for details about user-defined functions.

Species

only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the NO_x formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation ([Equation 14–114](#) in the [Theory Guide](#)).

23.1.1.12. Defining Boundary Conditions for the NOx Model

At flow inlet boundaries, you will need to specify the **Pollutant NO Mass Fraction**, and if necessary, the **Pollutant HCN Mass Fraction**, **Pollutant NH₃ Mass Fraction**, and **Pollutant N₂O Mass Fraction**.

Boundary Conditions

You can retain the default inlet values of zero for these quantities or you can input nonzero numbers as appropriate for your combustion system.

23.1.2. Solution Strategies

To solve for NO_x products, perform the following steps:

- (optional) If the discrete phase model (DPM) is activated (by turning on the **Interaction with Continuous Phase**) to run with the NO_x model, then set the **Number of Continuous Phase Iterations per DPM Iteration** to 0 such that no DPM iterations are performed as the NO_x case is being solved.
- In the *Equations Dialog Box* (p. 2054) of the *Solution Controls Task Page* (p. 2052), turn off the solution of all variables except species NO (and HCN, NH₃, or N₂O, based on the model selected).

Solution Controls → Equations...

- Also in the **Solution Controls** task page, set a suitable value for the NO (and HCN, NH₃, or N₂O, if appropriate) under-relaxation. A value of 0.95 is suggested, although lower values may be required for certain problems (i.e., if convergence cannot be obtained, try a lower under-relaxation value).
- In the *Residual Monitors Dialog Box* (p. 2065), decrease the convergence criterion for NO (and HCN, NH₃, or N₂O, if appropriate) to 10⁻⁶.

Monitors → Residuals → Edit...

- Perform calculations until convergence (i.e., until the NO—and HCN, NH₃, or N₂O, if solved—species residuals are below 10⁻⁶) to ensure that the NO and HCN or NH₃ concentration fields are no longer evolving.

Run Calculation

23.1.3. Postprocessing

When you compute NO_x formation, the following additional variables will be available for postprocessing:

- **Mass fraction of Pollutant no**
- **Mass fraction of Pollutant hcn** (appropriate fuel NO_x model only)
- **Mass fraction of Pollutant nh3** (appropriate fuel NO_x model only)
- **Mass fraction of Pollutant n2o** (N₂O-intermediate model only)
- **Mass fraction of Pollutant urea** (SNCR urea injection)
- **Mass fraction of Pollutant hnco** (SNCR urea injection)

- **Mass fraction of Pollutant nco** (SNCR urea injection)
- **Mole fraction of Pollutant no**
- **Mole fraction of Pollutant hcn** (appropriate fuel NO_x model only)
- **Mole fraction of Pollutant nh3** (appropriate fuel NO_x model only)
- **Mole fraction of Pollutant n2o** (N_2O -intermediate model only)
- **Mole fraction of Pollutant urea** (SNCR urea injection)
- **Mole fraction of Pollutant hnco** (SNCR urea injection)
- **Mole fraction of Pollutant nco** (SNCR urea injection)
- **no Density**
- **hcn Density** (appropriate fuel NO_x model only)
- **nh3 Density** (appropriate fuel NO_x model only)
- **n2o Density** (N_2O -intermediate model only)
- **urea Density** (SNCR urea injection)
- **hnco Density** (SNCR urea injection)
- **nco Density** (SNCR urea injection)
- **Rate of no** (from the individual pathways)
- **Rate of hcn** (appropriate fuel NO_x model only)
- **Rate of nh3** (appropriate fuel NO_x model only)
- **Rate of n2o** (N_2O -intermediate model only)
- **Rate of urea** (SNCR urea injection)
- **Rate of hnco** (SNCR urea injection)
- **Rate of nco** (SNCR urea injection)

These variables are contained in the **NOx...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Additional NO rates from individual pathways, **Thermal**, **Prompt**, **Fuel**, **N2O Path**, and **SNCR** can be plotted.

23.2. SO_x Formation

The following sections describe how to use the SO_x model in ANSYS FLUENT. For information about the theory behind the SO_x models in ANSYS FLUENT, see [SO_x Formation](#) in the Theory Guide.

- [23.2.1. Using the SO_x Model](#)
- [23.2.2. Solution Strategies](#)
- [23.2.3. Postprocessing](#)

23.2.1. Using the SO_x Model

When the sulfur content in the fuel is low, SO_x concentrations that are generated in combustion generally have minimal influence on the predicted flow field, temperature, and major combustion product concentrations. The most efficient way to use the SO_x model is as a postprocessor to the main combus-

tion calculation. However, if the sulfur content is high, then SO_x formation should be coupled with the gas phase combustion process rather than treating it as a postprocessing step.

The procedure for activating and setting up the model for a decoupled solution is as follows:

1. Calculate your combustion problem using ANSYS FLUENT.

Important

The premixed combustion model is not compatible with the SO_x model.

2. Enable the SO_x model, define the fuel streams, and set the appropriate parameters, as described in this section.

Models → **SOx** → **Edit...**

3. Define the boundary conditions for SO₂ and H₂S (and SO₃, SH, or SO if necessary) at flow inlets.

Boundary Conditions

4. In the *Equations Dialog Box* (p. 2054), turn off the solution of all variables except species SO₂ and H₂S (and SO₃, SH, or SO, based on your selections).

Solution Controls → **Equations...**

5. Perform calculations until convergence (i.e., until the SO₂ and H₂S—and SO₃, SH, or SO, if solved—species residuals are below 10⁻⁶) to ensure that the SO₂ and H₂S concentration fields are no longer evolving.

Run Calculation

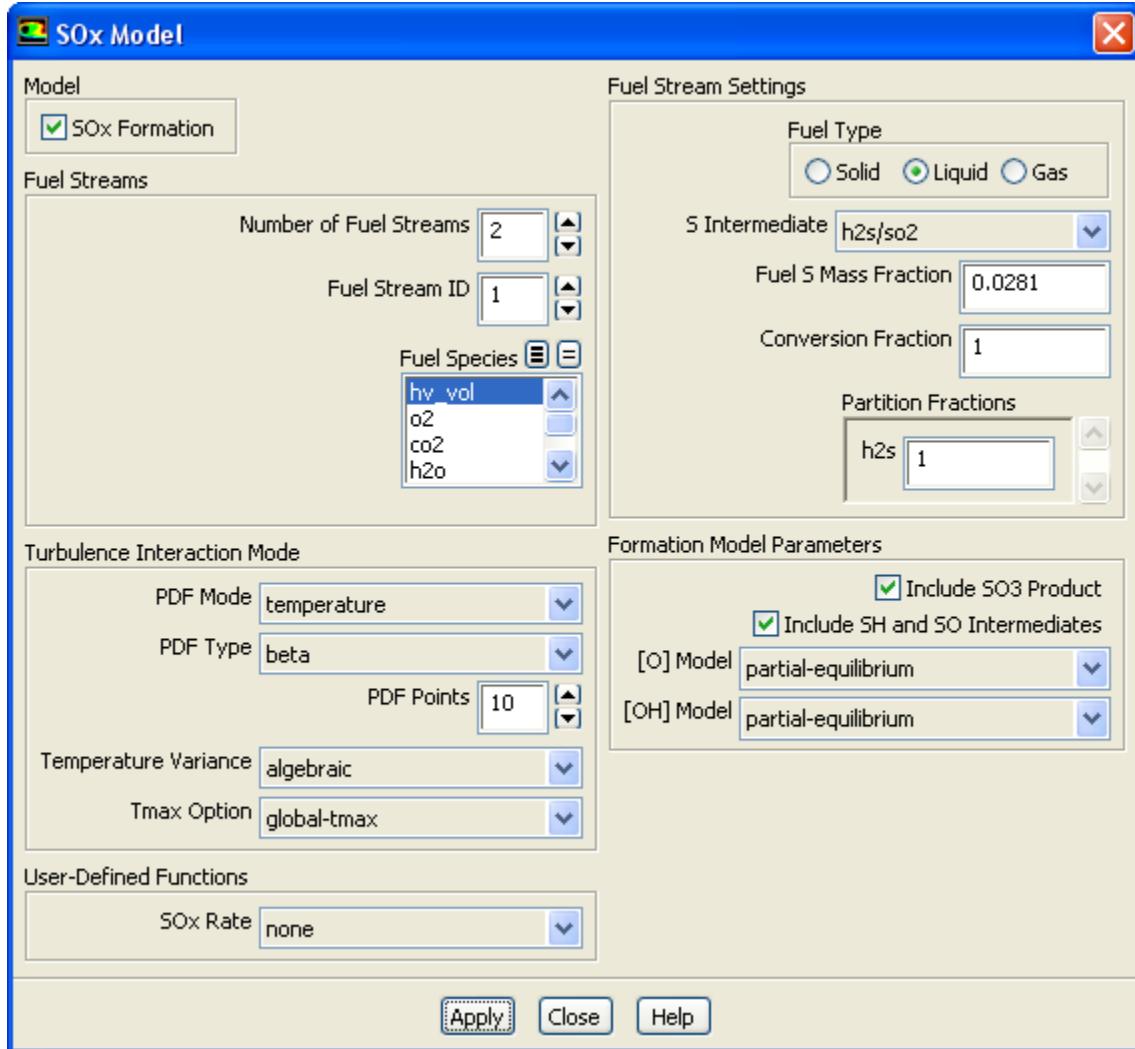

6. Review the mass fractions of SO₂ and H₂S (and SO₃, SH, or SO) by generating graphical plots or alphanumeric reports in the usual way.
7. Save a new set of case and data files, if desired.

File → **Write** → **Case & Data...**

23.2.1.1. Enabling the SOx Model

To model SO_x formation, enable the **SOx Formation** option in the *SOx Model Dialog Box* (p. 1846) (*Figure 23.6* (p. 1028)).

Models → **SOx** → **Edit...**

Figure 23.6 The SOx Model Dialog Box

23.2.1.2. Defining the Fuel Streams

ANSYS FLUENT allows you to define multiple fuel streams when you are modeling SO_x formation, as shown in the following steps:

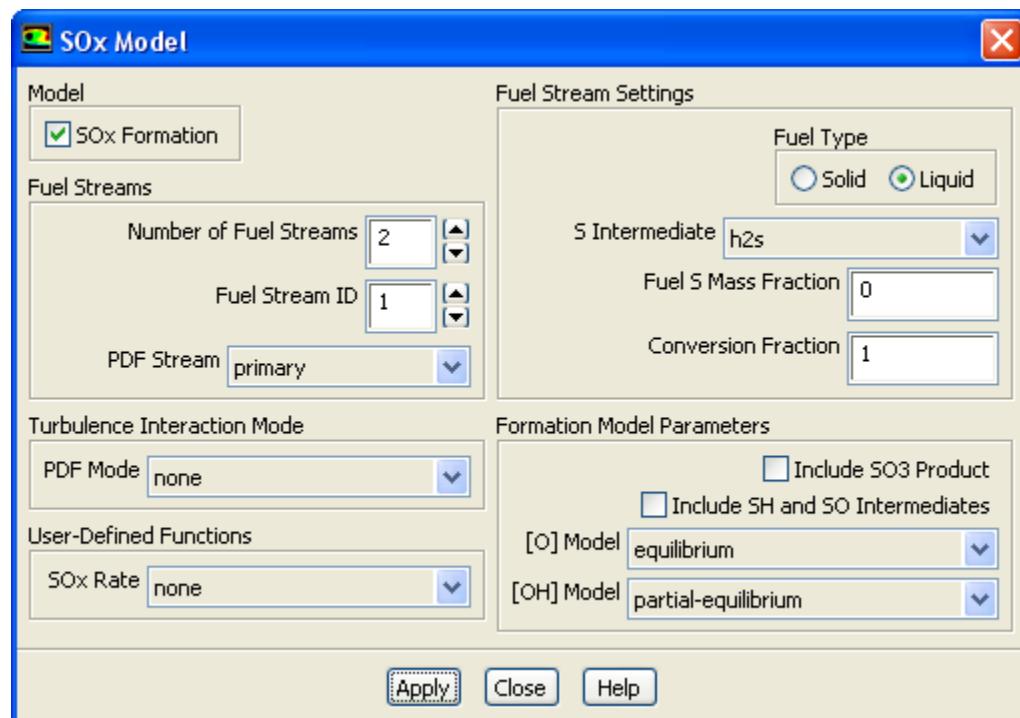

1. Specify the **Number of Fuel Streams** in the **Fuel Streams** group box. You are allowed up to three separate fuel streams.
2. Define the first fuel stream.
 - a. Select the fuel stream to be defined by using the arrow keys of the **Fuel Stream ID** text box.
 - b. When the non-premixed combustion model is not enabled, select the fuel species from the **Fuel Species** list. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10.
 - c. When the non-premixed combustion model is enabled ([Figure 23.7 \(p. 1029\)](#)), make a selection from the **PDF Stream** drop-down list to define the species for this stream. You can select either the **primary** or **secondary** fuel stream species, as defined in the PDF table.
 - d. Specify the parameters for this particular fuel stream in the **Fuel Stream Settings** group box. See [Defining the SOx Fuel Stream Settings \(p. 1030\)](#) for details.

3. Repeat steps 2.(a)–2.(d) for each additional fuel stream.
4. Set the formation model parameters that apply to all of the fuel streams in the **Formation Model Parameters** group box:
 - You have the option of including SO₃ as a product, and including SH and SO as intermediates by enabling the **Include SO₃ Product** and the **Include SH and SO Intermediates** options, respectively. See [Reaction Mechanisms for Sulfur Oxidation](#) in the [Theory Guide](#) for further information.
 - Specify the method by which O and OH will be calculated. The SO_x routines employ three methods for reduction calculations of SO_x:
 - You can select **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[O] Model** drop-down list.
 - You can select **none**, **partial-equilibrium**, or **instantaneous** in the **[OH] Model** drop-down list.

Important

To use the predicted O and/or OH concentration, select **instantaneous** in the **[O] Model** or **[OH] Model** drop-down list.

Figure 23.7 The SOx Model Dialog Box with Non-Premixed Combustion

Note that the following limitations apply when you are modeling SO_x formation with multiple fuel streams, if more than one fuel stream has the same fuel type (as defined in the **Fuel Type** list in the **Fuel Stream Settings** group box):

- You should only use multiple liquid fuel streams or multiple solid (coal) fuel streams when you have streams that have different destination species. Therefore, you must make sure that the injectors associated with the fuel streams specify these unique destination species correctly, as defined in

the **Devolatilizing Species** drop-down list in the [Set Injection Properties Dialog Box \(p. 2255\)](#) (see [Defining Injection Properties \(p. 1114\)](#) for details).

- For multiple solid (coal) fuel streams, the fuel streams should have the same char-related parameter values in the **Fuel Stream Settings** group box — i.e., the **Char S Mass Fraction** and the **Partition Fractions** (for char S) values. Note that even if different values are set for these char-related parameters, ANSYS FLUENT will only recognize those specified for the solid fuel stream with the lowest ID number, and then apply them to all of the other solid fuel streams.

For more information about the limitations associated with multiple fuel streams with the same fuel type, contact your ANSYS FLUENT support engineer.

Important

Note that if you read a case file with SO_x settings that was set up in a version of ANSYS FLUENT previous to 12, you must make a selection for the fuel species. This selection should be made either in the **PDF Stream** drop-down list for non-premixed combustion, or in the **Fuel Species** list for all other combustion models.

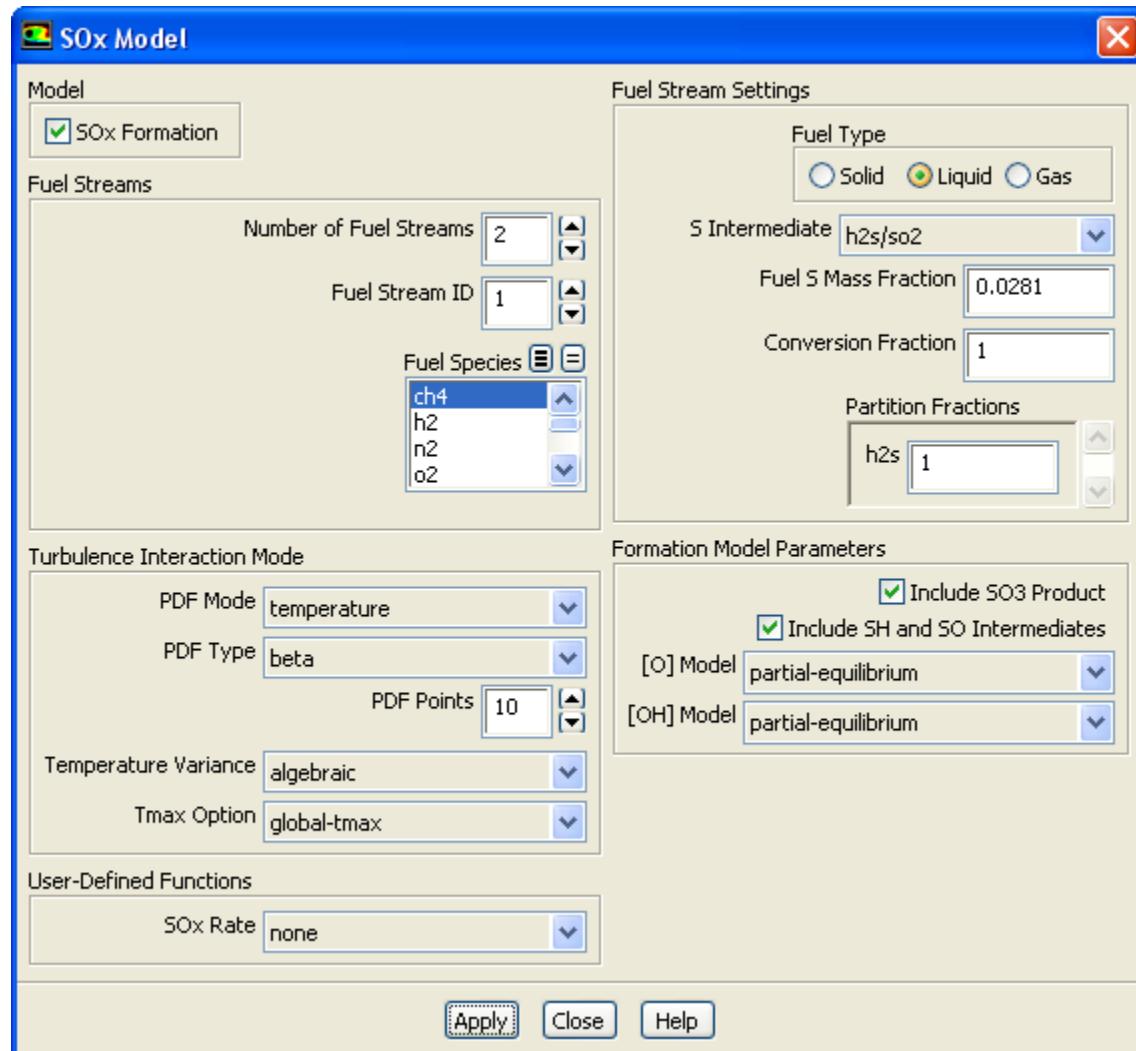

23.2.1.3. Defining the SO_x Fuel Stream Settings

When using the SO_x model, you must set the parameters in the **Fuel Stream Settings** group box for each fuel stream specified in the **Fuel Stream ID** text box.

To begin, specify the fuel type in the following manner:

- To calculate SO_x formation from a solid fuel, select **Solid** under **Fuel Type**.
- To calculate SO_x formation from a liquid fuel, select **Liquid** under **Fuel Type**.
- To calculate SO_x formation from a gaseous fuel, select **Gas** under **Fuel Type**.

Figure 23.8 The SOx Model Dialog Box Displaying Liquid Fuel Parameters

Note that you can use only one of the fuel types for a given fuel stream. The **Gas** option is available only when the **Species Transport** model is enabled (see *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857)).

23.2.1.3.1. Setting SOx Parameters for Gaseous and Liquid Fuel Types

If you have selected **Gas** or **Liquid** as the **Fuel Type**, you will also need to specify the following:

- Select the intermediate species (**h2s**, **so2**, or **h2s/so2**) in the **S Intermediate** drop-down list.
- Set the correct mass fraction of sulfur in the fuel (kg sulfur per kg fuel) in the **Fuel S Mass Fraction** field.
- Specify the overall fraction of the fuel S, by mass, that will be converted to the intermediate species and/or product SO₂ in the **Conversion Fraction** field. Thus, any remaining S will not contribute to SO_x formation. This is based on the assumption that the remaining volatile S will convert to gas phase sulfur. The **Conversion Fraction** for the **S Intermediate** has a default value of 1.
- If you selected **h2s/so2** as the intermediate, you will need to set the fraction of the converted fuel S, by mass, that will become **h2s** under **Partition Fractions**. The fraction of fuel S that will become SO₂ will be calculated by the remainder.

Note that setting a partition fraction of 0 for H₂S is equivalent to assuming that all fuel S is converted to the final product SO₂.

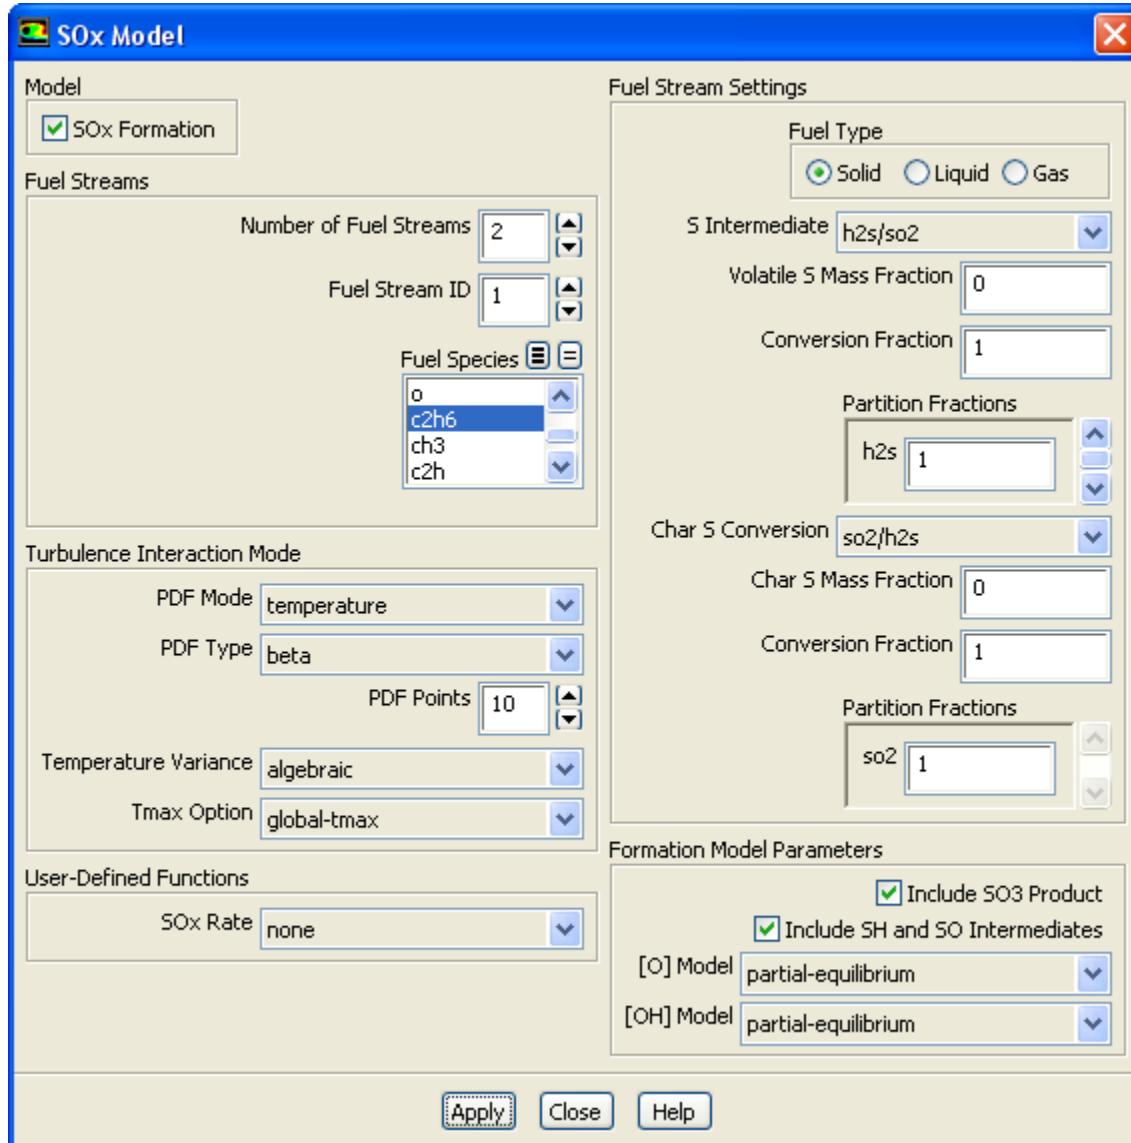

Important

Note that there is a limitation that must be considered when defining more than one liquid fuel stream. See [Defining the Fuel Streams \(p. 1012\)](#) for details.

23.2.1.3.2. Setting SO_x Parameters for a Solid Fuel

For solid fuel, several inputs are required for the SO_x model.

Figure 23.9 The SO_x Model Dialog Box Displaying Solid Fuel Parameters

- Select the intermediate species (**h2s**, **so2**, or **h2s/so2**) in the **S Intermediate** drop-down list.
- Specify the mass fraction of sulfur in the volatiles in the **Volatile S Mass Fraction** field.

- Specify the overall fraction of the volatile S, by mass, that will be converted to the intermediate species and/or product SO₂ in the **Conversion Fraction** field.
- If you selected **h2s/so2** as the volatile S intermediate, you will need to specify the fraction of the converted volatile S, by mass, that will become **h2s** under **Partition Fractions**. The fraction of volatile S that will become SO₂ will be calculated by the remainder.
- Select the char S conversion path from the **Char S Conversion** drop-down list as **so2, h2s, or so2/h2s**.
- Specify the mass fraction of sulfur in the char in the **Char S Mass Fraction** field.
- Specify the overall fraction of the char S, by mass, that will be converted to the intermediate species and/or product SO₂ in the **Conversion Fraction** field.
- If you selected **so2/h2s** from the **Char S Conversion** drop-down list, you will need to specify the fraction of the converted char S, by mass, that will become SO₂ under **Partition Fractions**. The fraction of char S that will become H₂S will be calculated by the remainder.

Important

Note that there are limitations that must be considered when defining more than one solid fuel stream. See *Defining the Fuel Streams* (p. 1028) for details.

The following equations are used to determine the mass fraction of sulfur in the volatiles and char:

$$\dot{m}_{S_{v/c}} = \dot{m}_{v/c} * mf_{S_{v/c}} \quad (23-8)$$

where

$\dot{m}_{S_{v/c}}$ = rate of release of fuel sulfur in kg/s

$\dot{m}_{v/c}$ = rate of release of volatiles (v) or char (c) in kg/s

$mf_{S_{v/c}}$ = mass fraction of sulfur in volatiles or char

Let

TS_{fuel} = total sulfur mass fraction in daf coal (i.e., from daf ultimate analysis)

S_{split} = char sulfur as a fraction of total sulfur

F_{vol} = mass fraction of volatiles in daf coal

F_{char} = mass fraction of char in daf coal

Then the following should hold:

$$F_{vol} + F_{char} = 1 \quad (23-9)$$

$$\frac{F_{char} * mf_{S_c}}{TS_{fuel}} = S_{split} \quad (23-10)$$

$$F_{vol} * mf_{S_v} + F_{char} * mf_{S_c} = TS_{fuel} \quad (23-11)$$

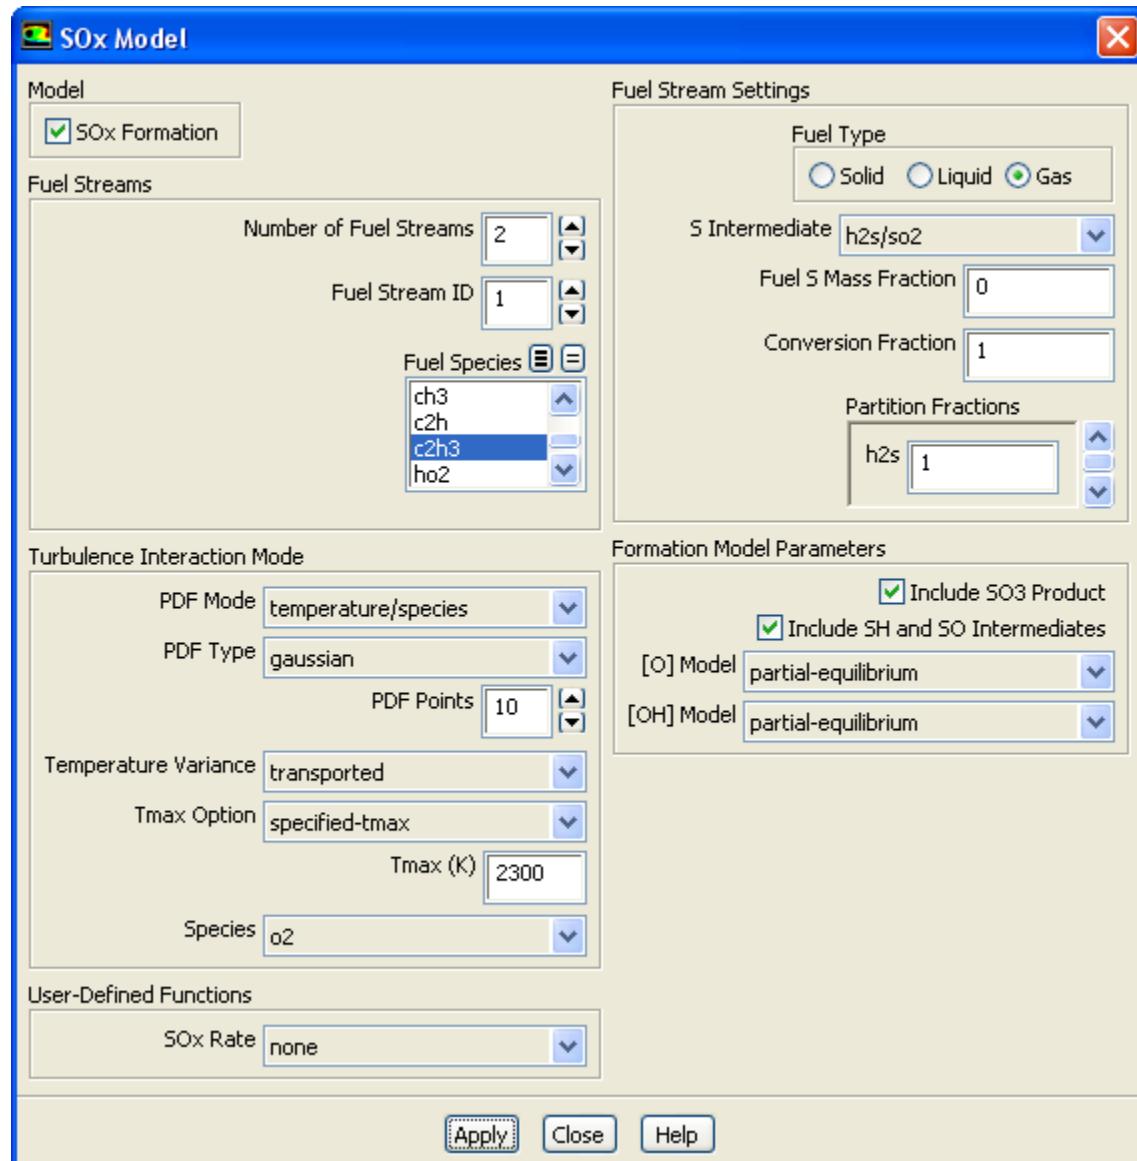

$$mf_{S_v} = (1 - S_{split}) * \frac{TS_{fuel}}{F_{vol}} \quad (23-12)$$

$$mf_{S_c} = S_{split} * \frac{TS_{fuel}}{F_{char}} \quad (23-13)$$

23.2.1.4. Setting Turbulence Parameters

If you want to take into account turbulent fluctuations when you compute the specified SO₂ formation, define the turbulence parameters in the **Turbulence Interaction Mode** group box.

Figure 23.10 The SOx Model Dialog Box for a Gas Fuel Type with Turbulence

Select one of the options in the **PDF Mode** drop-down list:

- Select **temperature** to take into account fluctuations of temperature.
- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s).

Important

When modeling the formation of other pollutants along with SO_x , you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** tab of the [NOx Model Dialog Box](#) (p. 1839) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially premixed combustion model to model the reacting system. If you use the **mixture fraction** option, the instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous SO_x rates are calculated at each cell. The PDF used for convoluting the instantaneous SO_x rates is the same as the one used to compute the mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF for mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous SO_x rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** group box:

PDF Type

allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using [Equation 14–108](#) in the [Theory Guide](#). If you select **gaussian**, the PDF will be modeled using [Equation 14–111](#) in the [Theory Guide](#).

PDF Points

allows you to specify the number of points used to integrate the beta or Gaussian function in [Equation 14–105](#) or [Equation 14–106](#) in the [Theory Guide](#) on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (e.g., 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see [Equation 14–114](#) in the [Theory Guide](#)). You have the option of selecting **transported** to instead solve [Equation 14–113](#) in the [Theory Guide](#). Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature:

- The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field.
- You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.
- You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**.
- If you have selected a user-defined function from the **SO_x Rate** drop-down menu in the **User-Defined Functions** group box, then you can select **user-defined** so that the limit is specified by a UDF. See the [UDF Manual](#) for details about user-defined functions.

Species

only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the SO_x formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation ([Equation 14–114](#) in the [Theory Guide](#)).

23.2.1.5. Specifying a User-Defined Function for the SO_x Rate

You can choose to specify a user-defined function for the rate of SO_x production. By default, the rate returned from the UDF is added to the rate returned from the standard SO_x production options. You also have the option of replacing ANSYS FLUENT's SO_x rate calculations with your own user-defined SO_x rate.

In addition to or instead of using the UDF to specify the SO_x rate, you can use it to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

To use a UDF to add a rate to ANSYS FLUENT's SO_x rate calculations, you must compile and load the desired function, and then select it from the **SOx Rate** drop-down list in the **User-Defined Functions** group box. After you have selected the UDF, you have the following options:

- You can specify that your custom rate is added to the ANSYS FLUENT SO_x rate calculations, by retaining the default selection of **Add to the FLUENT Rate** in the **UDF Rate** group box.
- You can replace the ANSYS FLUENT SO_x rate calculations with your custom rate, by selecting **Replace FLUENT Rate** in the **UDF Rate** group box.
- You can specify custom values for T_{max} , by selecting **user-defined** from the **Tmax Option** drop-down list in the **Turbulence Interaction Mode** group box.

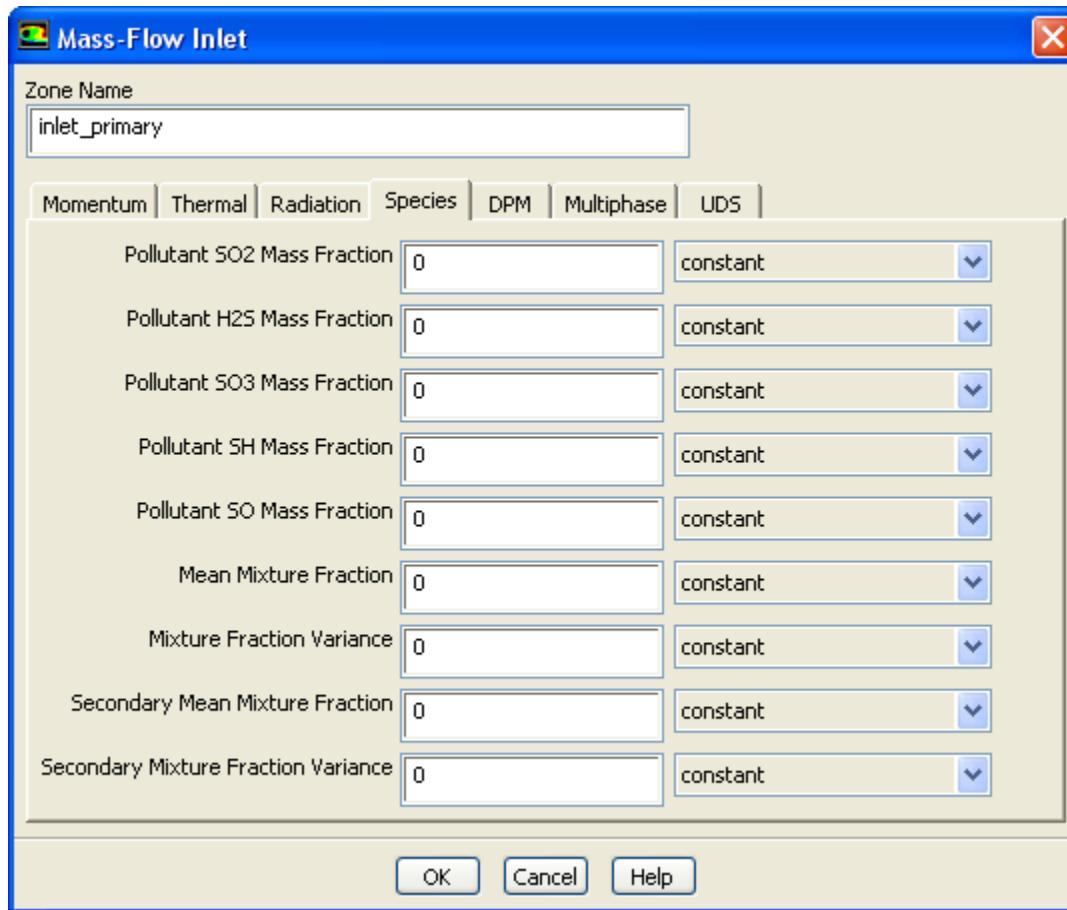

See the [UDF Manual](#) for details about user-defined functions.

23.2.1.6. Defining Boundary Conditions for the SO_x Model

At flow inlet boundaries, you will need to specify the **Pollutant SO Mass Fraction**, and if necessary, the **Pollutant SH Mass Fraction**, **Pollutant H₂S Mass Fraction**, **Pollutant SO₃ Mass Fraction**, and **Pollutant SO₂ Mass Fraction** in the **Species** tab, as demonstrated in [Figure 23.11](#) (p. 1038).

Boundary Conditions

You can retain the default inlet values of zero for these quantities or you can input nonzero numbers as appropriate for your combustion system.

Figure 23.11 The Mass-Flow Inlet Dialog Box and the Species Tab

23.2.2. Solution Strategies

To solve for SO_x products:

- (optional) If the discrete phase model (DPM) is activated (by turning on the **Interaction with Continuous Phase**) to run with the SO_x model, then set the **Number of Continuous Phase Iterations per DPM Iteration** to 0 such that no DPM iterations are performed as the SO_x case is being solved.
- In the *Equations Dialog Box* (p. 2054), turn off the solution of all variables except **Pollutant so2** and **Pollutant h2s** (and **Pollutant so3**, **Pollutant sh**, and **Pollutant so**, if applicable).

↳ Solution Controls → Equations...

- Also in the *Solution Controls Task Page* (p. 2052), set suitable values for the pollutant SO₂ and H₂S (and SO₃, SH, and SO, if applicable) under-relaxation factors. A value of 0.95 is suggested, although lower values may be required for certain problems. That is, if convergence cannot be obtained, try a lower under-relaxation value.

↳ Solution Controls

- Under **Spatial Discretization** in the *Solution Methods Task Page* (p. 2048), select the desired scheme for each of the pollutants, SO₂ and H₂S (and SO₃, SH, and SO, if applicable)

Solution Methods

- In the [Residual Monitors Dialog Box \(p. 2065\)](#), decrease the convergence criterion for the pollutants SO₂ and H₂S (and SO₃, SH, and SO, if applicable) to 10⁻⁶.

Solve → Monitors → Residual...

- Perform calculations until convergence (i.e., until the SO₂ and H₂S—and SO₃, SH, and SO—pollutant residuals are below 10⁻⁶) to ensure that the SO₂ and H₂S (and SO₃, SH, and SO) concentration fields are no longer evolving.

Run Calculation

- Review the mass fractions of pollutants, SO₂ and H₂S (and SO₃, SH, and SO), by generating graphical plots or alphanumeric reports as described in [Postprocessing \(p. 1039\)](#).

23.2.3. Postprocessing

When you compute SO_x formation, the following additional variables will be available for postprocessing. They are contained in the **SOx...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

- **Mass fraction of pollutant so2**
- **Mass fraction of pollutant h2s**
- **Mass fraction of pollutant so3**
- **Mass fraction of pollutant sh**
- **Mass fraction of pollutant so**
- **Mole fraction of pollutant so2**
- **Mole fraction of pollutant h2s**
- **Mole fraction of pollutant so3**
- **Mole fraction of pollutant sh**
- **Mole fraction of pollutant so**
- **so2 Density**
- **h2s Density**
- **so3 Density**
- **sh Density**
- **so Density**
- **Rate of so2**
- **Rate of h2s**
- **Rate of so3**
- **Rate of sh**
- **Rate of so**

23.3. Soot Formation

This section contains information about using the soot formation models in ANSYS FLUENT. For information about the theory behind the soot models in ANSYS FLUENT, see [Soot Formation](#) in the [Theory Guide](#).

23.3.1. Using the Soot Models

When the mass fraction of soot is relatively large (e.g., 10%) or if your problem involves the effect of radiation, the soot formation should be computed as part of the main combustion solution and not through postprocessing (as is done for the NO_x and SO_x models). The procedure for setting up and solving a soot formation model is outlined below, and described in detail on the pages that follow. Remember that only the steps that are pertinent to soot modeling are shown here. For information about inputs related to other models that you are using in conjunction with the soot formation model, see the appropriate sections for those models.

1. Set up your combustion problem using ANSYS FLUENT as usual. Note the following limitations:
 - None of the soot models are compatible with premixed combustion.
 - Only the Moss-Brookes model and the Hall extension are compatible with non-premixed and partially premixed combustion.
 - The one-step and two-step soot formation models are only available for turbulent flows.
2. Enable the desired soot formation model and set the related parameters, as described in this section.

Models → **Soot** → **Edit...**

3. Define the boundary conditions for soot (and nuclei, if you are not using the one-step model) at flow inlets.

Boundary Conditions

4. In the [Solution Controls Task Page](#) (p. 2052), set a suitable value for the soot (and nuclei, if you are not using the one-step model) under-relaxation factor(s). The default value is 0.9. If convergence cannot be obtained with this value, try a lower under-relaxation value.

Solution Controls

5. Perform calculations until convergence (i.e., until the soot / nuclei residual is below 10^{-6}) to ensure that the soot (and nuclei) field is no longer evolving.

Run Calculation

Note that when **Soot-Radiation Interaction** is enabled in the **Soot Model** dialog box, soot equations (soot, nuclei, and tar species, if available) must be solved together with the combustion solution to obtain correct radiation coupling. Therefore, when **Soot-Radiation Interaction** is enabled, the soot equations are not available for pollutant postprocessing, but will be solved together with the combustion solution. However, if other pollutants are to be solved (while soot/radiation interaction is enabled), those pollutant equations will be postprocessed if you so desire.

6. Review the mass fraction of soot (and nuclei) by generating graphical plots or alphanumeric reports in the usual way.

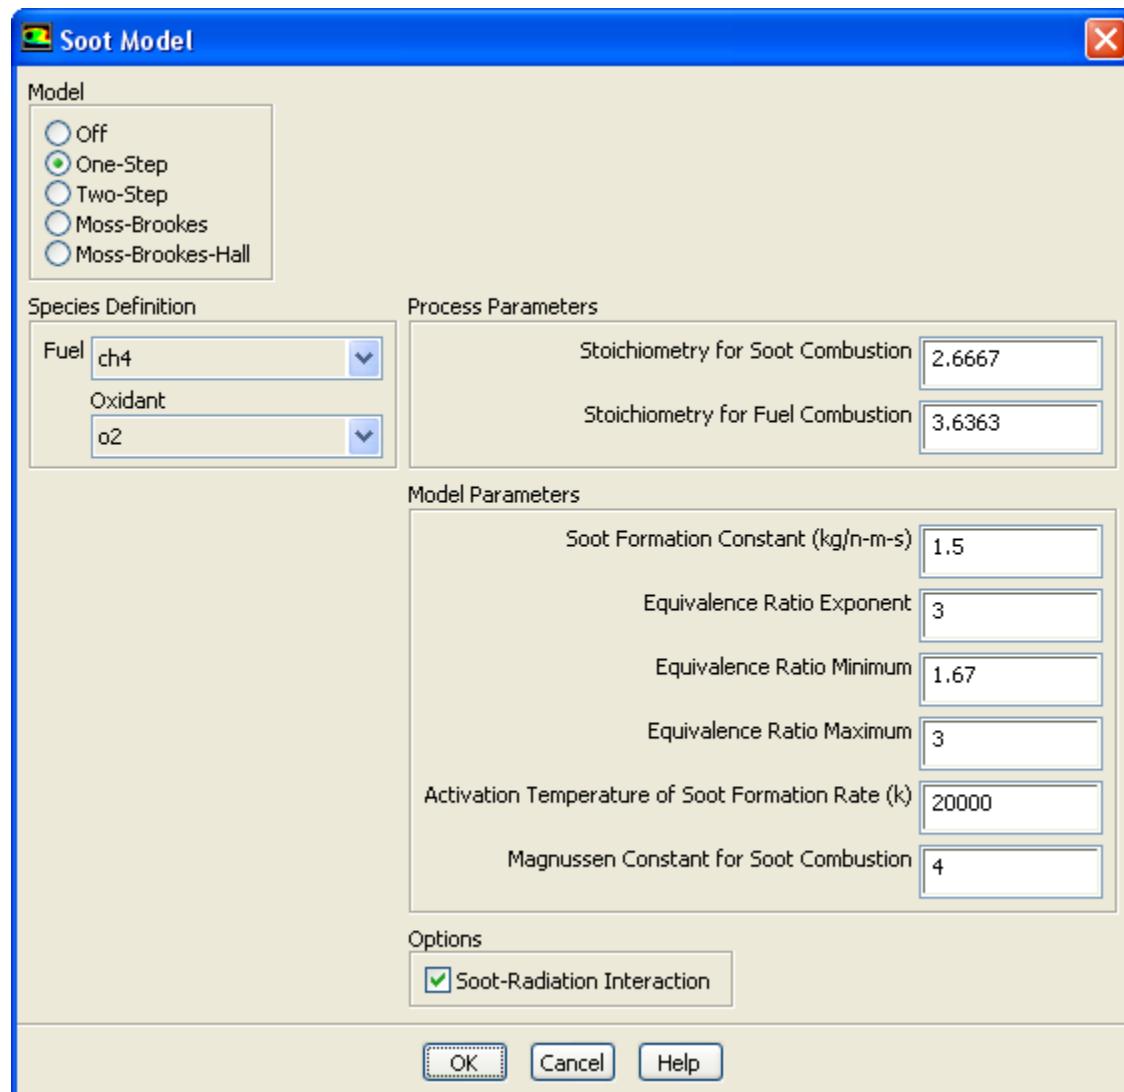

- Save a new set of case and data files, if desired.

23.3.1.1. Setting Up the One-Step Model

You can enable and set up the one-step soot formation model by using the *Soot Model Dialog Box* (p. 1850) (*Figure 23.12* (p. 1041)).

◆ Models → Soot → Edit...

Figure 23.12 The Soot Model Dialog Box for the One-Step Model

Under **Model**, select **One-Step**. The dialog box will expand to show the appropriate inputs.

Next, you need to tell ANSYS FLUENT which chemical species in your model should be used as the fuel and oxidizer. Under **Species Definition**, select the fuel in the **Fuel** drop-down list and the oxidizer in the **Oxidant** drop-down list. If you are using the non-premixed model for the combustion calculation and your fuel stream consists of a mixture of components, you should choose the most appropriate species as the **Fuel** species for the soot formation model. Similarly, the most significant oxidizing component (e.g., O₂) should be selected as the **Oxidant**.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see [The Effect of Soot on the Absorption Coefficient](#) in the [Theory Guide](#).

You must next define the **Process Parameters**, by inputting the stoichiometry of the fuel and soot combustion for the one-step model:

Stoichiometry for Soot Combustion

is the mass stoichiometry, v_{soot} , in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate. The default value supplied by ANSYS FLUENT (2.6667) assumes that the soot is pure carbon and that the oxidizer is O_2 .

Stoichiometry for Fuel Combustion

is the mass stoichiometry, v_{fuel} , in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate. The default value supplied by ANSYS FLUENT (3.6363) is for combustion of propane (C_3H_8) by oxygen (O_2).

You must then set the **Modeling Parameters** that are used in [Equation 14–128](#), [Equation 14–130](#), and [Equation 14–131](#) in the [Theory Guide](#):

Soot Formation Constant

is the parameter C_s in [Equation 14–128](#) in the [Theory Guide](#).

Equivalence Ratio Exponent

is the exponent r in [Equation 14–128](#) in the [Theory Guide](#).

Equivalence Ratio Minimum

and **Equivalence Ratio Maximum** are the minimum and maximum values of the fuel equivalence ratio ϕ in [Equation 14–128](#) in the [Theory Guide](#). This equation will be solved only if **Equivalence Ratio Minimum** < ϕ < **Equivalence Ratio Maximum**; if ϕ is outside of this range, there is no soot formation.

Activation Temperature of Soot Formation Rate

is the term E/R in [Equation 14–128](#) in the [Theory Guide](#).

Magnussen Constant for Soot Combustion

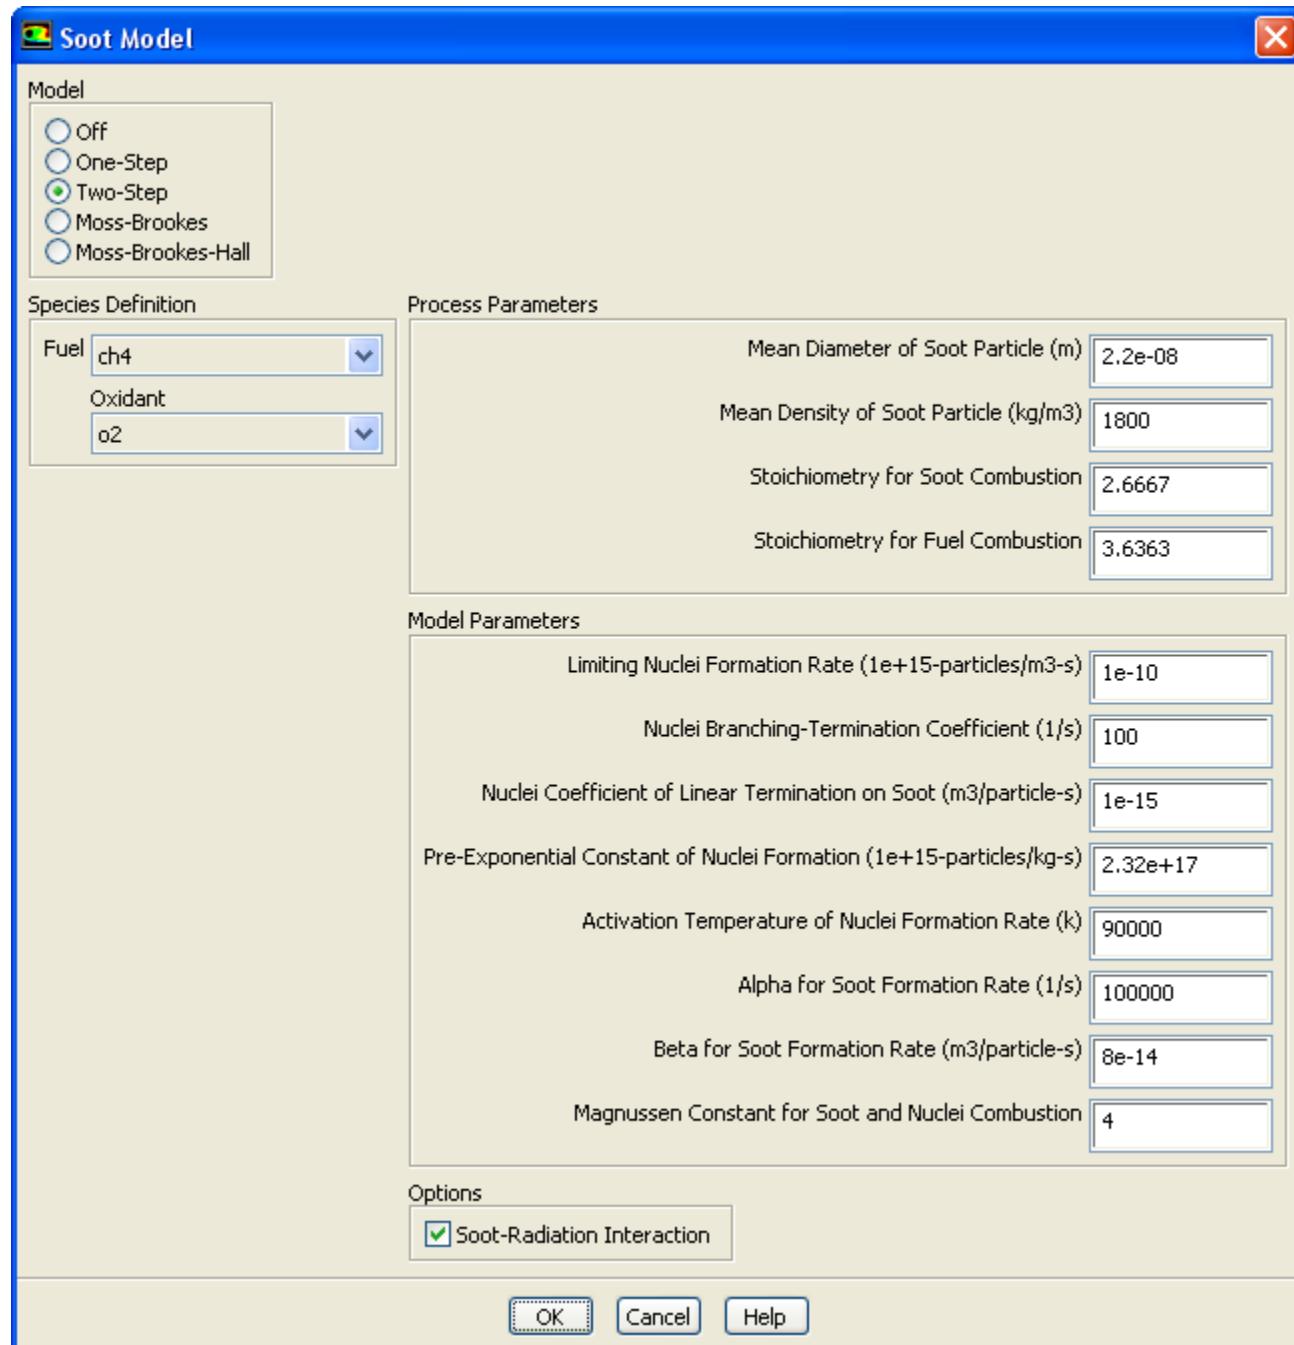

is the constant A used in the rate expressions governing the soot combustion rate ([Equation 14–130](#) and [Equation 14–131](#) in the [Theory Guide](#)).

Note that the default values for these parameters are for propane fuel [15] (p. 2367), [98] (p. 2372), and are considered to be valid for a wide range of hydrocarbon fuels.

23.3.1.2. Setting Up the Two-Step Model

You can enable and set up the two-step soot formation model by using the [Soot Model Dialog Box](#) (p. 1850) ([Figure 23.13](#) (p. 1043)).

Models →  Soot → Edit...

Figure 23.13 The Soot Model Dialog Box for the Two-Step Model

Under **Model**, select **Two-Step**. The dialog box will expand to show the appropriate inputs.

Important

Note that the two-step Tesner model should only be used when the eddy-dissipation model is used to define the turbulence-chemistry interaction.

Next, you need to tell ANSYS FLUENT which chemical species in your model should be used as the fuel and oxidizer. Under **Species Definition**, select the fuel in the **Fuel** drop-down list and the oxidizer in the **Oxidant** drop-down list. If you are using the non-premixed model for the combustion calculation

and your fuel stream consists of a mixture of components, you should choose the most appropriate species as the **Fuel** species for the soot formation model. Similarly, the most significant oxidizing component (e.g., O₂) should be selected as the **Oxidant**.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see [The Effect of Soot on the Absorption Coefficient](#) in the [Theory Guide](#).

You must next define the **Process Parameters**, by inputting the stoichiometry of the fuel and soot combustion, as well as the average size and density of the soot particles, for the two-step model:

Mean Diameter of Soot Particle

and **Mean Density of Soot Particle** are the assumed average diameter and average density of the soot particles in the combustion system, used to compute the soot particle mass, m_p , in [Equation 14–134](#) in the [Theory Guide](#) for the two-step model. Note that the default values for soot density and diameter are taken from [49] (p. 2369).

Stoichiometry for Soot Combustion

is the mass stoichiometry, ν_{soot} , in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate. The default value supplied by ANSYS FLUENT (2.6667) assumes that the soot is pure carbon and that the oxidizer is O₂.

Stoichiometry for Fuel Combustion

is the mass stoichiometry, ν_{fuel} , in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate. The default value supplied by ANSYS FLUENT (3.6363) is for combustion of propane (C₃H₈) by oxygen (O₂).

You must then set the **Modeling Parameters** that are used in [Equation 14–130](#), [Equation 14–131](#), [Equation 14–134](#), [Equation 14–136](#), and [Equation 14–137](#) in the [Theory Guide](#):

Limiting Nuclei Formation Rate

is the limiting value of the kinetic nuclei formation rate, η_0 , in [Equation 14–137](#) in the [Theory Guide](#). Below this limiting value, the branching and termination term, ($f - g$) in [Equation 14–136](#) in the [Theory Guide](#), is not included.

Nuclei Branching-Termination Coefficient

is the term ($f - g$) in [Equation 14–136](#) in the [Theory Guide](#).

Nuclei Coefficient of Linear Termination on Soot

is the term g_0 in [Equation 14–136](#) in the [Theory Guide](#).

Pre-Exponential Constant of Nuclei Formation

is the pre-exponential term a_0 in the kinetic nuclei formation term, [Equation 14–137](#) in the [Theory Guide](#).

Activation Temperature of Nuclei Formation Rate

is the term E/R in the kinetic nuclei formation term, [Equation 14–137](#) in the [Theory Guide](#).

Alpha for Soot Formation Rate

is α , the constant in the soot formation rate equation, [Equation 14–134](#) in the [Theory Guide](#).

Beta for Soot Formation Rate

is β , the constant in the soot formation rate equation, [Equation 14–134](#) in the [Theory Guide](#).

Magnussen Constant for Soot and Nuclei Combustion

is the constant A used in the rate expressions governing the soot combustion rate ([Equation 14–130](#) and [Equation 14–131](#) in the [Theory Guide](#)).

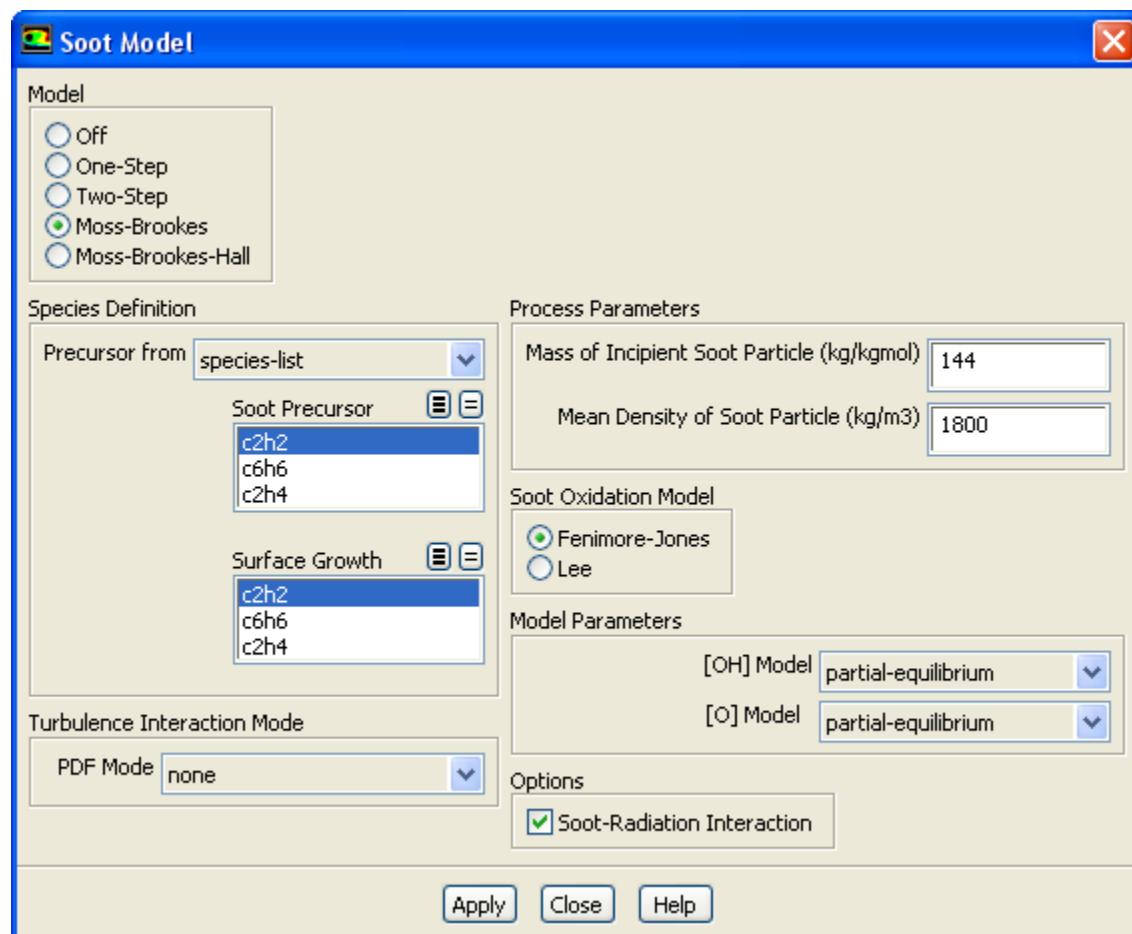

The default values for the two-step model are the same as in Magnussen and Hjertager [49] (p. 2369) (for an acetylene flame), except for a_0 , which is assumed to have the original value from Tesner et al. [95] (p. 2372). If your model involves propane fuel rather than acetylene, it is recommended that you change the value of α to 3.5×10^8 [5] (p. 2367). For best results, you should modify both of these parameters, using empirically determined inputs for your specific combustion system.

23.3.1.3. Setting Up the Moss-Brookes Model and the Hall Extension

You can enable and set up the Moss-Brookes and Moss-Brookes-Hall soot formation models by using the [Soot Model Dialog Box](#) (p. 1850) (*Figure 23.14* (p. 1045)).

◆ Models → Soot → Edit...

Figure 23.14 The Soot Model Dialog Box for the Moss-Brookes Model

Under **Model**, select **Moss-Brookes** or **Moss-Brookes-Hall**. The dialog box will expand to show the appropriate inputs. Note the following about these models:

- The **Moss-Brookes** model was originally proposed for soot prediction in methane flames. However, it can be equally applicable to higher hydrocarbon species by appropriately modifying the soot precursor and participating surface growth species.
- The **Moss-Brookes-Hall** model is applicable for higher hydrocarbon fuels (e.g., kerosene) and will only be available when C_2H_2 , C_6H_6 , C_6H_5 , and H_2 are present in the gas phase species list.

You must next define the precursor species in the **Species Definition** group box. When suitable precursor species are present in the species list, you can select **species-list** from the **Precursor from** drop-down list, and then select the **Soot Precursor** species and the **Surface Growth** species from the selection lists. Note that for the **Moss-Brookes** model, you can select acetylene (**c2h2**), ethylene (**c2h4**), and/or benzene (**c6h6**) for the **Soot Precursor**; if neither are present or if you would like to specify a different precursor correlation, then curve fitting will be used to determine the precursor and surface growth species mass fractions (see *Species Definition for the Moss-Brookes Model with a User-Defined Precursor Correlation* (p. 1048) for further details regarding curve fitting).

Next, specify how turbulent fluctuations will be accounted for in the soot formation calculations, by defining the turbulence parameters in the **Turbulence Interaction Mode** group box.

Select one of the options in the **PDF Mode** drop-down list:

- Select **none** to ignore turbulence and use laminar soot rate calculations.
- Select **temperature** to take into account fluctuations of temperature.
- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s). This is the recommended approach, as it generally yields the best results and accuracy.

Important

When modeling the formation of other pollutants along with soot, you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** tab of the *NOx Model Dialog Box* (p. 1839) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially premixed combustion model to model the reacting system. If you use the **mixture fraction** option, the instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous soot production rates are calculated at each cell. The PDF used for convoluting the instantaneous soot rates is the same as the one used to compute the mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF in terms of mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous soot rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** group box:

PDF Type

allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using [Equation 14–108](#) in the [Theory Guide](#). If you select **gaussian**, the PDF will be modeled using [Equation 14–111](#) in the [Theory Guide](#).

PDF Points

allows you to specify the number of points used to integrate the beta or Gaussian function in [Equation 14–105](#) or [Equation 14–106](#) in the [Theory Guide](#) on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (e.g., 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see [Equation 14–114](#) of the [Theory Guide](#)). You have the option of selecting **transported** to instead solve [Equation 14–113](#) in the [Theory Guide](#). Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature. The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field. You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**. You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**. Finally, if you have compiled a user-defined function for the soot rate and loaded the library into ANSYS FLUENT, then you can select **user-defined** so that the limit is specified by a UDF.

Species

only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the soot formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation ([Equation 14–114](#) in the [Theory Guide](#)).

Under **Process Parameters**, you must enter information about the mass and mean density of the soot particles:

Mass of Incipient Soot Particles

is M_p in [Equation 14–142](#) and [Equation 14–144](#) in the [Theory Guide](#). Note that this value was assumed to be 144 kg/kmol (12 carbon atoms) in the work of Brookes and Moss, whereas the Hall extension model assumed it to be 1200 kg/kmol (100 carbon atoms).

Mean Density of Soot Particle

is ρ_{soot} in [Equation 14–141](#) in the [Theory Guide](#) and ρ in [Equation 14–144](#) in the [Theory Guide](#). Note that this value was assumed to be 1800 kg/m³ in the work of Brookes and Moss [12] (p. 2367), whereas Hall et al. [30] (p. 2368) assumed it to be 2000 kg/m³.

Next, you must select the **Soot Oxidation Model**. Your choices include the **Fenimore-Jones** model, as originally used in Brookes and Moss' work, or the **Lee** extended model. The **Lee** model will model soot oxidation due to hydroxyl radicals as in the **Fenimore-Jones** model, as well as the oxidation due to molecular oxygen.

You must then set the **Modeling Parameters**:

[OH] Model

allows you to specify the method by which the OH radical concentration is calculated. The recommended selection from the drop-down list is **instantaneous**, although this option is only available when OH is available in the species list and is calculated by the combustion model. The other option is the **partial-equilibrium** model, which necessitates the availability of [O] atom concentration within the field.

[O] Model

must be defined when you have selected **partial-equilibrium** for the **[OH] Model**, and specifies the method by which the O radical concentration is calculated. The options include **equilibrium**, **partial-equilibrium**, and **instantaneous**.

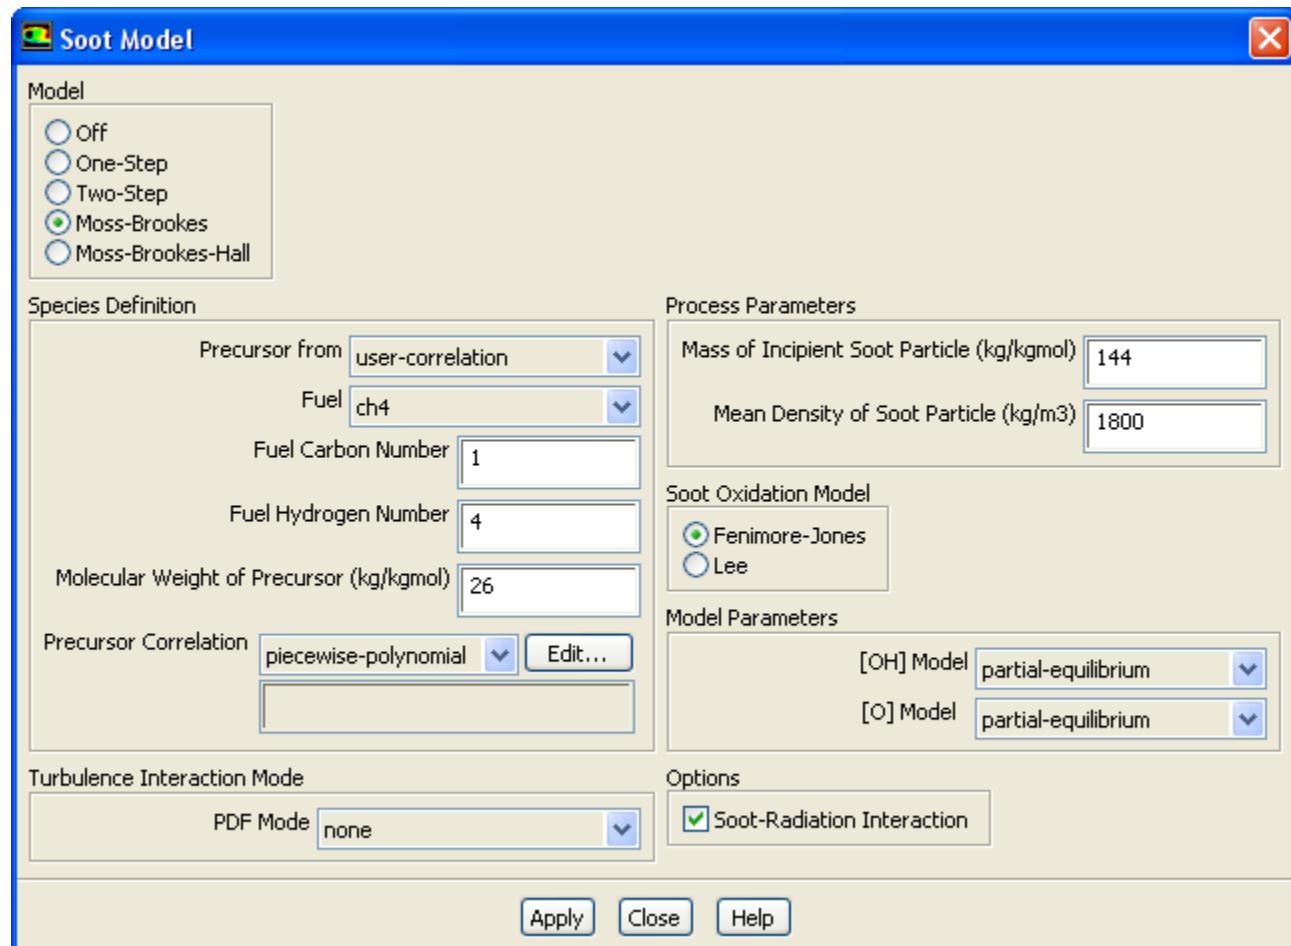

Note that in ANSYS FLUENT, the oxidation rate scaling parameter (C_{oxid} in [Equation 14–142](#) in the [Theory Guide](#)) is set to unity. If you would like to change the value of this parameter, you can use the `define/models/soot-parameters` text command. A lower value will reduce the amount of soot oxidation.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see [The Effect of Soot on the Absorption Coefficient](#) in the [Theory Guide](#).

23.3.1.3.1. Species Definition for the Moss-Brookes Model with a User-Defined Precursor Correlation

ANSYS FLUENT accepts the following as possible precursor species for the Moss-Brookes model: C_2H_2 , C_6H_6 , and C_2H_4 . If none of these species are present in the species list (as is often the case when using the eddy-dissipation model) or if you would prefer to specify a different precursor correlation, your setup for the Moss-Brookes model will be different than noted previously. Under such circumstances, you should select **user-correlation** from the **Precursor from** drop-down list in the **Species Definition** group box (note that this is only option possible when the appropriate species are not present). The [Soot Model Dialog Box \(p. 1850\)](#) will then be as shown in [Figure 23.15 \(p. 1049\)](#). The parameters you set in the **Species Definition** group box allow ANSYS FLUENT to calculate a mixture fraction based on the mass fractions of the oxidant and the carbon/hydrogen contributed by a designated fuel species. The precursor species mass fraction will then be computed as a function (which you will also define) of this mixture fraction.

Figure 23.15 The Soot Model Dialog Box for the Moss-Brookes Model with a User-Defined Precursor Correlation

In the **Species Definition** group box, you will first select a **Fuel** species and enter the related **Fuel Carbon Number** and **Fuel Hydrogen Number** for use in the mixture fraction calculation. Next, enter the **Molecular Weight of Precursor** (the default value is for acetylene). Then make a selection in the **Precursor Correlation** drop-down list to indicate how the precursor mass fraction will be related to the mixture fraction. A **piecewise-polynomial** profile is defined by default.

Important

Note that the default values for the **piecewise-polynomial** profile are only valid for a methane diffusion flame simulation, in which both the air and fuel initial temperatures are set to 290 K, and acetylene is assumed as the soot precursor.

If you decide not to use the default values for **Precursor Correlation**, you must define the correlation between the precursor mass fraction and the mixture fraction. This correlation should be based on a laminar flamelet profile that you have generated: if possible, you should generate the profile using the **Species Model** dialog box (as described in *Setting Up the Steady and Unsteady Laminar Flamelet Models* (p. 909)), being sure to select **Steady Flamelet** in the **Chemistry** tab; if there is no mechanism, you can generate the profile using the equilibrium chemistry model (see *Setting Up the Equilibrium Chemistry Model* (p. 905) for details); you may also use a third-party software package of your choosing. You should then apply a curve-fitting technique to your generated profile, to obtain either a constant value or a piecewise-polynomial function.

In a piecewise-polynomial function, the laminar flamelet profile is divided into a number of mixture fraction ranges. In each range, the precursor species mass fraction Y_{prec} is defined using the following equation:

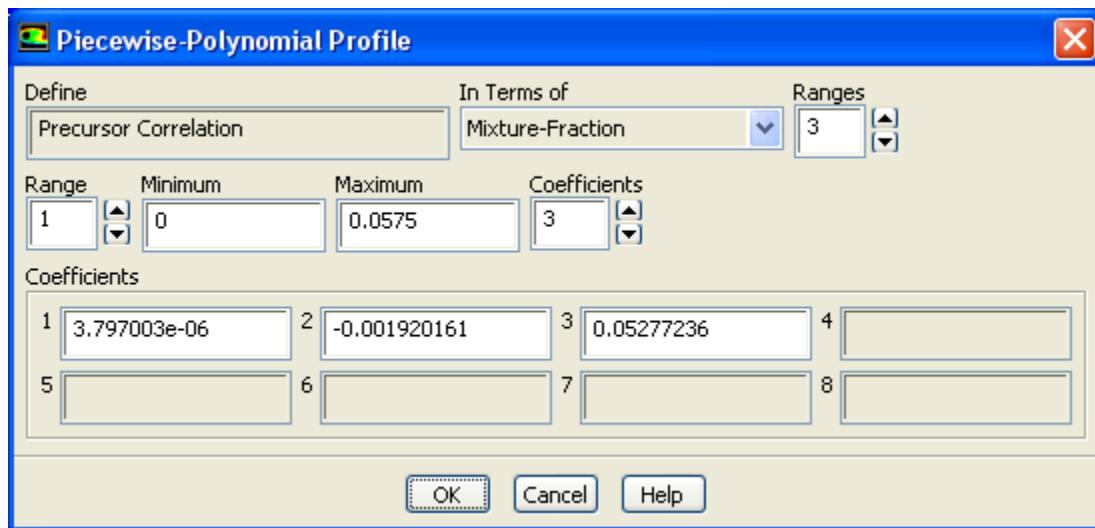

$$Y_{prec} = \sum_{i=1}^{i=NC} C_i f^{i-1} \quad (23-14)$$

where NC is the number of coefficients C , and f is the mixture fraction. The following piecewise-polynomial function corresponds to the default settings in ANSYS FLUENT:

$$Y_{prec} = \begin{cases} \text{for } 0 \leq f < 0.0575 : \\ 3.797003 \times 10^{-6} - 1.920161 \times 10^{-3}f \\ + 5.277237 \times 10^{-2}f^2 \\ \text{for } 0.0575 \leq f < 0.128 : \\ 1.051312 - 71.34743f + 1964.038f^2 + 281825.9f^3 \\ + 223543.4f^4 + 932192f^5 + 1599627f^6 \\ \text{for } 0.128 \leq f < 1 : \\ 7.988928 \times 10^{-3} - 8.440912 \times 10^{-3}f \\ + 4.273195 \times 10^{-4}f^2 \end{cases} \quad (23-15)$$

To define a piecewise-polynomial profile to relate the precursor mass fraction to the mixture fraction, select **piecewise-polynomial** from the **Precursor Correlation** drop-down list and click the **Edit...** button. The *Piecewise-Polynomial Profile Dialog Box* (p. 1898) (*Figure 23.16* (p. 1050)) will open.

Figure 23.16 The Piecewise-Polynomial Profile Dialog Box

Then perform the following steps in the **Piecewise-Polynomial Profile** dialog box:

1. Enter the number of **Ranges**. For the example shown in [Equation 23–15 \(p. 1050\)](#), three ranges of mixture fraction are defined, which is the maximum allowed.
2. For the first range (**Range** = 1), enter the **Minimum** and **Maximum** mixture fraction values, and the number of **Coefficients**. (Up to eight coefficients are available.) The number of coefficients defines the order of the polynomial. An input of 1 defines a polynomial of order 0, and the mass fraction will be constant and equal to the single coefficient. An input of 2 defines a polynomial of order 1, and the mass fraction will vary linearly with mixture fraction, and so on.
3. Define the values for the coefficients in the **Coefficients** group box. The dialog box in [Figure 23.16 \(p. 1050\)](#) shows the inputs for the first range of [Equation 23–15 \(p. 1050\)](#).
4. Increase the value of **Range** and enter the **Minimum** and **Maximum** mixture fractions, number of **Coefficients**, and the values for the **Coefficients** for the next range. Repeat if there is a third range.

Important

Note when defining the ranges, you must start with the lowest mixture fraction range, and then proceed in order to the highest range. The solver will *not* sort them for you.

To define a constant profile to relate the precursor mass fraction to the mixture fraction, select **constant** from the **Precursor Correlation** drop-down list and enter a value in the accompanying text entry box.

23.3.1.4. Defining Boundary Conditions for the Soot Model

At flow inlet boundaries, you will need to specify the **Soot Mass Fraction** and (when not using the one-step model) the **Nuclei** mass concentration. These correspond to Y_{soot} in [Equation 14–126](#) and [Equation 14–140](#) and b_{nuc}^* in [Equation 14–132](#) and [Equation 14–140](#) in the Theory Guide, respectively.

Boundary Conditions

You can retain the default inlet values of zero for both quantities or you can input nonzero numbers as appropriate for your combustion system.

23.3.1.5. Reporting Soot Quantities

ANSYS FLUENT provides additional reporting options when your model includes soot formation. You can generate graphical plots or alphanumeric reports of the following items:

- **Mass fraction of Soot**
- **Mole fraction of Soot**
- **Soot Density**
- **Soot Volume fraction**
- **Rate of Soot**
- **Normalized Concentration of Nuclei** (unavailable for one-step model)
- **Rate of Nuclei** (unavailable for one-step model)
- **Rate of Soot Mass Nucleation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Surface Growth** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Oxidation** (Moss-Brookes and Moss-Brookes-Hall models only)

- **Rate of Nucleation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Coagulation** (Moss-Brookes and Moss-Brookes-Hall models only)

These parameters are contained in the **Soot...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

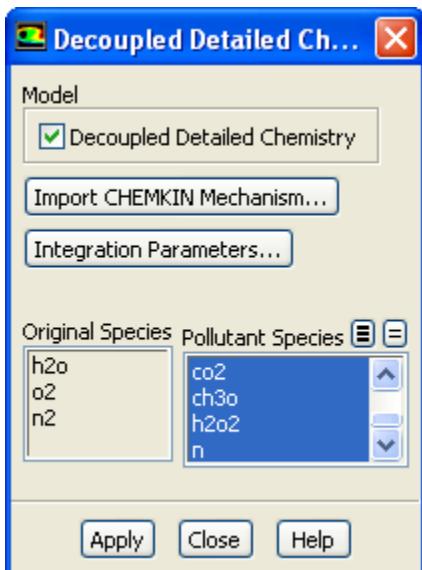

23.4. Using the Decoupled Detailed Chemistry Model

The decoupled detailed chemistry pollutant model is used to postprocess slowly-forming, trace pollutant species on a steady-state flow field using detailed chemical kinetic mechanisms. For theoretical information, please refer to [Decoupled Detailed Chemistry Model](#). The recommended procedure is as follows:

1. Calculate your steady combustion problem using the Species Transport, Non-Premixed, Partially-Premixed, or PDF Transport models in ANSYS FLUENT. It is recommended that you save your case and data file, as it may be difficult to revert to the original settings after you set up the decoupled detailed chemistry pollutant model.
2. Enable the **Decoupled Detailed Chemistry** option in the **Decoupled Detailed Chemistry** dialog box. To access this dialog box, make sure that either the non-premixed or partially premixed model is selected, or that reactions are enabled if the species transport or PDF transport models are used.

↳ **Models** → **Decoupled Detailed Chemistry** → **Edit...**

Figure 23.17 The Decoupled Detailed Chemistry Dialog Box

3. Click **Import CHEMKIN Mechanism...** to import your detailed chemistry mechanism in CHEMKIN format. The **CHEMKIN Mechanism Import** dialog box (described in [Importing a Volumetric Kinetic Mechanism in CHEMKIN Format \(p. 883\)](#)) will open, where you will browse to the file. After the CHEMKIN mechanism is imported, the **Decoupled Detailed Chemistry** dialog box will expand to include the species.
4. Select the **Pollutant Species** and click **Apply**. The pollutant species are typically slowly forming (far from chemical equilibrium), and occur at minuscule mass fractions. ANSYS FLUENT will create a mixture material called **pollutant-mixture** and enable the **Species Transport** model with the **Stiff Chemistry Solver**. All species in the imported mechanism that were not in the original combustion model and are not pollutant species will be calculated by chemical equilibrium at the cell temperature. The solution of all transport equations, except the selected pollutant species, are disabled.

Note

Species which are not identified as pollutants and do not participate in the reactions amongst the pollutant species are eliminated. Similarly, reactions in the imported CHEMKIN mechanism, which do not include any pollutant species are also eliminated.

5. Click **Integration Parameters...** to open the **Integration Parameters** dialog box. Set the **ISAT Parameters**, such as the **ISAT Error Tolerance** and **Max. Storage**. An **ISAT Error Tolerance** of 1e-5 is recommended, and **Max. Storage** should be set to a large fraction of the free RAM memory available. To learn more about setting integration parameters, please refer to [Using ISAT \(p. 988\)](#).
6. Define the boundary conditions for all pollutants at flow inlets (these are usually zero).

 **Boundary Conditions**

7. Iterate until convergence.

 **Run Calculation**

8. Review the mass fractions of pollutants by generating graphical plots or alphanumeric reports in the usual way.
9. Save a new set of case and data files, if desired.

File → Write → Case & Data...

Chapter 24: Predicting Aerodynamically Generated Noise

This chapter provides an overview of ANSYS FLUENT's approaches to computing aerodynamically generated sound, the model setup, and the procedure for computing sound. For more information about the underlying theory behind aerodynamically generated sound, see "[Aerodynamically Generated Noise](#)" in the [Theory Guide](#).

24.1. Overview

24.2. Using the Ffowcs-Williams and Hawkings Acoustics Model

24.3. Using the Broadband Noise Source Models

24.1. Overview

Considering the breadth of the discipline and the challenges encountered in aerodynamically generated noise, it is not surprising that a number of computational approaches have been proposed over the years whose sophistication, applicability, and cost widely vary.

ANSYS FLUENT offers three approaches to computing aerodynamically generated noise; a direct method, an integral method based on acoustic analogy and a method that utilizes broadband noise source models.

For additional information, please see the following sections:

24.1.1. Direct Method

24.1.2. Integral Method Based on Acoustic Analogy

24.1.3. Broadband Noise Source Models

24.1.1. Direct Method

In this method, both generation and propagation of sound waves are directly computed by solving the appropriate fluid dynamics equations. Prediction of sound waves always requires time-accurate solutions to the governing equations. Furthermore, in most practical applications of the direct method, one has to employ governing equations that are capable of modeling viscous and turbulence effects, such as unsteady Navier-Stokes equations (i.e., DNS), RANS equations, and filtered equations used in DES and LES.

The direct method is thus computationally difficult and expensive inasmuch as it requires highly accurate numerics, very fine computational meshes all the way to receivers, and acoustically nonreflecting boundary conditions. The computational cost becomes prohibitive when sound is to be predicted in the far field (e.g., hundreds of chord-lengths in the case of an airfoil). The direct method becomes feasible when receivers are in the near field (e.g., cabin noise). In many such situations involving near-field sound, sounds (or pseudo-sounds for that matter) are predominantly due to local hydrodynamic pressure which can be predicted with a reasonable cost and accuracy.

Since sound propagation is directly resolved in this method, one normally needs to solve the compressible form of the governing equations (e.g., compressible RANS equations, compressible form of filtered equations for LES). Only in situations where the flow is low subsonic and the receivers in the near field sense primarily local hydrodynamic pressure fluctuations (i.e., pseudo sound) can incompressible flow

formulations be used. But this incompressible treatment will also not allow to simulate resonance and feedback phenomena.

24.1.2. Integral Method Based on Acoustic Analogy

For predictions of mid- to far-field noise, the methods based on Lighthill's acoustic analogy [44] (p. 2369) offer viable alternatives to the direct method. In this approach, the near-field flow obtained from appropriate governing equations such as unsteady RANS equations, DES, or LES are used to predict the sound with the aid of analytically derived integral solutions to wave equations. The acoustic analogy essentially decouples the propagation of sound from its generation, allowing one to separate the flow solution process from the acoustics analysis.

ANSYS FLUENT offers a method based on the Ffowcs-Williams and Hawking (FW-H) formulation [23] (p. 2368). The FW-H formulation adopts the most general form of Lighthill's acoustic analogy, and is capable of predicting sound generated by equivalent acoustic sources such as monopoles, dipoles, and quadrupoles. ANSYS FLUENT adopts a time-domain integral formulation wherein time histories of sound pressure, or acoustic signals, at prescribed receiver locations are directly computed by evaluating a few surface integrals.

Time-accurate solutions of the flow-field variables, such as pressure, velocity components, and density on source (emission) surfaces, are required to evaluate the surface integrals. Time-accurate solutions can be obtained from unsteady Reynolds-averaged Navier-Stokes (URANS) equations, large eddy simulation (LES), or detached eddy simulation (DES) as appropriate for the flow at hand and the features that you want to capture (e.g., vortex shedding). The source surfaces can be placed not only on impermeable walls, but also on interior (permeable) surfaces, which enables you to account for the contributions from the quadrupoles enclosed by the source surfaces. Both broadband and tonal noise can be predicted depending on the nature of the flow (noise source) being considered, turbulence model employed, and the time scale of the flow resolved in the flow calculation.

The FW-H acoustics model in ANSYS FLUENT allows you to select multiple source surfaces and receivers. It also permits you either to save the source data for a future use, or to carry out an "on the fly" acoustic calculation simultaneously as the transient flow calculation proceeds, or both. Sound pressure signals thus obtained can be processed using the fast Fourier transform (FFT) and associated postprocessing capabilities to compute and plot such acoustic quantities as the overall sound pressure level (SPL) and power spectra.

One important limitation of ANSYS FLUENT's FW-H model is that it is applicable only to predicting the propagation of sound toward *free space*. Thus, while the model can be legitimately used to predict far-field noise due to external aerodynamic flows, such as the flows around ground vehicles and aircrafts, it cannot be used for predicting the noise propagation inside ducts or wall-enclosed space.

24.1.3. Broadband Noise Source Models

In many practical applications involving turbulent flows, noise does not have any distinct tones, and the sound energy is continuously distributed over a broad range of frequencies. In those situations involving *broadband noise*, statistical turbulence quantities readily computable from RANS equations can be utilized, in conjunction with semi-empirical correlations and Lighthill's acoustic analogy, to shed some light on the source of broadband noise.

ANSYS FLUENT offers several such *source models* that enable you to quantify the local contribution (per unit surface area or volume) to the total acoustic power generated by the flow. They include the following:

- Proudman's formula

- jet noise source model
- boundary layer noise source model
- source terms in the linearized Euler equations
- source terms in Lilley's equation

Considering that one would ultimately want to come up with some measures to mitigate the noise generated by the flow in question, the source models can be employed to extract useful diagnostics on the noise source to determine which portion of the flow is primarily responsible for the noise generation. Note, however, that these source models do not predict the sound at receivers.

Unlike the direct method and the FW-H integral method, the broadband noise source models do not require transient solutions to any governing fluid dynamics equations. All the source models need is what typical RANS models would provide, such as the mean velocity field, turbulent kinetic energy (k) and the dissipation rate (ε). Therefore, the use of broadband noise source models requires the least computational resources.

24.2. Using the Ffowcs-Williams and Hawkings Acoustics Model

The procedure for computing sound using the FW-H acoustics model in ANSYS FLUENT consists largely of two steps. In the first step, a time-accurate flow solution is generated from which time histories of the relevant variables (e.g., pressure, velocity, and density) on the selected source surfaces are obtained. In the second step, sound pressure signals at the user-specified receiver locations are computed using the source data collected during the first step.

Important

Note that you can also use the FW-H model for a steady-state simulation in the case where your model has a single moving reference frame. Here, the thickness and loading noise due to the motion of the noise sources is computed using the FW-H integrals (see [Equation 15–5](#) and [Equation 15–6](#) in the [Theory Guide](#)), except that the term involving the time derivative of surface pressure (contribution to \dot{L}_r in [Equation 15–6](#) in the [Theory Guide](#)) is set to zero.

In computing sound pressure using the FW-H integral solution, ANSYS FLUENT uses a so-called “forward-time projection” to account for the time delay between the emission time (the time at which the sound is emitted from the source) and the reception time (the time at which the sound arrives at the receiver location). The forward-time projection approach enables you to compute sound at the same time “on the fly” as the transient flow solution progresses, without having to save the source data.

In this section, the procedure for setting up and using the FW-H acoustics model is outlined first, followed by detailed descriptions of each of the steps involved. Remember that only the steps that are pertinent to acoustics modeling are discussed here. For information about the inputs related to other models that you are using in conjunction with the FW-H acoustics model, see the appropriate sections for those models.

The general procedure for carrying out an FW-H acoustics calculation in ANSYS FLUENT is as follows:

1. Calculate a converged flow solution. For a transient case, run the transient solution until you obtain a “statistically steady-state” solution as described below.
2. Enable the FW-H acoustics model and set the associated model parameters.

Models → **Acoustics** → **Edit...**

3. Specify the source surface(s) and choose the options associated with acquisition and saving of the source data. For a steady-state case, specify the rotating surface zone(s) as the source surface(s).
4. Specify the receiver location(s).
5. Continue the transient solution for a sufficiently long period of time and save the source data (transient cases only).

Run Calculation

6. Compute and save the sound pressure signals.

Run Calculation → **Acoustic Signals...**

7. Postprocess the sound pressure signals.

Plots → **FFT** → **Set Up...**

Important

Before you start the acoustics calculation for a transient case, an ANSYS FLUENT transient solution should have been run to a point where the transient flow field has become “statistically steady”. In practice, this means that the unsteady flow field under consideration, including all the major flow variables, has become fully developed in such a way that its statistics do not change with time. Monitoring the major flow variables at selected points in the domain is helpful for determining if this condition has been met.

As discussed earlier, URANS, DES, and LES are all legitimate candidates for transient flow calculations. For stationary source surfaces, the frequency of the aerodynamically generated sound heard at the receivers is largely determined by the time scale or frequency of the underlying flow. Therefore, one way to determine the time-step size for the transient computation is to make it small enough to resolve the smallest characteristic time scale of the flow at hand that can be reproduced by the mesh and turbulence adopted in your model.

Once you have obtained a statistically stationary flow-field solution, you are ready to acquire the source data.

For additional information, please see the following sections:

- [24.2.1. Enabling the FW-H Acoustics Model](#)
- [24.2.2. Specifying Source Surfaces](#)
- [24.2.3. Specifying Acoustic Receivers](#)
- [24.2.4. Specifying the Time Step](#)
- [24.2.5. Postprocessing the FW-H Acoustics Model Data](#)

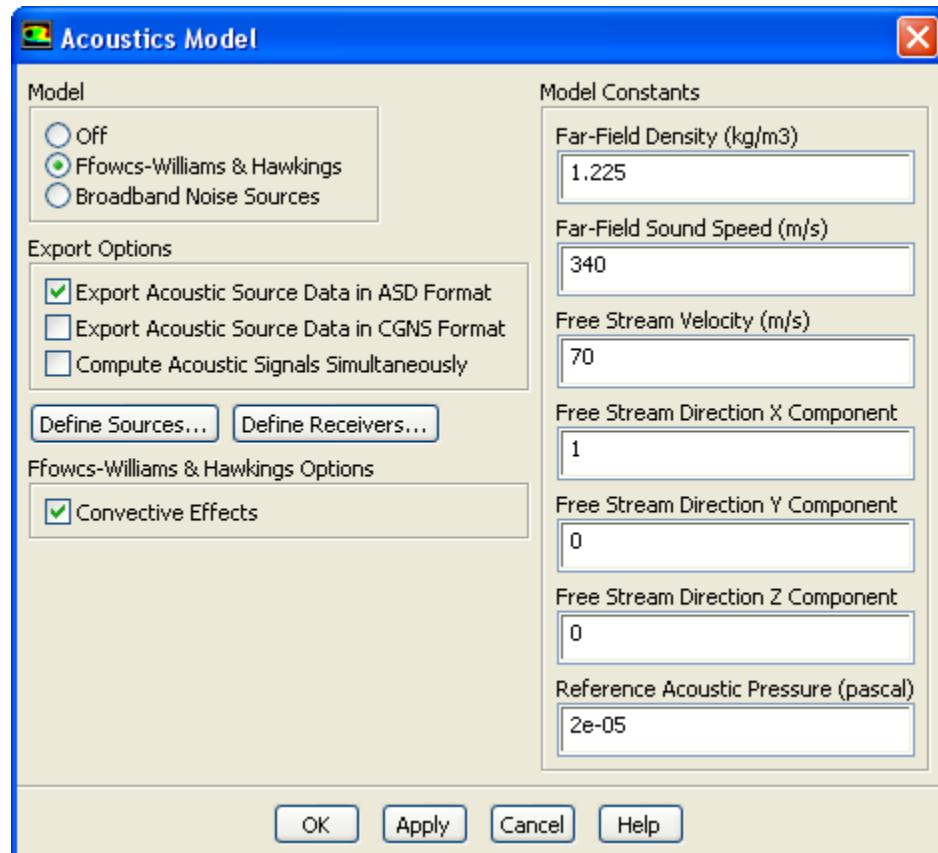

24.2.1. Enabling the FW-H Acoustics Model

To enable the FW-H acoustics model, select **Ffowcs-Williams & Hawkings** in the **Acoustics Model** dialog box ([Figure 24.1 \(p. 1059\)](#)).

Models → **Acoustics** → **Edit...**

When you select **Ffowcs-Williams & Hawkings**, the dialog box will expand to show the relevant fields for user inputs.

Figure 24.1 The Acoustics Model Dialog Box

24.2.1.1. Setting Model Constants

Under **Model Constants** in the **Acoustics Model** dialog box, specify the relevant acoustic parameters and constants used by the model.

Far-Field Density

(for example, ρ_0 in [Equation 15–1](#) in the [Theory Guide](#)) is the far-field fluid density.

Far-Field Sound Speed

(for example, a_0 in [Equation 15–1](#)) is the sound speed in the far field ($= \sqrt{\gamma R T_0}$).

Free Stream Velocity and Free Stream Direction

are required when the convective effects are taken into account. They become available in the interface when **Convective Effects** is enabled.

Important

The use of **Convective Effects** with the proper **Free Stream Velocity** and **Free Stream Direction** is strongly recommended for all cases dealing with external flows around bodies.

Reference Acoustic Pressure

(for example, p_{ref} in [Equation 32–39 \(p. 1630\)](#)) is used to calculate the sound pressure level in dB (see [Using the FFT Utility \(p. 1626\)](#)). The default reference acoustic pressure is 2×10^{-5} Pa.

Number of Time Steps Per Revolution

is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of equivalent time steps that it will take for the rotating zone to complete one revolution.

Number of Revolutions

is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of revolutions that will be simulated in the model.

Source Correlation Length

is required when sound is to be computed using a 2D flow result. The FW-H integrals will be evaluated over this length in the depth-wise direction using the identical source data (see [Figure 24.2 \(p. 1061\)](#)).

The default values are appropriate for sound propagating in air at atmospheric pressure and temperature.

24.2.1.2. Computing Sound “on the Fly”

The FW-H acoustics model in ANSYS FLUENT allows you to perform simultaneous calculation of the sound pressure signals at the prescribed receivers without having to write the source data to files, which can save a significant amount of disk space on your machine. To enable this “on-the-fly” calculation of sound, enable the **Compute Acoustic Signals Simultaneously** option in the **Acoustics Model** dialog box.

Important

Because the noise computation takes a negligible percentage of memory and computational time compared to a transient flow calculation, this option can be used by itself or along with the process of source data file export and sound calculation. For the latter, computing signals “on the fly” allows you to see when the signals have become statistically steady so you can know when to stop the simulation.

When the **Compute Acoustic Signals Simultaneously** option is enabled, the ANSYS FLUENT console window will print a message at the end of each time step indicating that the sound pressure signals have been computed (e.g., Computing sound signals at x receiver locations..., where x is the number of receivers you specified). Enabling this option instructs ANSYS FLUENT to compute sound pressure signals at the end of each time step, which will slightly increase the computation time.

Important

Note that this option is available only when the FW-H acoustics model has been enabled. See below for details about exporting source data without enabling the FW-H model.

24.2.1.3. Writing Source Data Files

Although the “on-the-fly” capability is a convenient feature, you will want to save the source data as well, because the acquisition of source data during a transient flow-field calculation is the most time-consuming part of acoustics computations, and you most likely will not want to discard it. By saving

the source data, you can always reuse it to compute the sound pressure signals at new or additional receiver locations.

To save the source data to files, enable either the **Export Acoustic Source Data in ASD Format** or the **Export Acoustic Source Data in CGNS Format** option, or both. After you have made your selection, the relevant source data at all face elements of the selected source surfaces will be written into the files you specify. The source data vary depending on the solver option you have chosen and whether the source surface is a wall or not. *Table 24.1: Source Data Saved in Source Data Files* (p. 1061) shows the flow variables saved as the source data.

Figure 24.2 The Acoustics Model Dialog Box for a 2D Steady-State Case with a Single Moving Reference Frame

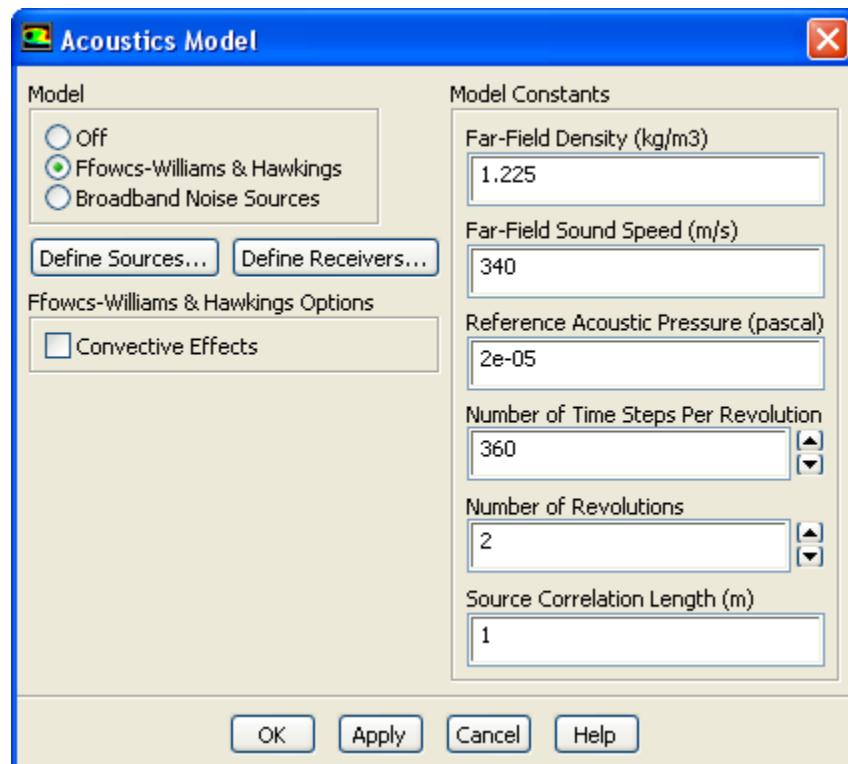

Table 24.1 Source Data Saved in Source Data Files

Solver Option	Source Surface	Source Data
incom-compressible	walls	p
incom-compressible	permeable surfaces	p, u, v, w
compressible	walls	p
compressible	permeable surfaces	ρ, p, u, v, w

See *Specifying Source Surfaces* (p. 1063) for details on how to specify parameters for exporting source data.

24.2.1.3.1. Exporting Source Data Without Enabling the FW-H Model: Using the ANSYS FLUENT ASD Format

You can export sound source data for use with SYSNOISE without having to enable the Ffowcs-Williams and Hawkins (FW-H) model. You will still need to specify source surfaces (see [Specifying Source Surfaces \(p. 1063\)](#)), as .index and .asd files are required by SYSNOISE. In addition, you can choose fluid zones as emission sources if you want to export quadrupole sources. To enable the selection of fluid zones as sources, use the

```
define → models → acoustics → export-volumetric-sources?
```

text command and change the selection to yes.

SYSNOISE also requires centroid data for source zones that are being exported.

For fan noise calculations, once you have specified the source zones in the **Acoustic Sources** dialog box and you have selected **Export Acoustic Source Data in ASD Format** from the **Acoustics Model** dialog box, you can export geometry in cylindrical coordinates by using the

```
define → models → acoustics → cylindrical-export?
```

text command and changing the selection to yes. By default, ANSYS FLUENT exports source zones for SYSNOISE in Cartesian coordinates.

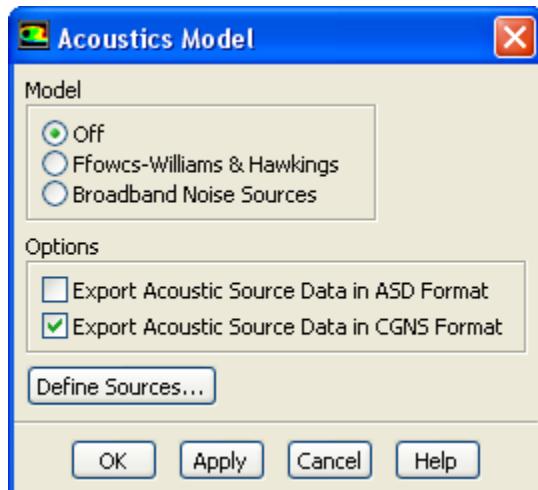

You can then export the centroid data to a data file using the following text command:

```
define → models → acoustics → write-centroid-info
```

Since you will not be using the FW-H model to compute signals, you will not need to specify any acoustic model parameters or receiver locations. Also, you will not be able to enable the **Compute Acoustic Signals Simultaneously** option in the **Acoustics Model** dialog box, and **Acoustic Signals...** will not be available in the **Run Calculation** task page.

24.2.1.3.2. Exporting Source Data Without Enabling the FW-H Model: Using the CGNS Format

The sound source data for non-permeable surfaces can be exported in the CGNS file format (for Virtual Lab) without having to enable the Ffowcs-Williams and Hawkins (FW-H) model. Enable the **Export Acoustic Source Data in CGNS Format** option in the **Acoustics Model** dialog box ([Figure 24.3 \(p. 1063\)](#)). Specify the source surfaces in the **Acoustics Sources** dialog box (see [Specifying Source Surfaces \(p. 1063\)](#)) where, by default, the **Number of Time Steps per File** is set to 1.

Figure 24.3 The Acoustics Model Dialog Box for Exporting in CGNS Format

Virtual Lab requires a mesh data file (named `<prefix>_mesh.cgns`) and a solution data file (named `<prefix>_<timestep>.cgns`). The string `<prefix>` is a generic name, which you will specify in the **Source Data Root File Name** in the **Acoustics Sources** dialog box. There is one single solution data file (.cgns) per time level exported, which contains the static pressure at the wall-face centroid location. The.cgns files will be stored in a directory, which you specify (named `<directory_name>/<prefix>`) in the **Source Data Root File Name**.

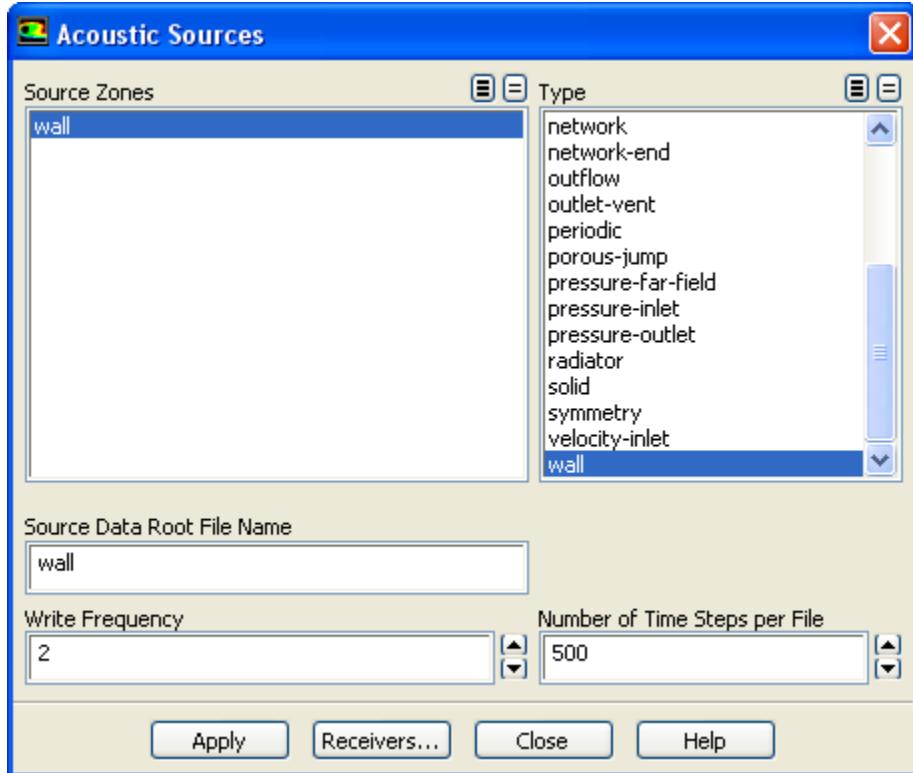

In addition, you can export quadrupole sources data by choosing fluid zones as emission sources. To enable the selection of fluid zones as sources, use the text command:

```
define → models → acoustics → export-volumetric-sources-cgns?
```

When asked if you would like to `Export volumetric sources?` enter `yes`. Note that Virtual Lab requires volumetric mesh data file (`<prefix>_Q_mesh.cgns`) and quadrupole solution data files (`<prefix>_Q_<timestep>.cgns`). The .cgns file will be stored in a similar way to that of dipole data export, in the directory specified by you in the **Source Data Root File Name** text entry box.

24.2.2. Specifying Source Surfaces

In the **Acoustics Model** dialog box, click the **Define Sources...** button to open the **Acoustic Sources** dialog box (Figure 24.4 (p. 1064)). Here you will specify the source surface(s) to be used in the acoustics calculation and the inputs associated with saving source data to files.

Figure 24.4 The Acoustic Sources Dialog Box

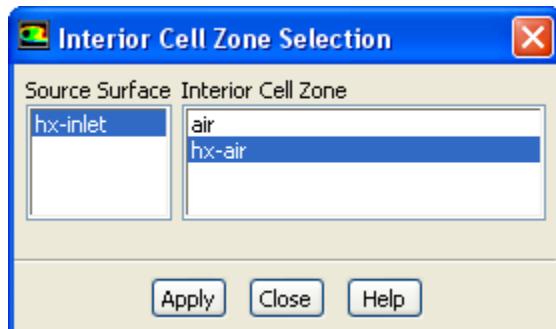

Under **Source Zones**, you can select multiple emission (source) surfaces and the surface **Type** that you can select is *not* limited to a **wall**. You can also choose **interior** surfaces and sliding interfaces (both stationary and rotating) as source surfaces.

Important

The ability to choose multiple source surfaces is useful for investigating the contributions from individual source surfaces. The results based on the use of multiple source surfaces are valid as long as there are negligible acoustic interactions among the surfaces. Thus, some caution needs to be taken when selecting multiple source surfaces.

In cases where multiple source surfaces are selected, no source surface may enclose any of the other source surfaces. Otherwise, the sound pressure calculated based on the source surfaces will not be accurate, as the contribution from the enclosed (inner) source surfaces is over predicted, since the FW-H model is unable to account for the shading of the sound from the inner source surfaces by the enclosure surface.

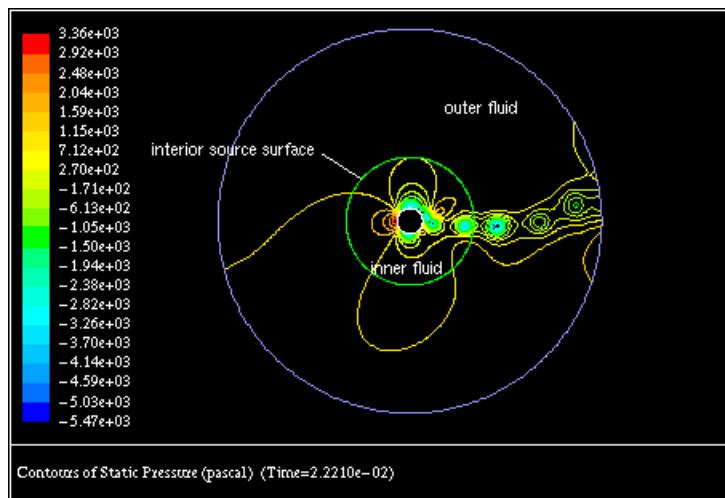

If you specify any interior surfaces as source surfaces, the interior surface must be generated in advance (e.g., in GAMBIT) in such a way that the two cell zones adjacent to the surface have different cell zone IDs. Furthermore, you must correctly specify which of the two zones is occupied by the quadrupole sources (interior cell zone). This will allow ANSYS FLUENT to determine the direction in which the sound will propagate. When you first attempt to select a legitimate interior surface (i.e., an interior surface having two different cell zones on both sides) as a source surface, the *Interior Cell Zone Selection Dialog Box* (p. 1875) (*Figure 24.5* (p. 1065)) will appear. You will then need to select the interior cell zones from the two zones listed under the **Interior Cell Zone**. *Figure 24.6* (p. 1065) shows an example of an interior source surface.

Figure 24.5 The Interior Cell Zone Selection Dialog Box

Like general interior surfaces, if the source surfaces selected are sliding interfaces, a dialog box similar to [Figure 24.5 \(p. 1065\)](#) will appear that will show the two adjacent cell zones and you will be asked to specify the zone which has the sound sources.

Important

When a permeable surface (either interior or sliding interface) is chosen as the source surface, other wall surfaces inside the volume enclosed by the permeable surface that generate sound should not be chosen for the acoustics calculation. For example, when running an "on-the-fly" calculation, if both these surfaces are selected, the sound pressure will be counted twice.

Figure 24.6 An Interior Source Surface

24.2.2.1. Saving Source Data

To save the source data, you have to specify the **Source Data Root File Name**, **Write Frequency** (in number of time steps), and **Number of Time Steps per File** in the **Acoustic Sources** dialog box.

The **Source Data Root File Name** is used to give the names of the source data files (e.g., acoustic_examplexxxx.asd, where xxxx is the global time-step index of the transient solution) and an index file (e.g., acoustic_example.index) that will store the information associated with the source data. The **Write Frequency** allows you to control how often the source data will be written. This will enable you to save disk space if the time-step size used in the transient flow simulation is smaller than necessary.

to resolve the sound frequency you are attempting to predict. In most situations, however, you will want to save the source data at every time step and use the default value of 1.

Since acoustics calculations usually generate thousands of time steps of source data, you may want to split the data into several files. Specifying the **Number of Time Steps per File** allows you to write the source data into separate files for different simulation intervals, the duration of which (in terms of the number of transient flow time steps) is specified by you. For example, if you specify 100 for this parameter, each file will contain source data for an interval length of 100 time steps regardless of the write frequency.

You will find this feature useful if you want to use a selected number of source data files to compute the sound pressure rather than using all the data. For example, you may want to exclude an initial portion of the source data from your acoustics calculation because you may realize later that the flow field has not fully attained a statistically steady state.

After you click **Apply**, ANSYS FLUENT will create the index file (e.g., `acoustics_example.index`), which contains information about the source data.

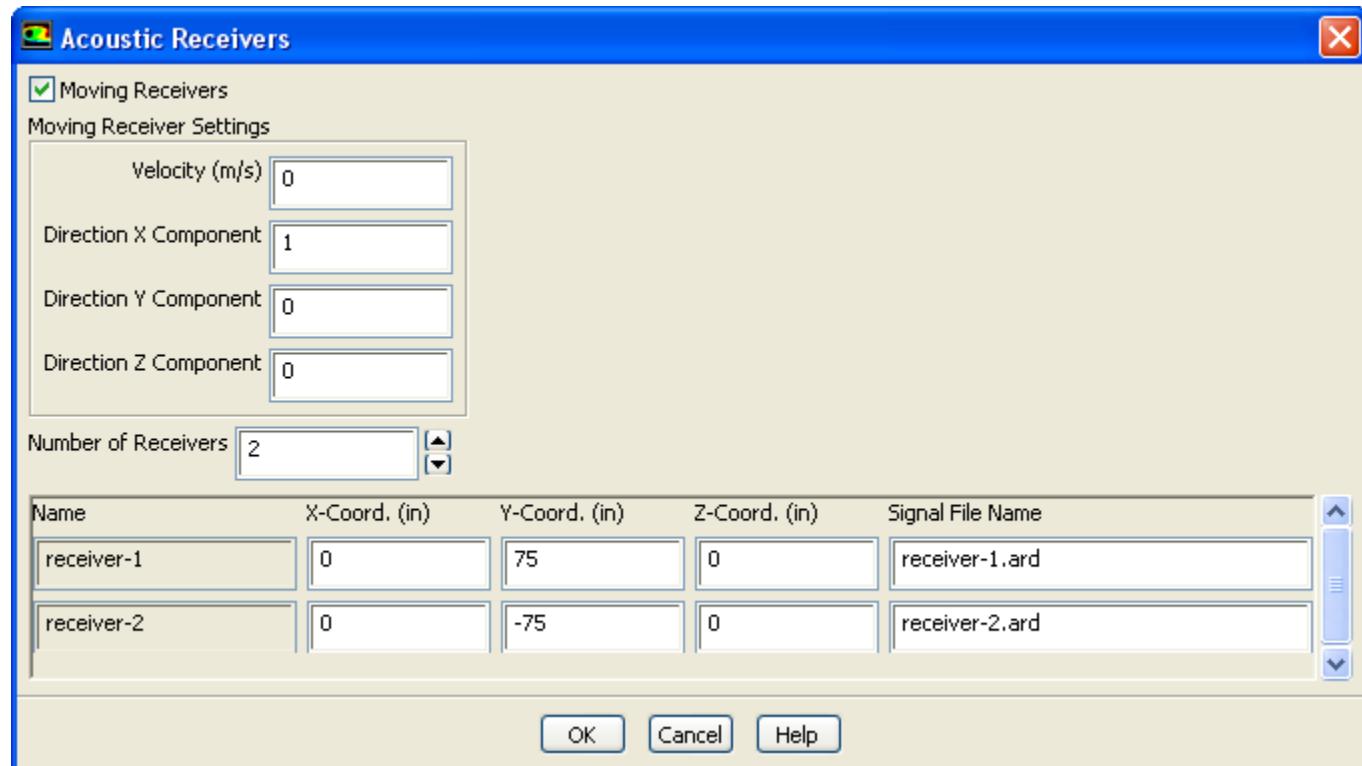

Important

If you choose to save source data, keep in mind that the source data can use up a considerable amount of disk space, especially if the mesh being used has a large number of face elements on the source surfaces you selected. ANSYS FLUENT will print out the disk space requirement per time step at the time of source surface selection if the **Export Acoustic Source Data in ASD Format** option is enabled in the **Acoustics Model** dialog box.

At this point, if you have chosen to perform your acoustics calculation in two steps, (i.e., saving the source data first, and computing the sound at a later time), you can go ahead and instruct ANSYS FLUENT to perform a suitable number of time steps, and the source data will be saved to the disk. If you have chosen to perform an “on-the-fly” acoustic calculation, then you will need to specify receiver locations (see [Specifying Acoustic Receivers \(p. 1066\)](#)) before you run the unsteady ANSYS FLUENT solution any further.

24.2.3. Specifying Acoustic Receivers

In the **Acoustics Model** dialog box, click the **Define Receivers...** button to open the **Acoustic Receivers** dialog box ([Figure 24.7 \(p. 1067\)](#)).

Figure 24.7 The Acoustic Receivers Dialog Box**Important**

Note that you can also open the **Acoustic Receivers** dialog box by clicking the **Receivers...** button in the **Acoustic Sources** or the **Acoustic Signals** dialog box.

If required, you can enable **Moving Receivers** to specify the receiver motion. In this case, the defined **Velocity** magnitude and **Direction** apply to all receivers. The receiver locations, defined below, are then interpreted as the starting locations at the time that sound emission originates. The origination of sound emission is determined as follows:

- For “on the Fly” use of the FW-H model (see *Computing Sound “on the Fly”* (p. 1060)) the sound emission time is counted from the physical time of activation of the **Compute Acoustic Signals Simultaneously** option (see *Figure 24.1* (p. 1059)).
- When the FW-H model reads the previously written acoustic source data (see *Reading Unsteady Acoustic Source Data* (p. 1070)), the sound emission time starts from the physical time associated with the first selected source data file.

Important

When using moving receivers, please note that if you start from a different source data file, this results in different receiver locations due to the different emission time origin associated with the different source data file.

Increase the **Number of Receivers** to the total number of receivers for which you want to compute sound, and enter the coordinates for each receiver in the **X-Coord.**, **Y-Coord.**, and **Z-Coord.** fields. Note that because ANSYS FLUENT’s acoustics model is ideally suited for far-field noise prediction, the receiver

locations you define should be at a reasonable distance from the sources of sound (i.e., the selected source surfaces). The receiver locations can also fall outside of the computational domain.

For each receiver, you can specify a file name in the **Signal File Name** field. These files will be used to store the sound pressure signals at the corresponding receivers. By default, the files will be named `receiver-1.ard`, `receiver-2.ard`, etc.

Once the receiver locations have been defined, the setup for your acoustic calculation is complete.

24.2.4. Specifying the Time Step

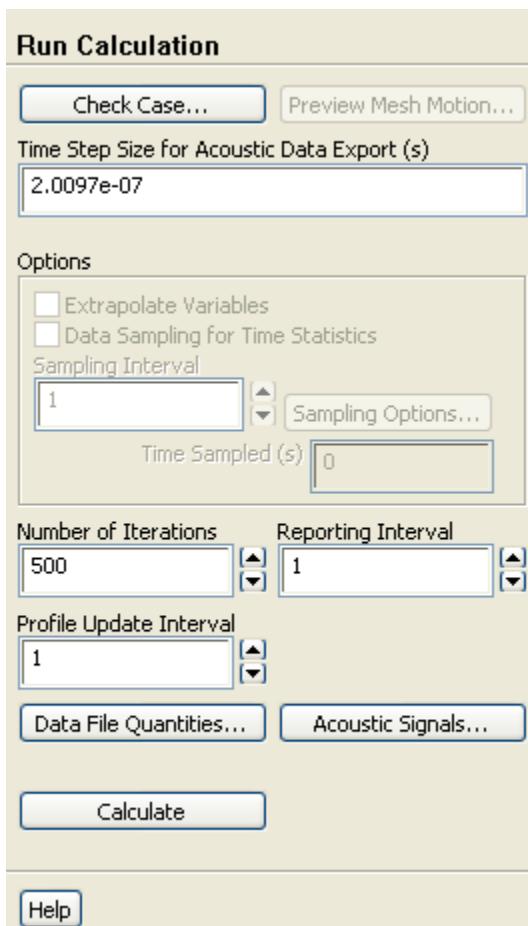

When using an implicit-in-time solution algorithm (dual-time stepping), and depending on the physical time step size and the most important time scales in the flow, you can write the acoustic source data at every time step. You can also coarsen it in time by a given frequency factor. The highest possible frequency the acoustic analysis can generate is based on the time step size of the collected acoustic source data.

When using the **Density-Based** explicit solver, with the **Explicit Transient Formulation** selected in the **Solution Methods** task page, the physical time step must be computed by the solver, based on the CFL condition (Courant number). Due to the possibly large fluctuations of the physical time step, an adapting time-stepping procedure can be used when the FW-H acoustics model is enabled. This allows you to use a user-specified time interval for sampling the acoustic data. In turn, the solver adapts its time step, when necessary, without violating the CFL conditions to make sure that data is available at the desired time interval (hence, avoiding data interpolations).

In the **Run Calculation** task page ([Figure 24.8 \(p. 1069\)](#)), enter the **Time Step Size for Acoustic Data Export** to specify the time interval for acoustic data sampling. The value of this constant time step size determines the highest frequency that the acoustic analysis reproduces.

You can refer to [Performing Time-Dependent Calculations \(p. 1365\)](#) for more information about the **Run Calculation** task page.

Figure 24.8 The Run Calculation Task Page

You can now proceed to instruct ANSYS FLUENT to perform a transient calculation for a suitable number of time steps. When the calculation is finished, you will have either the source data saved on files (if you chose to save it to a file or files), or the sound pressure signals (if you chose to perform an acoustic calculation “on the fly”), or both (if you chose to save the source data to files *and* if you chose to perform the acoustic calculation “on the fly”).

If you chose to save the source data to files, the ANSYS FLUENT console window will print a message at the end of each time step indicating that source data have been written (or appended to) a file (e.g., `acoustic_example240.asd`).

24.2.5. Postprocessing the FW-H Acoustics Model Data

At this point, you will have either the source data saved to files or the sound pressure signals computed, or both. You can process these data to compute and plot various acoustic quantities using ANSYS FLUENT’s FFT capabilities. See [Fast Fourier Transform \(FFT\) Postprocessing \(p. 1623\)](#) for more information.

24.2.5.1. Writing Acoustic Signals

If you chose to perform the acoustic calculation “on the fly”, you will need to write the sound pressure data to files. To do so, select **Write Acoustic Signals** under **Options** in the **Acoustic Signals** dialog box ([Figure 24.9 \(p. 1070\)](#)) and then click **Write**. The computed acoustic pressure will be saved from internal buffer memory into a separate file for each receiver you defined in the **Acoustic Receivers** dialog box (e.g., `receiver-1.ard`).

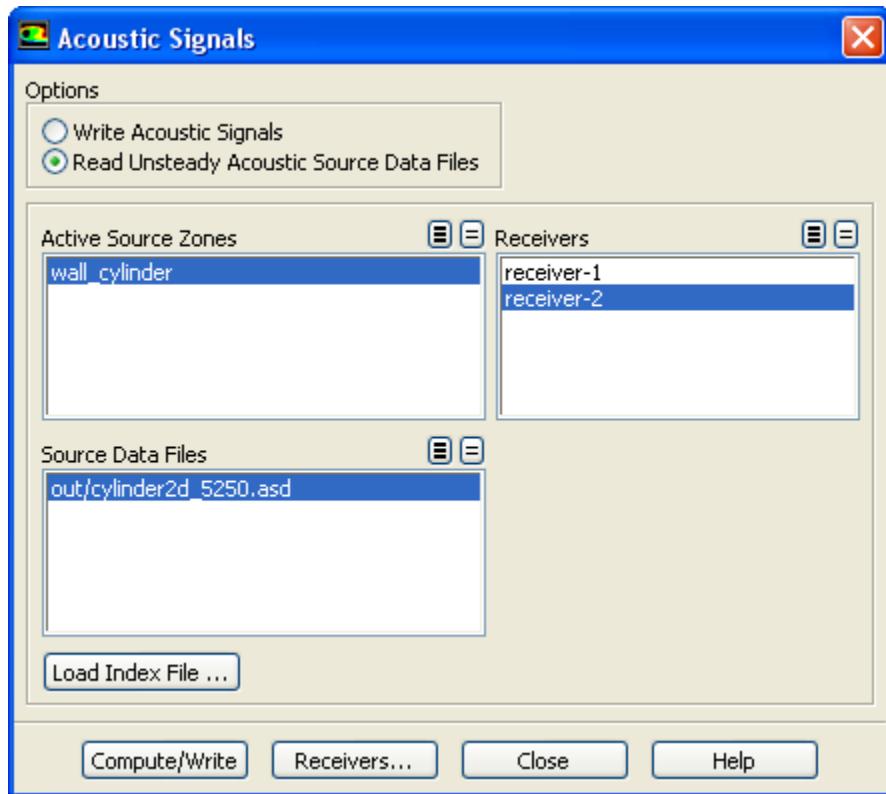

Run Calculation → Acoustic Signals...

24.2.5.2. Reading Unsteady Acoustic Source Data

Computing the sound pressure signals using the source data saved to files is done in the **Acoustic Signals** dialog box (*Figure 24.9 (p. 1070)*)

Run Calculation → Acoustic Signals...

Figure 24.9 The Acoustic Signals Dialog Box

To compute the sound data, use the following procedure:

1. In the **Acoustic Signals** dialog box, select **Read Unsteady Acoustic Source Data Files** under Options.
2. Click **Load Index File...** and select the index file for your computation in the **Select File** dialog box. The file will have the name you entered in the **Source Data Root File Name** field in the **Acoustic Sources** dialog box, followed by the .index suffix (e.g., acoustic_example.index).
3. In the **Source Data Files** list, select the source data files that you want to use to compute sound. Source data files will all contain the specified root file name followed by the suffix .asd.

Important

You can use any number of source data files. However, note that you should select only consecutive files.

4. In the **Active Source Zones** list, select the source zones you want to include to compute sound. See [Specifying Source Surfaces \(p. 1063\)](#) for details about proper source surface selection.
 5. In the **Receivers** list, select the receivers for which you want to compute and save sound.
- Optionally, you can click the **Receivers...** button to open the **Acoustic Receivers** dialog box and define additional receivers.
6. Click the **Compute/Write** button to compute and save the sound pressure data. One file will be saved for each receiver you previously specified in the **Acoustic Receivers** dialog box (e.g., receiver-1.ard).

Important

If you enabled both the **Export Acoustic Source Data in ASD Format** and **Compute Acoustic Signals Simultaneously** options in the **Acoustics Model** dialog box, you will need to first select the **Write Acoustic Signals** option in the **Acoustic Signals** dialog box after the flow simulation has been completed. If you select the **Read Unsteady Acoustic Source Data Files** before writing out the “on-the-fly” data in such a case, the data will be flushed out of the internal buffer memory. To avoid such a loss of data, you should save the ANSYS FLUENT case and data files whenever you begin to do an acoustic computation in the **Acoustic Signals** dialog box. The sound pressure data calculated “on the fly” will then be saved into the .dat file. Finally, after the “on-the-fly” data is saved, make sure to change the file names of the receivers before doing a sound pressure calculation with the **Read Unsteady Acoustic Source Data Files** option enabled, to avoid overwriting the “on-the-fly” signal files.

Important

Note that you can compute and write sound pressure signals only when the FW-H acoustics model has been enabled. See [Exporting Source Data Without Enabling the FW-H Model: Using the ANSYS FLUENT ASD Format \(p. 1062\)](#) for details about exporting source data (e.g., for SYS-NOISE) without enabling the FW-H model.

24.2.5.2.1. Pruning the Signal Data Automatically

Before the computed sound pressure data at each receiver is saved, it is by default automatically pruned. Pruning of the receiver data means clipping the tails of the signal where incomplete source information is available.

The acoustic source data is tabulated from time τ_0 to τ_n . Without auto-pruning, the receiver register begins receiving the earliest sound pressure signal at

$$t_0 = \tau_0 + \frac{r_{min}}{a_0} \quad (24-1)$$

where r_{min} is the shortest distance between the source surfaces and the receiver. However, the receiver will not receive the sound pressure signal from the farthest point on the source surfaces (r_{max}) until the receiver time becomes

$$t_l = \tau_0 + \frac{r_{max}}{a_0} \quad (24-2)$$

From time t_0 to t_l , the sound accumulated on the receiver register does not include the contribution from the entire source surface area, and thus the sound pressure data received during that time is not complete. The same thing occurs during the period from

$$t_m = \tau_m + \frac{r_{min}}{a_0} \quad (24-3)$$

to

$$t_n = \tau_n + \frac{r_{max}}{a_0} \quad (24-4)$$

Thus, pruning means clipping the signal on the incomplete ends, from t_0 to t_l and t_m to t_n . Auto-pruning can be disabled using the `define → models → acoustics → auto-prune` text command. Although auto-pruning can be disabled, it is expected that you will use only the complete sound pressure data.

24.2.5.3. Reporting the Static Pressure Time Derivative

The RMS value of the static pressure time derivative ($\partial p / \partial t$) is available for postprocessing only on wall surfaces, which are at the same time sources of sound, when the FW-H acoustics model is used.

You can select **Surface dpdt RMS** in the **Acoustics...** category only when you specify at least one wall surface, which is also marked as an acoustic source, in the relevant postprocessing dialog boxes.

24.2.5.4. Using the FFT Capabilities

Once the sound pressure signals are computed and saved in files, the sound data is ready to be analyzed using ANSYS FLUENT's FFT tools. In the **Fourier Transform** dialog box (*Figure 32.95 (p. 1627)*), click on **Load Input File...** and select the appropriate .ard file. If the receiver data is still in ANSYS FLUENT's memory, then it can directly be processed using the **Process Receiver** option. See *Fast Fourier Transform (FFT) Postprocessing (p. 1623)* for more information on ANSYS FLUENT's FFT capabilities.

Plots → **FFT** → **Set Up...**

24.3. Using the Broadband Noise Source Models

In this section, the procedure for setting up and using the broadband noise source models is outlined first, followed by descriptions of each of the steps involved.

The general procedure for carrying out a broadband noise source calculation in ANSYS FLUENT is as follows:

1. Calculate a steady or unsteady RANS solution.
2. Enable the broadband noise model and set the associated model parameters.

◆ **Models** → ◆ **Acoustics** → **Edit...**

3. Postprocess the noise sources.

◆ **Graphics and Animations** → ◆ **Contours** → **Set Up...**

For additional information, please see the following sections:

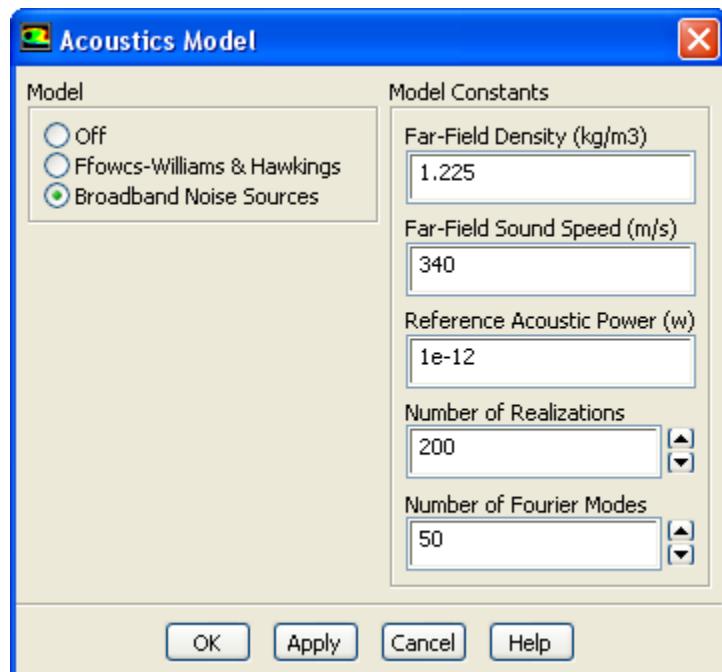

- 24.3.1. Enabling the Broadband Noise Source Models
- 24.3.2. Postprocessing the Broadband Noise Source Model Data

24.3.1. Enabling the Broadband Noise Source Models

To enable the broadband noise sources models, select **Broadband Noise Sources** in the **Acoustics Model** dialog box (*Figure 24.10* (p. 1073)).

◆ **Models** → ◆ **Acoustics** → **Edit...**

Figure 24.10 The Acoustics Model Dialog Box for Broadband Noise

24.3.1.1. Setting Model Constants

Under **Model Constants** in the **Acoustics Model** dialog box, specify the relevant acoustic parameters and constants used by the model. See *Enabling the FW-H Acoustics Model* (p. 1058) for the definitions of **Far-Field Density** and **Far-Field Sound Speed**.

Reference Acoustic Power

(for example, P_{ref} in *Equation 15–14* in the Theory Guide) is used to compute the acoustic power outputs in decibels (dB). The default value is 10^{-12} . Note that the units for the reference acoustic power will be different in 2D (W/m^2) and 3D (W/m^3) cases.

Number of Realizations

is the number of samples used in the SNGR to compute the averaged source terms of LEE and Lilley's equations. The default value is 200.

Number of Fourier Modes

(N in [Equation 15–34](#) in the [Theory Guide](#)) is the number of the Fourier modes used to compute the turbulent velocity field and its derivatives. The turbulent velocity field is then used to compute the LEE and Lilley's source terms. The default value is 50.

24.3.2. Postprocessing the Broadband Noise Source Model Data

The final step in the broadband noise source modeling process is the postprocessing of acoustic power and noise source data. The following variables are available in the **Acoustics...** postprocessing category:

- **Acoustic Power Level (dB)**
- **Acoustic Power**
- **Jet Acoustic Power Level (dB)** (axisymmetric models only)
- **Jet Acoustic Power** (axisymmetric models only)
- **Surface Acoustic Power Level (dB)**
- **Surface Acoustic Power**
- **Lilley's Self-Noise Source**
- **Lilley's Shear-Noise Source**
- **Lilley's Total Noise Source**
- **LEE Self-Noise X-Source**
- **LEE Shear-Noise X-Source**
- **LEE Total Noise X-Source**
- **LEE Self-Noise Y-Source**
- **LEE Shear-Noise Y-Source**
- **LEE Total Noise Y-Source**
- **LEE Self-Noise Z-Source** (3D models only)
- **LEE Shear-Noise Z-Source** (3D models only)
- **LEE Total Noise Z-Source** (3D models only)

Chapter 25: Modeling Discrete Phase

This chapter describes how to use the Lagrangian discrete phase capabilities available in ANSYS FLUENT. For information about the theory behind the discrete phase models, see "Discrete Phase" in the [Theory Guide](#). Information is organized into the following sections:

- 25.1. Introduction
- 25.2. Steps for Using the Discrete Phase Models
- 25.3. Setting Initial Conditions for the Discrete Phase
- 25.4. Setting Boundary Conditions for the Discrete Phase
- 25.5. Setting Material Properties for the Discrete Phase
- 25.6. Solution Strategies for the Discrete Phase
- 25.7. Postprocessing for the Discrete Phase
- 25.8. Parallel Processing for the Discrete Phase Model

25.1. Introduction

In addition to solving transport equations for the continuous phase, ANSYS FLUENT allows you to simulate a discrete second phase in a Lagrangian frame of reference. This second phase consists of spherical particles (which may be taken to represent droplets or bubbles) dispersed in the continuous phase. ANSYS FLUENT computes the trajectories of these discrete phase entities, as well as heat and mass transfer to/from them. The coupling between the phases and its impact on both the discrete phase trajectories and the continuous phase flow can be included.

ANSYS FLUENT provides the following discrete phase modeling options:

- calculation of the discrete phase trajectory using a Lagrangian formulation that includes the discrete phase inertia, hydrodynamic drag, and the force of gravity, for both steady and unsteady flows
- prediction of the effects of turbulence on the dispersion of particles due to turbulent eddies present in the continuous phase
- heating/cooling of the discrete phase
- vaporization and boiling of liquid droplets
- combusting particles, including volatile evolution and char combustion to simulate coal combustion
- optional coupling of the continuous phase flow field prediction to the discrete phase calculations
- droplet breakup and coalescence
- consideration of particle/particle collisions and voidage of discrete phase

These modeling capabilities allow ANSYS FLUENT to simulate a wide range of discrete phase problems including particle separation and classification, spray drying, aerosol dispersion, bubble stirring of liquids, liquid fuel combustion, and coal combustion. The physical equations used for these discrete phase calculations are described in [Particle Motion Theory – Laws for Heat and Mass Exchange](#) in the [Theory Guide](#), and instructions for setup, solution, and postprocessing are provided in [Steps for Using the Discrete Phase Models \(p. 1077\)](#) – [Postprocessing for the Discrete Phase \(p. 1142\)](#).

For additional information, please see the following sections:

- 25.1.1. Overview

25.1.2. Limitations

25.1.1. Overview

Currently, there are three approaches for the numerical calculation of multiphase flows: the Euler-Lagrange approach (discussed in [Introduction in the Theory Guide](#)), the Euler-Euler approach (discussed in [Approaches to Multiphase Modeling](#)), and the Dense Discrete Phase Model which is a hybrid Euler-Euler and Euler-Lagrange approach (discussed in [Dense Discrete Phase Model](#) in the [Theory Guide](#)).

25.1.2. Limitations

25.1.2.1. Limitation on the Particle Volume Fraction

The discrete phase formulation used by ANSYS FLUENT contains the assumption that the second phase is sufficiently dilute that particle-particle interactions and the effects of the particle volume fraction on the gas phase are negligible. In practice, these issues imply that the discrete phase must be present at a fairly low volume fraction, usually less than 10–12%. Note that the mass loading of the discrete phase may greatly exceed 10–12%: you may solve problems in which the mass flow of the discrete phase equals or exceeds that of the continuous phase. See [Modeling Multiphase Flows \(p. 1173\)](#) for information about when you might want to use one of the general multiphase models instead of the discrete phase model.

25.1.2.2. Limitation on Modeling Continuous Suspensions of Particles

The steady-particle Lagrangian discrete phase model is suited for flows in which particle streams are injected into a continuous phase flow with a well-defined entrance and exit condition. The Lagrangian model does not effectively model flows in which particles are suspended indefinitely in the continuum, as occurs in solid suspensions within closed systems such as stirred tanks, mixing vessels, or fluidized beds. The unsteady-particle discrete phase model, however, is capable of modeling continuous suspensions of particles. See [Modeling Multiphase Flows \(p. 1173\)](#) for information about when you might want to use one of the general multiphase models instead of the discrete phase models.

25.1.2.3. Limitations on Using the Discrete Phase Model with Other ANSYS FLUENT Models

The following restrictions exist on the use of other models with the discrete phase model:

- When tracking particles in parallel, the DPM model cannot be used with any of the multiphase flow models (VOF, mixture, or Eulerian – see [Modeling Multiphase Flows \(p. 1173\)](#)) if the shared memory option is enabled ([Parallel Processing for the Discrete Phase Model \(p. 1168\)](#)). (Note that using the message passing or hybrid option, when running in parallel, enables the compatibility of all multiphase flow models with the DPM model.)
- When using the DPM model with the Eulerian multiphase model, the tracked particles rely only on the primary phase to compute drag, heat, and mass transfer. Also, any DPM related source terms are applied to the primary phase. Particle tracking relative to a secondary phase is not provided.
- Streamwise periodic flow (either specified mass flow rate or specified pressure drop) cannot be modeled with steady particle tracks in coupled simulation. It is possible using transient particle tracks.
- Only nonreacting particles can be included when the premixed combustion model is used.
- Surface injections will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used, however only those surfaces associated with a boundary will be recalculated. Injections from cut plane surfaces will not be moved with the mesh and will be deleted when remeshing occurs.

- The cloud model is not available for unsteady particle tracking, or in parallel, when using the message passing or hybrid option for the particles.
- The wall-film model is only valid for liquid materials. If a nonliquid particle interacts with a wall-film boundary, the boundary condition will default to the reflect boundary condition.
- When multiple reference frames are used in conjunction with the discrete phase model, the display of particle tracks will not, by default, be meaningful. Similarly, coupled discrete-phase calculations are not meaningful.

An alternative approach for particle tracking and coupled discrete-phase calculations with multiple reference frames is to track particles based on absolute velocity instead of relative velocity. To make this change, use the `define/models/dpm/ options/track-in-absolute-frame` text command. Note that the results may strongly depend on the location of walls inside the multiple reference frame.

The particle injection velocities (specified in the **Set Injection Properties** dialog box) are defined relative to the frame of reference in which the particles are tracked. By default, the injection velocities are specified relative to the local reference frame. If you enable the `track-in-absolute-frame` option, the injection velocities are specified relative to the absolute frame.

- Relative particle tracking cannot be used in combination with sliding and moving deforming meshes. If sliding and/or deforming meshes are used with the DPM model, the particles will always be tracked in the absolute frame. Switching to the relative frame is not permitted.
- Boundedness of planes is not considered during sampling of particle tracks, which means that all particle tracks crossing the unbounded plane are sampled.

25.2. Steps for Using the Discrete Phase Models

You can include a discrete phase in your ANSYS FLUENT model by defining the initial position, velocity, size, and temperature of individual particles. These initial conditions, along with your inputs defining the physical properties of the discrete phase, are used to initiate trajectory and heat/mass transfer calculations. The trajectory and heat/mass transfer calculations are based on the force balance on the particle and on the convective/radiative heat and mass transfer from the particle, using the local continuous phase conditions as the particle moves through the flow. The predicted trajectories and the associated heat and mass transfer can be viewed graphically and/or alphanumerically.

The procedure for setting up and solving a problem involving a discrete phase is outlined below, and described in detail in [Options for Interaction with the Continuous Phase \(p. 1078\)](#) – [Postprocessing for the Discrete Phase \(p. 1142\)](#). Only the steps related specifically to discrete phase modeling are shown here. For information about inputs related to other models that you are using in conjunction with the discrete phase models, see the appropriate sections for those models.

1. Enable any of the discrete phase modeling options, if relevant, as described in [Options for Interaction with the Continuous Phase \(p. 1078\)](#).
2. Choose a transient or steady treatment of particles as described in [Steady/Transient Treatment of Particles \(p. 1078\)](#).
3. Specify tracking parameters and select a drag law as described in [Tracking Parameters for the Discrete Phase Model \(p. 1080\)](#).
4. Enable the required physical submodels for the discrete phase model, as described in [Physical Models for the Discrete Phase Model \(p. 1083\)](#).
5. Set the numerics parameters and solve the problem, as described in [Numerics of the Discrete Phase Model \(p. 1092\)](#) and [Solution Strategies for the Discrete Phase \(p. 1138\)](#).

6. Specify the initial conditions and particle size distributions in injections, as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#).
7. Define the boundary conditions, as described in [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#).
8. Define the material properties, as described in [Setting Material Properties for the Discrete Phase \(p. 1128\)](#).
9. Initialize the flow field.
10. Solve the coupled or uncoupled flow ([Solution Strategies for the Discrete Phase \(p. 1138\)](#)).
11. For transient cases, advance the solution in time by taking the desired number of time steps. Particle positions will be updated as the solution advances in time. If you are solving an uncoupled flow, the particle position will be updated at the end of each time step. For a coupled calculation, the positions are iterated on or within each time step.
12. Examine the results, as described in [Postprocessing for the Discrete Phase \(p. 1142\)](#).

25.2.1. Options for Interaction with the Continuous Phase

If the discrete phase interacts (i.e., exchanges mass, momentum, and/or energy) with the continuous phase, you should enable the **Interaction with Continuous Phase** option in the **Discrete Phase Model** dialog box ([Figure 25.1 \(p. 1081\)](#)).

Models → Discrete Phase → Edit...

An input for the **Number of Continuous Phase Iterations per DPM Iteration** will appear, which allows you to control the frequency at which the particles are tracked and the DPM sources are updated.

For steady-state simulations, increasing the **Number of Continuous Phase Iterations per DPM Iteration** will increase stability but require more iterations to converge.

In addition, another option exists which allows you to control the numerical treatment of the source terms and how they are applied to the continuous phase equations. **Update DPM Sources Every Flow Iteration** is recommended when doing unsteady simulations; at every DPM Iteration, the particle source terms are recalculated. The source terms applied to the continuous phase equations transition to the new values every flow iteration based on [Equation 16–328](#) to [Equation 16–330](#) in the [Theory Guide](#). This process is controlled by the under-relaxation factor, specified in the **Solution Controls** task page, see [Under-Relaxation of the Interphase Exchange Terms \(p. 1141\)](#).

25.2.2. Steady/Transient Treatment of Particles

The Discrete Phase Model utilizes a Lagrangian approach to derive the equations for the underlying physics which are solved transiently. Transient numerical procedures in the Discrete Phase Model can be applied to resolve steady flow simulations as well as transient flows.

In the [Discrete Phase Model Dialog Box \(p. 1859\)](#) you have the option of choosing whether you want to treat the particles in an unsteady or a steady fashion. This option can be chosen independent of the settings for the solver. Thus, you can perform steady state trajectory simulations even when selecting a transient solver for numerical reasons. You can also specify unsteady particle tracking when solving the steady continuous phase equations. This can be used to improve numerical stability for very large particle source terms or simply for postprocessing purposes. Whenever you enable a breakup or collision model to simulate sprays, the **Unsteady Particle Tracking** will be switched on automatically.

When **Unsteady Particle Tracking** is enabled, several new options appear. If steady state equations are solved for the continuous phase, you simply enter the **Particle Time Step Size** and the **Number**

of Time Steps, thus tracking particles every time a DPM iteration is conducted. When you increase the **Number of Time Steps**, the droplets penetrate the domain faster.

When solving unsteady equations for the continuous phase, you must decide whether you want to use **Fluid Flow Time Step** to inject the particles, or whether you prefer a **Particle Time Step Size** independent of the **Fluid Flow Time Step**. With the latter option, you can use the Discrete Phase Model in combination with changes in the time step for the continuous equations, as it is done when using adaptive flow time stepping.

If you do not use **Fluid Flow Time Step**, you will need to decide when to inject the particles for a new time step. You can either **Inject Particles at Particle Time Step** or at the **Fluid Flow Time Step**. In any case, the particles will always be tracked in such a way that they coincide with the flow time of the continuous flow solver.

You can use a user-defined function (`DEFINE_DPM_TIMESTEP`) to change the time step for DPM particle tracking. The time step can be prescribed for special applications where a certain time step is needed. For more information about changing the time step size for DPM particle tracking, see [DEFINE_DPM_TIMESTEP](#) in the [UDF Manual](#).

Important

When the density-based solver is used with the explicit unsteady formulation, the particles are advanced once per time step and are calculated at the start of the time step (before the flow is updated).

Additional inputs are required for each injection in the [Set Injection Properties Dialog Box \(p. 2255\)](#), as detailed in [Defining Injection Properties \(p. 1114\)](#). For **Unsteady Particle Tracking**, the injection **Start Time** and **Stop Time** must be specified under **Point Properties**. Injections with start and stop times set to zero will be injected only at the start of the calculation ($t = 0$). If the In-Cylinder mesh motion is enabled, the start and stop times are replaced by **Start Crank Angle** and **Stop Crank Angle**, respectively. The injection specified in this way will be repeated at the starting and stopping crank angle if the simulation is run through more than one cycle. Changing injection settings during a transient simulation will not affect particles currently released in the domain. At any point during a simulation, you can clear particles that are currently in the domain by clicking the **Clear Particles** button in the [Discrete Phase Model Dialog Box \(p. 1859\)](#).

For transient simulations, several methods can be chosen to control when the particles are advanced.

- If the **Number of Continuous Phase Iterations per DPM Iteration** is less than the number of iterations specified to converge the continuous phase between time steps, then sub-iterations are done. Here, particles are tracked to their new positions during a time step and DPM sources are updated; particles are then returned to their original state at the beginning of the time step. At the end of the time step, particles are advanced to their new positions based on the continuous-phase solution.
- If the **Number of Continuous Phase Iterations per DPM Iteration** is larger than the number of iterations specified to converge the continuous phase between time steps, the particles are advanced at the beginning of the time step to compute the particle source terms.
- When you specify a value of zero as the **Number of Continuous Phase Iterations per DPM Iteration**, the particles are advanced at the end of the time step. For this option, it may be better if the particle source terms are not reset at the beginning of the time step. This can be done with the TUI command `define/models/dpm/interaction/reset-sources-at-timestep?`.

In all the above cases, you must provide a sufficient number of particle source term updates to better control when the particles are advanced, see [Figure 25.30](#) (p. 1142).

Important

In steady-state discrete phase modeling, particles do not interact with each other and are tracked one at a time in the domain.

Important

If the collision model is used, you will not be able to set the **Number of Continuous Phase Iterations per DPM Iteration**. Refer to [Collision and Droplet Coalescence Model Theory](#) in the [Theory Guide](#) for details about this limitation.

25.2.3. Tracking Parameters for the Discrete Phase Model

You will use two parameters to control the time integration of the particle trajectory equations:

- the maximum number of time steps

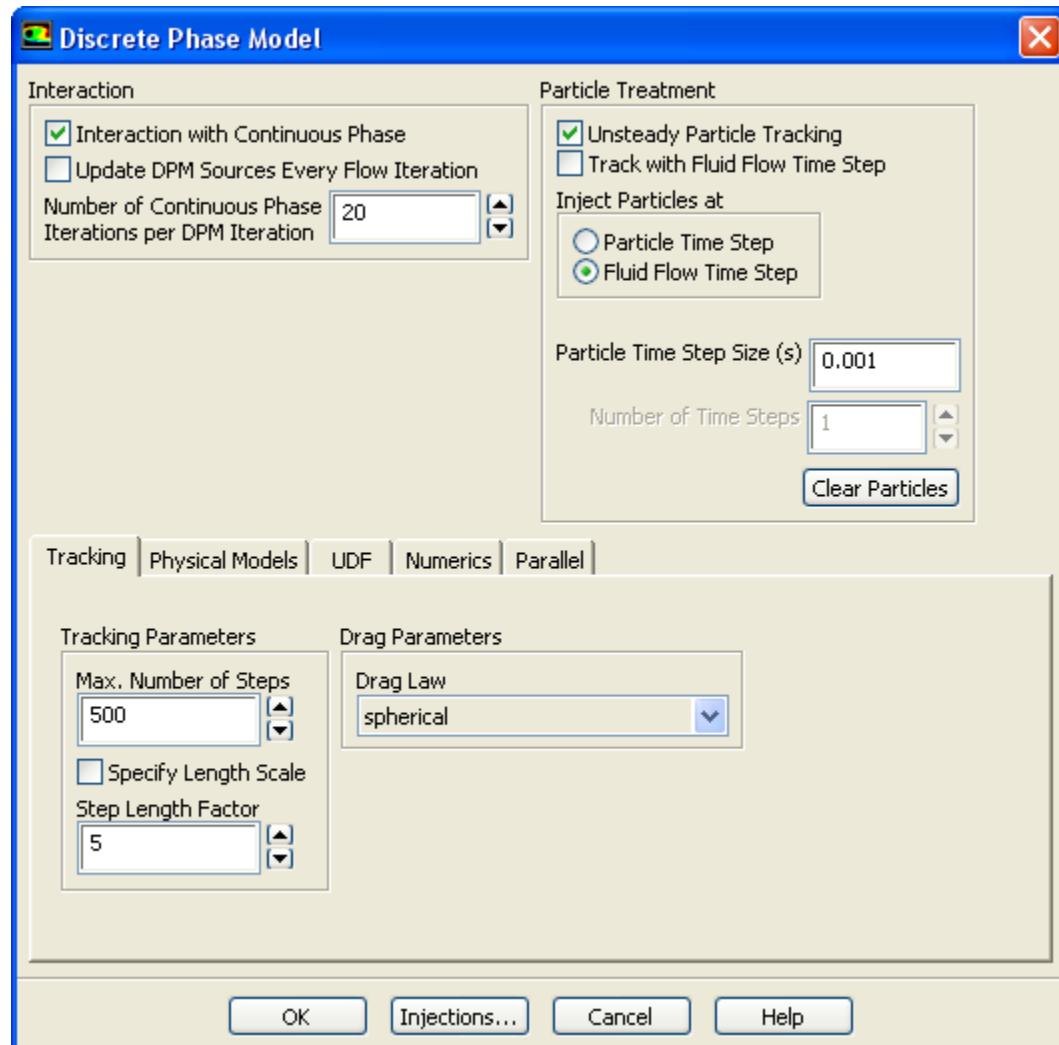

This factor is used to abort trajectory calculations when the particle never exits the flow domain.

- the length scale/step length factor

This factor is used to set the time step for integration within each control volume.

Each of these parameters is set in the [Discrete Phase Model Dialog Box](#) (p. 1859) ([Figure 25.1](#) (p. 1081)) under **Tracking Parameters** in the **Tracking** tab.

 **Models** →  **Discrete Phase** → **Edit...**

Figure 25.1 The Discrete Phase Model Dialog Box and the Tracking Parameters

Max. Number of Steps

is the maximum number of time steps used to compute a single particle trajectory via integration of [Equation 16-1](#) in the [Theory Guide](#). When the maximum number of steps is exceeded, ANSYS FLUENT abandons the trajectory calculation for the current particle injection and reports the trajectory fate as "incomplete". The limit on the number of integration time steps eliminates the possibility of a particle being caught in a recirculating region of the continuous phase flow field and being tracked indefinitely. Note that you may easily create problems in which the default value of 500 time steps is insufficient for completion of the trajectory calculation. In this case, when trajectories are reported as incomplete within the domain and the particles are not recirculating indefinitely, you can increase the maximum number of steps (up to a limit of 10^9).

Length Scale

controls the integration time step size used to integrate the equations of motion for the particle. The integration time step is computed by ANSYS FLUENT based on a specified length scale L , and the velocity of the particle (u_p) and of the continuous phase (u_c):

$$\Delta t = \frac{L}{u_p + u_c} \quad (25-1)$$

where L is the **Length Scale** that you define. As defined by [Equation 25–1 \(p. 1082\)](#), L is proportional to the integration time step and is equivalent to the distance that the particle will travel before its motion equations are solved again and its trajectory is updated. A smaller value for the **Length Scale** increases the accuracy of the trajectory and heat/mass transfer calculations for the discrete phase.

(Note that particle positions are always computed when particles enter/leave a cell; even if you specify a very large length scale, the time step used for integration will be such that the cell is traversed in one step.)

Length Scale will appear in the **Discrete Phase Model** dialog box when the **Specify Length Scale** option is enabled.

Step Length Factor

also controls the time step size used to integrate the equations of motion for the particle. It differs from the **Length Scale** in that it allows ANSYS FLUENT to compute the time step in terms of the number of time steps required for a particle to traverse a computational cell. To set this parameter instead of the **Length Scale**, turn off the **Specify Length Scale** option.

The integration time step is computed by ANSYS FLUENT based on a characteristic time that is related to an estimate of the time required for the particle to traverse the current continuous phase control volume. If this estimated transit time is defined as Δt^* , ANSYS FLUENT chooses a time step Δt as

$$\Delta t = \frac{\Delta t^*}{\lambda} \quad (25-2)$$

where λ is the **Step Length Factor**. As defined by [Equation 25–2 \(p. 1082\)](#), λ is inversely proportional to the integration time step and is roughly equivalent to the number of time steps required to traverse the current continuous phase control volume. A larger value for the **Step Length Factor** decreases the discrete phase integration time step. The default value for the **Step Length Factor** is 5. **Step Length Factor** will appear in the **Discrete Phase Model** dialog box when the **Specify Length Scale** option is off (the default setting).

One simple rule of thumb to follow when setting the parameters above is that if you want the particles to advance through a domain consisting of N mesh cells into the main flow direction, the **Step Length Factor** times N should be approximately equal to the **Max. Number of Steps**.

When **Accuracy Control** is activated in the **Numerics** tab, the settings for **Step Length Factor** and **Length Scale** will be used only to estimate the time step of the first integration step. In all subsequent integration steps, the particle integration time step is adapted to achieve the tolerance specified in [Numerics of the Discrete Phase Model \(p. 1092\)](#).

25.2.4. Drag Laws

There are eight drag laws for the particles that can be selected from the **Drag Law** drop-down list under **Drag Parameters**.

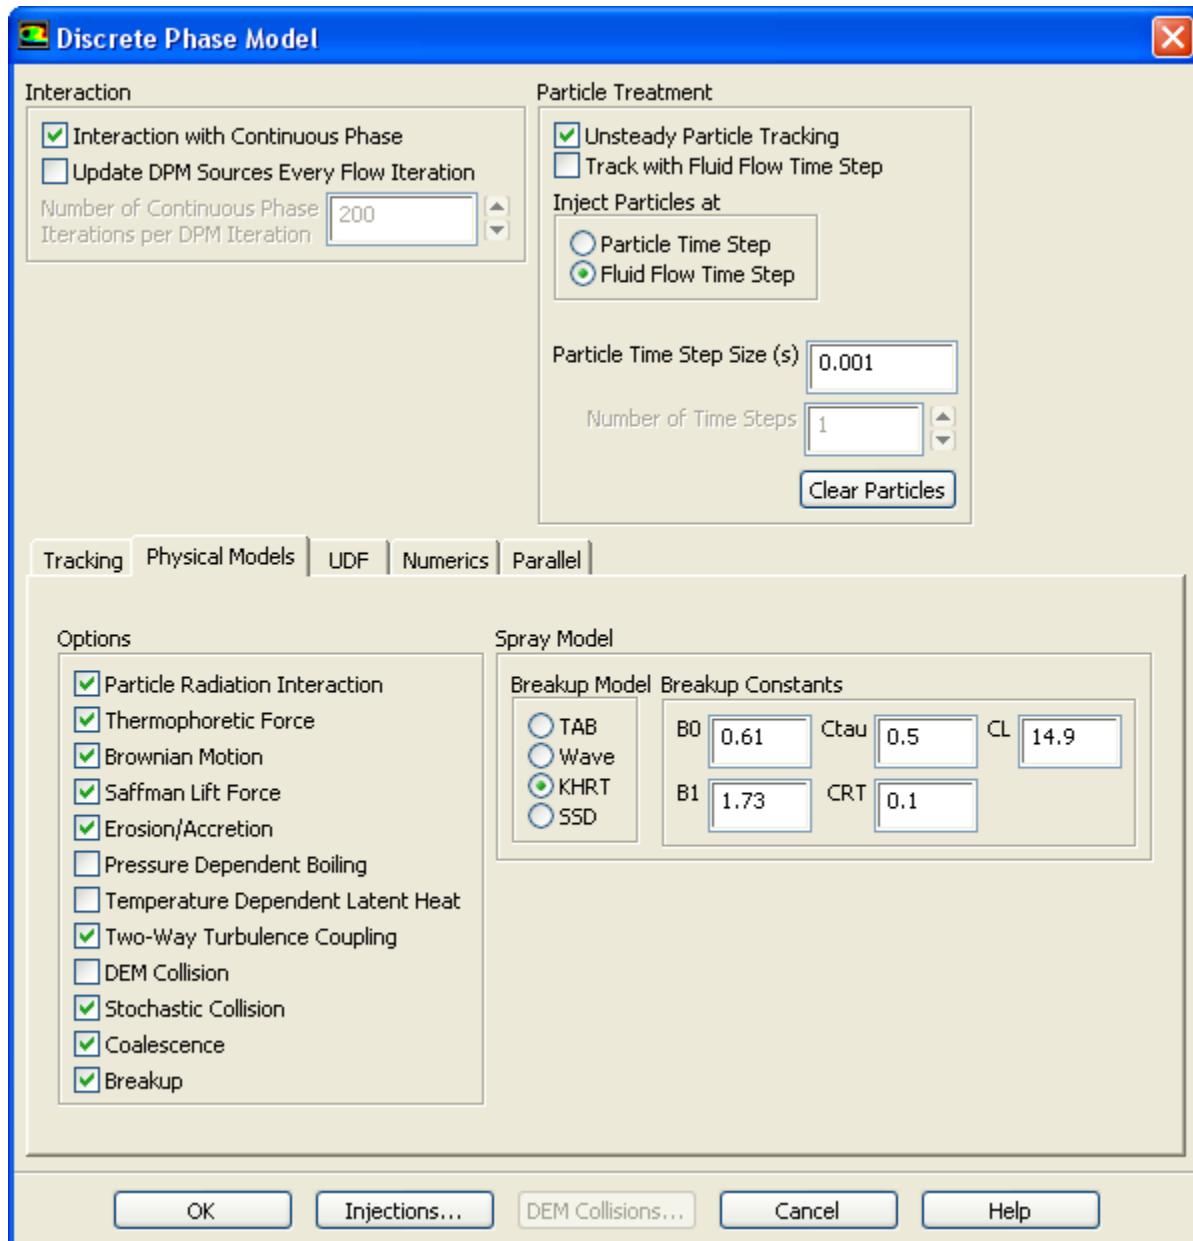

The **spherical**, **nonspherical**, **Stokes-Cunningham**, and **high-Mach-number** laws described in [Particle Force Balance](#) in the [Theory Guide](#) are always available, and the **dynamic-drag** law described in [Dynamic Drag Model Theory](#) in the [Theory Guide](#) is available only when one of the droplet breakup models is used in conjunction with unsteady tracking. See [Modeling Spray Breakup](#) (p. 1086) for information about enabling the droplet breakup models. The remaining three, **Wen-Yu**, **Gidaspow**, and **Syamlal-O'Brien** are available only when the dense discrete phase model is enabled ([Including the Dense Discrete Phase Model](#) (p. 1254)) and the flow regime consists of a dense gas-solid. However, with these models, you cannot verify whether it really is a dense flow or a gas-solid flow. It is up to you to decide. In any case, these drag formulations are suitable for dense gas-solid flows.

If the **spherical**, **high-Mach-number**, **dynamic-drag**, **Wen-Yu**, **Gidaspow**, or **Syamlal-O'Brien** drag law is selected, no further inputs are required. If the **nonspherical** law is selected, the particle **Shape Factor** (ϕ in [Equation 16-66](#) in the [Theory Guide](#)) must be specified. The shape factor value cannot exceed 1. For the **Stokes-Cunningham** law, the **Cunningham Correction** factor (C_c in [Equation 16-68](#) in the [Theory Guide](#)) must be specified.

25.2.5. Physical Models for the Discrete Phase Model

This section provides instructions for using the optional discrete phase models available in ANSYS FLUENT. All of them can be enabled in the **Physical Models** tab of the **Discrete Phase Model** dialog box ([Figure 25.2](#) (p. 1084)).

Models → Discrete Phase → Edit...

Figure 25.2 The Discrete Phase Model Dialog Box and the Physical Models

25.2.5.1. Including Radiation Heat Transfer Effects on the Particles

If you want to include the effect of radiation heat transfer to the particles (Equation 5–34 in the [Theory Guide](#)), you must enable the **Particle Radiation Interaction** option under the **Physical Models** tab, in the [Discrete Phase Model Dialog Box \(p. 1859\)](#) ([Figure 25.2 \(p. 1084\)](#)). You will also need to define additional properties for the particle materials (emissivity and scattering factor), as described in [Description of the Properties](#) (p. 1133). This option is available only when the P-1 or discrete ordinates radiation model is used.

25.2.5.2. Including Thermophoretic Force Effects on the Particles

If you want to include the effect of the thermophoretic force on the particle trajectories (Equation 16–8 in the [Theory Guide](#)), enable the **Thermophoretic Force** option under the **Physical Models** tab, in the

Discrete Phase Model Dialog Box (p. 1859). You will also need to define the thermophoretic coefficient for the particle material, as described in *Description of the Properties* (p. 1133).

25.2.5.3. Including Brownian Motion Effects on the Particles

For sub-micron particles in laminar flow, you may want to include the effects of Brownian motion (described in **Brownian Force** in the **Theory Guide**) on the particle trajectories. To do so, enable the **Brownian Motion** option under the **Physical Models** tab. When Brownian motion effects are included, it is recommended that you also select the **Stokes-Cunningham** drag law in the **Drag Law** drop-down list under **Drag Parameters**, and specify the **Cunningham Correction** (C_c in [Equation 16–68](#) in the **Theory Guide**).

25.2.5.4. Including Saffman Lift Force Effects on the Particles

For sub-micron particles, you can also model the lift due to shear (the Saffman lift force, described in **Saffman's Lift Force** in the **Theory Guide**) in the particle trajectory. To do this, enable the **Saffman Lift Force** option under the **Physical Models** tab, in the *Discrete Phase Model Dialog Box* (p. 1859).

25.2.5.5. Monitoring Erosion/Accretion of Particles at Walls

Particle erosion and accretion rates can be monitored at wall boundaries. These rate calculations can be enabled in the *Discrete Phase Model Dialog Box* (p. 1859) when the discrete phase is coupled with the continuous phase (i.e., when **Interaction with Continuous Phase** is selected). Enabling the **Erosion/Accretion** option will cause the erosion and accretion rates to be calculated at wall boundary faces when particle tracks are updated. You will also need to set the **Impact Angle Function** ($f(\alpha)$) in [Equation 16–211](#) in the **Theory Guide**, **Diameter Function** ($C(d_p)$) in [Equation 16–211](#), and **Velocity Exponent Function** ($b(v)$) in [Equation 16–211](#) in the **Wall** boundary conditions dialog box for each wall zone (as described in *Discrete Phase Boundary Condition Types* (p. 1126)).

25.2.5.6. Enabling Pressure Dependent Boiling

With this option you can modify the condition for switching from droplet vaporization (Law 2) to boiling (Law 3). By default ANSYS FLUENT will switch from the vaporization to the boiling law when the particle temperature has reached the boiling point defined for the droplet material ([Equation 16–95](#) in the **Theory Guide**). When the **Pressure Dependent Boiling** option is enabled, the switching condition will change to $P_{sat} > P$, where P_{sat} is the saturation vapor pressure at the droplet temperature and P is the domain pressure. If $P_{sat} < P$ while in the boiling law, the model will switch back to the vaporization law. If this option is enabled it is essential to enter the appropriate droplet saturation vapor pressure data to cover the complete pressure/temperature range in your model.

When **Pressure Dependent Boiling** is enabled, then the **Temperature Dependent Latent Heat** model automatically applies (see *Including the Effect of Droplet Temperature on Latent Heat* (p. 1086)).

Setting the **Pressure Dependent Boiling** option has no effect on the multicomponent particles, where switching from the vaporization to the boiling regime is always based on the component saturation vapor pressures (see *Multicomponent Particle Definition (Law 7)* in the **Theory Guide**). Finally, selection of the **Pressure Dependent Boiling** option is not available with the real-gas models, as the pressure dependence always applies. See *Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models* (p. 486) for more information.

25.2.5.7. Including the Effect of Droplet Temperature on Latent Heat

To include the droplet temperature effects on the latent heat as described in [Equation 16–91](#) in the [Theory Guide](#), enable **Temperature Dependent Latent Heat** under the **Physical Models** tab. If you enable this option you need to provide accurate temperature dependent specific heat data for both the droplet and the evaporating species materials.

25.2.5.8. Including the Effect of Particles on Turbulent Quantities

Particles can damp or produce turbulent eddies [\[57\]](#) ([p. 2370](#)). In ANSYS FLUENT, the work done by the turbulent eddies on the particles is subtracted from the turbulent kinetic energy using the formulation described in [\[22\]](#) ([p. 2368](#)) and [\[6\]](#) ([p. 2367](#)).

If you want to consider these effects in the chosen turbulence model, you can enable this using **Two-Way Turbulence Coupling**, under the **Physical Models** tab.

25.2.5.9. Including Collision and Droplet Coalescence

To include the effect of collisions, as described in [Collision and Droplet Coalescence Model Theory](#) in the [Theory Guide](#), select **Stochastic Collision** and **Coalescence** under **Options**.

Note

Coalescence will appear under **Options** after **Stochastic Collision** has been enabled.

25.2.5.10. Including the DEM Collision Model

The DEM collision model is suitable for simulating granular matter, where such simulations are characterized by a high volume fraction of particles, and the particle-particle interaction is important. See [Modeling Collision Using the DEM Model](#) ([p. 1088](#)) for details about using this model.

25.2.5.11. Including Droplet Breakup

To model droplet breakup in ANSYS FLUENT, select the appropriate breakup model as describe in [Modeling Spray Breakup](#) ([p. 1086](#)).

25.2.5.12. Options for Spray Modeling

Select the spray model by going to the **Physical Models** tab in **Discrete Phase Model** dialog box. Two spray models are available: **Droplet Collision** and **Droplet Breakup**.

25.2.5.12.1. Modeling Spray Breakup

To enable the modeling of spray breakup, select the **Breakup Model** under **Spray Model** and then select the desired model (**TAB**, **Wave**, **KHRT**, or **SSD**). A detailed description of these models can be found in [Secondary Breakup Model Theory](#) in the [Theory Guide](#).

- For the **TAB** model, you will need to specify the following values:
 - y_0 is the initial distortion at time equal to zero y_0 in [Equation 16–261](#) in the [Theory Guide](#). The default value ($y_0 = 0$) is recommended.

- The number of **Breakup Parcels** (under **Breakup Constants**), to split the droplet into several child parcels, as described in [Velocity of Child Droplets](#) in the [Theory Guide](#). The diameter of the child parcels is sampled from a Rosin-Rammler distribution. This can be switched off in the TUI with the command:

```
/define/models/dpm/spray-modeling/randomize-tab-diameters?
```

- For the **Wave** model, you will need to specify the following values:
 - **B0** is the constant B_0 in [Equation 16–290](#) in the [Theory Guide](#).
 - **B1** is the constant B_l in [Equation 16–292](#) in the [Theory Guide](#).

Note

You will generally not need to modify the value of **B0**, as the default value 0.61 is acceptable for nearly all cases. A value of 1.73 is recommended for **B1**.

- For the **KHRT** model, you will need to specify the following values:
 - **B0** is the constant B_0 in [Equation 16–290](#) in the [Theory Guide](#).
 - **B1** is the constant B_l in [Equation 16–292](#) in the [Theory Guide](#).
 - **Ctau** is the constant C_τ in [Equation 16–297](#) in the [Theory Guide](#).
 - **CRT** is the constant C_{RT} in [Equation 16–298](#) in the [Theory Guide](#).
 - **CL** is the constant C_L in [Equation 16–293](#) in the [Theory Guide](#).
- The constants **B0** and **B1** are the same as for the Wave model.
- For the **SSD** model, you will need to specify the following values:
 - **Critical We** is the critical Weber number in [Equation 16–299](#) in the [Theory Guide](#).
 - **Core B1** is B in [Equation 16–300](#) in the [Theory Guide](#).
 - **Target Np** is the number of droplets given to each child parcel, before scaling is used to give the correct overall mass.
 - **Xi** is $\langle \xi \rangle$ in [Equation 16–301](#) in the [Theory Guide](#).

Note

Xi is a negative value: $\exp(\text{Xi})$ is a typical factor by which daughter particles are smaller than the original parcel.

For steady-state simulations, you will also need to specify an appropriate **Particle Time Step Size** and the **Number of Time Steps** which will control the spray density. See [Options for Interaction with the Continuous Phase \(p. 1078\)](#) for more information.

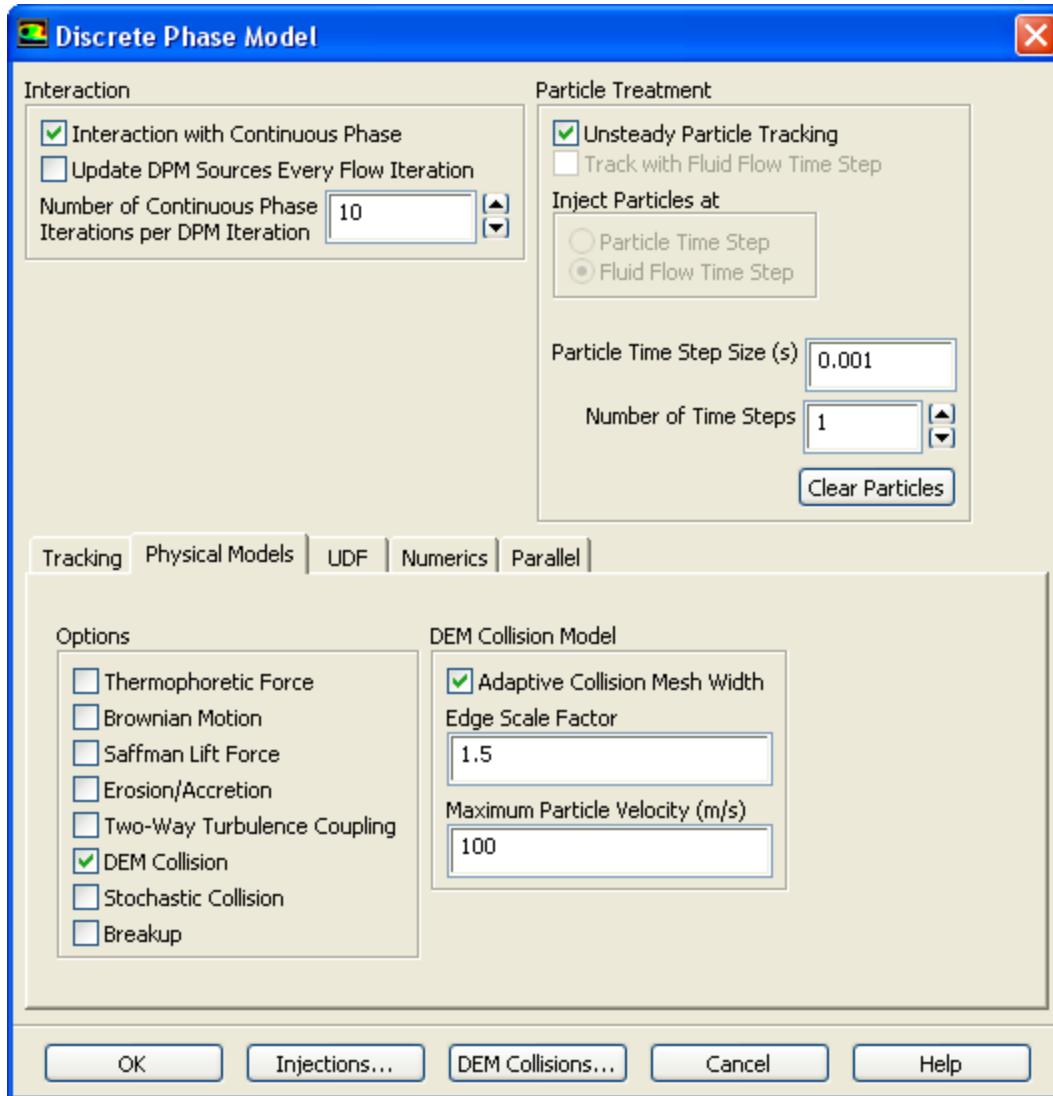

Note that you may want to use the dynamic drag law when you use one of the spray breakup models. See [Drag Laws \(p. 1082\)](#) for information about choosing the drag law.

25.2.5.13. Modeling Collision Using the DEM Model

To enable the DEM collision model, select **DEM Collision** under **Options**. A detailed description of this model can be found in **Discrete Element Method Collision Model** in the **Theory Guide**.

1. In the **Physical Models** tab of the **Discrete Phase Model** dialog box

Figure 25.3 Discrete Phase Dialog Box with DEM Collision Model

- a. Specify the settings your model requires under **DEM Collision Model**.
 - b. (Optional) By default, **Adaptive Collision Mesh Width** is enabled. This adjusts the width of the collision mesh to the largest parcel diameter multiplied by the **Edge Scale Factor**. If **Adaptive Collision Mesh Width** is disabled, a fixed **Static Collision Mesh Width** has to be given in the chosen units of length.
 - c. The **Maximum Particle Velocity** limits the maximum particle velocity to a physically plausible range.
2. Set up the injection.

Define → Injections...

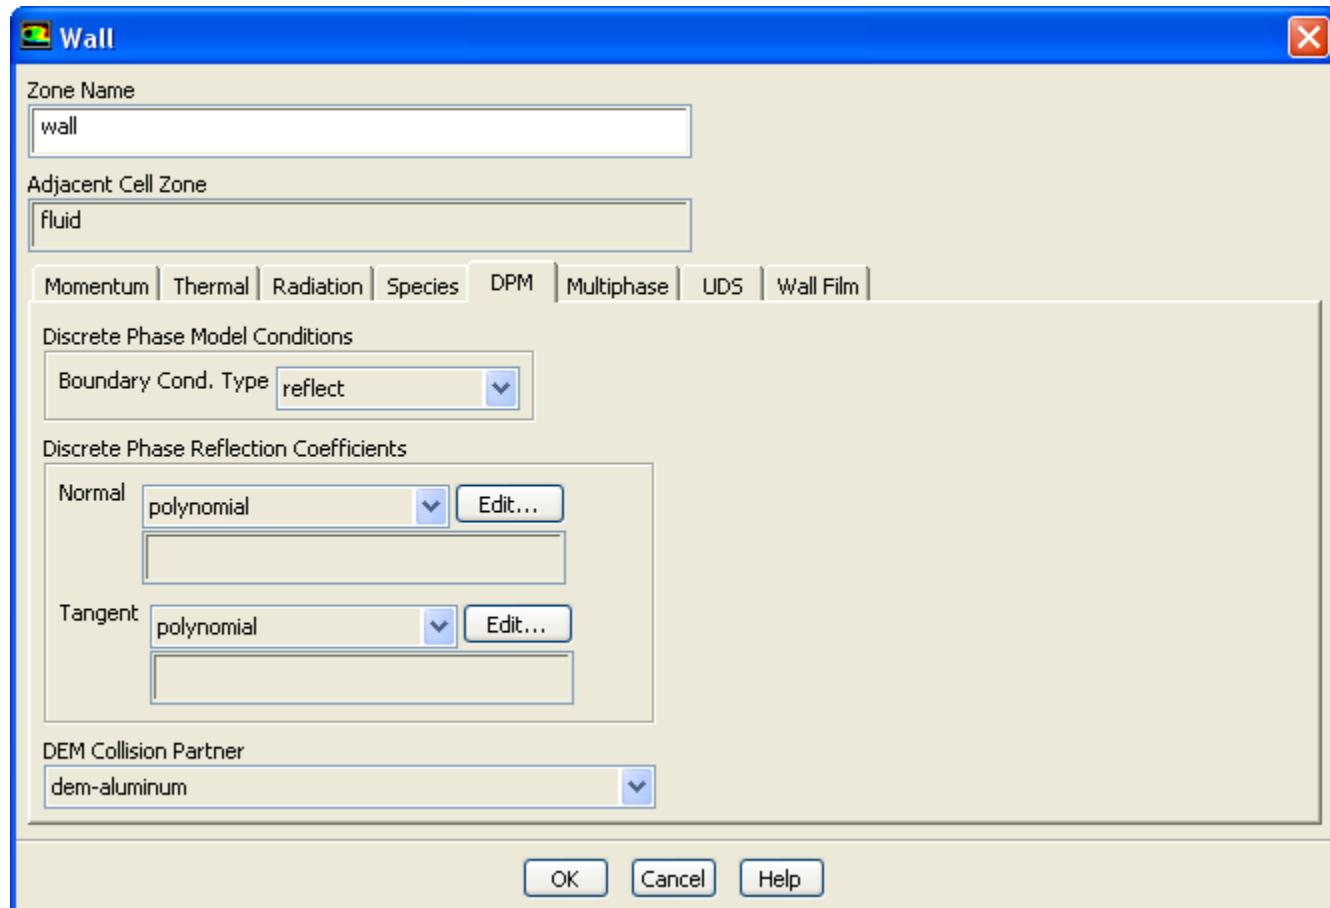

- a. In the **Set Injection Properties** dialog box, select a name from the **DEM Collision Partner** drop-down list that will serve as the collision partner. A default name using the particle material will be suggested.

Note

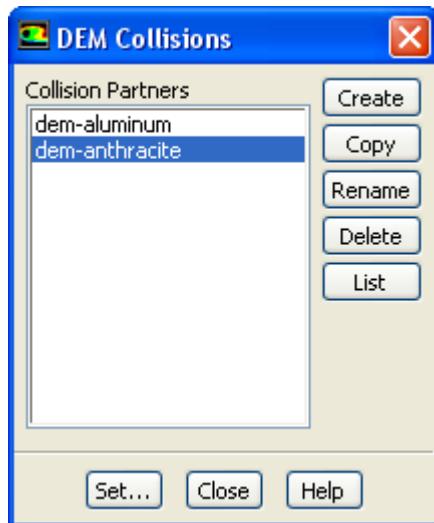

Selecting none from the drop-down list indicates that the particles released from this injection do not participate in the DEM collision computation.

3. Set the boundary conditions for the discrete phase as you normally would. If the **Boundary Cond. Type** is **reflect**, select a name from the **DEM Collision Partner** drop-down list to designate the collision partner. For example, in *Figure 25.4* (p. 1089), a wall boundary condition will suggest a wall material name, which will designate the collision partner. The name will have a **dem-** prefix. However, if the **DEM Collision Partner** is **none**, the wall will reflect particles like any other DPM particles using the settings for the **Discrete Phase Reflection Coefficients** in the **Normal** and **Tangent** directions. These settings generally apply for particles that are not colliding according to DEM, such as massless particles.

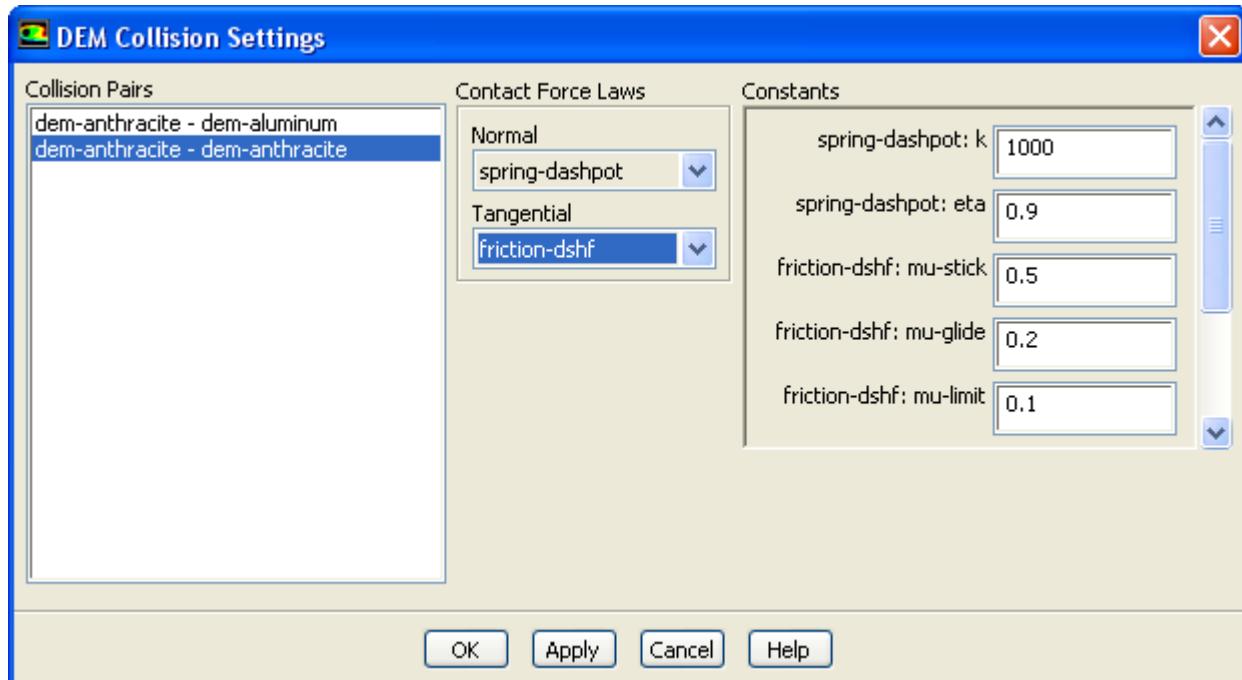

Figure 25.4 Wall Boundary Condition for the DEM Model

4. Define the particle interaction between the pairs of the collision partners.
 - a. Click the **DEM Collisions...** button at the bottom of the **Discrete Phase Model** dialog box. The **DEM Collisions** dialog box (*Figure 25.5* (p. 1090)) will appear where you can manage the collision partners. You can **Create**, **Copy**, **Rename**, **Delete**, and **List** collision partners. To define collision laws for a collision partner, select a collision partner from the **Collision Partners** list and click the **Set...** button, or simply double click the collision partner in the list.

Figure 25.5 Collision Dialog Box

- b. In the **DEM Collision Settings** dialog box (Figure 25.6 (p. 1090)), a list of all the possible **Collision Pairs** will exist.

Figure 25.6 DEM Collision Settings Dialog Box

- Select a pair of collision partners from the **Collision Pairs** list.
- For this pair, select the **Contact Force Laws** that best describe the collision between these two partners. The **Normal** contact force laws that exist are **spring** or **spring-dashpot**, but you can also choose to exclude the contact force law by selecting **none**. For the **Tangential** contact force law, if included, you can select **friction-dshf** as the friction collision law. Each of the laws is described in [The Spring Collision Law](#), [The Spring-Dashpot Collision Law](#), and [The Friction Collision Law](#) in the Theory Guide.
- Enter the **Constants** for the chosen **Contact Force Laws**. Please refer to [Theory](#) in the Theory Guide for guidance on how to find reasonable values of the force-law constants.

- iv. Repeat for all other collision pairs.
- v. Click **OK** or **Apply** to apply these settings.

Note

- The choice of collision laws does not depend on the order in the pair of collision partners.
- Failing to specify a force law for a collision pair implies that respective particles will not collide.

25.2.5.13.1. Limitations

The following limitations currently apply when using the DEM collision model:

- Axisymmetric geometry cannot be used.
- Periodic boundaries cannot be used.
- DEM particles do not rotate.
- DEM particles do not transfer heat from particle to particle during contact.

25.2.5.13.2. Numeric Recommendations

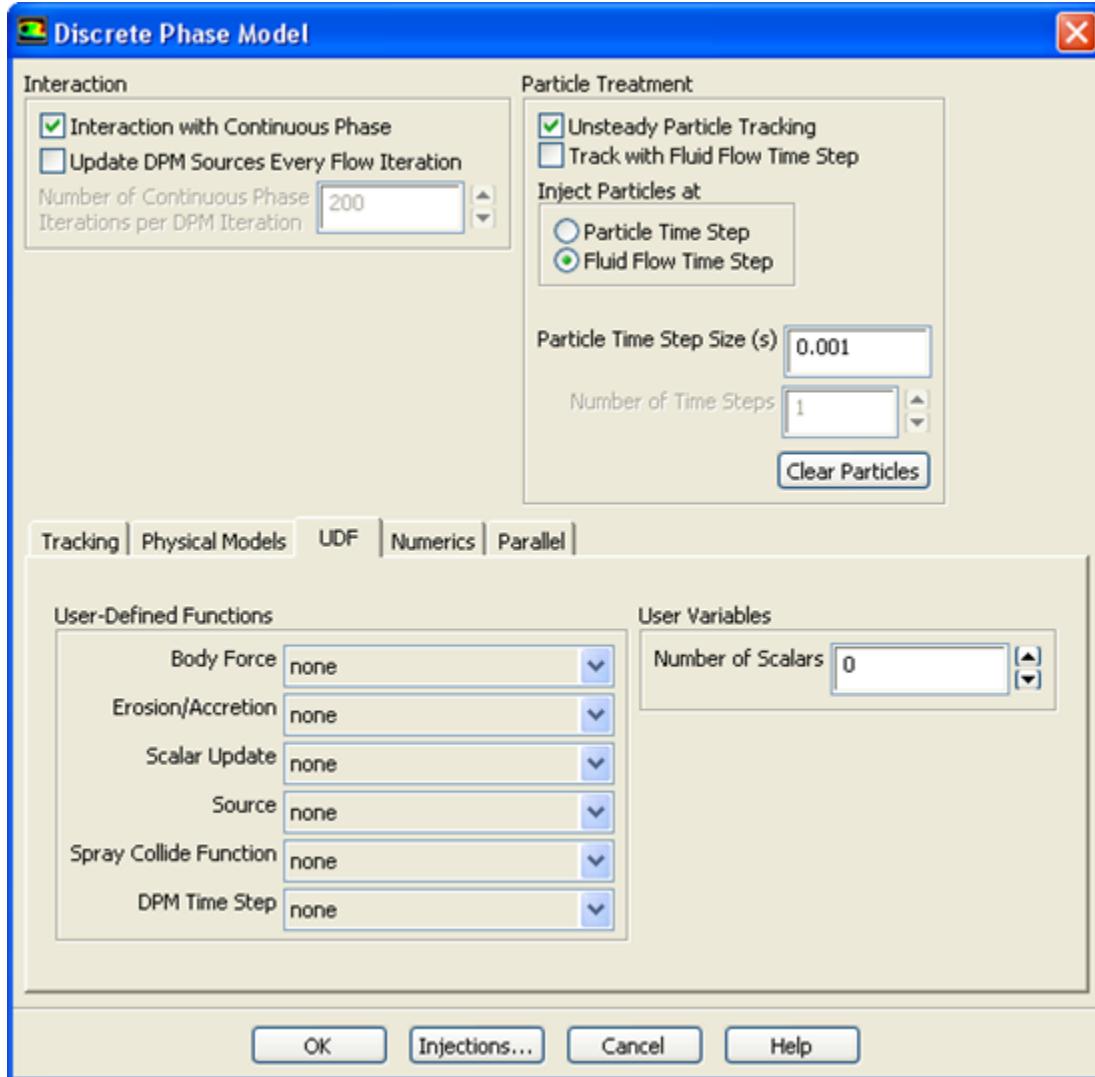

To better preserve energy during particle collision, the following settings need to be made in the **Numerics** tab in the **Discrete Phase Model** dialog box:

1. Disable **Accuracy Control** to ensure that DEM time stepping remains small.
2. Disable **Automated** under **Tracking Scheme Selection**.
3. Select **implicit** from the **Tracking Scheme** drop-down list.

Please refer to [Numerics for Tracking of the Particles \(p. 1093\)](#) for more information about the settings in the **Numerics** tab.

25.2.6. User-Defined Functions

User-defined functions can be used to customize the discrete phase model to include additional body forces, modify interphase exchange terms (sources), calculate or integrate scalar values along the particle trajectory, and incorporate nonstandard erosion rate definitions. More information about user-defined functions can be found in the [UDF Manual](#).

Figure 25.7 The Discrete Phase Model Dialog Box and the UDFs

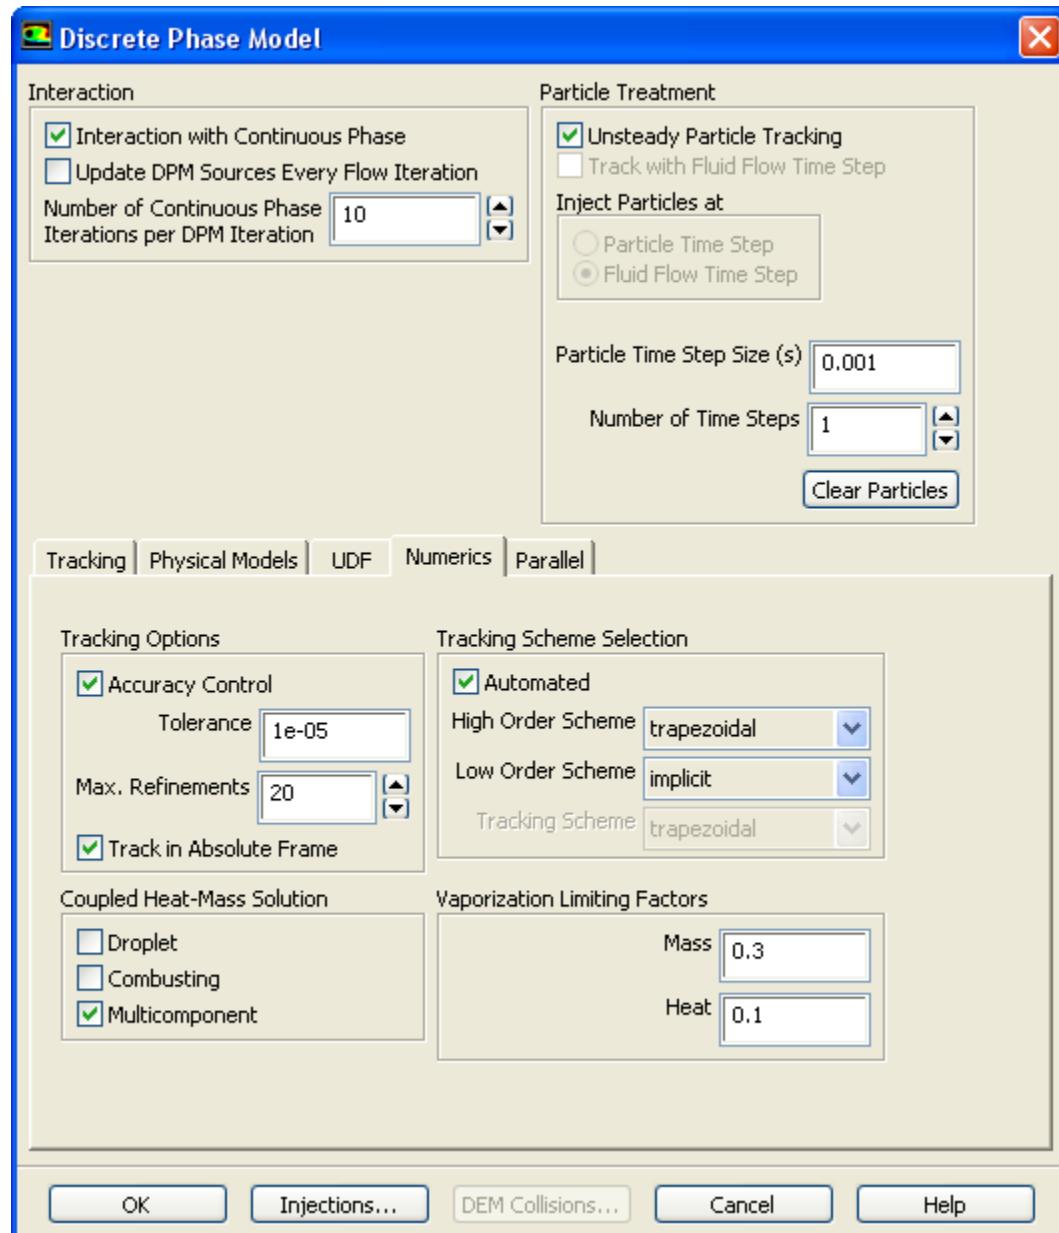

In the *Discrete Phase Model Dialog Box* (p. 1859), under **User-Defined Functions** in the **UDF** tab, there are drop-down lists labeled **Body Force**, **Scalar Update**, **Source**, **Spray Collide Function**, and **DPM Time Step** (*Figure 25.7* (p. 1092)). If **Erosion/Accretion** is enabled under the **Physical Models** tab, there will be an additional drop-down list labeled **Erosion/Accretion**. These lists will show available user-defined functions that can be selected to customize the discrete phase model.

In addition, you can specify a **Number of Scalars** which are allocated to each particle and can be used to store information when implementing your own particle models.

A user defined drag law needs to be selected in the **Tracking** tab.

25.2.7. Numerics of the Discrete Phase Model

The underlying physics of the Discrete Phase Model is described by ordinary differential equations (ODE) as opposed to the continuous flow which is expressed in the form of partial differential equations (PDE). Therefore, the Discrete Phase Model uses its own numerical mechanisms and discretization schemes, which are completely different from other numerics used in ANSYS FLUENT.

Figure 25.8 The Discrete Phase Model Dialog Box and the Numerics

The **Numerics** tab gives you control over the numerical schemes for particle tracking as well as solutions of heat and mass equations (Figure 25.8 (p. 1093)).

25.2.7.1. Numerics for Tracking of the Particles

To solve equations of motion for the particles, the following numerical schemes are available:

implicit

uses an implicit Euler integration of [Equation 16–1](#) in the [Theory Guide](#) which is unconditionally stable for all particle relaxation times.

trapezoidal

uses a semi-implicit trapezoidal integration.

analytic

uses an analytical integration of [Equation 16–1](#) of the [Theory Guide](#) where the forces are held constant during the integration.

runge-kutta

facilitates a 5th order Runge Kutta scheme derived by Cash and Karp [\[13\]](#) (p. 2367).

For additional details, see [Solution Strategies for the Discrete Phase](#) (p. 1138).

You can either choose a single tracking scheme, or switch between higher order and lower order tracking schemes using an automated selection based on the accuracy to be achieved and the stability range of each scheme. In addition, you can control how accurately the equations need to be solved.

Accuracy Control

enables the solution of equations of motion within a specified tolerance. This is done by computing the error of the integration step and reducing the integration step if the error is too large. If the error is within the given tolerance, the integration step will also be increased in the next steps.

Tolerance

is the maximum relative error which has to be achieved by the tracking procedure. Based on the numerical scheme, different methods are used to estimate the relative error. The implemented Runge-Kutta scheme uses an embedded error control mechanism. The error of the other schemes is computed by comparing the result of the integration step with the outcome of a two step procedure with half the step size.

Max. Refinements

is the maximum number of step size refinements in one single integration step. If this number is exceeded the integration will be conducted with the last refined integration step size.

Automated Tracking Scheme Selection

provides a mechanism to switch in an automated fashion between numerically stable lower order schemes and higher order schemes, which are stable only in a limited range. In situations where the particle is far from hydrodynamic equilibrium, an accurate solution can be achieved very quickly with a higher order scheme, since these schemes need less step refinements for a certain tolerance. When the particle reaches hydrodynamic equilibrium, the higher order schemes become inefficient since their step length is limited to a stable range. In this case, the mechanism switches to a stable lower order scheme and facilitates larger integration steps.

Important

This mechanism is only available when **Accuracy Control** is enabled.

Higher Order Scheme

can be chosen from the group consisting of **trapezoidal** and **runge-kutta** scheme.

Lower Order Scheme

consists of **implicit** and the exponential **analytic** integration scheme.

Tracking Scheme

is selectable only if **Automated** is switched off. You can choose any of the tracking schemes. You also can combine each of the tracking schemes with **Accuracy Control**.

Note

Please refer to [Numeric Recommendations](#) (p. 1091) for suggested settings when using the DEM collision model.

25.2.7.2. Including Coupled Heat-Mass Solution Effects on the Particles

By default, the particle heat and mass equations are solved in a segregated manner using an implicit Euler integration over the time step used for the trajectory calculation. If you enable the **Coupled Heat-Mass Solution** option for the **Droplet**, **Combusting**, or **Multicomponent** particles, ANSYS FLUENT will solve the corresponding equations using a coupled ODE solver with error tolerance control. The increased accuracy, however, comes at the expense of increased computational time.

To ensure solution accuracy for the **Droplet** and **Multicomponent** particles, ANSYS FLUENT will automatically switch to the coupled algorithm during the integration time step when the evaporated mass is greater than the limiting mass change Δm_p (defined in [Equation 25-3](#) (p. 1095)), or when the particle temperature change is greater than the limiting temperature change ΔT_p (defined in [Equation 25-4](#) (p. 1095)).

$$\Delta m_p = m_p a_m \quad (25-3)$$

where m_p is the particle mass (kg) and a_m is the vaporization limiting factor for the mass.

$$\Delta T_p = \min \left(|T_p - T_\infty|, a_T, T_p a_T \right) \quad (25-4)$$

where T_p is the particle temperature (K), T_∞ is the bulk temperature (K), and a_T is the vaporization limiting factor for the temperature.

You will enter the **Vaporization Limiting Factors** for **Mass** a_m and **Heat** a_T . The defaults 0.3 and 0.1 are recommended.

25.2.7.3. Tracking in a Reference Frame

Particle tracking is related to a coordinate system. With **Track in Absolute Frame** enabled, you can choose to track the particles in the absolute reference frame. All particle coordinates and velocities are then computed in this frame. The forces due to friction with the continuous phase are transformed to this frame automatically.

In rotating flows it might be appropriate for numerical reasons to track the particles in the relative reference frame. If several reference frames exist in one simulation, then the particle velocities are transformed to each reference frame when they enter the fluid zone associated with this reference frame.

When the impact of particles with walls in multiple rotating reference frames is important, as it is the case with a rotating impeller in a stationary baffled tank, it is necessary to model the flow as a sliding mesh simulation.

25.2.7.4. Staggering of Particles in Space and Time

In order to obtain a better representation of an injector, the particles can be *staggered* either spatially or temporally. When particles are staggered spatially, ANSYS FLUENT randomly samples from the region in which the spray is specified (e.g., the sheet thickness in the pressure-swirl atomizer) so that as the calculation progresses, trajectories will originate from the entire region. This allows the entire geometry specified in the atomizer to be sampled while specifying fewer streams in the input dialog box, thus decreasing computational expense.

When injecting particles in a transient calculation using relatively large time steps in relation to the spray event, the particles can clump together in discrete bunches. The clumps do not look physically realistic, though ANSYS FLUENT calculates the trajectory for each particle as it passes through a cell and the coupling to the gas phase is properly accounted for. To obtain a statistically smoother representation of the spray, the particles can be staggered in time. During the first time step, the particle is tracked for a random percentage of its initial step. This results in a sample of the initial volume swept out by the particle during the first time step and a smoother, more uniform spatial distribution at longer time intervals.

The menu for staggering is available in the text user interface (TUI), under

```
define/models/dpm/options/particle-staggering.
```

The “staggering factor” in the TUI is a constant which multiplies the random sample. The staggering factor controls the percentage of the initial time step that will be sampled. For example, if the staggering factor is 0.5, then the parcels in the injection will be tracked between half and all of their full initial time step. If the staggering factor is 0.1, then the parcels will be tracked between ninety percent and all of their initial time step. If the staggering factor is set to 0.9, the parcels will be tracked between ten percent and all of their initial time step. This allows you to control the amount of smoothing between injections.

The default values for the options in the TUI are no temporal staggering and a temporal staggering factor of 1.0. The temporal staggering factor is inactive until the flag for temporal staggering is enabled.

25.3. Setting Initial Conditions for the Discrete Phase

The primary inputs that you must provide for the discrete phase calculations in ANSYS FLUENT are the initial conditions that define the starting positions, velocities, and other parameters for each particle stream and the physical effects acting on the particle streams, requiring additional particle properties. You will define the initial conditions for a particle/droplet stream by creating an “injection” and assigning properties to it.

The required initial conditions depend on the injection type, while the physical effects are selected by choosing an appropriate particle type. For some injection types you can provide a particle size distribution, like the Rosin-Rammler distribution, see [Using the Rosin-Rammler Diameter Distribution Method \(p. 1109\)](#).

The initial conditions provide the starting values for all of the dependent discrete phase variables that describe the instantaneous conditions of an individual particle, and include the following:

- position (x, y, z coordinates) of the particle
- velocities (u, v, w) of the particle

Velocity magnitudes and spray cone angle can also be used (in 3D) to define the initial velocities (see [Point Properties for Cone Injections \(p. 1101\)](#)). For moving reference frames, relative velocities should be specified.

- diameter of the particle, d_p
- temperature of the particle, T_p
- mass flow rate of the particle stream that will follow the trajectory of the individual particle/droplet, \dot{m}_p (required only for coupled calculations)
- additional parameters if one of the atomizer models described in [Atomizer Model Theory](#) in the [Theory Guide](#) is used for the injection

Important

When an atomizer model is selected, you will not input initial diameter, velocity, and position quantities for the particles due to the complexities of sheet and ligament breakup. Instead of initial conditions, the quantities you will input for the atomizer models are global parameters.

These dependent variables (temperature, diameter, etc.) are updated according to the equations of motion ([Particle Motion Theory](#) in the [Theory Guide](#)) and according to the heat/mass transfer relations applied ([Laws for Heat and Mass Exchange](#) in the [Theory Guide](#)) as the particle/droplet moves along its trajectory. You can define any number of different sets of initial conditions for discrete phase particles/droplets provided that your computer has sufficient memory.

For the setup of transient particle cases, the point properties for mass flow and velocity can be specified using transient profiles (see [Point Properties for Transient Injections](#) (p. 1123)).

For additional information, please see the following sections:

- [25.3.1. Injection Types](#)
- [25.3.2. Particle Types](#)
- [25.3.3. Point Properties for Single Injections](#)
- [25.3.4. Point Properties for Group Injections](#)
- [25.3.5. Point Properties for Cone Injections](#)
- [25.3.6. Point Properties for Surface Injections](#)
- [25.3.7. Point Properties for Plain-Orifice Atomizer Injections](#)
- [25.3.8. Point Properties for Pressure-Swirl Atomizer Injections](#)

- [25.3.18. Defining Properties Common to More than One Injection](#)
- [25.3.19. Point Properties for Transient Injections](#)

25.3.1. Injection Types

ANSYS FLUENT provides 11 types of injections:

- single

- group
- cone (only in 3D)
- solid-cone (only in 3D)
- surface
- plain-orifice atomizer
- pressure-swirl atomizer
- air-blast-atomizer
- flat-fan-atomizer
- effervescent-atomizer
- file

For each nonatomizer injection type, you will specify each of the initial conditions listed in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#), the type of particle that possesses these initial conditions, and any other relevant parameters for the particle type chosen.

You should create a single injection when you want to specify a single value for each of the initial conditions ([Figure 25.9 \(p. 1098\)](#)). Create a group injection ([Figure 25.10 \(p. 1098\)](#)) when you want to define a range for one or more of the initial conditions (e.g., a range of diameters or a range of initial positions). To define hollow spray cone injections in 3D problems, create a cone injection ([Figure 25.11 \(p. 1099\)](#)). To release particles from a surface (either a zone surface or a surface you have defined using the items in the **Surface** menu), you will create a surface injection. (If you create a surface injection, a particle stream will be released from each facet of the surface. You can use the **Bounded** and **Sample Points** options in the **Plane Surface** dialog box to create injections from a rectangular mesh of particles in 3D (see [Plane Surfaces \(p. 1482\)](#) for details).

Figure 25.9 Particle Injection Defining a Single Particle Stream

Figure 25.10 Particle Injection Defining an Initial Spatial Distribution of the Particle Streams

Figure 25.11 Particle Injection Defining an Initial Spray Distribution of the Particle Velocity

Particle initial conditions (position, velocity, diameter, temperature, and mass flow rate) can also be read from an external file if none of the injection types listed above can be used to describe your injection distribution.

The inputs for setting injections are described in detail in [Defining Injection Properties \(p. 1114\)](#).

25.3.2. Particle Types

When you define a set of initial conditions (as described in [Defining Injection Properties \(p. 1114\)](#)), you will need to specify the type of particle. The particle types available to you depend on the range of physical models that you have defined.

- A **massless** particle is a discrete element that follows the flow and temperature of the continuous phase. As it has no mass, it has no associated physical properties, and no force is exerted on it. However, you can assign a User-Defined Law to be applied to the massless particle. The massless particle type is available with all ANSYS FLUENT models.
- An **inert** particle is a discrete phase element (particle, droplet, or bubble) that obeys the force balance ([Equation 16–1](#) in the [Theory Guide](#)) and is subject to heating or cooling via Law 1 ([Inert Heating or Cooling \(Law 1/Law 6\)](#) in the [Theory Guide](#)). The inert type is available for all ANSYS FLUENT models.
- A **droplet** particle is a liquid droplet in a continuous-phase gas flow that obeys the force balance ([Equation 16–1](#) in the [Theory Guide](#)) and that experiences heating/cooling via Law 1 followed by vaporization and boiling via Laws 2 and 3 ([Droplet Vaporization \(Law 2\)](#) and [Droplet Boiling \(Law 3\)](#) in the [Theory Guide](#)). The droplet type is available when heat transfer is being modeled and at least two chemical species are active or the nonpremixed or partially premixed combustion model is active. You should use the ideal gas law to define the gas-phase density (in the [Create/Edit Materials](#) dialog box, as discussed in [Density Inputs for the Incompressible Ideal Gas Law \(p. 423\)](#)) when you select the droplet type.
- A **combusting** particle is a solid particle that obeys the force balance ([Equation 16–1](#)), and, after an initial phase of inert heating (Law 1), undergoes devolatilization ([Devolatilization \(Law 4\)](#)) and then a heterogeneous surface reaction via Law 5 ([Surface Combustion \(Law 5\)](#) in the [Theory Guide](#)). Finally, the nonvolatile portion of a combusting particle is subject to inert heating via Law 6. You can also include an evaporating material with the combusting particle by selecting the **Wet Combustion** option in the [Set Injection Properties Dialog Box \(p. 2255\)](#). This allows you to include a material that evaporates and boils via Laws 2 and 3 ([Droplet Vaporization \(Law 2\)](#) and [Droplet Boiling \(Law 3\)](#) in the [Theory Guide](#)) before devolatilization of the particle material begins. The combusting type is available when heat transfer is being modeled and at least three chemical species are active or the nonpremixed combustion model is active. You should use the ideal gas law to define the gas-phase density (in the [Create/Edit Materials Dialog Box \(p. 1882\)](#)) when you select the combusting particle type.
- A **multicomponent** particle is, as the name implies, a droplet particle containing a mixture of several components or species. The conservation equations of all components, the energy equation, and vapor-liquid-equilibrium at the multicomponent particle surface form a coupled system of differential equations.

Law 7, the multicomponent law ([Multicomponent Particle Definition \(Law 7\)](#) in the [Theory Guide](#)) is used for such systems. You should use the volume weighted mixing law to define the particle mixture density (in the [Create/Edit Materials Dialog Box \(p. 1882\)](#)) when you select the particle-mixture material type.

Particle Type	Description	Laws Activated
Massless	–	–
Inert	inert/heating or cooling	1, 6
Droplet	heating/evaporation/boiling	1, 2, 3, 6
Combusting	heating; evolution of volatiles/swelling; heterogeneous surface reaction	1, 4, 5, 6
Multicomponent	multicomponent droplets/particles	7

25.3.3. Point Properties for Single Injections

For a single injection, you will define the following initial conditions for the particle stream under the **Point Properties** heading (in the [Set Injection Properties Dialog Box \(p. 2255\)](#)):

- position

Set the x , y , and z positions of the injected stream along the Cartesian axes of the problem geometry in the **X-**, **Y-**, and **Z-Position** fields. (**Z-Position** will appear only for 3D problems.)

- velocity

Set the x , y , and z components of the stream's initial velocity in the **X-**, **Y-**, and **Z-Velocity** fields. (**Z-Velocity** will appear only for 3D problems.)

- diameter

Set the initial diameter of the injected particle stream in the **Diameter** field.

- temperature

Set the initial (absolute) temperature of the injected particle stream in the **Temperature** field.

- mass flow rate

For coupled phase calculations (see [Solution Strategies for the Discrete Phase \(p. 1138\)](#)), set the mass of particles per unit time that follows the trajectory defined by the injection in the **Flow Rate** field.

Note that in axisymmetric problems the mass flow rate is defined per 2π radians and in 2D problems per unit meter depth (regardless of the reference value for length).

- duration of injection

For unsteady particle tracking (see [Steady/Transient Treatment of Particles \(p. 1078\)](#)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.

For the massless particle type, you will only need to define the position of the injection. The particle injection velocity is set by the solver equal to the velocity of the continuous phase at the injection point.

25.3.4. Point Properties for Group Injections

For group injections, you will define the properties position, velocity, diameter, temperature, and flow rate for the **First Point** and **Last Point** in the group. That is, you will define a range of values, ϕ_1 through ϕ_N , for each initial condition ϕ by setting values for ϕ_1 and ϕ_N . ANSYS FLUENT assigns a value of ϕ to the i th injection in the group using a linear variation between the first and last values for ϕ :

$$\phi_i = \phi_1 + \frac{\phi_N - \phi_1}{N - 1} (i - 1) \quad (25-5)$$

Thus, for example, if your group consists of 5 particle streams and you define a range for the initial x location from 0.2 to 0.6 meters, the initial x location of each stream is as follows:

- Stream 1: $x = 0.2$ meters
- Stream 2: $x = 0.3$ meters
- Stream 3: $x = 0.4$ meters
- Stream 4: $x = 0.5$ meters
- Stream 5: $x = 0.6$ meters

Important

In general, you should supply a range for only one of the initial conditions in a given group—leaving all other conditions fixed while a single condition varies among the stream numbers of the group. Otherwise you may find, for example, that your simultaneous inputs of a spatial distribution and a size distribution have placed the small droplets at the beginning of the spatial range and the large droplets at the end of the spatial range.

The specified flow rate is defined per particle stream and can also be interpolated using [Equation 25-5 \(p. 1101\)](#). When a Rosin-Rammler sized distribution is specified the total flow rate will be specified.

For the massless particle type, you will only need to define the first and last point of the injection group position. The particle velocities are set by the solver equal to the velocity of the continuous phase at the injection points.

Note that you can use a different method for defining the size distribution of the particles, as discussed below.

25.3.5. Point Properties for Cone Injections

In 3D problems, you can define a hollow or solid cone of particle streams using the **cone** or **solid-cone** injection type, respectively. For both types of cone injections, the inputs are as follows:

- position
Set the coordinates of the origin of the spray cone in the **X-, Y-, and Z-Position** fields.
- diameter
Set the diameter of the particles in the stream in the **Diameter** field.

- temperature

Set the temperature of the streams in the **Temperature** field.

- axis

Set the x , y , and z components of the vector defining the cone's axis in the **X-Axis**, **Y-Axis**, and **Z-Axis** fields.

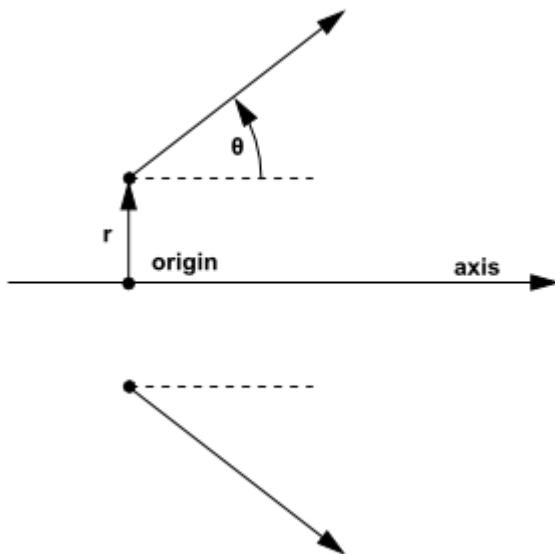

- velocity

Set the velocity magnitude of the particle streams that will be oriented along the specified spray cone angle in the **Velocity Mag.** field.

- cone angle

Set the included half-angle, θ , of the hollow spray cone in the **Cone Angle** field, as shown in [Figure 25.12 \(p. 1102\)](#).

Figure 25.12 Cone Half Angle and Radius

- radius

A nonzero inner radius can be specified to model injectors that do not emanate from a single point. Set the radius r (defined as shown in [Figure 25.12 \(p. 1102\)](#)) in the **Radius** field. The particles will be distributed about the axis with the specified radius.

- swirl fraction (hollow cone only)

Set the fraction of the velocity magnitude to go into the swirling component of the flow in the **Swirl Fraction** field. The direction of the swirl component is defined using the right-hand rule about the axis (a negative value for the swirl fraction can be used to reverse the swirl direction).

- mass flow rate

For coupled calculations, set the total mass flow rate for the streams in the spray cone in the **Total Flow Rate** field.

The distribution of the velocity directions in the particle streams for the solid cone injection is random. Furthermore, duplicating this injection may not necessarily result in the same distribution, at the same location.

Important

For transient calculations, the spatial distribution of streams at the initial injection location is recalculated at each time step. Sampling different possible trajectories allows a more accurate representation of a solid cone using fewer computational parcels. For steady state calculations, the trajectories are initialized one time and kept the same for subsequent DPM iterations. The trajectories are recalculated when a change in the **Injections** dialog box occurs or when a case and data file are saved. If the residuals and solution change when a small change is made to the injection or when a case and data file are saved, it may mean that there are not enough trajectories being used to represent the solid cone with sufficient accuracy.

Note that you may want to define multiple spray cones emanating from the same initial location in order to specify a known size distribution of the spray or to include a known range of cone angles.

For the massless particle type, you will only need to define position, axis, cone angle and radius. The particle velocities are set by the solver equal to the velocity of the continuous phase at the injection points.

25.3.6. Point Properties for Surface Injections

For surface injections, you will define all the properties described in [Point Properties for Single Injections \(p. 1100\)](#) for single injections except for the initial position of the particle streams. The initial positions of the particles will be the location of the data points on the specified surface(s). Note that you will set the **Total Flow Rate** of all particles released from the surface (required for coupled calculations only). If you want, you can scale the individual mass flow rates of the particles by the ratio of the area of the face they are released from to the total area of the surface. To scale the mass flow rates, select the **Scale Flow Rate By Face Area** option under **Point Properties**. For the massless particle type, you will not need to enter any information to define a surface injection. The particle velocities are set by the solver equal to the velocities of the continuous phase at the injection points.

Note that many surfaces have nonuniform distributions of points. If you want to generate a uniform spatial distribution of particle streams released from a surface in 3D, you can create a bounded plane surface with a uniform distribution using the [Plane Surface Dialog Box \(p. 2080\)](#), as described in [Plane Surfaces \(p. 1482\)](#). In 2D, you can create a rake using the [Line/Rake Surface Dialog Box \(p. 2079\)](#), as described in [Line and Rake Surfaces \(p. 1479\)](#).

In addition to the option of scaling the flow rate by the face area, the normal direction of a face can be used for the injection direction. To use the face normal direction for the injection direction, select the **Inject Using Face Normal Direction** option under **Point Properties** ([Figure 25.18 \(p. 1116\)](#)). Once this option is selected, you only need to specify the velocity magnitude of the injection, not the individual components of the velocity magnitude.

Important

Note also that only surface injections from boundary surfaces will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used.

Important

For moving or deforming mesh simulations only zonal surfaces can be selected.

A nonuniform size distribution can be used for surface injections, as described below.

25.3.6.1. Using the Rosin-Rammler Diameter Distribution Method

The Rosin-Rammler size distributions described in [Using the Rosin-Rammler Diameter Distribution Method \(p. 1109\)](#) for group injections is also available for surface injections. If you select one of the Rosin-Rammler distributions (**rosin-rammler** or **rosin-rammler-logarithmic**), you will need to specify the following parameters under **Point Properties**, in addition to the initial velocity, temperature, and total flow rate:

- **Min. Diameter**

This is the smallest diameter to be considered in the size distribution.

- **Max. Diameter**

This is the largest diameter to be considered in the size distribution.

- **Mean Diameter**

This is the size parameter, \bar{d} , in the Rosin-Rammler equation ([Equation 25–7 \(p. 1110\)](#)).

- **Spread Parameter**

This is the exponential parameter, n , in [Equation 25–7 \(p. 1110\)](#).

- **Number of Diameters**

This is the number of diameters in each distribution (i.e., the number of different diameters in the stream injected from each face of the surface).

ANSYS FLUENT will inject streams of particles from each face on the surface, with diameters defined by the Rosin-Rammler distribution function. The total number of injection streams tracked for the surface injection will be equal to the number of diameters in each distribution (**Number of Diameters**) multiplied by the number of faces on the surface.

25.3.7. Point Properties for Plain-Orifice Atomizer Injections

For a plain-orifice atomizer injection, you will define the following initial conditions under **Point Properties**:

- position

Set the x , y , and z positions of the injected stream along the Cartesian axes of the problem geometry in the **X-Position**, **Y-Position**, and **Z-Position** fields. (**Z-Position** will appear only for 3D problems).

- axis (3D only)

Set the x , y , and z components of the vector defining the axis of the orifice in the **X-Axis**, **Y-Axis**, and **Z-Axis** fields.

- temperature

- Set the temperature of the streams in the **Temperature** field.
 - mass flow rate
- Set the total mass flow rate for the streams in the atomizer in the **Flow Rate** field. Note that in 3D sectors, the flow rate must be appropriate for the sector defined by the **Azimuthal Start Angle** and **Azimuthal Stop Angle**.
- duration of injection
- For unsteady particle tracking (see *Steady/Transient Treatment of Particles* (p. 1078)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.
- vapor pressure
- Set the vapor pressure governing the flow through the internal orifice (p_v in Table 16.2: "List of Governing Parameters for Internal Nozzle Flow" in the Theory Guide) in the **Vapor Pressure** field.
- diameter
- Set the diameter of the orifice in the **Injector Inner Diameter** field (d in Table 16.2: "List of Governing Parameters for Internal Nozzle Flow" in the Theory Guide).
- orifice length
- Set the length of the orifice in the **Orifice Length** field (L in Table 16.2: "List of Governing Parameters for Internal Nozzle Flow" in the Theory Guide).
- radius of curvature
- Set the radius of curvature of the inlet corner in the **Corner Radius of Curvature** field (r in Table 16.2: "List of Governing Parameters for Internal Nozzle Flow" in the Theory Guide).
- nozzle parameter
- Set the constant for the spray angle correlation in the **Constant A** field (C_A in Equation 16–230 in the Theory Guide).
- azimuthal angles
- For 3D sectors, set the **Azimuthal Start Angle** and **Azimuthal Stop Angle**.

See [The Plain-Orifice Atomizer Model](#) in the Theory Guide for details about how these inputs are used.

25.3.8. Point Properties for Pressure-Swirl Atomizer Injections

For a pressure-swirl atomizer injection, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate, duration of injection (if unsteady), injector inner diameter, and azimuthal angles (if relevant) described in [Point Properties for Plain-Orifice Atomizer Injections](#) (p. 1104), you will need to specify the following parameters under **Point Properties**:

- spray angle

Set the value of the spray angle of the injected stream in the **Spray Half Angle** field (θ in Equation 16–239 in the Theory Guide).

- pressure
Set the absolute pressure upstream of the injection in the **Upstream Pressure** field (p_1 in [Table 16.2: "List of Governing Parameters for Internal Nozzle Flow" in the Theory Guide](#)).
- sheet breakup
Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Sheet Constant** field ($\ln\left(\frac{\eta_b}{\eta_0}\right)$ in [Equation 16–244 in the Theory Guide](#)).
- ligament diameter
For short waves, set the proportionality constant that linearly relates the ligament diameter, d_L , to the wavelength that breaks up the sheet in the **Ligament Constant** field (see [Equation 16–245 – Equation 16–248 in the Theory Guide](#)).
- dispersion angle
For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** for a flat fan atomizer is depicted in [Figure 25.13 \(p. 1108\)](#).

See [The Pressure-Swirl Atomizer Model](#) in the Theory Guide for details about how these inputs are used.

25.3.9. Point Properties for Air-Blast/Air-Assist Atomizer Injections

For an air-blast/air-assist atomizer, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate, duration of injection (if unsteady), injector inner diameter, and azimuthal angles (if relevant) described in [Point Properties for Plain-Orifice Atomizer Injections \(p. 1104\)](#), you will need to specify the following parameters under **Point Properties**:

- outer diameter
Set the outer diameter of the injector in the **Injector Outer Diameter** field. This value is used in conjunction with the **Injector Inner Diameter** to set the thickness of the liquid sheet (t in [Equation 16–236 in the Theory Guide](#)).
- spray angle
Set the initial trajectory of the film as it leaves the end of the orifice in the **Spray Half Angle** field (θ in [Equation 16–239 in the Theory Guide](#)).
- relative velocity
Set the maximum relative velocity that is produced by the sheet and air in the **Relative Velocity** field.
- sheet breakup
Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Sheet Constant** field ($\ln\left(\frac{\eta_b}{\eta_0}\right)$ in [Equation 16–244 in the Theory Guide](#)).
- ligament diameter

For short waves, set the proportionality constant (C_L in [Equation 16–247](#) in the [Theory Guide](#)) that linearly relates the ligament diameter, d_L , to the wavelength that breaks up the sheet in the **Ligament Constant** field.

- dispersion angle

For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** for a flat fan atomizer is depicted in [Figure 25.13](#) (p. 1108).

See [The Air-Blast/Air-Assist Atomizer Model](#) in the [Theory Guide](#) for details about how these inputs are used.

25.3.10. Point Properties for Flat-Fan Atomizer Injections

The flat-fan atomizer model is available only for 3D models. For this type of injection, you will define the following initial conditions under **Point Properties**:

- arc position

Set the coordinates of the center point of the arc from which the fan originates in the **X-Center**, **Y-Center**, and **Z-Center** fields (see [Figure 25.13](#) (p. 1108)).

- virtual position

Set the coordinates of the virtual origin of the fan in the **X-Virtual Origin**, **Y-Virtual Origin**, and **Z-Virtual Origin** fields. This point is the intersection of the lines that mark the sides of the fan (see [Figure 25.13](#) (p. 1108)).

- normal vector

Set the direction that is normal to the fan in the **X-Fan Normal Vector**, **Y-Fan Normal Vector**, and **Z-Fan Normal Vector** fields.

- temperature

Set the temperature of the streams in the **Temperature** field.

- mass flow rate

Set the mass flow rate for the streams in the atomizer in the **Flow Rate** field.

- duration of injection

For unsteady particle tracking (see [Steady/Transient Treatment of Particles](#) (p. 1078)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.

- spray half angle

Set the initial half angle of the drops as they leave the end of the orifice in the **Spray Half Angle** field.

- orifice width

Set the width of the orifice (in the normal direction) in the **Orifice Width** field.

- sheet breakup

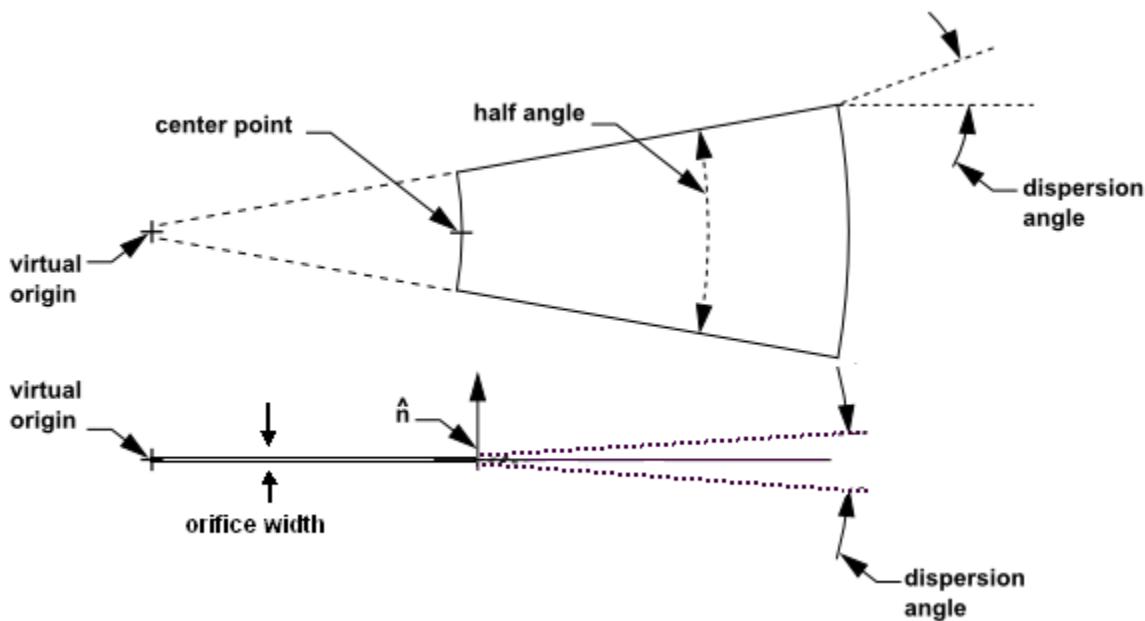

Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Flat Fan Sheet Constant** field (see [Equation 16–244](#) in the Theory Guide).

- dispersion angle

For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** is depicted in [Figure 25.13 \(p. 1108\)](#).

See [The Flat-Fan Atomizer Model](#) in the Theory Guide for details about how these inputs are used.

Figure 25.13 Flat Fan Viewed from Above and from the Side

25.3.11. Point Properties for Effervescent Atomizer Injections

For an effervescent atomizer injection, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate (including both flashing and nonflashing components), duration of injection (if unsteady), vapor pressure, injector inner diameter, and azimuthal angles (if relevant) described in [Point Properties for Plain-Orifice Atomizer Injections \(p. 1104\)](#), you will need to specify the following parameters under **Point Properties**:

- mixture quality

Set the mass fraction of the injected mixture that vaporizes in the **Mixture Quality** field (x in [Equation 16–254](#) in the Theory Guide).

- saturation temperature

Set the saturation temperature of the volatile substance in the **Saturation Temp.** field.

- droplet dispersion

Set the parameter that controls the spatial dispersion of the droplet sizes in the **Dispersion Constant** field (C_{eff} in [Equation 16–254](#) in the Theory Guide).

- spray angle

Set the initial trajectory of the film as it leaves the end of the orifice in the **Maximum Half Angle** field.

See [The Effervescent Atomizer Model](#) in the [Theory Guide](#) for details about how these inputs are used.

25.3.12. Point Properties for File Injections

The file for a file injection has the following form:

```
(( x y z u v w diameter temperature mass-flow) name )
```

with all of the parameters in SI units. All the parentheses are required, but the `name` is optional.

Sample files generated during sampling of trajectories for steady particles (see [Sampling of Trajectories](#) (p. 1163)) can also be used as injection files since they have a similar file format.

25.3.13. Using the Rosin-Rammler Diameter Distribution Method

For liquid sprays, a convenient representation of the droplet size distribution is the Rosin-Rammler expression. The complete range of sizes is divided into an adequate number of discrete intervals; each represented by a mean diameter for which trajectory calculations are performed. If the size distribution is of the Rosin-Rammler type, the mass fraction of droplets of diameter greater than d is given by

$$Y_d = e^{-(d/\bar{d})^n} \quad (25-6)$$

where \bar{d} is the size constant and n is the size distribution parameter.

By default, you will define the size distribution of particles by inputting a diameter for the first and last points and using the linear equation ([Equation 25-5 \(p. 1101\)](#)) to vary the diameter of each particle stream in the group. When you want a different mass flow rate for each particle/droplet size, however, the linear variation may not yield the distribution you need. Your particle size distribution may be defined most easily by fitting the size distribution data to the Rosin-Rammler equation. In this approach, the complete range of particle sizes is divided into a set of discrete size ranges, each to be defined by a single stream that is part of the group. Assume, for example, that the particle size data obeys the following distribution:

Diameter Range (μm)	Mass Fraction in Range
0–70	0.05
70–100	0.10
100–120	0.35
120–150	0.30
150–180	0.15
180–200	0.05

The Rosin-Rammler distribution function is based on the assumption that an exponential relationship exists between the droplet diameter, d , and the mass fraction of droplets with diameter greater than d , Y_d :

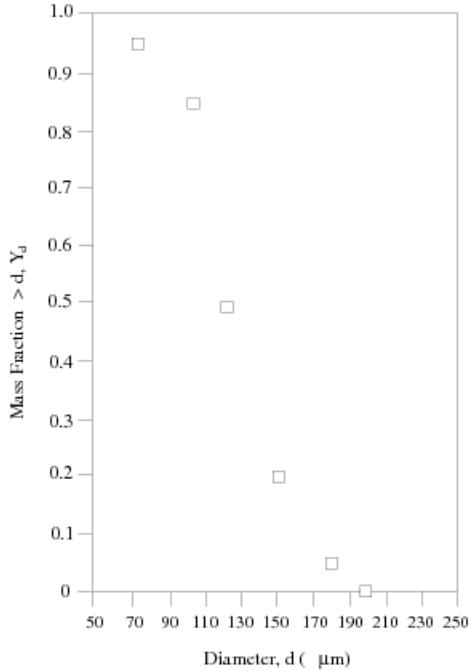

$$Y_d = e^{-(d/\bar{d})^n} \quad (25-7)$$

ANSYS FLUENT refers to the quantity \bar{d} in [Equation 25-7 \(p. 1110\)](#) as the **Mean Diameter** and to n as the **Spread Parameter**. These parameters are input by you (in the [Set Injection Properties Dialog Box \(p. 2255\)](#) under the **First Point** heading) to define the Rosin-Rammler size distribution. To solve for these parameters, you must fit your particle size data to the Rosin-Rammler exponential equation. To determine these inputs, first recast the given droplet size data in terms of the Rosin-Rammler format. For the example data provided above, this yields the following pairs of d and Y_d :

Diameter, d (μm)	Mass Fraction with Diameter Greater than d , Y_d
70	0.95
100	0.85
120	0.50
150	0.20
180	0.05
200	(0.00)

A plot of Y_d vs. d is shown in [Figure 25.14 \(p. 1110\)](#).

Figure 25.14 Example of Cumulative Size Distribution of Particles

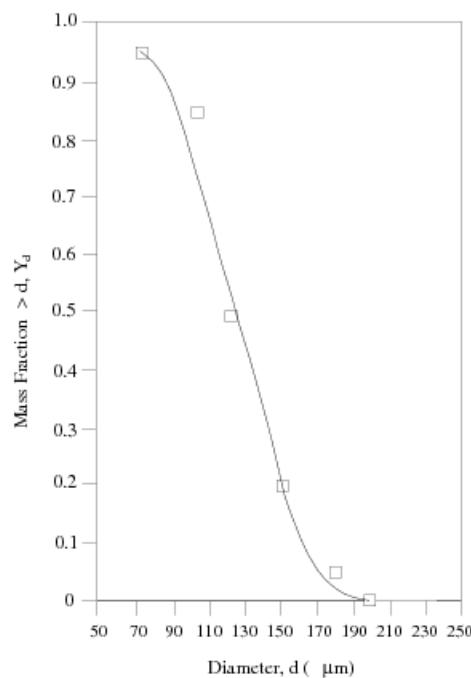

Next, derive values of \bar{d} and n such that the data in [Figure 25.14 \(p. 1110\)](#) fit [Equation 25-7 \(p. 1110\)](#). The value for \bar{d} is obtained by noting that this is the value of d at which $Y_d = e^{-1} \approx 0.368$. From [Figure 25.14 \(p. 1110\)](#), you can estimate that this occurs for $d \approx 131\mu\text{m}$. The numerical value for n is given by

$$n = \frac{\ln(-\ln Y_d)}{\ln(d/\bar{d})} \quad (25-8)$$

By substituting the given data pairs for Y_d and d/\bar{d} into this equation, you can obtain values for n and find an average. Doing so yields an average value of $n = 4.52$ for the example data above. The resulting Rosin-Rammler curve fit is compared to the example data in [Figure 25.15 \(p. 1111\)](#). You can input values for \bar{d} and n , as well as the diameter range of the data and the total mass flow rate for the combined individual size ranges, using the [Set Injection Properties Dialog Box \(p. 2255\)](#).

This technique of fitting the Rosin-Rammler curve to spray data is used when reporting the Rosin-Rammler diameter and spread parameter in the **Discrete Phase Summary** dialog box in [Summary Reporting of Current Particles \(p. 1166\)](#).

Figure 25.15 Rosin-Rammler Curve Fit for the Example Particle Size Data

A second Rosin-Rammler distribution is also available based on the natural logarithm of the particle diameter. If in your case, the smaller-diameter particles in a Rosin-Rammler distribution have higher mass flows in comparison with the larger-diameter particles, you may want better resolution of the smaller-diameter particle streams, or "bins". You can therefore choose to have the diameter increments in the Rosin-Rammler distribution done uniformly by $\ln d$.

In the standard Rosin-Rammler distribution, a particle injection may have a diameter range of 1 to 200 μm . In the logarithmic Rosin-Rammler distribution, the same diameter range would be converted to a range of $\ln 1$ to $\ln 200$, or about 0 to 5.3. In this way, the mass flow in one bin would be less-heavily skewed as compared to the other bins.

When a Rosin-Rammler size distribution is being defined for the group of streams, you should define (in addition to the initial velocity, position, and temperature) the following parameters, which appear under the heading for the **First Point**:

- **Total Flow Rate**

This is the total mass flow rate of the N streams in the group. Note that in axisymmetric problems this mass flow rate is defined per 2π radians and in 2D problems per unit meter depth.

- **Min. Diameter**

This is the smallest diameter to be considered in the size distribution.

- **Max. Diameter**

This is the largest diameter to be considered in the size distribution.

- **Mean Diameter**

This is the size parameter, \bar{d} , in the Rosin-Rammler equation ([Equation 25–7 \(p. 1110\)](#)).

- **Spread Parameter**

This is the exponential parameter, n , in [Equation 25–7 \(p. 1110\)](#).

25.3.13.1. The Stochastic Rosin-Rammler Diameter Distribution Method

For atomizer injections, a Rosin-Rammler distribution is assumed for the particles exiting the injector. In order to decrease the number of particles necessary to accurately describe the distribution, the diameter distribution function is randomly sampled for each instance where new particles are introduced into the domain.

The Rosin-Rammler distribution can be written as

$$1 - Y = \exp \left[- \left(\frac{D}{\bar{d}} \right)^n \right] \quad (25-9)$$

where Y is the mass fraction smaller than a given diameter D , \bar{d} is the Rosin-Rammler diameter and n is the Rosin-Rammler exponent. This expression can be inverted by taking logs of both sides and rearranging, where Y is the mass fraction smaller than a given diameter D , \bar{d} is the Rosin-Rammler diameter and n is the Rosin-Rammler exponent. This expression can be inverted by taking logs of both sides and rearranging,

$$D = \bar{d} \left(- \ln(1 - Y) \right)^{1/n}. \quad (25-10)$$

Given a mass fraction Y along with parameters \bar{d} and n , this function will explicitly provide a diameter, D . Diameters for the atomizer injectors described in [Point Properties for Plain-Orifice Atomizer Injections \(p. 1104\)](#) are obtained by uniformly sampling Y in [Equation 25–10 \(p. 1112\)](#).

25.3.14. Creating and Modifying Injections

You will use the [Injections Dialog Box \(p. 2254\)](#) ([Figure 25.16 \(p. 1113\)](#)) to create, copy, delete, list, read, and write injections.

Define → Injections...

1112

Release 14.0 - © SAS IP, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 25.16 The Injections Dialog Box

(You can also click the **Injections...** button in the *Discrete Phase Model Dialog Box* (p. 1859) to open the **Injections** dialog box.)

25.3.14.1. Creating Injections

To create an injection, click the **Create** button. The *Set Injection Properties Dialog Box* (p. 2255) will open automatically to allow you to set the injection properties (as described in *Defining Injection Properties* (p. 1114)). After the injection is created, the new injection will appear in the **Injections** list, in the **Injections** dialog box.

25.3.14.2. Modifying Injections

To modify an existing injection, select its name in the **Injections** list and click the **Set...** button. The **Set Injection Properties** dialog box will open, and you can modify the properties as needed.

If you have two or more injections for which you want to set some of the same properties, select their names in the **Injections** list and click the **Set...** button. The **Set Multiple Injection Properties** dialog box will open, which will allow you to set the common properties. For instructions about using this dialog box, see *Defining Properties Common to More than One Injection* (p. 1121).

25.3.14.3. Copying Injections

To copy an existing injection to a new injection, select the existing injection in the **Injections** list and click the **Copy** button. The *Set Injection Properties Dialog Box* (p. 2255) will open with a new injection that has the same properties as the injection you selected. This is useful if you want to set another injection with similar properties.

25.3.14.4. Deleting Injections

You can delete an injection by selecting its name in the **Injections** list and clicking the **Delete** button.

25.3.14.5. Listing Injections

To list the initial conditions for the particle streams in the selected injection, click the **List** button. ANSYS FLUENT reports the initial conditions (in SI units) in the console under various columns:

- The particle stream number is in the column headed **NO.**
- The particle type (**IN**for inert, **DR**for droplet, or **CP** for combusting particle) is in the column headed **TYP.**
- The *x*, *y*, and *z* positions are in the columns headed **(X)**, **(Y)**, and **(Z)**.
- The *x*, *y*, and *z* velocities are in the columns headed **(U)**, **(V)**, and **(W)**.
- The temperature is in the column headed **(T)**.
- The diameter is in the column headed **(DIAM)**.
- The mass flow rate is in the column headed **(MFLOW)**.

25.3.14.6. Reading and Writing Injections

To transfer information about DPM injections from one case file to another, use the **Read...** and **Write...** buttons. You can write selected injections to a file, which can be read into a different ANSYS FLUENT session, simplifying the setup of new case files. To write the injection, select the injection from the list, then click **Write...**. The [Select File Dialog Box \(p. 33\)](#) will open where you can enter the name of your injection file. To read in an injection, click **Read...** to open [The Select File Dialog Box \(p. 33\)](#) where you will select the injection file to read in. If the injection that you imported has the same name as that in your current case, then ANSYS FLUENT will rename the imported injection.

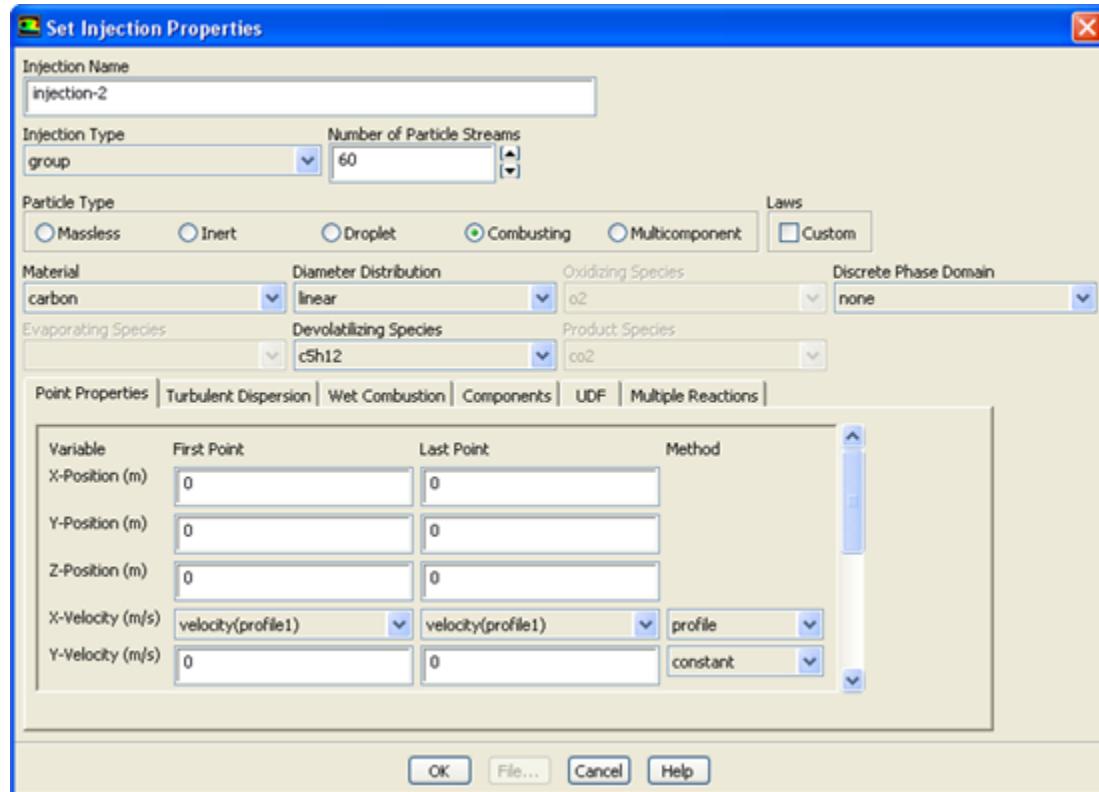

After reading injections, you may need to visit the **Injections** dialog box to modify the settings for the injection material and the DPM laws since the presumed settings may have changed in the current case file setup.

25.3.14.7. Shortcuts for Selecting Injections

ANSYS FLUENT provides a shortcut for selecting injections with names that match a specified pattern. To use this shortcut, enter the pattern under **Injection Name Pattern** and then click **Match** to select the injections with names that match the specified pattern. For example, if you specify **drop***, all injections that have names beginning with **drop** (e.g., **drop-1**, **droplet**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **drop?**, all surfaces with names consisting of **drop** followed by a single character will be selected (or deselected, if they are all selected already).

25.3.15. Defining Injection Properties

Once you have created an injection (using the [Injections Dialog Box \(p. 2254\)](#), as described in [Creating and Modifying Injections \(p. 1112\)](#)), you will use the [Set Injection Properties Dialog Box \(p. 2255\)](#) ([Figure 25.17 \(p. 1115\)](#)) to define the injection properties. (Remember that this dialog box will open when you create a new injection, or when you select an existing injection and click the **Set...** button in the **Injections** dialog box.)

Figure 25.17 The Set Injection Properties Dialog Box

The procedure for defining an injection is as follows:

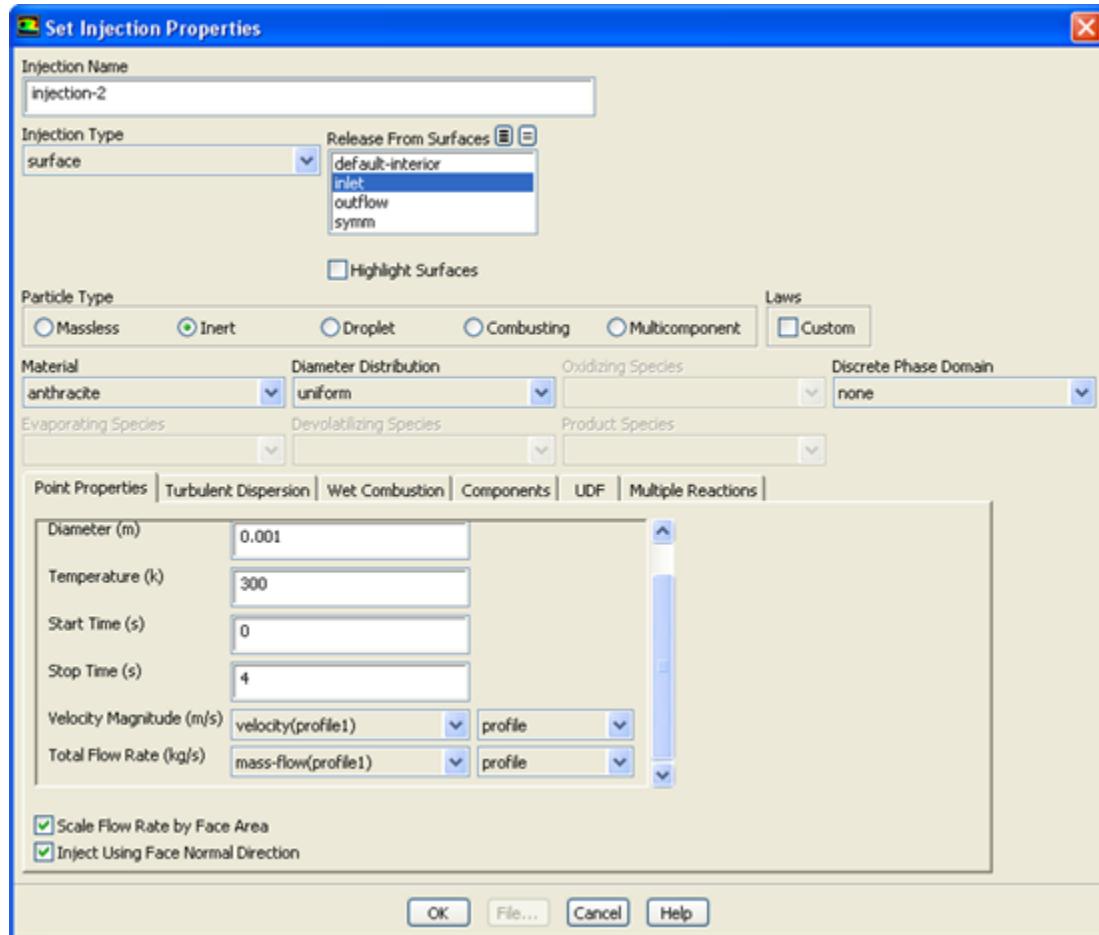

1. If you want to change the name of the injection from its default name, enter a new one in the **Injection Name** field. This is recommended if you are defining a large number of injections so you can easily distinguish them. When assigning names to your injections, keep in mind the selection shortcut described in *Creating and Modifying Injections* (p. 1112).
2. Choose the type of injection in the **Injection Type** drop-down list. The eleven choices (**single**, **group**, **cone**, **solid-cone**, **surface**, **plain-orifice-atomizer**, **pressure-swirl-atomizer**, **air-blast-atomizer**, **flat-fan-atomizer**, **effervescent-atomizer**, and **file**) are described in *Injection Types* (p. 1097). Note that if you select any of the atomizer models, you will also need to set the **Viscosity** and **Droplet Surface Tension** in the **Create/Edit Materials** dialog box.

Important

Note that only surface injections from boundary surfaces will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used.

3. If you are defining a **single** injection, go to the next step. For a **group**, **cone**, **solid-cone**, or any of the **atomizer** injections, set the **Number of Particle Streams** in the group, spray cone, or atomizer.

If you are defining a **surface** injection (see *Figure 25.18* (p. 1116)), choose the surface(s) from which the particles will be released in the **Release From Surfaces** list. If you are reading the injection from a file, click the **File...** button at the bottom of the *Set Injection Properties Dialog Box* (p. 2255) and specify the file to be read in the resulting **Select File** dialog box. The parameters in the injection file must be in SI units.

Figure 25.18 Setting Surface Injection Properties

4. Select **Massless**, **Inert**, **Droplet**, **Combusting**, or **Multicomponent** as the **Particle Type**. The available types are described in *Particle Types* (p. 1099).
5. Choose the material

for the particle(s) in the **Material** drop-down list. If this is the first time you have created a particle of this type, you can choose from all of the materials of this type defined in the database. If you have already created a particle of this type, the only available material will be the material you selected for that particle. You can define additional materials by copying them from the database or creating them from scratch, as discussed in *Setting Discrete-Phase Physical Properties* (p. 1131) and described in detail in *Using the Materials Task Page* (p. 405).

Important

Note that you will not choose a **Material** for a **Massless** particle type.

6. If you are defining a **group** or **surface** injection and you want to change from the default **linear** (for group injections) or **uniform** (for surface injections) interpolation method used to determine the size of the particles, select **rosin-rammler** or **rosin-rammler-logarithmic** in the **Diameter Distribution** drop-down list. The Rosin-Rammler method for determining the range of diameters for a group injection is described in *Using the Rosin-Rammler Diameter Distribution Method* (p. 1109).

7. If you have created a customized particle law using user-defined functions, enable the **Custom** option under **Laws** and specify the appropriate laws as described in [Custom Particle Laws \(p. 1120\)](#).
8. If your particle type is **Inert**, go to the next step. If you are defining **Droplet** particles, select the gas phase species created by the vaporization and boiling laws (Laws 2 and 3) in the **Evaporating Species** drop-down list.

If you are defining **Combusting** particles, select the gas phase species created by the devolatilization law (Law 4) in the **Devolatilizing Species** drop-down list, the gas phase species that participates in the surface char combustion reaction (Law 5) in the **Oxidizing Species** list, and the gas phase species created by the surface char combustion reaction (Law 5) in the **Product Species** list. Note that if the **Combustion Model** for the selected combusting particle material (in the **Create/Edit Materials** dialog box) is the **multiple-surface-reaction** model, then the **Oxidizing Species** and **Product Species** lists will be disabled because the reaction stoichiometry has been defined in the mixture material.

If you are defining **Multicomponent** particles, maw 7 will go into effect. Notice that the **Components** tab will become active when this particle type is selected. See below for information on the **Components** tab.

9. Click the **Point Properties** tab (the default), and specify the point properties (position, velocity, diameter, temperature, and—if appropriate—mass flow rate and any atomizer-related parameters) as described for each injection type in [Point Properties for Single Injections \(p. 1100\)](#) – [Point Properties for Effervescent Atomizer Injections \(p. 1108\)](#).

For surface injections, you can enable the **Scale Flow Rate by Face Area** and you can choose the injection direction. To use the face normal direction for the injection direction, select the **Inject Using Face Normal Direction** option under **Point Properties** ([Figure 25.18 \(p. 1116\)](#)). Once this option is selected, you only need to specify the velocity magnitude of the injection, not the individual components of the velocity magnitude.

10. If the flow is turbulent and you wish to include the effects of turbulence on the particle dispersion, click the **Turbulent Dispersion** tab, enable the **Discrete Random Walk Model** under **Stochastic tracking** or the **Cloud Model**, and set the related parameters as described in [Specifying Turbulent Dispersion of Particles \(p. 1118\)](#).
11. If your combusting particle includes an evaporating material, click the **Wet Combustion** tab, select the **Wet Combustion Model** option, and then select the material that is evaporating/boiling from the particle before devolatilization begins in the **Liquid Material** drop-down list. You should also set the volume fraction of the liquid present in the particle by entering the value of the **Liquid Fraction**. Finally, select the gas phase species created by the evaporating and boiling laws in the **Evaporating Species** drop-down list in the top part of the dialog box.
12. If you include multicomponent droplets as the material in your discrete phase model, the **Components** tab will become active. In this tab, you will specify the **Mass Fraction** of each of the components. Note that the sum of the mass fractions should add up to unity, otherwise ANSYS FLUENT will adjust the values such that you have a sum of 1 for the mass fraction, and will prompt you to accept the entry. Under **Evaporating Species**, select **not-vaporizing** if the component in the particle does not vaporize. Otherwise, select the species that will be vaporized.

To change the components of a materials from the **FLUENT Database Materials** dialog box, or define the droplet materials in the **Create/Edit Materials** dialog box, then add them to the **Selected Species** list in the **Species** dialog box by clicking the **Edit...** button (in the **Create/Edit Materials** dialog box) next to **Mixture Species**.

13. If you want to use a user-defined function to initialize the injection properties, click the **UDF** tab to access the UDF inputs. You can select an **Initialization** function under **User-Defined Functions** to

modify injection properties at the time the particles are injected into the domain. This allows the position and/or properties of the injection to be set as a function of flow conditions. More information about user-defined functions can be found in the [UDF Manual](#).

14. If you have defined more than one particle surface species, for example, carbon (C_{ss}) and sulfur (S_{ss}), you will need to specify the mass fraction of each particle surface species in the combustible particle. To do so, click the **Multiple Reactions** tab, and enter the **Species Mass Fractions**. These mass fractions refer to the combustible fraction of the combustible particle, and should sum to 1. If there is only one surface species in the mixture material, the mass fraction of that species will be set to 1, and you will not specify anything under **Multiple Surface Reactions**.

25.3.16. Specifying Turbulent Dispersion of Particles

As mentioned in [Defining Injection Properties \(p. 1114\)](#), you can choose for each injection stochastic tracking or cloud tracking as the method for modeling turbulent dispersion of particles.

25.3.16.1. Stochastic Tracking

For turbulent flows, if you choose to use the stochastic tracking technique, you must enable the **Discrete Random Walk Model** and specify the **Number of Tries**. Stochastic tracking includes the effect of turbulent velocity fluctuations on the particle trajectories using the DRW model described in [Stochastic Tracking](#) in the [Theory Guide](#).

1. Click the **Turbulent Dispersion** tab in the **Set Injection Properties** dialog box.
2. Enable stochastic tracking by turning on the **Discrete Random Walk Model** under **Stochastic Tracking**.
3. Specify the **Number of Tries**:

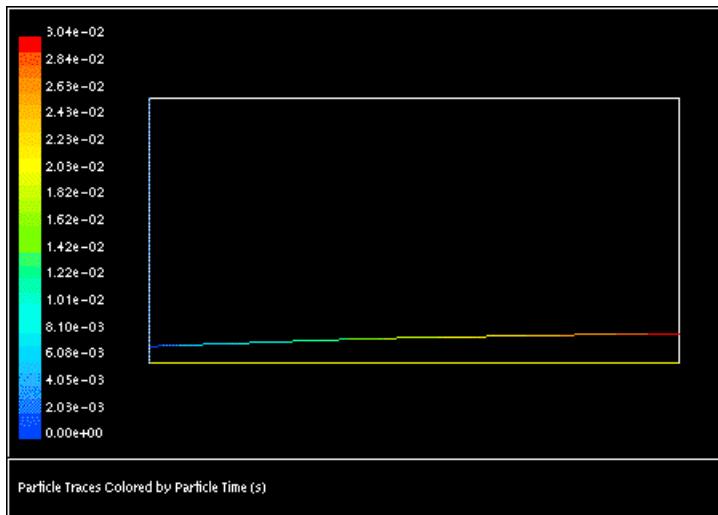

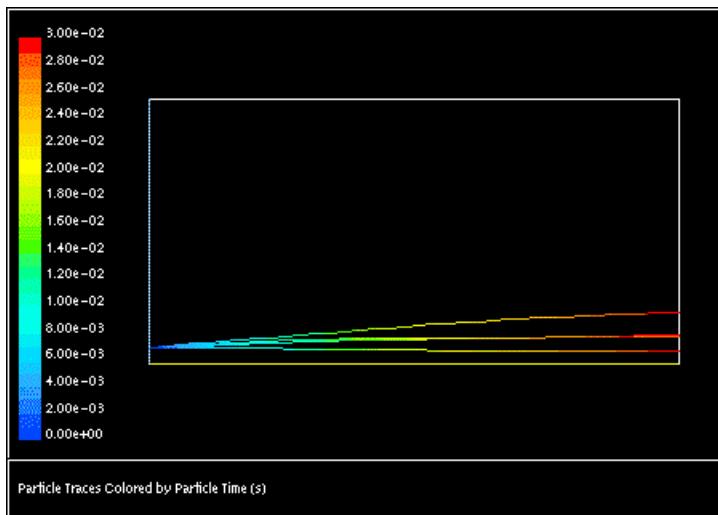

Selecting the **Turbulent Dispersion** model tells ANSYS FLUENT to include turbulent velocity fluctuations in the particle force balance as in [Equation 16–14](#) in the [Theory Guide](#). The trajectory is computed more than once if your input exceeds 1: two trajectory calculations are performed if you input 2, three trajectory calculations are performed if you input 3, etc. Each trajectory calculation includes a new stochastic representation of the turbulent contributions to the trajectory equation.

When a sufficient number of tries is requested, the trajectories computed will include a statistical representation of the spread of the particle stream due to turbulence. Note that for unsteady particle tracking, the **Number of Tries** is set to 1 if using stochastic tracking.

If you want the characteristic lifetime of the eddy to be random ([Equation 16–25](#) in the [Theory Guide](#)), enable the **Random Eddy Lifetime** option. You will generally not need to change the **Time Scale Constant** (C_L in [Equation 16–16](#) in the [Theory Guide](#)) from its default value of 0.15, unless you are using the Reynolds Stress turbulence model (RSM), in which case a value of 0.3 is recommended.

[Figure 25.19 \(p. 1119\)](#) illustrates a discrete phase trajectory calculation computed without turbulent dispersion and [Figure 25.20 \(p. 1119\)](#) illustrates the “stochastic” tracking (number of tries ≥ 1) option.

When multiple stochastic trajectory calculations are performed, the momentum and mass defined for the injection are divided evenly among the multiple particle/droplet tracks, and are thus spread out in terms of the interphase momentum, heat, and mass transfer calculations. Including turbulent dispersion in your model can thus have a significant impact on the effect of the particles on the continuous phase when coupled calculations are performed.

Figure 25.19 Mean Trajectory in a Turbulent Flow**Figure 25.20 Stochastic Trajectories in a Turbulent Flow**

25.3.16.2. Cloud Tracking

For turbulent flows, you can also include the effects of turbulent dispersion on the injection. Note that cloud tracking is not available for the massless particle type. When cloud tracking is used, the trajectory will be tracked as a cloud of particles about a mean trajectory, as described in [Particle Cloud Tracking](#) in the [Theory Guide](#).

1. Click the **Turbulent Dispersion** tab in the **Set Injection Properties** dialog box.
2. Enable cloud tracking by turning on the **Cloud Model** under **Cloud Tracking**.
3. Specify the minimum and maximum cloud diameters. Particles enter the domain with an initial cloud diameter equal to the **Min. Cloud Diameter**. The particle cloud's maximum allowed diameter is specified by the **Max. Cloud Diameter**.

You may want to restrict the **Max. Cloud Diameter** to a relevant length scale for the problem to improve computational efficiency in complex domains where the mean trajectory may become stuck in recirculation regions.

Important

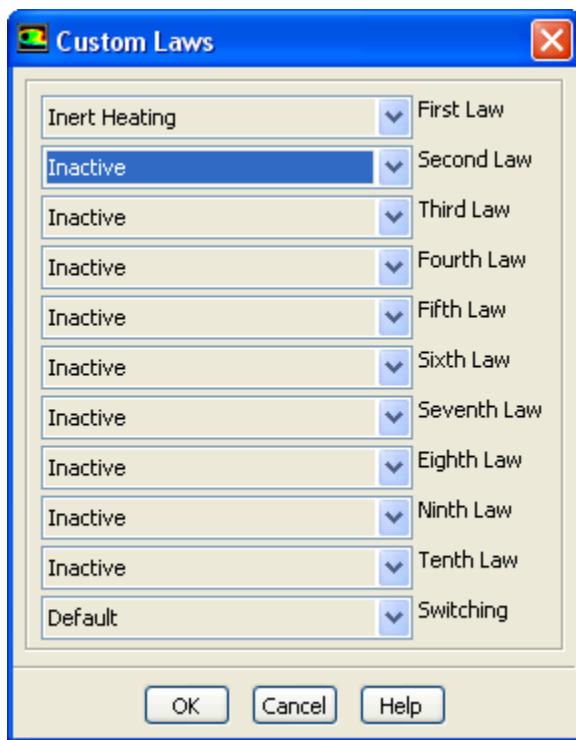

Note that this model is available only in serial or for shared memory tracking.

25.3.17. Custom Particle Laws

If the standard ANSYS FLUENT laws, Laws 1 through 7, do not adequately describe the physics of your discrete phase model, you can modify them by creating custom laws with user-defined functions. More information about user-defined functions can be found in the [UDF Manual](#). You can also create custom laws by using a subset of the existing ANSYS FLUENT laws (e.g., Laws 1, 2, and 4), or a combination of existing laws and user-defined functions.

Once you have defined and loaded your user-defined function(s), you can create a custom law by enabling the **Custom** option under **Laws** in the [Set Injection Properties Dialog Box \(p. 2255\)](#). This will open the [Custom Laws Dialog Box \(p. 2260\)](#). In the drop-down list to the left of each of the particle laws, you can select the appropriate particle law for your custom law. Each list contains the available options that can be chosen (the standard laws plus any user-defined functions you have loaded).

Figure 25.21 The Custom Laws Dialog Box

There is a final drop-down list in the [Custom Laws Dialog Box \(p. 2260\)](#) labeled **Switching**. You may wish to have ANSYS FLUENT vary the laws used depending on conditions in the model. You can customize the way ANSYS FLUENT switches between laws by selecting a user-defined function from this drop-down list (see [DEFINE_DPM_SWITCH](#) in the [UDF Manual](#)).

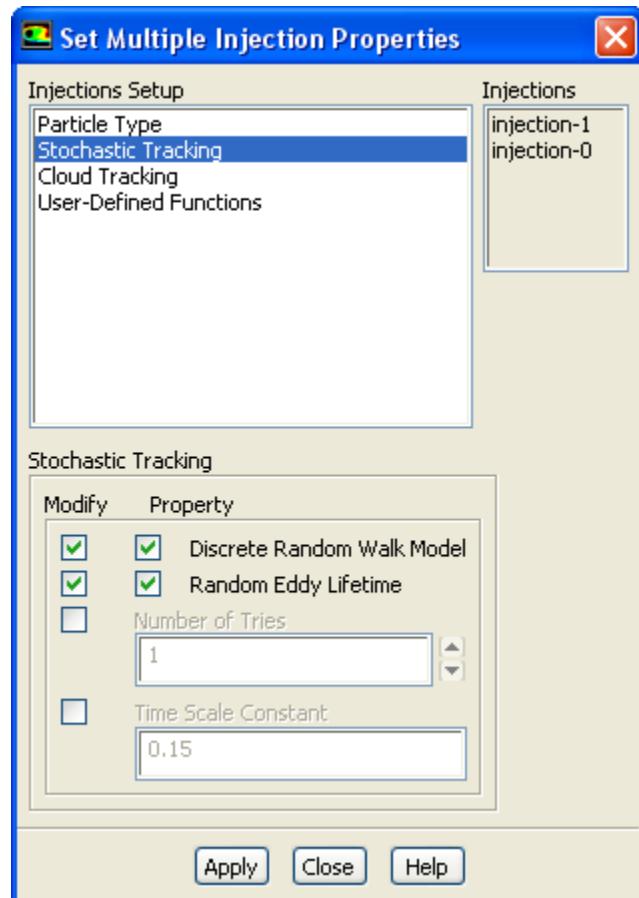

An example of when you might want to use a custom law might be to replace the standard devolatilization law with a specialized devolatilization law that more accurately describes some unique aspects of your model. After creating and loading a user-defined function that details the physics of your devolatilization law, you would visit the [Custom Laws Dialog Box \(p. 2260\)](#) and replace the standard devolatilization law (Law 2) with your user-defined function.

25.3.18. Defining Properties Common to More than One Injection

If you have a number of injections for which you want to set the same properties, ANSYS FLUENT provides a shortcut so that you do not need to visit the **Set Injection Properties** dialog box for each injection to make the same changes.

As described in *Defining Injection Properties* (p. 1114), if you select more than one injection in the **Injections** dialog box, clicking the **Set...** button will open the **Set Multiple Injection Properties** dialog box (*Figure 25.22 (p. 1121)*) instead of the **Set Injection Properties** dialog box.

Figure 25.22 The Set Multiple Injection Properties Dialog Box

Depending on the type of injections you have selected (single, group, atomizers, etc.), there will be different categories of properties listed under **Injections Setup**. The names of these categories correspond to the headings within the **Set Injection Properties** dialog box (e.g., **Particle Type** and **Stochastic Tracking**). Only those categories that are appropriate for all of your selected injections (which are shown in the **Injections** list) will be listed. If all of these injections are of the same type, more categories of properties will be available for you to modify. If the injections are of different types, you will have fewer categories to select from.

25.3.18.1. Modifying Properties

To modify a property, perform the following steps:

1. Select the appropriate category in the **Injections Setup** list. For example, if you want to set the same flow rate for all of the selected injections, select **Point Properties**. The dialog box will expand to show the properties that appear under that heading in the **Set Injection Properties** dialog box.
 2. Set the property (or properties) to be modified, as described below.
 3. Click **Apply**. ANSYS FLUENT will report the change in the console window.
-

Important

You must click **Apply** to save the property settings within each category. If, for example, you want to modify the flow rate and the stochastic tracking parameters, you will need to select **Point Properties** in the **Injections Setup** list, specify the flow rate, and click **Apply**. You would then repeat the process for the stochastic tracking parameters, clicking **Apply** again when you are done.

There are two types of properties that can be modified using the **Set Multiple Injection Properties** dialog box.

The first type involves one of the following actions:

- selecting a value from a drop-down list
- choosing an option using a radio button

The second type involves one of the following actions:

- entering a value in a field
- turning an option on or off

Setting the first type of property works the same way as in the **Set Injection Properties** dialog box. For example, if you select **Particle Type** in the **Injections Setup** list, the dialog box will expand to show the portion of the **Set Injection Properties** dialog box where you choose the particle type. You can simply choose the desired type and click **Apply**.

Setting the second type of property requires an additional step. If you select a category in the **Injections Setup** list that contains this type of property, the expanded portion of the dialog box will look like the corresponding part of the **Set Injection Properties** dialog box, with the addition of **Modify** check buttons (see [Figure 25.22 \(p. 1121\)](#)). To change one of the properties, first turn on the **Modify** check button to its left, and then specify the desired status or value.

For example, if you would like to enable stochastic tracking, first turn on the **Modify** check button to the left of **Stochastic Model**. This will make the property active so you can modify its status. Then, under **Property**, turn on the **Stochastic Model** check button. (Be sure to click **Apply** when you are done setting stochastic tracking parameters.)

If you would like to change the value of **Number of Tries**, select the **Modify** check button to its left to make it active, and then enter the new value in the field. Make sure you click **Apply** when you have finished modifying the stochastic tracking properties.

Important

The setting for a property that has not been activated with the **Modify** check button is not relevant, because it will not be applied to the selected injections when you click **Apply**. After you turn on **Modify** for a particular property, clicking **Apply** will modify that property for all of the selected injections, so make sure that you have the settings the way that you want them before you do this. If you make a mistake, you will have to return to the **Set Injection Properties** dialog box for each injection to fix the incorrect setting, if it is not possible to do so in the **Set Multiple Injection Properties** dialog box.

25.3.18.2. Modifying Properties Common to a Subset of Selected Injections

Note that it is possible to change a property that is relevant for only a subset of the selected injections. For example, if some of the selected injections are using stochastic tracking and some are not, enabling the **Random Eddy Lifetime** option and clicking **Apply** will turn this option on only for those injections that are using stochastic tracking. The other injections will be unaffected.

25.3.19. Point Properties for Transient Injections

Simulations of transient particles often require time dependent injection conditions. Potentially most of the point properties may change over time. One method to accomplish this is the use of an **Initialization** function as described in [DEFINE_DPM_INJECTION_INIT](#) in the [UDF Manual](#).

An easier way is to use transient profiles containing one or more variables based on the time or crank angle that can be assigned to various point properties: (Total) **Mass Flow Rate**, **X-, Y-, Z- Velocity**, and **Velocity Magnitude** depending on the injection type selected. See [Point Properties for Single Injections](#) (p. 1100) to [Point Properties for Effervescent Atomizer Injections](#) (p. 1108) for the description of the individual properties.

Before transient profile variables can be assigned to point properties of injections, a profile file has to be read into ANSYS FLUENT using the

File → Read → Profile...

menu item. In the **Select File** dialog box a **transient profile** in tabular format with extension **.ttab** has to be chosen. Alternatively, you can read this file into ANSYS FLUENT using the **read-transient-table** text command.

file → read-transient-table

The profile name should not exceed 63 characters. See [Defining Transient Cell Zone and Boundary Conditions](#) (p. 393) for the format description. The following example illustrates an injection within 3 intervals of 2.5 milliseconds injection time, where the second injection has an elevated velocity.

```
mv-profile 3 13 0
time      mass-flow    velocity
0          0            0.1
0.00999   0            0.1
0.01       0.001        0.1
0.0125    0.001        0.1
0.01251   0            0.1
0.01999   0            0.1
0.02       0.001        5
0.0225    0.001        5
0.02251   0            0.1
0.02999   0            0.1
```

0.03	0.001	0.1
0.0325	0.001	0.1
0.03251	0	0.1

For the setting of point properties go to the **Point Properties** tab in the **Set Injection Properties** dialog box.

When transient profiles are loaded, you can choose either a **constant** method (the default) or **profile** from the **Method** drop-down list. If you select **profile**, you will also need to choose a profile from the corresponding drop-down list that appears in the **Value** column. The variable angle or time from the file is used as an independent interpolation variable and cannot be chosen as a profile.

25.4. Setting Boundary Conditions for the Discrete Phase

When a particle reaches a physical boundary (e.g., a wall or inlet boundary) in your model, ANSYS FLUENT applies a discrete phase boundary condition to determine the fate of the trajectory at that boundary. One of several contingencies may arise:

- The particle may be reflected via an elastic or inelastic collision.
- The particle may escape through the boundary. The particle is lost from the calculation at the point where it impacts the boundary.
- The particle may be trapped at the wall. Nonvolatile material is lost from the calculation at the point of impact with the boundary; volatile material present in the particle or droplet is released to the vapor phase at this point.
- The particle may pass through an internal boundary zone, such as radiator or porous jump.
- The particle may slide along the wall, depending on particle properties and impact angle.
- The particle may form a film (Wall-Film Model).

You also have the option of implementing a user-defined function to model the particle behavior when hitting the boundary. More information about user-defined functions can be found in the [UDF Manual](#).

The boundary condition, or trajectory fate, can be defined separately for each zone in your ANSYS FLUENT model.

For additional information, please see the following sections:

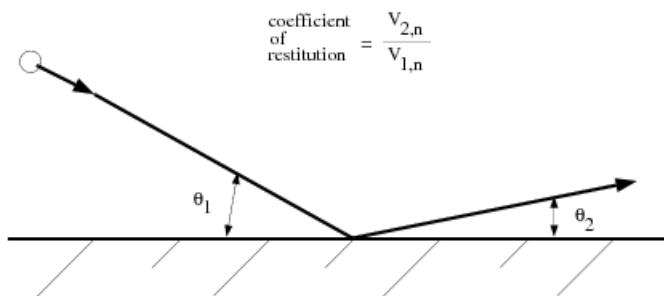

- [25.4.1. Discrete Phase Boundary Condition Types](#)
- [25.4.2. Setting Particle Erosion and Accretion Parameters](#)

25.4.1. Discrete Phase Boundary Condition Types

The available boundary conditions are

- **reflect**

The particle rebounds the off the boundary in question with a change in its momentum as defined by the coefficient of restitution. (See [Figure 25.23 \(p. 1125\)](#).)

Figure 25.23 “Reflect” Boundary Condition for the Discrete Phase

The normal coefficient of restitution defines the amount of momentum in the direction normal to the wall that is retained by the particle after the collision with the boundary [89] (p. 2371):

$$e_n = \frac{v_{2,n}}{v_{1,n}} \quad (25-11)$$

where v_n is the particle velocity normal to the wall and the subscripts 1 and 2 refer to before and after collision, respectively. Similarly, the tangential coefficient of restitution, e_t , defines the amount of momentum in the direction tangential to the wall that is retained by the particle.

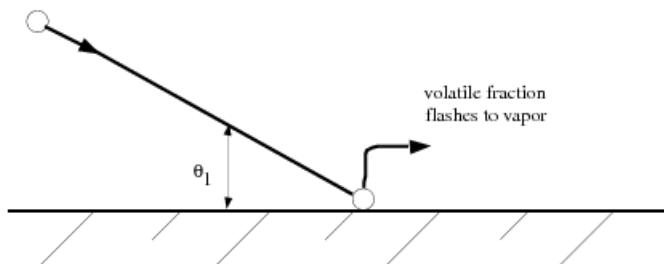

A normal or tangential coefficient of restitution equal to 1.0 implies that the particle retains all of its normal or tangential momentum after the rebound (an elastic collision). A normal or tangential coefficient of restitution equal to 0.0 implies that the particle retains none of its normal or tangential momentum after the rebound.

Nonconstant coefficients of restitution can be specified for wall zones with the **reflect** type boundary condition. The coefficients are set as a function of the impact angle, θ_i , in [Figure 25.23 \(p. 1125\)](#).

Note that the default setting for both coefficients of restitution is a constant value of 1.0 (all normal and tangential momentum retained).

- **trap**

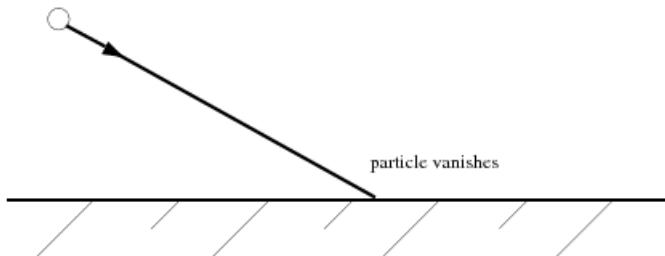

The trajectory calculations are terminated and the fate of the particle is recorded as “trapped”. In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See [Figure 25.24 \(p. 1125\)](#). In the case of combusting particles, the remaining volatile mass is passed into the vapor phase.

Figure 25.24 “Trap” Boundary Condition for the Discrete Phase

- **escape**

The particle is reported as having “escaped” when it encounters the boundary in question. Trajectory calculations are terminated. See [Figure 25.25 \(p. 1126\)](#).

Figure 25.25 “Escape” Boundary Condition for the Discrete Phase

- **wall-jet**

The **wall-jet** type boundary condition is appropriate for high-temperature walls where no significant liquid film is formed, and in high-Weber-number impacts where the spray acts as a jet. The model is not appropriate for regimes where film is important (e.g., port fuel injection in SI engines, rain-water runoff, etc.).

A more detailed description of underlying theory is available in [Wall-Jet Model Theory](#) in the [Theory Guide](#).

- **wall-film**

This boundary condition consists of four regimes: stick, rebound, spread, and splash, which are based on the impact energy and wall temperature. Detailed information on the wall-film model can be found in [Wall-Film Model Theory](#) in the [Theory Guide](#).

Important

Note that the **Workpile Algorithm** option is not available with the wall film boundary condition. It will be disabled automatically when choosing to simulate a wall film on a wall.

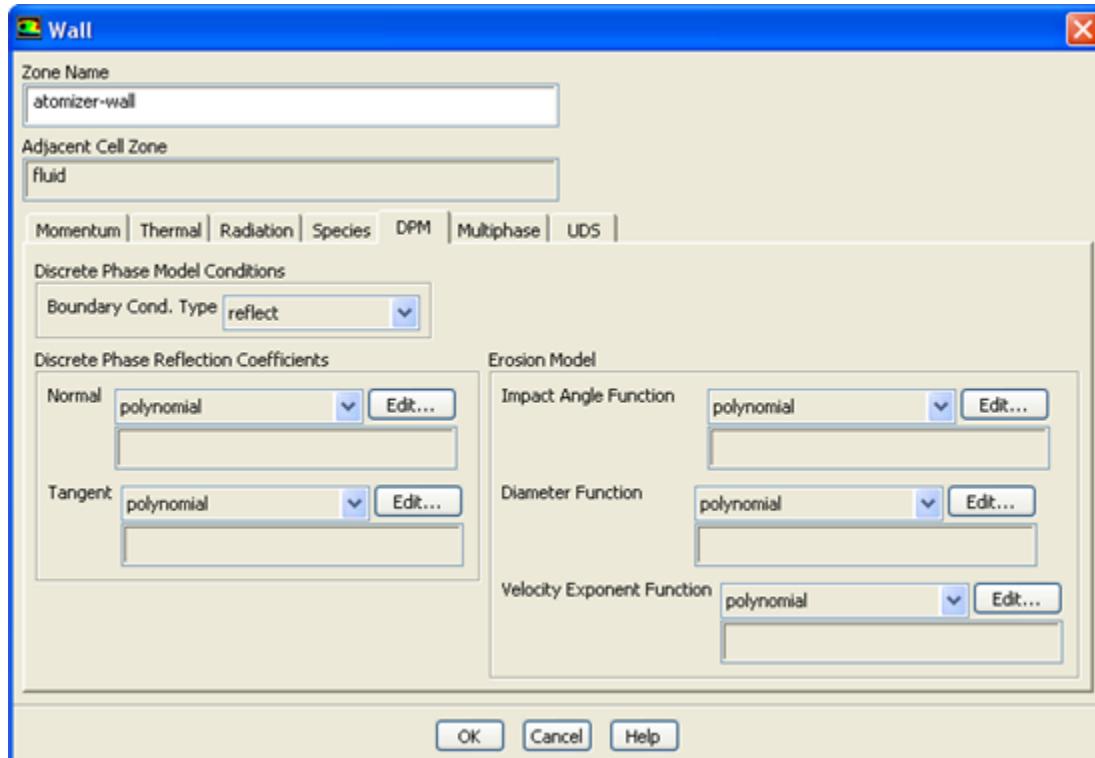

- **interior**

This boundary condition means that the particles will pass through the internal boundary. This option is available only for internal boundary zones, such as a radiator or a porous jump.

It is also possible to use a user-defined function to compute the behavior of the particles at a physical boundary. More information about user-defined functions can be found in the [UDF Manual](#).

Because you can stipulate any of these conditions at flow boundaries, it is possible to incorporate mixed discrete phase boundary conditions in your ANSYS FLUENT model.

Discrete phase boundary conditions can be set for boundaries in the dialog boxes opened from the **Boundary Conditions** task page. When one or more injections have been defined, inputs for the discrete phase will appear in the dialog boxes (e.g., [Figure 25.26 \(p. 1127\)](#)).

Figure 25.26 Discrete Phase Boundary Conditions in the Wall Dialog Box

Select **reflect**, **trap**, **escape**, **wall-jet**, **wall-film**, **interior**, or **user-defined** from the **Boundary Cond. Type** drop-down list under **Discrete Phase Model Conditions**, as shown in [Figure 25.26 \(p. 1127\)](#). (In the **Walls** dialog boxes, you will need to click the **DPM** tab to access the **Discrete Phase Model Conditions**.) If you select **user-defined**, you can select a user-defined function in the **Boundary Cond. Function** drop-down list. For internal boundary zones, such as a radiator or a porous jump, you can also choose an **interior** boundary condition. The **interior** condition means that the particles will pass through the internal boundary.

If you select the **reflect** type at a wall (only), you can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Normal** and **Tangent** coefficients of restitution under **Discrete Phase Reflection Coefficients**. See [Discrete Phase Boundary Condition Types \(p. 1124\)](#) for details about the boundary condition types and the coefficients of restitution. The dialog boxes for defining the polynomial, piecewise-linear, and piecewise-polynomial functions are the same as those used for defining temperature-dependent properties. See [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#) for details.

25.4.1.1. Default Discrete Phase Boundary Conditions

ANSYS FLUENT makes the following assumptions regarding boundary conditions:

- The **reflect** type is assumed at wall, symmetry, and axis boundaries, with both coefficients of restitution equal to 1.0
- The **escape** type is assumed at all flow boundaries (pressure and velocity inlets, pressure outlets, etc.)
- The **interior** type is assumed at all internal boundaries (radiator, porous jump, etc.)

The coefficient of restitution can be modified only for wall boundaries.

25.4.2. Setting Particle Erosion and Accretion Parameters

If the **Erosion/Accretion** option is selected in the *Discrete Phase Model Dialog Box* (p. 1859), the erosion rate expression must be specified at the walls. The erosion rate is defined in [Equation 16–211](#) in the [Theory Guide](#) as a product of the mass flux and specified functions for the particle diameter, impact angle, and velocity exponent. Under **Erosion Model** in the *Wall Dialog Box* (p. 2011), you can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Impact Angle Function**, **Diameter Function**, and **Velocity Exponent Function** ($f(\alpha)$, $C(d_p)$, and $b(v)$) in [Equation 16–211](#) in the [Theory Guide](#)). See [Particle Erosion and Accretion Theory](#) in the [Theory Guide](#) and [Monitoring Erosion/Accretion of Particles at Walls](#) (p. 1085) for a detailed description of these functions and [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) for details about using the dialog boxes for defining polynomial, piecewise-linear, and piecewise-polynomial functions.

25.5. Setting Material Properties for the Discrete Phase

In order to apply the physical models described in earlier sections to the prediction of the discrete phase trajectories and heat/mass transfer, ANSYS FLUENT requires many physical property inputs.

For additional information, please see the following sections:

[25.5.1. Summary of Property Inputs](#)

[25.5.2. Setting Discrete-Phase Physical Properties](#)

25.5.1. Summary of Property Inputs

[Table 25.1: Property Inputs for Inert Particles](#) (p. 1128) – [Table 25.5: Property Inputs for Multicomponent Particles \(Law 7\)](#) (p. 1131) summarize which of these property inputs are used for each particle type and in which of the equations for heat and mass transfer each property input is used. Detailed descriptions of each input are provided in [Setting Discrete-Phase Physical Properties](#) (p. 1131).

Table 25.1 Property Inputs for Inert Particles

Property	Symbol

25.5.2. Setting Discrete-Phase Physical Properties

25.5.2.1. The Concept of Discrete-Phase Materials

When you create a particle injection and define the initial conditions for the discrete phase (as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#)), you choose a particular material as the particle's material. All particle streams of that material will have the same physical properties.

Important

Note that you will not choose a **Material** for a **Massless** particle type in the **Set Injections Properties** dialog box.

Discrete-phase materials are divided into four categories, corresponding to the four types of particles available. These material types are **inert-particle**, **droplet-particle**, **combusting-particle**, and **multicomponent-particle**. Each material type will be added to the **Material Type** list in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) when an injection of that type of particle is defined (in the **Set Injection Properties** or **Set Multiple Injection Properties** dialog box, as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#)). The first time you create an injection of each particle type, you will be able to choose a material from the database, and this will become the default material for that type of particle. That is,

if you create another injection of the same type of particle, your selected material will be used for that injection as well. You may choose to modify the predefined properties for your selected particle material, if you want (as described in [Modifying Properties of an Existing Material \(p. 406\)](#)). If you need only one set of properties for each type of particle, you need not define any new materials; you can simply use the same material for all particles.

Important

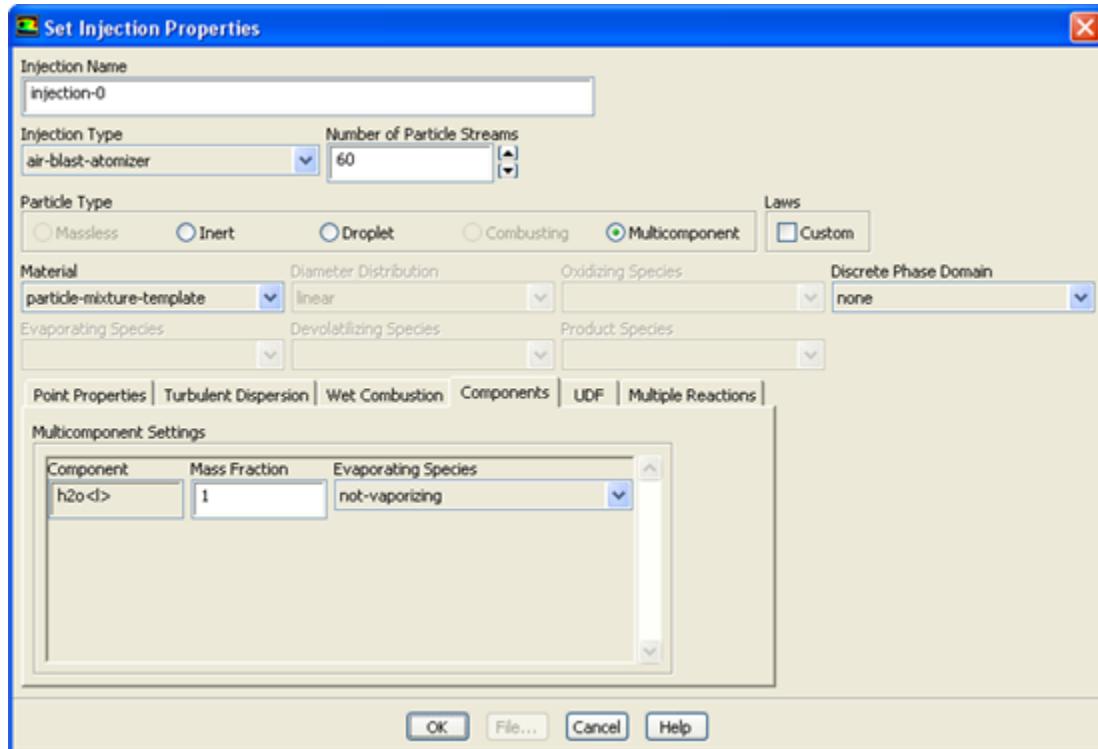

If you do not find the material you want in the database, you can select a material that is close to the one you wish to use, and then modify the properties and give the material a new name, as described in [Creating a New Material \(p. 408\)](#).

Important

Note that a discrete-phase material type will not appear in the **Material Type** list in the **Create/Edit Materials** dialog boxes until you have defined an injection of that type of particles. This means, for example, that you cannot define or modify any combusting-particle materials until you have defined a combusting particle injection (as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#)).

For a **particle-mixture** material type, you will need to select the species in your mixture. To do this, click the **Edit...** button next to **Mixture Species** in the **Create/Edit Materials** dialog box. The **Species** dialog box will open, where you will include your **Selected Species**. The selected species will now be available in the **Set Injection Properties** dialog box, under the **Components** tab ([Figure 25.27 \(p. 1132\)](#)).

Figure 25.27 The Components Tab

25.5.2.1.1. Defining Additional Discrete-Phase Materials

In many cases, a single set of physical properties (density, heat capacity, etc.) is appropriate for each type of discrete phase particle considered in a given model. Sometimes, however, a single model may contain two different types of inert, droplet, combusting particles, or multicomponent particles (e.g., heavy particles and gaseous bubbles or two different types of evaporating liquid droplets). In such cases, it is necessary to assign a different set of properties to the two (or more) different types of particles. This is easily accomplished by defining two or more inert, droplet, or combusting particle materials and using the appropriate one for each particle injection.

You can define additional discrete-phase materials either by copying them from the database or by creating them from scratch. See [Using the Materials Task Page \(p. 405\)](#) for instructions on using the [Create/Edit Materials Dialog Box \(p. 1882\)](#) to perform these actions.

Important

Recall that you must define at least one injection (as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#)) containing particles of a certain type before you will be able to define additional materials for that particle type.

25.5.2.2. Description of the Properties

The properties that appear in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) vary depending on the particle type (selected in the **Set Injection Properties** or **Set Multiple Injection Properties** dialog box, as described in [Defining Injection Properties \(p. 1114\)](#) and [Defining Properties Common to More than One Injection \(p. 1121\)](#)) and the physical models you are using in conjunction with the discrete-phase model.

Below, all properties you may need to define for a discrete-phase material are listed (alphabetically). See [Table 25.1: Property Inputs for Inert Particles \(p. 1128\)](#) – [Table 25.4: Property Inputs for Combusting Particles \(Law 5\) \(p. 1130\)](#) to see which properties are defined for each type of particle.

Binary Diffusivity

is the mass diffusion coefficient, $D_{i,m}$, used in the vaporization law, Law 2 ([Equation 16–86](#) in the [Theory Guide](#)). This input is also used to define the mass diffusion of the oxidizing species to the surface of a combusting particle, $D_{i,m}$, as given in [Equation 16–142](#) in the [Theory Guide](#). (Note that the diffusion coefficient inputs that you supply for the continuous phase are not used for the discrete phase.) For **Droplet Particle** type **Materials**, select **film-averaged** from the **Binary Diffusivity** drop-down list to apply the film-averaged model (see [Equation 16–90](#) in the [Theory Guide](#)).

Boiling Point

is the temperature, T_{bp} , at which the calculation of the boiling rate equation ([Equation 16–97](#) in the [Theory Guide](#)) is initiated by ANSYS FLUENT. When a droplet particle reaches the boiling point, ANSYS FLUENT applies Law 3 and assumes that the droplet temperature is constant at T_{bp} . The boiling point denotes the temperature at which the particle law transitions from the vaporization law to the boiling law.

For multicomponent particles the boiling point of the components is used only as a reference temperature of the latent heat. Instead, the boiling starts when the sum of the partial component saturation pressures reach the total fluid pressure. The definition of the saturation pressure curve is therefore essential for the boiling of multicomponent particles.

Burnout Stoichiometric Ratio

is the stoichiometric requirement, S_b , for the burnout reaction, [Equation 16–141](#) in the Theory Guide, in terms of mass of oxidant per mass of char in the particle.

Combustible Fraction

is the mass fraction of char, f_{comb} , in the coal particle, i.e., the fraction of the initial combusting particle that will react in the surface reaction, Law 5 ([Equation 16–140](#) in the Theory Guide).

Combustion Model

defines which version of the surface char combustion law (Law5) is being used. If you want to use the default diffusion-limited rate model, retain the selection of **diffusion-limited** in the drop-down list to the right of **Combustion Model**. No additional inputs are necessary, because the binary diffusivity defined above will be used in [Equation 16–142](#) in the Theory Guide.

To use the kinetics/diffusion-limited rate model for the surface combustion model, select **kinetics/diffusion-limited** in the drop-down list. The [Kinetics/Diffusion-Limited Combustion Model Dialog Box](#) (p. 1926) will appear and you will enter the **Mass Diffusion Limited Rate Constant** (C_1 in [Equation 16–143](#) in the Theory Guide), **Kinetics Limited Rate Pre-exponential Factor** (C_2 in [Equation 16–144](#)), and **Kinetics Limited Rate Activation Energy** (E in [Equation 16–144](#)).

Note that the **Kinetics/Diffusion-Limited Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.

To use the intrinsic model for the surface combustion model, select **intrinsic-model** in the drop-down list. The [Intrinsic Combustion Model Dialog Box](#) (p. 1927) will appear and you will enter the **Mass Diffusion Limited Rate Constant** (C_1 in [Equation 16–143](#) in the Theory Guide), **Kinetics Limited Rate Pre-exponential Factor** (A_i in [Equation 16–153](#)), **Kinetics Limited Rate Activation Energy** (E_i in [Equation 16–153](#)), **Char Porosity** (θ in [Equation 16–150](#)), **Mean Pore Radius** (\bar{r}_p in [Equation 16–152](#)), **Specific Internal Surface Area** (A_g in [Equation 16–147](#) [Equation 16–149](#)), **Tortuosity** (τ in [Equation 16–150](#)), and **Burning Mode, alpha** (α in [Equation 16–154](#)).

Note that the **Intrinsic Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.

To use the multiple surface reactions model, select **multiple-surface-reactions** in the drop-down list. ANSYS FLUENT will display a dialog box informing you that you will need to open the **Reactions** dialog box, where you can review or modify the particle surface reactions that you specified as described in [Overview of User Inputs for Modeling Species Transport and Reactions](#) (p. 855).

Important

If you have not yet defined any particle surface reactions, you must be sure to define them now. See [Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion](#) (p. 893) for more information about using the multiple surface reactions model.

You will notice that the **Burnout Stoichiometric Ratio** and **Heat of Reaction for Burnout** are no longer available in the **Create/Edit Materials** dialog box, as these parameters are now computed from the particle surface reactions you defined in the **Reactions** dialog box.

Note that the multiple surface reactions model is available only if the **Particle Surface** option for **Reactions** is enabled in the **Species Model** dialog box. See [User Inputs for Particle Surface Reactions \(p. 892\)](#) for details.

Cp

is the specific heat, c_p , of the particle. The specific heat may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Cp**. See [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#) for details about temperature-dependent properties. For multicomponent particles, it can be calculated as a mass-weighted value of the specific heat of the droplet component.

Density

is the density of the particulate phase in units of mass per unit volume of the discrete phase. This density is the mass density and not the volumetric density. Since certain particles may swell during the trajectory calculations, your input is actually an “initial” density.

Devolatilization Model

defines which version of the devolatilization model, Law 4, is being used. If you want to use the default constant rate devolatilization model, [Equation 16–103](#) in the [Theory Guide](#), retain the selection of **constant** in the drop-down list to the right of **Devolatilization Model** and input the rate constant A_0 in the field below the list.

You can activate one of the optional devolatilization models (the single kinetic rate, two kinetic rates, or CPD model, as described in [Devolatilization \(Law 4\)](#) in the [Theory Guide](#)) by choosing **single rate**, **two-competing-rates**, or **cpd-model** in the drop-down list.

When the single kinetic rate model (**single-rate**) is selected, the [Single Rate Devolatilization Dialog Box \(p. 1924\)](#) will appear and you will enter the **Pre-exponential Factor**, A_1 , and the **Activation Energy**, E , to be used in [Equation 16–105](#) in the [Theory Guide](#) for the computation of the kinetic rate.

When the two competing rates model (**two-competing-rates**) is selected, the [Two Competing Rates Model Dialog Box \(p. 1925\)](#) will appear and you will enter, for the **First Rate** and the **Second Rate**, the **Pre-exponential Factor** (A_1 in [Equation 16–107](#) and A_2 in [Equation 16–108](#) in the [Theory Guide](#)), **Activation Energy** (E_1 in [Equation 16–107](#) and E_2 in [Equation 16–108](#)), and **Weighting Factor** (α_1 and α_2 in [Equation 16–109](#)). The constants you input are used in [Equation 16–107](#) through [Equation 16–109](#).

When the CPD model (**cpd-model**) is selected, the **CPD Model** dialog box will appear and you will enter the **Initial Fraction of Bridges in Coal Lattice** (p_0 in [Equation 16–120](#) of the [Theory Guide](#)), **Initial Fraction of Char Bridges** (c_0 in [Equation 16–119](#)), **Lattice Coordination Number** ($\sigma + 1$ in [Equation 16–131](#)), **Cluster Molecular Weight** ($M_{w,1}$ in [Equation 16–131](#)), and **Side Chain Molecular Weight** ($M_{w,\delta}$ in [Equation 16–130](#)).

Note that the **Single Rate Devolatilization Model**, **Two Competing Rates Model**, and **CPD Model** dialog boxes are modal dialog boxes, which means that you must tend to them immediately before continuing the property definitions.

Heat of Pyrolysis

is the heat of the instantaneous pyrolysis reaction, h_{pyrol} , that the evaporating/boiling species may undergo when released to the continuous phase. This input represents the conversion of the evaporating species to lighter components during the evaporation process. The heat of pyrolysis should be input as a positive number for exothermic reaction and as a negative number for endothermic reaction. The default

value of zero implies that the heat of pyrolysis is not considered. This input is used in [Equation 16–324](#) in the [Theory Guide](#).

Heat of Reaction for Burnout

is the heat released by the surface char combustion reaction, Law 5 ([Equation 16–141](#) in the [Theory Guide](#)). This parameter is input in terms of heat release (e.g., Joules) per unit mass of char consumed in the surface reaction.

Latent Heat

is the latent heat of vaporization, h_{fg} , required for phase change from an evaporating liquid droplet ([Equation 16–92](#) in the [Theory Guide](#)) or for the evolution of volatiles from a combusting particle ([Equation 16–135](#) in the [Theory Guide](#)). This input is supplied in units of J/kg in SI units or of Btu/lb_m in British units and is treated as a constant by ANSYS FLUENT. For the droplet particle, the latent heat value at the boiling point temperature should be used.

React. Heat Fraction Absorbed by Solid

is the parameter f_h ([Equation 16–155](#) in the [Theory Guide](#)), which controls the distribution of the heat of reaction between the particle and the continuous phase. The default value of zero implies that the entire heat of reaction is released to the continuous phase.

Saturation Vapor Pressure

is the saturated vapor pressure, p_{sat} , defined as a function of temperature, which is used in the vaporization law, Law 2 ([Equation 16–84](#) in the [Theory Guide](#)). The saturated vapor pressure may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of its name. (See [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) for details about temperature-dependent properties.) In the case of unrealistic inputs, ANSYS FLUENT restricts the range of P_{sat} to between 0.0 and the operating pressure. Correct input of a realistic vapor pressure curve is essential for accurate results from the vaporization model.

Swelling Coefficient

is the coefficient C_{sw} in [Equation 16–134](#) in the [Theory Guide](#), which governs the swelling of the coal particle during the devolatilization law, Law 4 ([Devolatilization \(Law 4\)](#) in the [Theory Guide](#)). A swelling coefficient of unity (the default) implies that the coal particle stays at constant diameter during the devolatilization process.

Thermal Conductivity

is the thermal conductivity of the particle. This input is specified in units of W/m-K in SI units or Btu/ft·h·°F in British units and is treated as a constant by ANSYS FLUENT.

Thermophoretic Coefficient

is the coefficient $D_{T,p}$ in [Equation 16–8](#) in the [Theory Guide](#), and appears when the thermophoretic force (which is described in [Thermophoretic Force](#) in the [Theory Guide](#)) is included in the trajectory calculation (i.e., when the **Thermophoretic Force** option is enabled in the **Discrete Phase Model** dialog box). The default is the expression developed by Talbot [90] (p. 2372) (**talbot-diffusion-coeff**) and requires no input from you. You can also define the thermophoretic coefficient as a function of temperature by selecting one of the function types from the drop-down list to the right of **Thermophoretic Coefficient**. See [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) for details about temperature-dependent properties.

Vaporization Temperature

is the temperature, T_{vap} , at which the calculation of vaporization from a liquid droplet or devolatilization from a combusting particle is initiated by ANSYS FLUENT. Until the particle temperature reaches T_{vap} ,

the particle is heated via Law 1, [Equation 16–74](#) in the [Theory Guide](#). This temperature input represents a modeling decision rather than any physical characteristic of the discrete phase.

Vapor-Particle-Equilibrium

is the selected approach for the calculation of the vapor concentration of the components at the surface. This can be Raoult's law ([Equation 16–167](#) in the [Theory Guide](#)), the Peng-Robinson real gas model ([Equation 16–175](#) in the [Theory Guide](#)), or a user-defined function that defines the equilibrium.

Vaporization Model

defines which vaporization model is used for pure droplets (Law 2) and for multicomponent droplets (Law 7). If you want to use the default diffusion controlled model, retain the selection of **diffusion-controlled** from the drop-down list to the right of **Vaporization Model**. This will apply [Equation 16–83](#) in the [Theory Guide](#).

To use the convection/diffusion controlled model for vaporization select **convection/diffusion-controlled** from the drop-down list. [Equation 16–88](#) in the [Theory Guide](#) will be applied for the calculation of the vaporization rate, and [Equation 16–94](#) in the [Theory Guide](#) will be applied in the particle heat transfer calculations. This model is recommended when evaporation rates are high. For slowly evaporating droplets both models are expected to give similar results.

Volatile Component Fraction

(f_{v0}) is the mass fraction of a droplet particle that may vaporize via Laws 2 and/or 3 ([Droplet Vaporization \(Law 2\)](#) in the [Theory Guide](#)). For combusting particles, it is the mass fraction of volatiles that may be evolved via Law 4 ([Devolatilization \(Law 4\)](#) in the [Theory Guide](#)).

When the effect of particles on radiation is enabled (for the P-1 or discrete ordinates radiation model only) in the [Discrete Phase Model Dialog Box](#) (p. 1859), you will need to define the following additional parameters:

Particle Emissivity

is the emissivity of particles in your model, ϵ_p , used to compute radiation heat transfer to the particles ([Equation 16–74](#), [Equation 16–92](#), [Equation 16–100](#), [Equation 16–135](#), and [Equation 16–155](#) in the [Theory Guide](#)) when the P-1 or discrete ordinates radiation model is active. Note that you must enable radiation to particles, using the **Particle Radiation Interaction** option in the [Discrete Phase Model Dialog Box](#) (p. 1859). Recommended values of particle emissivity are 1.0 for coal particles and 0.5 for ash [47] (p. 2369).

Particle Scattering Factor

is the scattering factor, f_p , due to particles in the P-1 or discrete ordinates radiation model ([Equation 5–34](#) in the [Theory Guide](#)). Note that you must enable particle effects in the radiation model, using the **Particle Radiation Interaction** option in the [Discrete Phase Model Dialog Box](#) (p. 1859). The recommended value of f_p for coal combustion modeling is 0.9 [47] (p. 2369). Note that if the effect of particles on radiation is enabled, scattering in the continuous phase will be ignored in the radiation model.

When an atomizer injection model and/or the droplet breakup or collision model is enabled in the [Set Injection Properties Dialog Box](#) (p. 2255) (atomizers) and/or [Discrete Phase Model Dialog Box](#) (p. 1859) (droplet breakup/collision), you will need to define the following additional parameters:

Droplet Surface Tension

is the droplet surface tension, σ . The surface tension may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Droplet Surface Tension**. See [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) for details about temperature dependent properties. You also have the option of implementing a user-defined function to model the droplet surface tension. More information about user-defined functions can be found in the [UDF Manual](#).

Viscosity

is the droplet viscosity, μ_d . The viscosity may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Viscosity**. See [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#) for details about temperature-dependent properties. You also have the option of implementing a user-defined function to model the droplet viscosity. More information about user-defined functions can be found in the [UDF Manual](#).

25.6. Solution Strategies for the Discrete Phase

Solution of the discrete phase implies integration in time of the force balance on the particle ([Equation 16–1](#) in the [Theory Guide](#)) to yield the particle trajectory. As the particle is moved along its trajectory, heat and mass transfer between the particle and the continuous phase are also computed via the heat/mass transfer laws ([Laws for Heat and Mass Exchange](#) in the [Theory Guide](#)). The accuracy of the discrete phase calculation thus depends on the time accuracy of the integration and upon the appropriate coupling between the discrete and continuous phases when required. Numerical controls are described in [Numerics of the Discrete Phase Model \(p. 1092\)](#). Coupling and performing trajectory calculations are described in [Performing Trajectory Calculations \(p. 1138\)](#). [Resetting the Interphase Exchange Terms \(p. 1142\)](#) and [Parallel Processing for the Discrete Phase Model \(p. 1168\)](#) provide information about resetting interphase exchange terms and using the parallel solver for a discrete phase calculation.

For additional information, please see the following sections:

25.6.1. Performing Trajectory Calculations

25.6.2. Resetting the Interphase Exchange Terms

25.6.1. Performing Trajectory Calculations

The trajectories of your discrete phase injections are computed when you display the trajectories using graphics or when you perform solution iterations. That is, you can display trajectories without impacting the continuous phase, or you can include their effect on the continuum (termed a coupled calculation). In turbulent flows, trajectories can be based on mean (time-averaged) continuous phase velocities or they can be impacted by instantaneous velocity fluctuations in the fluid. This section describes the procedures and commands you use to perform coupled or uncoupled trajectory calculations, with or without stochastic tracking or cloud tracking.

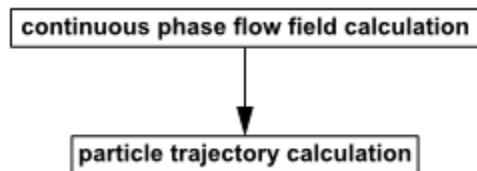

25.6.1.1. Uncoupled Calculations

For the uncoupled calculation, you will perform the following two steps:

1. Solve the continuous phase flow field.
2. Plot (and report) the particle trajectories for discrete phase injections of interest.

In the uncoupled approach, this two-step procedure completes the modeling effort, as illustrated in [Figure 25.28 \(p. 1139\)](#). The particle trajectories are computed as they are displayed, based on a fixed continuous-phase flow field. Graphical and reporting options are detailed in [Postprocessing for the Discrete Phase \(p. 1142\)](#).

Figure 25.28 Uncoupled Discrete Phase Calculations

This procedure is adequate when the discrete phase is present at a low mass and momentum loading, in which case the continuous phase is not impacted by the presence of the discrete phase.

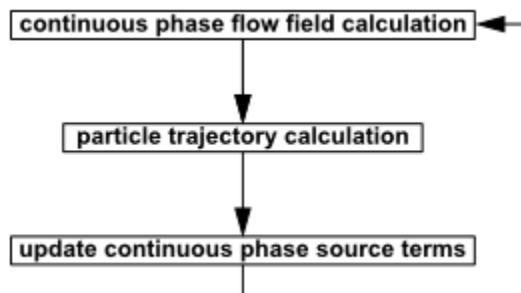

25.6.1.2. Coupled Calculations

In a coupled two-phase simulation, ANSYS FLUENT modifies the two-step procedure above as follows:

1. Solve the continuous phase flow field (prior to introduction of the discrete phase).
2. Introduce the discrete phase by calculating the particle trajectories for each discrete phase injection.
3. Recalculate the continuous phase flow, using the interphase exchange of momentum, heat, and mass determined during the previous particle calculation.
4. Recalculate the discrete phase trajectories in the modified continuous phase flow field.
5. Repeat the previous two steps until a converged solution is achieved in which both the continuous phase flow field and the discrete phase particle trajectories are unchanged with each additional calculation.

This coupled calculation procedure is illustrated in [Figure 25.29 \(p. 1139\)](#). When your ANSYS FLUENT model includes a high mass and/or momentum loading in the discrete phase, the coupled procedure must be followed in order to include the important impact of the discrete phase on the continuous phase flow field.

Figure 25.29 Coupled Discrete Phase Calculations

Important

When you perform coupled calculations, all defined discrete phase injections will be computed. You cannot calculate a subset of the injections you have defined. If there are massless particle injections defined, these will have no effect in the coupled calculation.

25.6.1.2.1. Procedures for a Coupled Two-Phase Flow

If your ANSYS FLUENT model includes prediction of a coupled two-phase flow, you should begin with a partially (or fully) converged continuous-phase flow field. You will then create your injection(s) and set up the coupled calculation.

For each discrete-phase iteration, ANSYS FLUENT computes the particle/droplet trajectories and updates the interphase exchange of momentum, heat, and mass in each control volume. These interphase exchange terms then impact the continuous phase when the continuous phase iteration is performed. During the coupled calculation, ANSYS FLUENT will perform the discrete phase iteration at specified intervals during the continuous-phase calculation. The coupled calculation continues until the continuous phase flow field no longer changes with further calculations (i.e., all convergence criteria are satisfied). When convergence is reached, the discrete phase trajectories no longer change either, since changes in the discrete phase trajectories would result in changes in the continuous phase flow field.

The steps for setting up the coupled calculation are as follows:

1. Solve the continuous phase flow field.
2. In the *Discrete Phase Model Dialog Box* (p. 1859) (*Figure 25.1* (p. 1081)), enable the **Interaction with Continuous Phase** option.
3. Set the frequency with which the particle trajectory calculations are introduced in the **Number of Continuous Phase Iterations Per DPM Iteration** field. If you set this parameter to 5, for example, a discrete phase iteration will be performed every fifth continuous phase iteration. The optimum number of iterations between trajectory calculations depends upon the physics of your ANSYS FLUENT model.

Important

Note that if you set this parameter to 0, ANSYS FLUENT will not perform any discrete phase iterations.

During the coupled calculation (which you initiate using the *Run Calculation Task Page* (p. 2107) in the usual manner) you will see the following information in the ANSYS FLUENT console as the continuous and discrete phase iterations are performed:

```

iter continuity x-velocity y-velocity k epsilon energy time/it
 314 2.5249e-01 2.8657e-01 1.0533e+00 7.6227e-02 2.9771e-02 9.8181e-03 :00:05

 318 3.2820e-01 5.5508e-02 6.0900e-01 5.9018e-02 2.6619e-02 4.0394e-02 :00:00

```

Note that you can perform a discrete phase calculation at any time by using the `solve/dpm-update` text command.

25.6.1.2.2. Stochastic Tracking in Coupled Calculations

If you include the stochastic prediction of turbulent dispersion in the coupled two-phase flow calculations, the number of stochastic tries applied each time the discrete phase trajectories are introduced during coupled calculations will be equal to the **Number of Tries** specified in the *Set Injection Properties Dialog*

[Box \(p. 2255\)](#). Note that for transient particle tracking the number of tries is set to 1. Input of this parameter is described in [Stochastic Tracking \(p. 1118\)](#).

Note that you need to disable **Stochastic Tracking** if you want to perform the coupled calculation. An input of $n \geq 1$ requests n stochastic trajectory calculations for each particle in the injection. Note that when the number of stochastic tracks included is small, you may find that the ensemble average of the trajectories is quite different each time the trajectories are computed. These differences may, in turn, impact the convergence of your coupled solution. For good convergence of a coupled solution, a statistical independent distribution of tracks can be achieved with an adequate number of stochastic tracks and/or a sufficient number of different starting locations of the tracks.

25.6.1.2.3. Under-Relaxation of the Interphase Exchange Terms

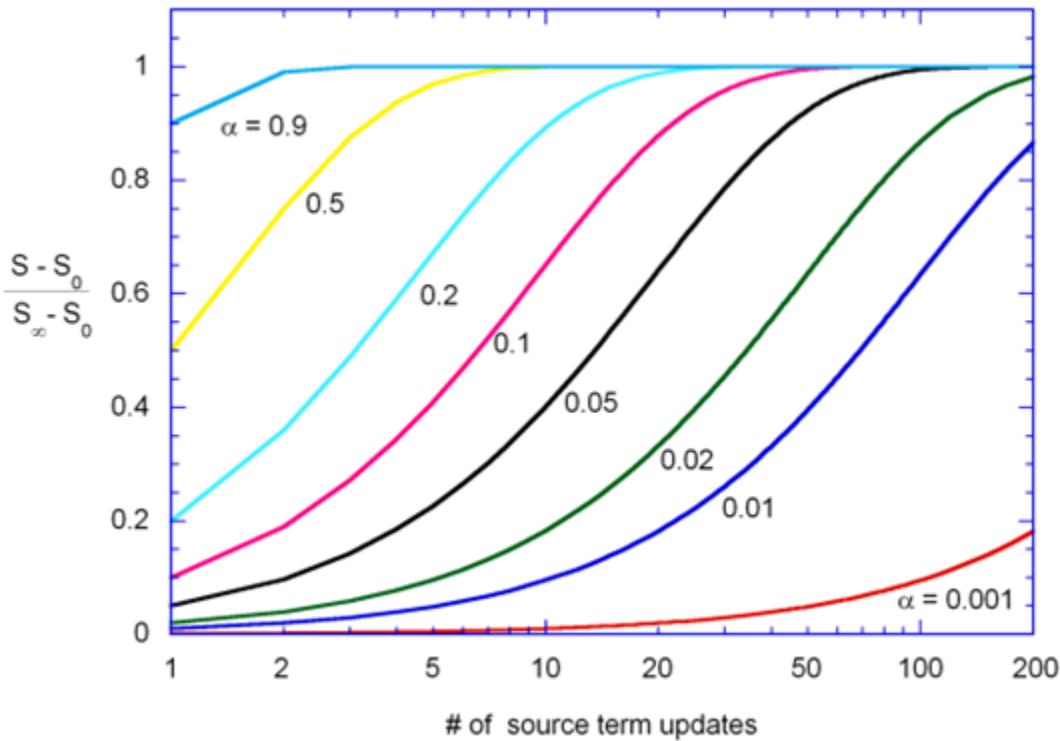

When you are coupling the discrete and continuous phases for steady-state calculations, using the calculation procedures noted above, ANSYS FLUENT applies under-relaxation to the momentum, heat, and mass transfer terms. This under-relaxation serves to increase the stability of the coupled calculation procedure by letting the impact of the discrete phase change only gradually:

$$E_{new} = E_{old} + \alpha (E_{calculated} - E_{old}) \quad (25-12)$$

where E_{new} is the exchange term, E_{old} is the previous value, $E_{calculated}$ is the newly computed value, and α is the particle/droplet under-relaxation factor. ANSYS FLUENT uses a default value of 0.5 for α . You can modify α by changing the value in the **Discrete Phase Sources** field under **Under-Relaxation Factors** in the **Solution Controls** task page. You may need to decrease α in order to improve the stability of coupled discrete phase calculations.

[Figure 25.30 \(p. 1142\)](#) shows how the source term, S , when applied to the flow equations, changes with the number of updates for varying under-relaxation factors. In [Figure 25.30 \(p. 1142\)](#), S_∞ is the final source term for which a value is reached after a certain number of updates and S_0 is the initial source term at the start of the computation. The value of S_0 is typically zero at the beginning of the calculation.

Figure 25.30 Effect of Number of Source Term Updates on Source Term Applied to Flow Equations

In a continuous flow simulation, with continuous DPM tracking, suppose that the DPM under-relaxation factor is chosen to be 0.5, with 20 continuous phase iterations per DPM iteration. From [Figure 25.30 \(p. 1142\)](#), we see that approximately 10 source term updates are required for the DPM sources to reach their final values. Therefore, in this example, at least 200 continuous phase iterations are required after any change to the DPM sources (for example, a new injection or a changed DPM mass flow rate), to ensure that the change has taken effect.

25.6.2. Resetting the Interphase Exchange Terms

If you have performed coupled calculations, resulting in nonzero interphase sources/sinks of momentum, heat, and/or mass that you do not want to include in subsequent calculations, you can reset these sources to zero.

↳ Solution Initialization → Reset DPM Sources

When you click the **Reset DPM Sources** button, the sources will immediately be reset to zero without any further confirmation from you.

25.7. Postprocessing for the Discrete Phase

After you have completed your discrete phase inputs and any coupled two-phase calculations of interest, you can display and store the particle trajectory predictions. ANSYS FLUENT provides both graphical and alphanumeric reporting facilities for the discrete phase, including the following:

- graphical display of the particle trajectories
- summary reports of trajectory fates

- step-by-step reports of the particle position, velocity, temperature, and diameter
- alphanumeric reports and graphical display of the interphase exchange of momentum, heat, and mass
- sampling of trajectories at boundaries and lines/planes
- summary reporting of current particles in the domain
- histograms of trajectory data at sample planes
- display of erosion/accretion rates
- exporting of trajectories to Fieldview and Ensight

This section provides detailed descriptions of each of these postprocessing options.

(Note that plotting or reporting trajectories does not change the source terms.)

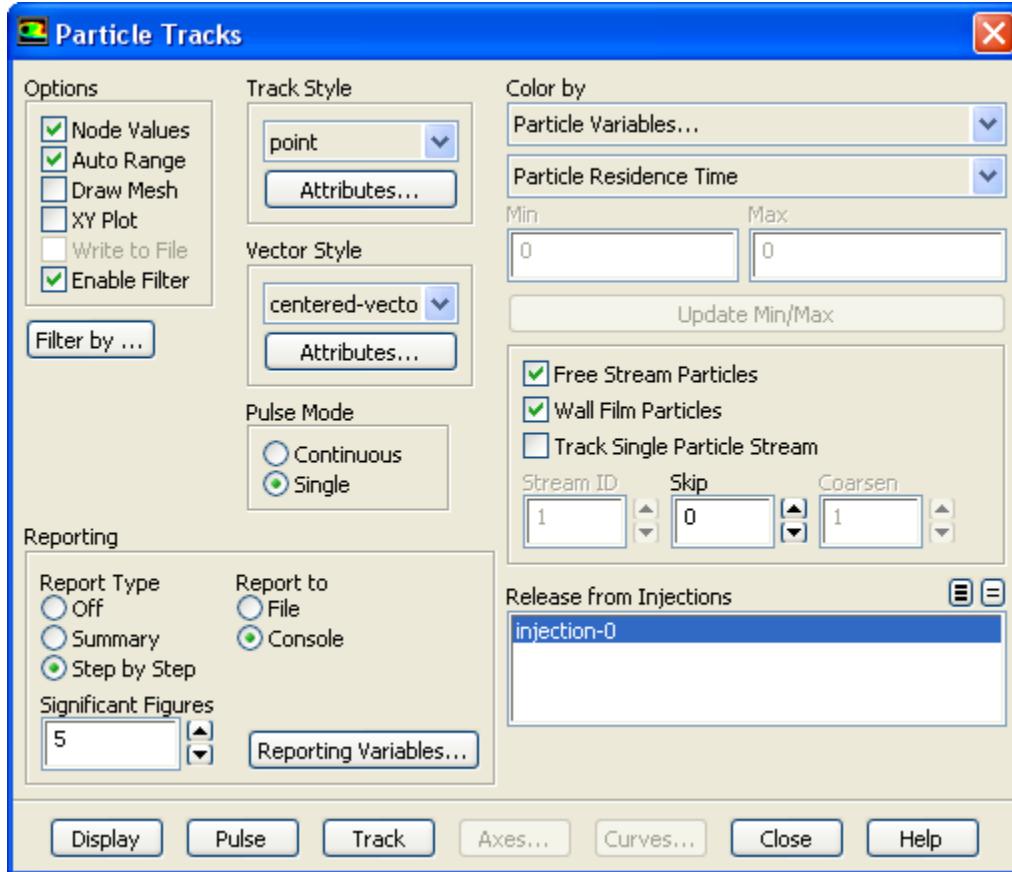

For additional information, please see the following sections:

- [25.7.1. Displaying of Trajectories](#)
- [25.7.2. Reporting of Trajectory Fates](#)
- [25.7.3. Step-by-Step Reporting of Trajectories](#)
- [25.7.4. Reporting of Current Positions for Unsteady Tracking](#)
- [25.7.5. Reporting of Interphase Exchange Terms and Discrete Phase Concentration](#)
- [25.7.6. Sampling of Trajectories](#)
- [25.7.7. Histogram Reporting of Samples](#)
- [25.7.8. Summary Reporting of Current Particles](#)
- [25.7.9. Postprocessing of Erosion/Accretion Rates](#)

25.7.1. Displaying of Trajectories

When you have defined discrete phase particle injections, as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#), you can display the trajectories of these discrete particles using the [Particle Tracks Dialog Box \(p. 2133\)](#) ([Figure 25.31 \(p. 1144\)](#)).

Graphics and Animations → **Particle Tracks** → **Set Up...**

Figure 25.31 The Particle Tracks Dialog Box

The procedure for drawing trajectories for particle injections is as follows:

1. Select the particle injection(s) you wish to track in the **Release from Injections** list. (You can choose to track a specific particle, instead, as described below.)
2. Set the length scale and the maximum number of steps in the *Discrete Phase Model Dialog Box* (p. 1859), as described in *Numerics of the Discrete Phase Model* (p. 1092).

Models → **Discrete Phase** → **Edit...**

If stochastic and/or cloud tracking is desired, set the related parameters in the **Set Injection Properties** dialog box, as described in *Stochastic Tracking* (p. 1118).

3. Set any of the display options described below.
4. Click the **Display** button to draw the trajectories or click the **Pulse** button to animate the particle positions. The **Pulse** button will become the **Stop!** button during the animation, and you must click **Stop!** to stop the pulsing.

Important

For unsteady particle tracking simulations, clicking **Display** will show only the current location of the particles. Typically, you should select **point** in the **Track Style** dropdown list when displaying transient particle locations since individual positions will be displayed. The **Pulse** button option is not available for unsteady tracking.

25.7.1.1. Specifying Particles for Display

You can display the trajectory for an individual particle stream instead of for all the streams in a given injection. Additionally, you can visualize the trajectories for the wall film particles (if they are present in the simulation) and/or free stream particles. To do so, you will first need to determine which particle is of interest. Use the [Injections Dialog Box \(p. 2254\)](#) to list the particle streams in the desired injection, as described in [Creating and Modifying Injections \(p. 1112\)](#).

Define → Injections...

Note the ID numbers listed in the first column of the listing printed in the ANSYS FLUENT console. Then perform the following steps after step 1 above. In the [Particle Tracks Dialog Box \(p. 2133\)](#):

1. Enable **Free Stream Particles** if you want to display those types of particles. Note that this option is available only when the Lagrangian wallfilm model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.
2. Enable **Wall Film Particles** if you want to display those types of particles. Note that this option is available only when the Lagrangian wallfilm model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.
3. Enable the **Track Single Particle Stream** to display those types of particles.
4. In the **Stream ID** field, specify the ID number of the particle stream for which you want to plot the trajectory.

25.7.1.1.1. Controlling the Particle Tracking Style

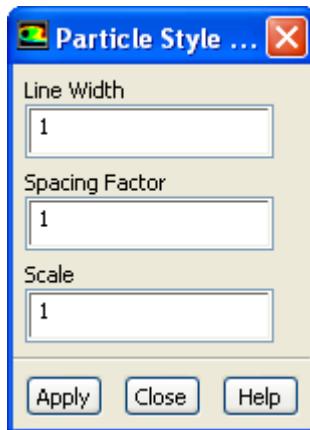

Particle tracking can be displayed as lines (with or without arrows), ribbons, cylinders (coarse, medium, or fine), triangles, spheres, or a set of points. You can choose **line**, **line-arrows**, **point**, **sphere**, **ribbon**, **triangle**, **coarse-cylinder**, **medium-cylinder**, or **fine-cylinder** in the **Track Style** drop-down list in the **Particle Tracks** dialog box. Pulsing can be done only on **point**, **sphere**, or **line** styles.

Once you have selected the track style, click the **Attributes...** button to specify how you would like to display the particle tracks.

Note

The **Track Style** options that will appear depend on whether you are running a transient or steady state simulation. For a transient case, the only **Track Style** options available are the **point** and **sphere** styles.

- If you are using the **line** or **line-arrows** style, set the **Line Width** in the **Particle Style Attributes** dialog box ([Figure 25.32 \(p. 1146\)](#)) that appears when you click the **Attributes...** button. For **line-arrows** you will also set the **Spacing Factor**, which controls the spacing between the particles tracks. The size of the arrow heads can be adjusted by entering a value in the **Scale** text-entry box.

Figure 25.32 The Particle Style Attributes Dialog Box

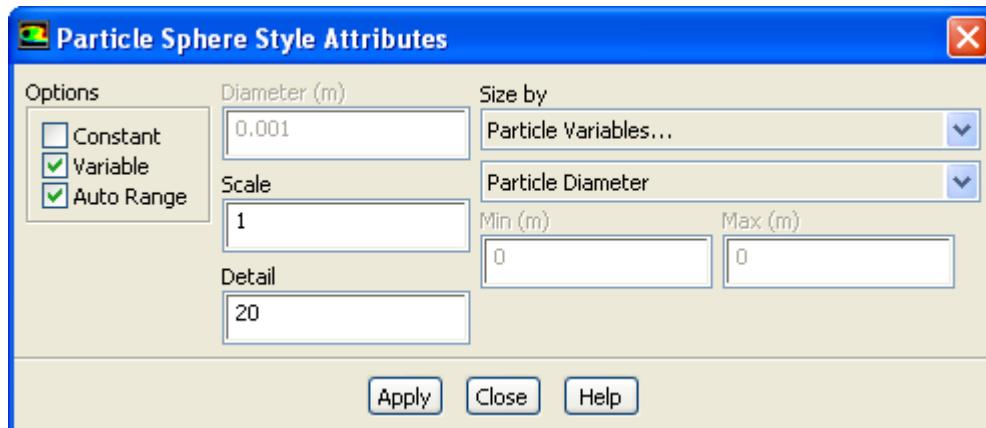

- If you are using the **point** style, you will set the **Marker Size** in the **Particle Style Attributes** dialog box. The thickness of the particle track will be the thickness of the marker.
- If you are using the **sphere** style, you will set the **Diameter**, **scale**, and **Detail** in the **Particle Sphere Style Attributes** dialog box (*Figure 25.33 (p. 1147)*). You have the option of specifying a constant diameter if you enable **Constant** under **Options** and you will then specify the **Diameter**. If you enable **Variable**, you can select a particle variable to estimate the size of the spheres. The spheres are scaled by the factor entered in the **Scale** entry box.

The best constant diameter to use will depend on the dimensions of the domain, the view, and the particle density. However, an adequate starting point would be a diameter on the order of 1/4 of the average cell size or 1/4 step size. Units for the **Diameter** field correspond to the mesh dimensional units.

The level of detail applied to the graphical rendering of the spheres can be controlled using the **Detail** field. The level of detail uses integer values ranging from 4 to 50. Note that the performance of the graphical rendering as well as the memory consumption will be better when using a small level of detail, i.e., very coarse spheres, such as 6 or 8. The rendering performance significantly decreases with higher levels of detail. You should gradually increase the detail to determine the best-case scenario between performance and quality.

Whenever **Auto Range** is disabled, the spheres are displayed only if they have values between **Min** and **Max**.

Also note that to take full advantage of spherical rendering, lighting should be turned on in the view. The Gouraud setting provides much smoother looking spheres than the Flat setting and better performance than the Phong setting. For more information on lighting, see *Adding Lights (p. 1544)*.

Figure 25.33 The Particle Sphere Style Attributes Dialog Box

- If you are using the **triangle** or any of the **cylinder** styles, you will set the **Width** in the **Particle Style Attributes** dialog box. For triangles, the specified value will be half the width of the triangle's base, and for cylinders, the value will be the cylinder's radius.
- If you are using the **ribbon** style, clicking on the **Attributes...** button will open the *Ribbon Attributes Dialog Box* (p. 2132), in which you can set the ribbon's **Width**. You can also specify parameters for twisting the ribbon tracks. In the **Twist By** drop-down list, you can select a scalar field on which the tracks twisting is based (e.g., helicity). Select the desired category in the upper list and then select a related quantity in the lower list. The twisting may not be displayed smoothly because the scalar field by which you are twisting the tracks is calculated at cell centers only (and not interpolated to a particle's position). The **Twist Scale** sets the amount of twist for the selected scalar field. To magnify the twist for a field with very little change, increase this factor; to display less twist for a field with dramatic changes, decrease this factor.

When you click **Compute**, the **Min** and **Max** fields will be updated to show the range of the **Twist By** scalar field.

25.7.1.1.2. Controlling the Vector Style of Particle Tracks

You can choose to have the particle tracks displayed as vectors. Choose the **Vector Style** from the drop-down list in the **Particle Tracks** dialog box:

- If you select **vector**, the vector will be generated starting in the center of the particle, as shown in *Figure 25.34* (p. 1148).
- If you select **centered-vector**, the midpoint of the vector will appear in the center of the particle, as shown in *Figure 25.35* (p. 1148).
- If you select **centered-cylinder**, the midpoint of the cylinder will appear in the center of the particle, as shown in *Figure 25.36* (p. 1149).

Figure 25.34 Particles with the Vector Style

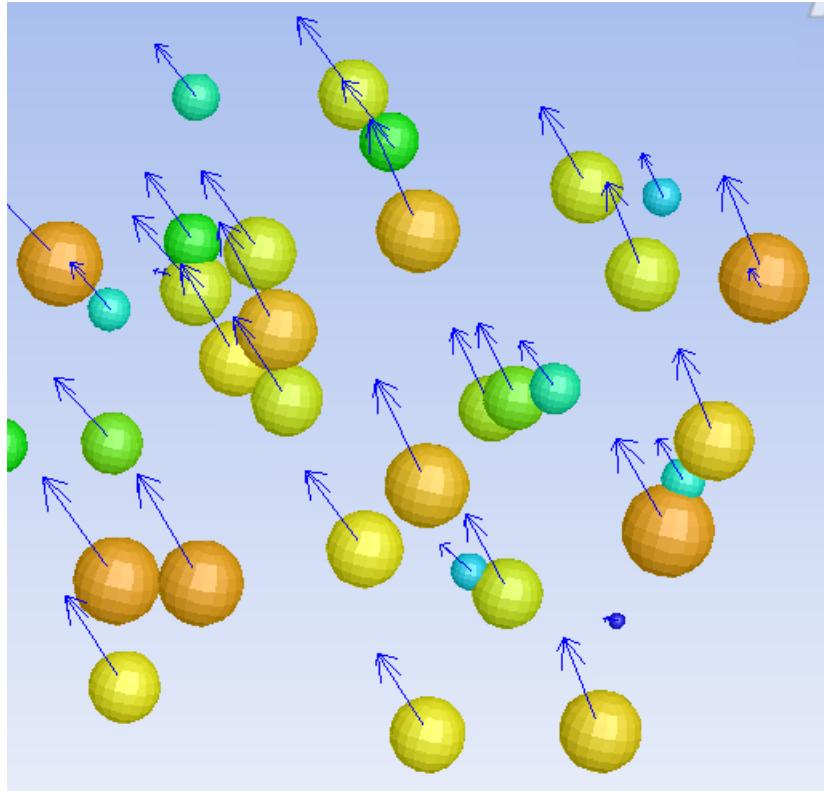

Figure 25.35 Particles with the Centered Vector Style

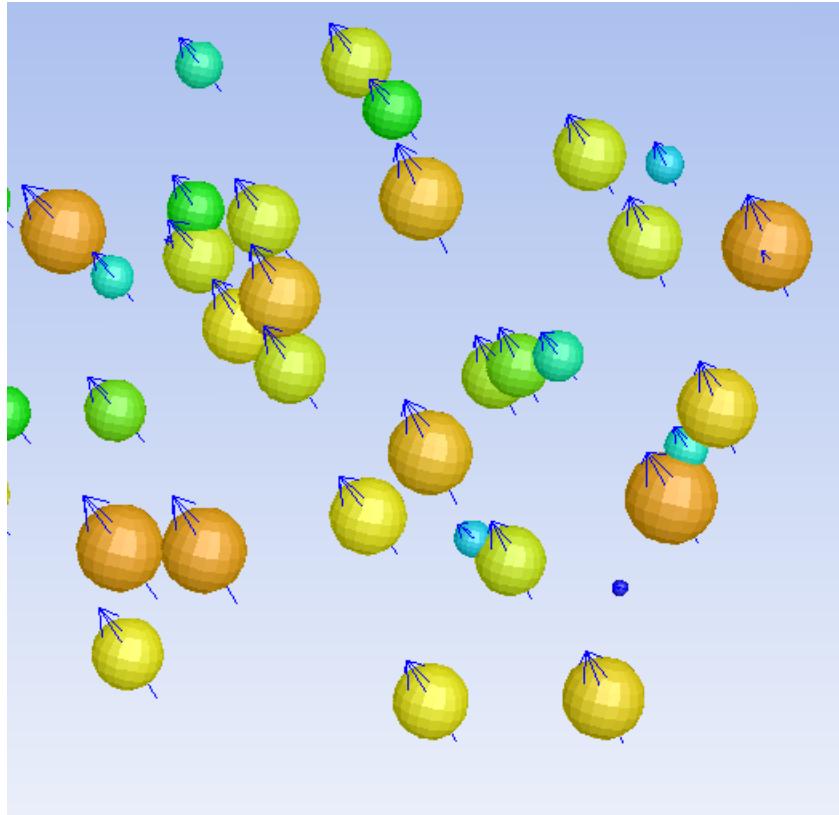

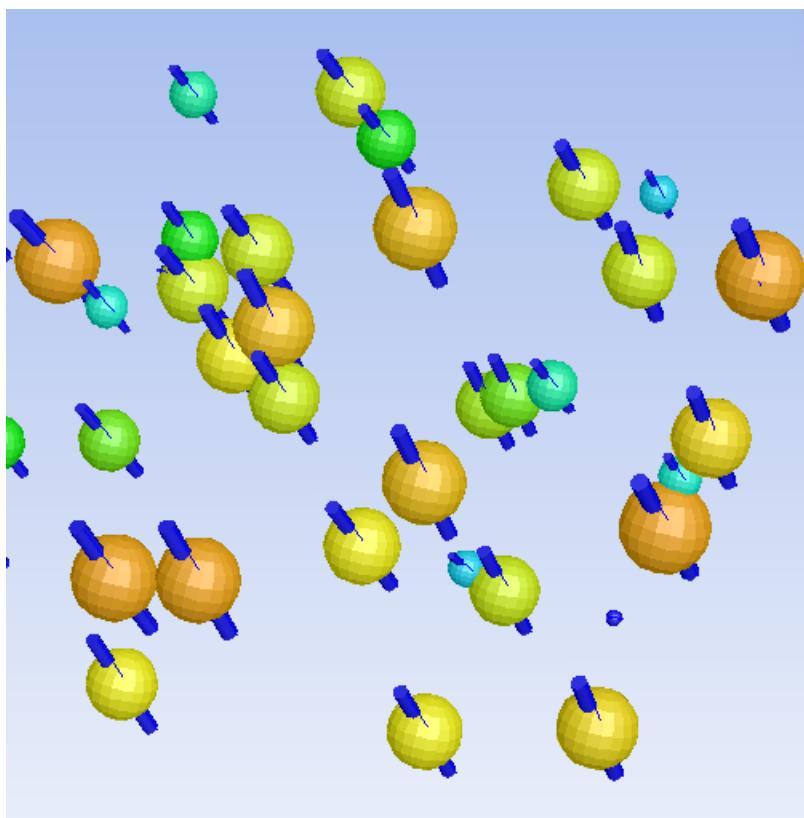

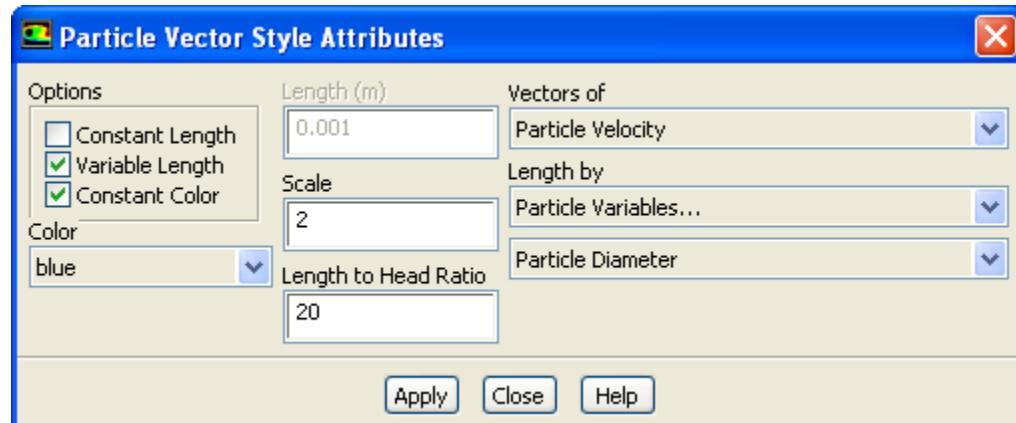

Figure 25.36 Particles with the Centered Cylinder Style

Click the **Attributes...** button to specify how you would like to display the particle tracks. In the **Particle Vector Style Attributes** dialog box (Figure 25.37 (p. 1149)) you will set the **Length**, **Scale**, and **Length to Head Ratio**. The direction of the vectors is displayed for the selected variable under **Vectors of**. You have the option of specifying a **Constant Length** or a **Variable Length**, which is based on the variable selected under **Length by**. If **Constant Color** is enabled, then all vectors/cylinders are colored by the color selected in the **Color** drop down list. Otherwise, it is the color selected in the **Particle Tracks** dialog box (seen in the **Mesh Colors** dialog box when **Draw Mesh** is enabled).

Vectors can be scaled by the factor given in the **Scale** entry box. The ratio of vector length to vector head size can be changed in the box **Length to Head Ratio**. In the case of a cylinder, the ratio of the length to the diameter is affected.

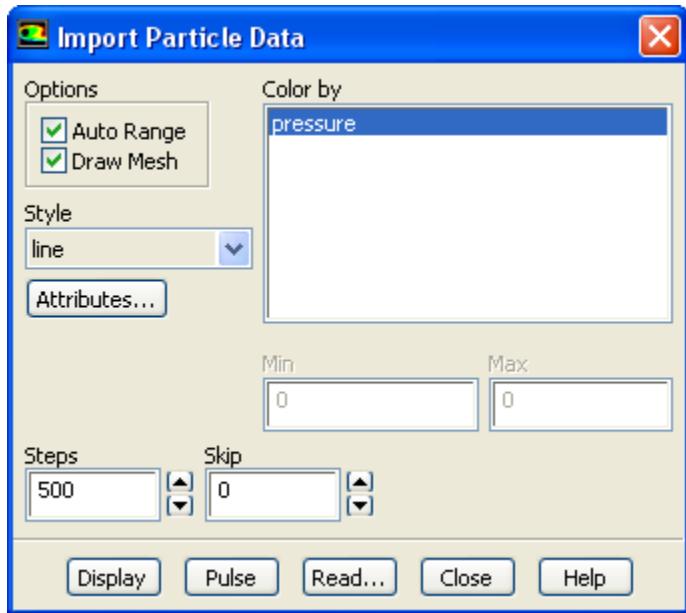

Figure 25.37 The Particle Vector Style Attributes Dialog Box

25.7.1.2. Importing Particle Data

Use the **Import Particle Data** dialog box (*Figure 25.38 (p. 1150)*) to import particle data to display in the graphics window.

Display → Import Particle Data...

Figure 25.38 The Import Particle Data Dialog Box

1. Click **Read...** to display a file selection dialog box where you can enter a file name and a directory that contains the imported data.
2. Choose from the available import options by selecting **Auto Range** and/or **Draw Mesh** under **Options**. If you prefer to restrict the range of the scalar field, disable the **Auto Range** option and set the **Min** and **Max** values manually beneath the **Color by** list.
3. Choose to color the particle pathlines by any of the scalar fields in the **Color by** list.
4. Select a pathline style under **Style**. To set pathline style attributes, click the **Attributes...** button. For more information about the pathline style types, see *Controlling the Pathline Style (p. 1523)*.
5. The value of **Steps** sets the maximum number of steps a particle can advance. A particle will stop when it has traveled this number of steps or when it leaves the domain.
6. If your pathline plot is difficult to understand because there are too many paths displayed, you can “thin out” the pathlines by changing the **Skip** value.
7. Click the **Display** button to draw the pathlines, or click the **Pulse** button to animate the particle positions. The **Pulse** button will become the **Stop !** button during the animation, and you must click **Stop !** to stop the pulsing.

25.7.1.3. Options for Particle Trajectory Plots

You can include the mesh in the trajectory display, control the style of the trajectories (including the twisting of ribbon-style trajectories), color them by different scalar fields and control the color scale, and coarsen trajectory plots. You can also choose node or cell values for display. If you are “pulsing” the trajectories, you can control the pulse mode. Finally, you can generate an XY plot of the particle

trajectory data (e.g., residence time) as a function of time or path length and save this XY plot data to a file.

Plotting particle trajectories can be very time consuming, therefore, to reduce the plotting time, a coarsening factor can be used to reduce the number of points that are plotted. Providing a coarsening factor of n , will result in each n th point being plotted for a given trajectory in any cell. This coarsening factor is specified in the [Particle Tracks Dialog Box \(p. 2133\)](#), in the **Coarsen** field and is only valid for steady state cases. For example, if the coarsening factor is set to 2, then ANSYS FLUENT will plot alternate points.

Important

Note that if any particle or pathline enters a new cell, this point will always be plotted.

To reduce plotting time in transient cases, ANSYS FLUENT has available an option to skip plotting every n th particle in an injection. Selecting this option is also done in the [Particle Tracks Dialog Box \(p. 2133\)](#) by specifying a nonzero integer in the **Skip** field. For example, if an individual stream is selected and the skip option is set to 1, every other particle will be plotted. If the entire injection is selected with a skip option of 1, every other particle will be plotted for all streams in the injection.

These options are controlled in exactly the same way that pathline-plotting options are controlled. See [Options for Pathline Plots \(p. 1522\)](#) for details about setting the trajectory plotting options mentioned above.

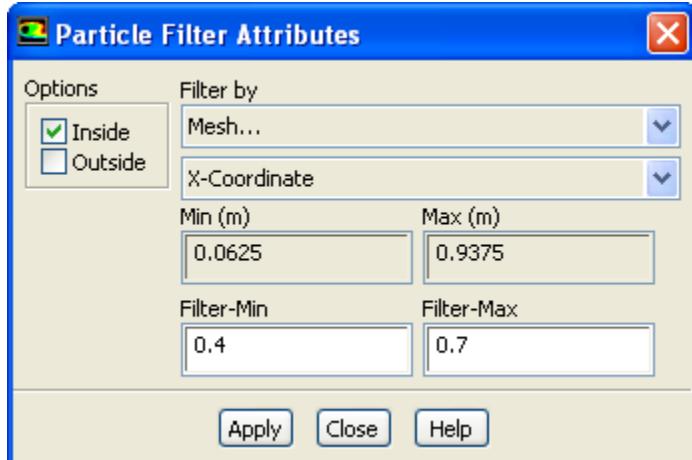

Note that in addition to coloring the trajectories by continuous phase variables, you can also color them according to the following discrete phase variables: particle time, particle velocity, particle diameter, particle density, particle mass, particle temperature, particle law number, particle time step, and particle Reynolds number. These variables are included in the **Particle Variables...** category of the **Color by** list. To display the minimum and maximum values in the domain, click the **Update Min/Max** button.

25.7.1.4. Particle Filtering

You can specify how you would like to filter the particles being displayed, by first activating the **Enable Filter** option, then clicking the **Filter by...** button. In the **Particle Filter Attributes** dialog box, select the field variable by which you want to filter, then specify whether you would like to display all the particle tracks **Inside** or **Outside** the **Filter-Min** and **Filter-Max** range, as shown in [Figure 25.39 \(p. 1152\)](#).

Note

All particle variables as well as any field variable except for **Custom Field Functions...** can be used as a filter variable.

Figure 25.39 The Particle Filter Attributes Dialog Box

25.7.1.5. Graphical Display for Axisymmetric Geometries

For axisymmetric problems in which the particle has a nonzero circumferential velocity component, the trajectory of an individual particle is often a spiral about the centerline of rotation. ANSYS FLUENT displays the r and x components of the trajectory (but not the θ component) projected in the axisymmetric plane.

25.7.2. Reporting of Trajectory Fates

When you perform trajectory calculations by displaying the trajectories (as described in [Displaying of Trajectories \(p. 1143\)](#)), ANSYS FLUENT will provide information about the trajectories as they are completed. By default, the number of trajectories with each possible fate (escaped, aborted, evaporated, etc.) is reported:

```
DPM Iteration ....
num. tracked = 7, escaped = 4, aborted = 0, trapped = 0, evaporated = 3, inco
Done.
```

You can also track particles through the domain without displaying the trajectories by clicking the **Track** button at the bottom of the dialog box. This allows the listing of reports without also displaying the tracks.

25.7.2.1. Trajectory Fates

The possible fates for a particle trajectory are as follows:

- “Escaped” trajectories are those that terminate at a flow boundary for which the “escape” condition is set.
- “Incomplete” trajectories are those that were terminated when the maximum allowed number of time steps—as defined by the **Max. Number of Steps** input in the [Discrete Phase Model Dialog Box \(p. 1859\)](#) (see [Numerics of the Discrete Phase Model \(p. 1092\)](#)) — was exceeded.
- “Incomplete_parallel” may appear as an additional fate for parallel simulations. This means that the number of particle exchanges between partitions has been exceeded. Any remaining particles on the compute nodes are stopped which is indicated by the number following this fate. Therefore no further source terms from these particles are considered. The number of particle exchanges is limited to avoid very long computational time due to incomplete particles. You can change the default value of 1000

to a value of 20000 with a scheme command. Please contact the technical support engineer for this information.

- “Trapped” trajectories are those that terminate at a flow boundary where the “trap” condition has been set.
- “Evaporated” trajectories include those trajectories along which the particles were evaporated within the domain.
- “Aborted” trajectories are those that fail to complete due to roundoff reasons. You may want to retry the calculation with a modified length scale and/or different initial conditions.
- “Shed” trajectories are newly generated particles during the breakup of a larger droplet. They appear only if a breakup model is enabled.
- “Coalesced” trajectories are removed particles which have coalesced after particle-particle collisions. They appear only if the coalescence model is enabled.
- “Splashed” trajectories are particles which are newly generated when a particle touches a wall-film. Those trajectories appear only if the wall-film model is enabled.

25.7.2.2. Summary Reports

You can request additional detail about the trajectory fates as the particles exit the domain, including the mass flow rates through each boundary zone, mass flow rate of evaporated droplets, and composition of the particles.

1. Follow steps 1 and 2 in *Displaying of Trajectories* (p. 1143) for displaying trajectories.
2. Select **Summary** as the **Report Type** and click **Display** or **Track**.

Important

For steady-state simulations, DPM summary data is not stored in the.dat file, since it is possible to track particles on single or combinations of injections. Transient simulations store this data since it is accumulated over time starting from initialization.

A detailed report similar to the following example will appear in the console window. (You may also choose to write this report to a file by selecting **File** as the **Report to** option, clicking the **Write...** button (which was originally the **Display** button), and specifying a file name for the summary report file in *The Select File Dialog Box* (p. 33).)

```

The report groups together particles with each possible fate, and reports the number of particles, the time elapsed during trajectories, and the mass and energy transfer. This information can be very useful for obtaining information such as where particles are escaping from the domain, where particles are colliding with surfaces, and the extent of heat and mass transfer to/from the particles within the domain. Additional information is reported for combusting particles and multicomponent particles.

25.7.2.2.1. Elapsed Time

The number of particles with each fate is listed under the Number heading. (Particles that escape through different zones or are trapped at different zones are considered to have different fates, and are therefore listed separately.) The minimum, maximum, and average time elapsed during the trajectories of these particles, as well as the standard deviation about the average time, are listed in the Min, Max, Avg, and Std Dev columns. This information indicates how much time the particle(s) spent in the domain before they escaped, aborted, evaporated, or were trapped.

Fate	Number	Elapsed Time (s)	Min	Max	Avg	Std Dev
Incomplete	2	1.485e+01	2.410e+01	1.947e+01	4.623e+00	
Escaped - Zone 7	8	4.940e+00	2.196e+01	1.226e+01	4.871e+00	

Also, on the right side of the report are listed the injection name and index of the trajectories with the minimum and maximum elapsed times. (You may need to use the scroll bar to view this information.)

Elapsed Time (s)	Injection, Index
Min	Min
Max	Max
Avg	
Std Dev	

+01	2.410e+01	1.947e+01	4.623e+00	injection-0	1	injection-0	0
+00	2.196e+01	1.226e+01	4.871e+00	injection-0	9	injection-0	2

25.7.2.2.2. Mass Transfer Summary

For all droplet or combusting particles with each fate, the total initial and final mass flow rates and the change in mass flow rate are reported in the Initial, Final, and Change columns. With this information, you can determine how much mass was transferred to the continuous phase from the particles.

For unsteady tracking, the report lists the time-integrated mass flow rate of the particle streams that have reached a particular fate at the current flow time. In other words, the report does not include particles that are still being tracked in the domain.

(*) - Mass Transfer Summary - (*)			
Fate	Mass Initial	Flow Final	(kg/s) Change
Incomplete	1.388e-03	1.943e-04	1.194e-03
Escaped - Zone 7	1.502e-03	2.481e-04	-1.254e-03

25.7.2.2.3. Energy Transfer Summary

This report tells you how much heat was transferred from the particles to the continuous phase. The report is organized in two sections. For steady simulations, there is a Heat Rate and a Change of Heat section. For unsteady particle tracking, there is an Energy and a Change of Energy section. The Heat Rate and Energy sections are the same for all particle types, while the other sections report the change of heat due to the various transfer processes, which differ for each particle type. For steady simulations, the report lists the rate and the change of heat for the particle streams organized according to the particle stream fates. For unsteady tracking, the report lists the time integrated heat rate and change of the particle streams that have reached a particular fate at the current flow time. Note that the report does not include particles that are still being tracked in the domain.

25.7.2.2.4. Heat Rate and Energy Reporting

For all particles with each fate, the total initial and final heat content are reported in the Initial and Final columns. The particle heat content H_p is defined as follows:

Inert Particles:

$$H_p = m_p \int_{T_{ref}}^{T_p} C_{p,p} dT \quad (25-13)$$

where:

m_p = mass flow rate of particles (kg/s)

T_p = temperature of particles (K)

$C_{p,p}$ = heat capacity of particles (J/kg/K)

T_{ref} = reference temperature for enthalpy (K)

Droplet Particles:

$$H_p = m_p [f_v \left(-H_{lat_{ref}} + H_{pyrol} \right) + \int_{T_{ref}}^{T_p} C_{p_p} dT] \quad (25-14)$$

where:

H_{pyrol} = heat of pyrolysis (J/kg)

$H_{lat_{ref}}$ = latent heat of evaporation at reference conditions (J/kg)

The latent heat at the reference conditions $H_{lat_{ref}}$ is defined in Equation 16–325 in the Theory Guide.

Combusting Particles:

$$H_p = H_w + H_{dry} \quad (25-15)$$

H_w is the heat content of the evaporating/boiling liquid material if Wet Combustion is selected (otherwise $H_w = 0$).

$$H_w = f_w m_p \left[\left(-H_{lat_{ref}} + H_{pyrol} \right) + \int_{T_{ref}}^{T_p} C_{p_p} dT \right] \quad (25-16)$$

where:

f_w is the mass fraction of the liquid in the combusting particle

$H_{lat_{ref}}$, H_{pyrol} , and C_{p_p} are properties of the evaporating liquid material

H_{dry} is the heat content of the dry combusting particle and is calculated as

$$H_{dry} = (1 - f_w) m_p \left[f_v \left(-H_{lat_{ref}} \right) + f_{comb} H_{comb} + \int_{T_{ref}}^{T_p} C_{p_p} dT \right] \quad (25-17)$$

where:

f_v is the volatile fraction

f_{comb} is the combustible fraction

Important

The Heat Rate section of the report is not provided for the multiple surface reactions model.

Multicomponent Particles:

$$H_p = m_p \sum_i \left(y_i H_{p_i} \right) \quad (25-18)$$

where: y_i = mass fraction of component i in particle

H_{p_i} = heat content of component i

and

$$H_{p_i} = \left[-H_{lat_{ref_i}} + H_{pyrol_i} + \int_{T_{ref}}^{T_p} C_{p_{p_i}} dT \right] \quad (25-19)$$

where:

H_{pyrol_i} = heat of pyrolysis for component i (J/kg)

$H_{lat_{ref_i}}$ = latent heat of evaporation at reference conditions for component i (J/kg)

$C_{p_{p_i}}$ = specific heat of component i (J/kg/K)

25.7.2.2.4.1. Change of Heat and Change of Energy Reporting

This section reports the total heat transferred from the particle to the continuous phase and is analyzed in components of Sensible heat, Latent heat and heat of Reaction. The Total change reported equals the difference between the Initial and Final states of the particle streams. The sensible heat component is reported for all particle types, the latent heat for the droplet, combusting and multicomponent particle, while the heat of reaction is reported for the combusting particle type only. A positive Change of Heat denotes that heat is expelled from the continuous phase and absorbed by the particle, while a negative Change of Heat denotes heat is released by the particle to the continuous phase.

Steady and Transient Simulations

For steady simulations the report lists the heat rate H_p , while for unsteady tracking the time integrated energy E_p from time 0 to current flow time ts is reported.

$$E_p = \int_0^{ts} H_p(t) dt \quad (25-20)$$

Below is an example of an Energy Transfer Summary report for evaporating droplets:

Fate	(*)- Energy Transfer Summary -(*)			Change of Heat (W)		
	Heat Rate (W)	Initial	Final	Sensible	Latent	Total
Evaporated	-4.530e+004	0.000e+000		-4.750e+002	4.577e+004	4.530e+004
Escaped-Zone	6	-1.723e+005	-4.670e+004	-2.552e+003	1.282e+005	1.256e+005
Trapped-Zone	7	-2.176e+005	0.000e+000	-1.058e+003	2.187e+005	2.176e+005

Net	-4.353e+005	-4.670e+004	-4.085e+003	3.927e+005	3.886e+005
-----	-------------	-------------	-------------	------------	------------

Below is an example of an Energy Transfer Summary report for combusting particles:

(*)- Energy Transfer Summary -(*)						
Fate	Heat Rate (W)		Change of Heat (W)			
	Initial	Final	Sensible	Latent	Reaction	Tot
Escaped-Zone 5	1.697e+005	2.555e+004	3.166e+003	1.034e+000	-1.473e+005	-1.44
Trapped-Zone 6	1.886e+004	1.938e+004	5.731e+002	1.149e-001	-5.370e+001	5.19
Net	1.886e+005	4.493e+004	3.739e+003	1.149e+000	-1.474e+005	-1.43

Important

In a coupled calculation, for all types of steady flows, the Total Net Change of Heat reported in the Energy Transfer Summary should balance with the opposite of the Sum over all fluid cells of the DPM Sensible Enthalpy Source. If this is not the case, this means that the coupled discrete-continuous phase calculation has not converged, and more DPM phase iterations are required. For more information on coupled calculations, see [Performing Trajectory Calculations \(p. 1138\)](#).

DPM	Sensible	Enthalpy	Source	Sum (w)
-----				-----
fluid-1				-388937.41

25.7.2.2.5. Combusting Particles

If combusting particles are present, ANSYS FLUENT will include additional reporting on the volatiles and char converted. These reports are intended to help you identify the composition of the combusting particles as they exit the computational domain.

(*)- Combusting Particles -(*)						
Fate	Volatile Content (kg/s)			Char Content (kg/s)		
	Initial	Final	%Conv	Initial	Final	%Conv
Incomplete	6.247e-04	0.000e+00	100.00	5.691e-04	0.000e+00	100.00
Escaped - Zone 7	6.758e-04	0.000e+00	100.00	6.158e-04	3.782e-05	93.86

The total volatile content at the start and end of the trajectory is reported in the Initial and Final columns under Volatile Content. The percentage of volatiles that has been devolatilized is reported in the %Conv column.

The total reactive portion (char) at the start and end of the trajectory is reported in the Initial and Final columns under Char Content. The percentage of char that reacted is reported in the %Conv column.

25.7.2.2.6. Combusting Particles with the Multiple Surface Reaction Model

If the multiple surface reaction model is used with combusting particles, ANSYS FLUENT will include additional reporting on the mass of the individual solid species that constitute the particle mass.

(*)- Multiple Surface Reactions -(*)				
Fate	Species Names	Species Initial	Content Final	%Conv
Escaped - Zone 6	c<s>	6.080e-02	1.487e-06	100.00
Escaped - Zone 6	s<s>	3.200e-03	5.077e-06	99.84

Escaped	-	Zone 6	cao	0.000e+000	1.153e-03	0.00
Escaped	-	Zone 6	caso4	0.000e+000	9.266e-04	0.00
Escaped	-	Zone 6	caco3	8.000e-003	5.260e-003	34.25

The total mass of each solid species in the particles at the start and end of the trajectory is reported in the Initial and Final columns, respectively. The percentage of each species that is reacted is reported in the %Conv column. Note that for the solid reaction products (e.g., if the mass of a solid species has increased in the particle), the conversion is reported to be 0.

25.7.2.2.7. Multicomponent Particles

If your simulation includes multicomponent particles, ANSYS FLUENT generates an additional report for the particle components.

Fate	(*) - Multicomponent Droplet - (*)	Species Names	Species Content (kg/s)		
			Initial	Final	%Conv

25.7.3. Step-by-Step Reporting of Trajectories

At times, you may want to obtain a detailed, step-by-step report of the particle trajectory/trajectories. Such reports can be obtained in alphanumeric format. This capability allows you to monitor the particle position, velocity, temperature, or diameter as the trajectory proceeds.

The procedure for generating files containing step-by-step reports is listed below:

1. Follow steps 1 and 2 in *Displaying of Trajectories* (p. 1143) **Track Single Particle Stream** option.
2. Select **Step by Step** as the **Report Type**.

Important

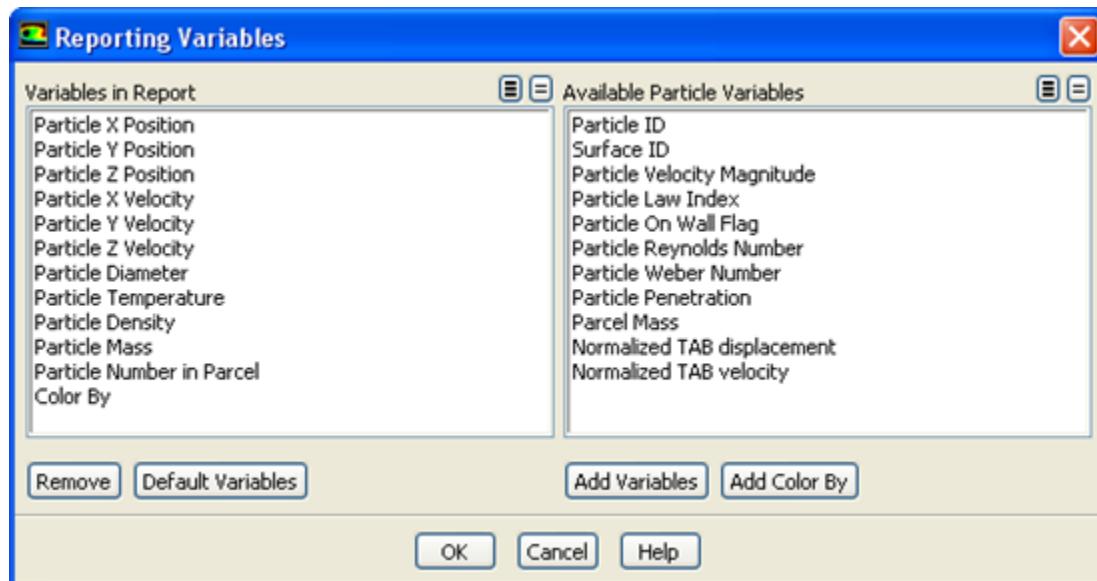

This option is only available for steady-state cases. For transient cases, see *Reporting of Current Positions for Unsteady Tracking* (p. 1161).

3. Select **File** as the **Report to** option. (The **Display** button will become the **Write...** button.)
4. In the **Significant Figures** field, enter the number of significant figures to be used in the step-by-step report.
5. Click the **Reporting Variables...** button. The **Reporting Variables** dialog box will appear (*Figure 25.40* (p. 1160)), where you can change the variables in the report. The list under **Variables in Report** contains all variables currently reported. The **Remove** button removes selected variables from that list. The **Default Variables** button restores the default list. The list under **Particle Variables** contains the particle variables that are available for you to select. You can add selections to the report using the **Add Variable** button. Clicking the **Add Color by** button adds the **Color by** variable to the list of **Variables in Report**, which is the only way to get cell values or customized field functions into the report.

Important

Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

Figure 25.40 The Reporting Variables Dialog Box

- Click the **Write...** button and specify a file name for the step-by-step report file in [The Select File Dialog Box \(p. 33\)](#).

A detailed report similar to the following example will be saved to the specified file before the trajectories are plotted. (You may also choose to print the report in the console by choosing **Console** as the **Report to** option and clicking **Display** or **Track**, but the report is very long that it is unlikely to be of use to you in that form.)

```

FILE  TYPE: 1
COLUMNS: 12
TITLE: TRACK HISTORY

COLUMN      TYPE      VARIABLE          ( UNITS )
-----      ----      -----          -----
 1          2        TIME             (SECONDS)
 2          10       X-POSITION        (METERS)
 3          10       Y-POSITION        (METERS)
 4          10       Z-POSITION        (METERS)
 5          10       U-VELOCITY        (M/SEC)
 6          10       V-VELOCITY        (M/SEC)
 7          10       W-VELOCITY        (M/SEC)
 8          10       DIAMETER         (METERS)
 9          10       TEMPERATURE       (KELVIN)
10          10       DENSITY          (KG/M3 )
11          10       MASS             (KG)
12          10       NUMBER           -
-----
0.00000e+00  5.00000e-02  5.00000e-02  5.00000e-02  2.00000e+01  0.0000 . . .
1.07087e-07  5.00000e-02  5.00000e-02  5.00000e-02  1.23339e+01  2.6696 . . .
2.51617e-07  5.00000e-02  5.00000e-02  5.00000e-02  1.04417e+01  3.3286 . . .
. . .
. . .
. . .

```

The default step-by-step report lists the position, velocity, diameter, temperature, density and mass of the particle at selected time steps along the trajectory. In addition, the variable you have selected in the **Color by** list is also included. If you choose **Console** as the **Report to** option, the variable names are written as the header of each column. (You may need to use the scroll bar to view all variables in this column.)

Time	X-Position	Y-Position	Z-Position	X-Velocity	Y-Velocity	Z-Veloc
0.000e+00	1.000e-03	3.120e-02	0.000e+00	1.000e+01	5.000e+00	0.000e
1.672e-05	1.168e-03	3.128e-02	0.000e+00	1.010e+01	4.988e+00	0.000e
3.342e-05	1.337e-03	3.137e-02	0.000e+00	1.019e+01	4.977e+00	0.000e
5.010e-05	1.508e-03	3.145e-02	0.000e+00	1.028e+01	4.965e+00	0.000e
6.675e-05	1.680e-03	3.153e-02	0.000e+00	1.038e+01	4.954e+00	0.000e
8.338e-05	1.854e-03	3.161e-02	0.000e+00	1.047e+01	4.942e+00	0.000e
.
.

If you change the reporting variables, only those selected will appear in the report. The particle time is always reported in the first column. Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

When the report is written to a file, a table at the beginning of the file lists all variables selected with the corresponding unit. Thus you can display or export any variable along a particle trajectory to the console or to a file.

Note that the **Coarsen** option affects the step-by-step report.

25.7.4. Reporting of Current Positions for Unsteady Tracking

In transient cases, when using unsteady tracking, you may want to obtain a report of the particle trajectory/trjectories showing the current positions of the particles. Selecting **Current Positions** under **Report Type** in the *Particle Tracks Dialog Box* (p. 2133) enables the display of the current positions of the particles.

The procedure for generating files containing current position reports is listed below:

1. Follow steps 1 and 2 in *Displaying of Trajectories* (p. 1143) for displaying trajectories. You may want to track only one particle stream at a time, using the **Track Single Particle Stream** option.
2. Select **Current Position** as the **Report Type**.
3. Select **File** as the **Report to** option. (The **Display** button will become the **Write...** button.)
4. In the **Significant Figures** field, enter the number of significant figures to be used in the step-by-step report.
5. Click the **Reporting Variables...** button. The **Reporting Variables** dialog box will appear (*Figure 25.40* (p. 1160)), where you can change the variables in the report. The list under **Variables in Report** contains all variables currently reported. The **Remove** button removes selected variables from that list. The **Default Variables** button restores the default list. The list under **Particle Variables** contains the particle variables that are available for you to select. You can add selections to the report using the **Add Variable** button. Clicking the **Add Color by** button adds the **Color by** variable to the list of **Variables in Report**, which is the only way to get cell values or customized field functions into the report.

Important

Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

6. Click the **Write...** button and specify a file name for the current position report file in *The Select File Dialog Box (p. 33)*.

The default current position report lists the position, velocity, diameter, temperature, density, mass and number in parcel of the particle at selected time steps along the trajectory. In addition, the variable you have selected in the **Color by** list is also included. If you change the reporting variables, only those selected will appear in the report. The particle time is always reported in the first column. It is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

The output to a file or to the console has the same format as the step-by-step report for steady-state cases.

Time	X-Position	Y-Position	Z-Position	X-Velocity	Y-Velocity	Z-Velocity
0.000e+00	1.000e-03	3.120e-02	0.000e+00	1.000e+01	5.000e+00	0.000e+00
1.672e-05	1.168e-03	3.128e-02	0.000e+00	1.010e+01	4.988e+00	0.000e+00
3.342e-05	1.337e-03	3.137e-02	0.000e+00	1.019e+01	4.977e+00	0.000e+00
5.010e-05	1.508e-03	3.145e-02	0.000e+00	1.028e+01	4.965e+00	0.000e+00
6.675e-05	1.680e-03	3.153e-02	0.000e+00	1.038e+01	4.954e+00	0.000e+00
8.338e-05	1.854e-03	3.161e-02	0.000e+00	1.047e+01	4.942e+00	0.000e+00
.
.
.

Also listed are the diameter, temperature, density, mass of the particles, number in parcel and the variable selected from the **Color by** list. (You may need to use the scroll bar to view this information.)

Time	Diameter	Temperature	Density	Mass	Number	ColorBy
9.999e-04	9.352e-05	3.710e+02	6.840e+02	2.929e-10	2.792e+02	4.783e-02
1.999e-03	7.952e-05	3.710e+02	6.840e+02	1.801e-10	2.792e+02	3.834e-02
3.000e-03	6.660e-05	3.710e+02	6.840e+02	1.058e-10	2.792e+02	2.989e-02
4.001e-03	5.425e-05	3.710e+02	6.840e+02	5.719e-11	2.792e+02	3.719e-02
5.001e-03	4.184e-05	3.710e+02	6.840e+02	2.624e-11	2.792e+02	2.978e-02
.
.
.

25.7.5. Reporting of Interphase Exchange Terms and Discrete Phase Concentration

ANSYS FLUENT reports the magnitudes of the interphase exchange of momentum, heat, and mass in each control volume in your ANSYS FLUENT model. It can also report the total concentration of the discrete phase. You can display these variables graphically, by drawing contours, profiles, etc. They are all contained in the **Discrete Phase Model...** category of the variable selection drop-down list that appears in postprocessing dialog boxes:

- **DPM Mass Source**
- **DPM Erosion Rate**
- **DPM Accretion Rate**
- **DPM X,Y,Z Momentum Source**

- **DPM Swirl Momentum Source**
- **DPM Turbulent Kinetic Energy Source**
- **DPM Turbulent Dissipation Source**
- **DPM Sensible Enthalpy Source**
- **DPM Enthalpy Source**
- **DPM Number Density**
- **DPM Volume Fraction**
- **DPM Volume**
- **DPM Number of Particles**
- **DPM Number of Parcels**
- **DPM Number of Collisions**
- **DPM Absorption Coefficient**
- **DPM Emission**
- **DPM Scattering**
- **DPM Burnout**
- **DPM Evaporation/Devolatilization**
- **DPM Concentration**
- **DPM (species) Source**
- **DPM (species) Concentration**

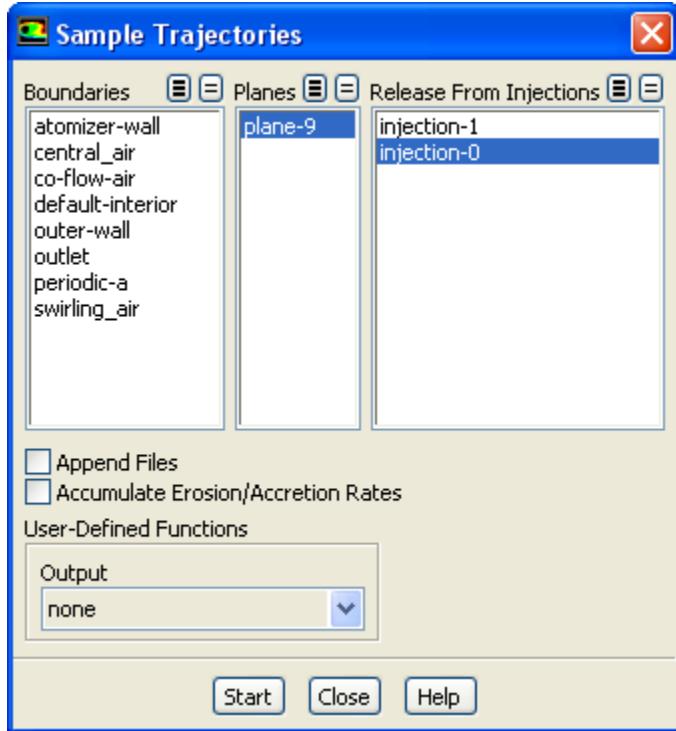

See [Field Function Definitions \(p. 1653\)](#) for definitions of these variables.

Note that these exchange terms are updated and displayed only when coupled calculations are performed. Displaying and reporting particle trajectories (as described in [Displaying of Trajectories \(p. 1143\)](#) and [Reporting of Trajectory Fates \(p. 1152\)](#)) will not affect the values of these exchange terms.

25.7.6. Sampling of Trajectories

Particle states (position, velocity, diameter, temperature, and mass flow rate) can be written to files at various boundaries and planes (lines in 2D) using the [Sample Trajectories Dialog Box \(p. 2193\)](#) (*Figure 25.41 (p. 1164)*).

Reports → **Sample** → **Set Up...**

Figure 25.41 The Sample Trajectories Dialog Box

The procedure for generating files containing the particle samples is listed below:

1. Select the injections to be tracked in the **Release From Injections** list.
2. Select the surfaces at which samples will be written. These can be boundaries from the **Boundaries** list or planes from the **Planes** list (in 3D) or lines from the **Lines** list (in 2D).
3. Click the **Compute** button. Note that for unsteady particle tracking, the **Compute** button will become the **Start** button (to initiate sampling) or a **Stop** button (to stop sampling).

Clicking the **Compute** button will cause the particles to be tracked and their status to be written to files when they encounter selected surfaces. The file names will be formed by appending .dpm to the surface name.

For unsteady particle tracking, clicking the **Start** button will open the files and write the file header sections. If the solution is advanced in time by computing some time steps, the particle trajectories will be updated and the particle states will be written to the files as they cross the selected planes or boundaries. Clicking the **Stop** button will close the files and end the sampling.

For stochastic tracking, it may be useful to repeat this process multiple times and append the results to the same file, while monitoring the sample statistics at each update. To do this, enable the **Append Files** option before repeating the calculation (clicking **Compute**). Similarly, you can cause erosion and accretion rates to be accumulated for repeated trajectory calculations by turning on the **Accumulate Erosion/Accretion Rates** option. (See also *Postprocessing of Erosion/Accretion Rates* (p. 1168).) The format and the information written for the sample output can also be controlled through a user-defined function, which can be selected in the **Output** drop-down list. More information about user-defined functions can be found in the [UDF Manual](#).

When sampling steady particle tracks the generated sample files can be used as injection file in a file injection. Both files use a similar file format.

Note

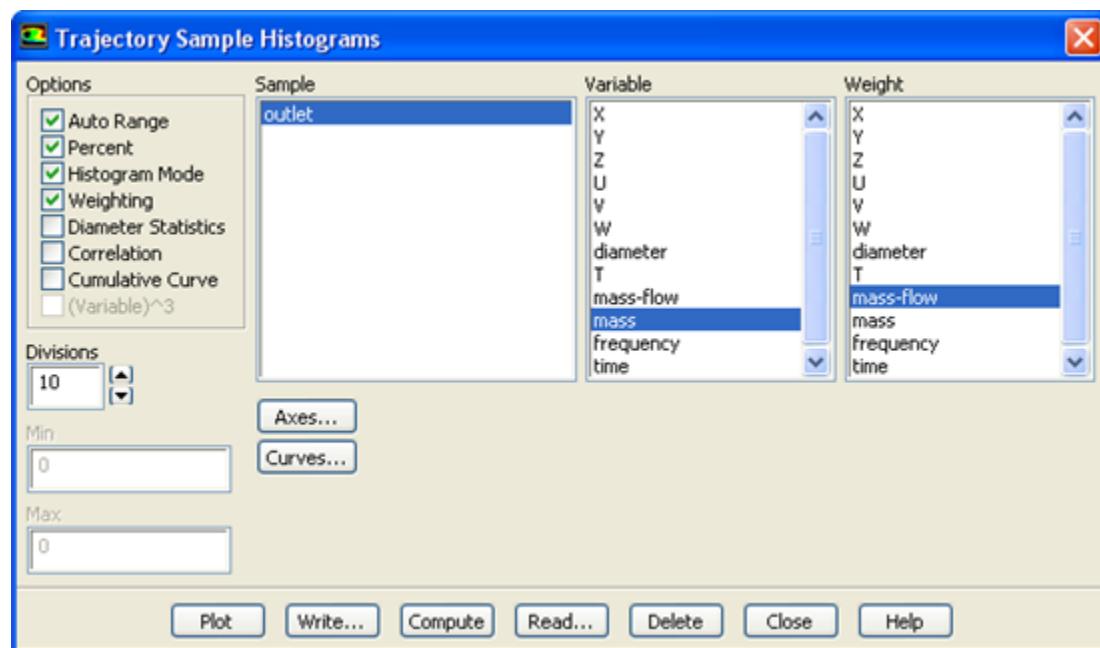

Boundedness of planes is not considered during sampling of particle tracks, which means that all particle tracks crossing the unbounded plane are sampled.

25.7.7. Histogram Reporting of Samples

Histograms can be plotted from sample files created in the *Sample Trajectories Dialog Box* (p. 2193) (as described in *Sampling of Trajectories* (p. 1163)) using the *Trajectory Sample Histograms Dialog Box* (p. 2195) (*Figure 25.42* (p. 1165)).

Reports → Histogram → Set Up...

Figure 25.42 The Trajectory Sample Histograms Dialog Box

The procedure for plotting histograms from data in a sample file is listed below:

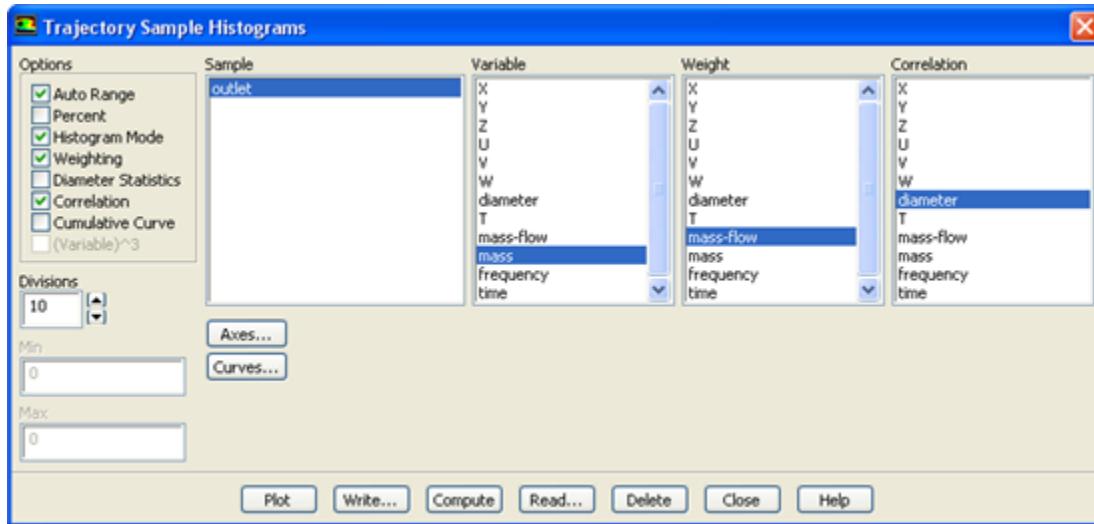

1. Select a file to be read by clicking the **Read...** button. After you read in the sample file, the boundary name will appear in the **Sample** list.
2. Select the data sample in the **Sample** list, and then select the data to be plotted from the **Variable** list.
3. Select the data to weight the variable from the **Weight** list.
4. Click the **Plot** button at the bottom of the dialog box to display the histogram.

By default, the percent of particles will be plotted on the *y* axis. You can plot the actual number of particles by deselecting **Percent** under **Options**. The number of “bins” or intervals in the plot can be set in the **Divisions** field. You can delete samples from the list with the **Delete** button and update the **Min/Max** values with the **Compute** button. To display the histogram without the bars, deselect **Histogram Mode** under **Options**. A summary similar to that in *Summary Reporting of Current Particles* (p. 1166) will be displayed in the console for the selected variables when **Diameter Statistics** is enabled. Although these statistics are computed for the selected variable in the **Variable** list, it is applicable only to the

diameter information. When the sampled particle streams all have the same flow rate, you can disable the **Weighting**. To postprocess the histograms with other tools, you can store them in an XY-plot file format using the **Write...** button.

When investigating the behavior of particles, it is sometimes desirable to know how one type of particle variable depends on another particle variable. To facilitate this, the **Correlation** option exists. When you enable this option, an additional column of sampled variables appears, allowing you to choose the correlation variable (see [Figure 25.43 \(p. 1166\)](#)).

Figure 25.43 The Trajectory Sample Histograms Dialog Box

If you want to know the continuous cumulative distributions, enable the **Cumulative Curve** option. A cumulative distribution curve is computed of the variable which is selected in the **Variable** list. However, if the **Correlation** option is enabled along with the **Cumulative Curve**, then the cumulative curve of the variable selected in the **Correlation** list is plotted. For a constant particle density, you can plot the cumulative mass distribution by selecting the diameter and enabling $(\text{Variable})^3$.

25.7.8. Summary Reporting of Current Particles

For many mass-transfer and flow processes, it is desirable to know the mean diameter of the particles. A mean diameter, D_{jk} , is calculated from the particle size distribution using the following general expression [42] (p. 2369):

$$\left(D_{jk}\right)^{j-k} \equiv \frac{\int_0^{\infty} D^j f(D) dD}{\int_0^{\infty} D^k f(D) dD} \quad (25-21)$$

where j and k are integers and $f(D)$ is the distribution function (e.g., Rosin-Rammler). D_{10} , for example, is the average (arithmetic) particle diameter. The Sauter mean diameter (SMD), D_{32} , is the diameter of a particle whose ratio of volume to surface area is equal to that of all particles in the com-

tation. A summary of common mean diameters is given in *Table 25.6: Common Mean Diameters and Their Fields of Application* (p. 1167).

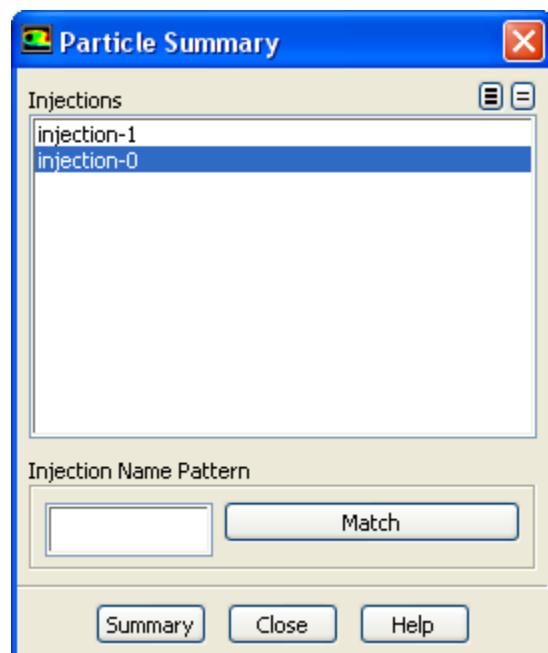

Table 25.6 Common Mean Diameters and Their Fields of Application

j	k	Order $j + k$	Name	Field of Application
1	0	1	Mean diameter, D_{10}	Comparisons, evaporation
2	0	2	Mean surface diameter, D_{20}	Absorption
3	0	3	Mean volume diameter, D_{30}	Hydrology
2	1	3	Overall surface diameter, D_{21}	Adsorption
3	1	4	Overall volume diameter, D_{31}	Evaporation, molecular diffusion
3	2	5	Sauter mean diameter, D_{32}	Combustion, mass transfer, and efficiency studies
4	3	7	De Brouckere diameter, D_{43}	Combustion equilibrium

Summary information (number, mass, average diameter) for particles currently in the computational domain can be reported using the *Particle Summary Dialog Box* (p. 2196) (*Figure 25.44* (p. 1167))

Reports → Summary → Set Up...

Figure 25.44 The Particle Summary Dialog Box

The procedure for reporting a summary for particle injections is as follows:

1. Select the particle injection(s) for which you want to generate a summary in the **Injections** list.

ANSYS FLUENT provides a shortcut for selecting injections with names that match a specified pattern. To use this shortcut, enter the pattern under **Injection Name Pattern** and then click **Match** to select the injections with names that match the specified pattern. For example, if you specify **drop***, all injections that have names beginning with **drop** (e.g., **drop-1**, **droplet**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **drop?**, all surfaces with names consisting of **drop** followed by a single character will be selected (or deselected, if they are all selected already).

2. Click **Summary** to display the injection summary in the console window.

```
(*)- Summary for Injection: injection-0 -(*)

Total number of parcels : 1862
Total number of particles : 1.196710e+05
Total mass : 1.128303e-05 (kg)
Maximum RMS distance from injector : 7.372527e-01 (m)
Maximum particle diameter : 3.072739e-04 (m)
Minimum particle diameter : 1.756993e-06 (m)
Overall RR Spread Parameter : 1.446806e+00
Maximum Error in RR fit : 1.071220e-01
Overall RR diameter (D_RR) : 9.051303e-05 (m)
Overall mean diameter (D_10) : 4.663269e-05 (m)
Overall mean surface area (D_20) : 5.344694e-05 (m)
Overall mean volume (D_30) : 6.121478e-05 (m)
Overall surface diameter (D_21) : 6.125692e-05 (m)
Overall volume diameter (D_31) : 7.013570e-05 (m)
Overall Sauter diameter (D_32) : 8.030141e-05 (m)
Overall De Brouckere diameter (D_43) : 1.082971e-04 (m)
```

25.7.9. Postprocessing of Erosion/Accretion Rates

You can calculate the erosion and accretion rates in a cumulative manner (over a series of injections) by using the **Sample Trajectories** dialog box. First select an injection in the **Release From Injections** list and compute its trajectory. Then enable the **Accumulate Erosion/Accretion Rates** option, select the next injection (after deselecting the first one), and click **Compute** again. The rates will accumulate at the surfaces each time you click **Compute**.

Important

Both the erosion rate and the accretion rate are defined at wall face surfaces only, so they cannot be displayed at node values.

25.8. Parallel Processing for the Discrete Phase Model

ANSYS FLUENT offers three modes of parallel processing for the discrete phase model: the **Shared Memory**, the **Message Passing**, and the **Hybrid** options under the **Parallel** tab, in the **Discrete Phase Model** dialog box. The **Shared Memory** method is suitable for computations where the machine running the ANSYS FLUENT host process is an adequately large, shared-memory, multiprocessor machine. The **Message Passing** option is suitable for generic distributed memory cluster computing. The **Hybrid** option is enabled by default and is suitable for modern multicore memory cluster computing.

Important

When tracking particles in parallel, the DPM model cannot be used with any of the multiphase flow models (VOF, mixture, or Eulerian) if the **Shared Memory** option is enabled. (Note that using the **Message Passing** or **Hybrid** option, when running in parallel, enables the compatibility of all multiphase flow models with the DPM model.)

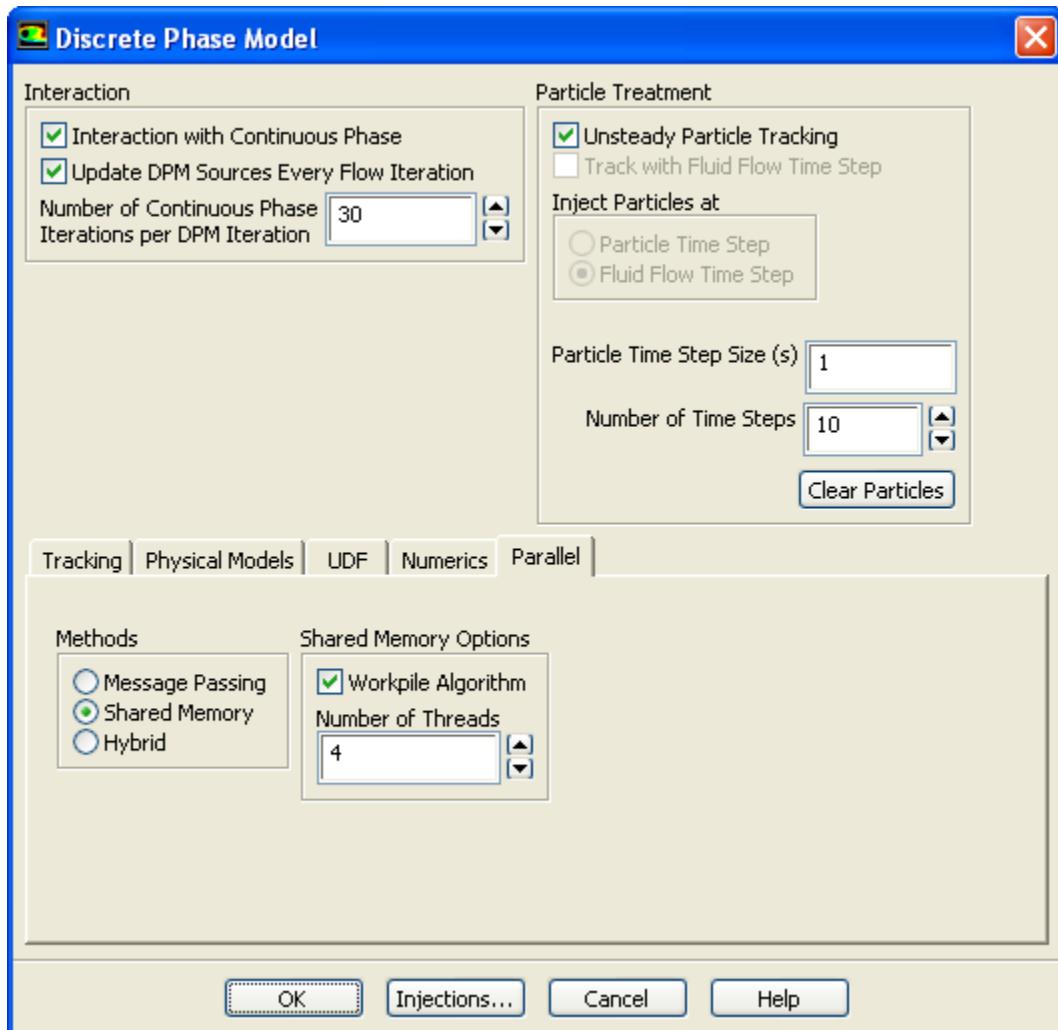

The **Shared Memory** option (*Figure 25.45 (p. 1170)*) is implemented using POSIX Threads (pthreads) based on a shared-memory model. Once the **Shared Memory** option is enabled, you can then select along with it the **Workpile Algorithm** and specify the **Number of Threads**. By default, the **Number of Threads** is equal to the number of compute nodes specified for the parallel computation. You can modify this value based on the computational requirements of the particle calculations. If, for example, the particle calculations require more computation than the flow calculation, you can increase the **Number of Threads** (up to the number of available processors) to improve performance. When using the **Shared Memory** option, the particle calculations are entirely managed by the ANSYS FLUENT host process. You must make sure that the machine executing the host process has enough memory to accommodate the entire mesh.

Important

Note that the **Shared Memory** option on Windows based architectures, such as ntx86 and win64 provides only serial tracking on the host, since the **Workpile Algorithm** is not available due to lack of POSIX Threads on these platforms.

Important

Please note that the **Workpile Algorithm** option is not available with the wall film boundary condition. It will be disabled automatically when choosing to simulate a wall film on a wall.

Figure 25.45 The Shared Memory Option with Workpile Algorithm Enabled

The **Message Passing** option enables cluster computing and also works on shared-memory machines. With this option enabled, the compute node processes perform the particle work on their local partitions. Particle migration to other compute nodes is implemented using message passing primitives. There are no special requirements for the host machine. Note that this model is not available if the **Cloud Model** option is turned on under the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box. When running ANSYS FLUENT in parallel, by default, pathline displays are computed in serial on the host node. Pathline displays may be computed in parallel on distributed memory systems if the **Message Passing** parallel option is selected in the **Discrete Phase Model** dialog box.

The **Hybrid** option combines **Message Passing** and **OpenMP** for a dynamic load balancing without migration of cells, enables multicore cluster computing, and also works on shared-memory machines. With this option enabled, the compute node processes perform the particle calculations on their local partitions. **OpenMP** threads will be spawned, and the number of threads in each ANSYS FLUENT node process is based on the evaluation of the particle load on the current machine. The maximum number of threads on each machine can be controlled using the **Thread Control** dialog box (see [Controlling the Threads \(p. 1756\)](#) for details). The default value is the number of ANSYS FLUENT node processes on each machine. Particle migration to other compute nodes is implemented using message passing primitives. There are no special requirements for the host machine. Note that the **Hybrid** option is not available if the **Cloud Model** option is enabled in the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box. The **Message Passing** option will be used instead of the **Hybrid** option when

you are only performing PDF tracking, as no load imbalance occurs in this situation. When running ANSYS FLUENT in parallel, pathline displays are computed by default in serial on the host node. Pathline displays may also be computed in parallel on distributed memory systems if the **Message Passing** option is selected from the **Methods** list.

Important

Note that the **Hybrid** option is not available for the ntx86 platform (32-bit Windows).

You may seamlessly switch among the **Shared Memory** option, the **Message Passing** option, and the **Hybrid** option at any time during the ANSYS FLUENT session.

In addition to performing general parallel processing of the Discrete Phase Model, you have the option of implementing DPM-specific user-defined functions in parallel ANSYS FLUENT. For more information about the parallelization of DPM UDFs, see [Parallelization of Discrete Phase Model \(DPM\) UDFs](#) in the [UDF Manual](#).

When using the **Message Passing** or the **Hybrid** option you can make use of ANSYS FLUENT's automated load balancing capability by giving an appropriate weight to the particle steps in each cell. In this case the number of particle steps in each partition is considered in the load balancing procedure. Further details can be found in [Using the Partitioning and Load Balancing Dialog Box \(p. 1736\)](#).

Chapter 26: Modeling Multiphase Flows

This chapter discusses the general multiphase models that are available in ANSYS FLUENT. For information about the various theories behind the general multiphase models in ANSYS FLUENT, see "[Multiphase Flows](#)" in the [Theory Guide](#). Information about using the general multiphase models in ANSYS FLUENT is presented in the following sections:

- [26.1. Introduction](#)
- [26.2. Steps for Using a Multiphase Model](#)
- [26.3. Setting Up the VOF Model](#)
- [26.4. Setting Up the Mixture Model](#)
- [26.5. Setting Up the Eulerian Model](#)
- [26.6. Setting Up the Wet Steam Model](#)
- [26.7. Solution Strategies for Multiphase Modeling](#)
- [26.8. Postprocessing for Multiphase Modeling](#)

26.1. Introduction

The first step in solving any multiphase problem is to determine which of the regimes described in [Multiphase Flow Regimes](#) in the [Theory Guide](#) best represents your flow. [Model Comparisons](#) in the [Theory Guide](#) provides some broad guidelines for determining appropriate models for each regime, and [Detailed Guidelines](#) provides details and how to determine the degree of interphase coupling for flows involving bubbles, droplets, or particles, and the appropriate model for different amounts of coupling.

The following sections will guide you through the setup, solution, and postprocessing of multiphase flow models.

26.2. Steps for Using a Multiphase Model

The procedure for setting up and solving a general multiphase problem is outlined below, and described in detail in the subsections that follow. Remember that only the steps that are pertinent to general multiphase calculations are shown here. For information about inputs related to other models that you are using in conjunction with the multiphase model, see the appropriate sections for those models.

See also [Additional Guidelines for Eulerian Multiphase Simulations \(p. 1240\)](#) for guidelines on simplifying Eulerian multiphase simulations.

1. Enable the multiphase model you want to use (VOF, mixture, or Eulerian) and specify the number of phases. For the VOF and Eulerian models, specify the volume fraction scheme as well.

See [Enabling the Multiphase Model \(p. 1175\)](#) and [Choosing a Volume Fraction Formulation \(p. 1177\)](#) for details.

2. Copy the material representing each phase from the materials database.

Materials

If the material you want to use is not in the database, create a new material. See [Using the Materials Task Page \(p. 405\)](#) for details about copying from the database and creating new materials.

See [Modeling Compressible Flows \(p. 1230\)](#) and [Modeling Compressible Flows \(p. 1239\)](#) for additional information about specifying material properties for a compressible phase (VOF and mixture models only). It is possible to turn off reactions in some materials by selecting **none** in the **Reactions** drop-down list under **Properties** in the **Create/Edit Materials** dialog box.

Important

If your model includes a particulate (granular) phase, you will need to create a new material for it in the *fluid* materials category (*not* the solid materials category).

3. Define the phases, and specify any interaction between them (e.g., surface tension if you are using the VOF model, slip velocity functions if you are using the mixture model, or drag functions if you are using the Eulerian model).

Phases

See [Defining the Phases \(p. 1180\) – Defining the Phases for the Eulerian Model \(p. 1240\)](#) for details.

4. (Eulerian model only) If the flow is turbulent, define the multiphase turbulence model.

Models → Viscous → Edit...

See [Modeling Turbulence \(p. 1250\)](#) for details.

5. If body forces are present, enable gravity and specify the gravitational acceleration.

Cell Zone Conditions → Operating Conditions...

See [Including Body Forces \(p. 1180\)](#) for details.

6. Specify the boundary conditions, including the secondary-phase volume fractions at flow boundaries and (if you are modeling wall adhesion in a VOF simulation) the contact angles at walls.

Boundary Conditions

See [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#) for details.

7. Set any model-specific solution parameters.

Solution Methods

Solution Controls

See [Setting Time-Dependent Parameters for the VOF Model \(p. 1228\)](#) and [Solution Strategies for Multiphase Modeling \(p. 1276\)](#) for details.

8. Initialize the solution and set the initial volume fractions for the secondary phases.

 **Solution Initialization → Patch...**

See [Setting Initial Volume Fractions \(p. 1284\)](#) for details.

9. Calculate a solution and examine the results. Postprocessing and reporting of results are available for each phase that is selected.

See [Solution Strategies for Multiphase Modeling \(p. 1276\)](#) and [Postprocessing for Multiphase Modeling \(p. 1291\)](#) for details.

This section provides instructions and guidelines for using the VOF, mixture, and Eulerian multiphase models.

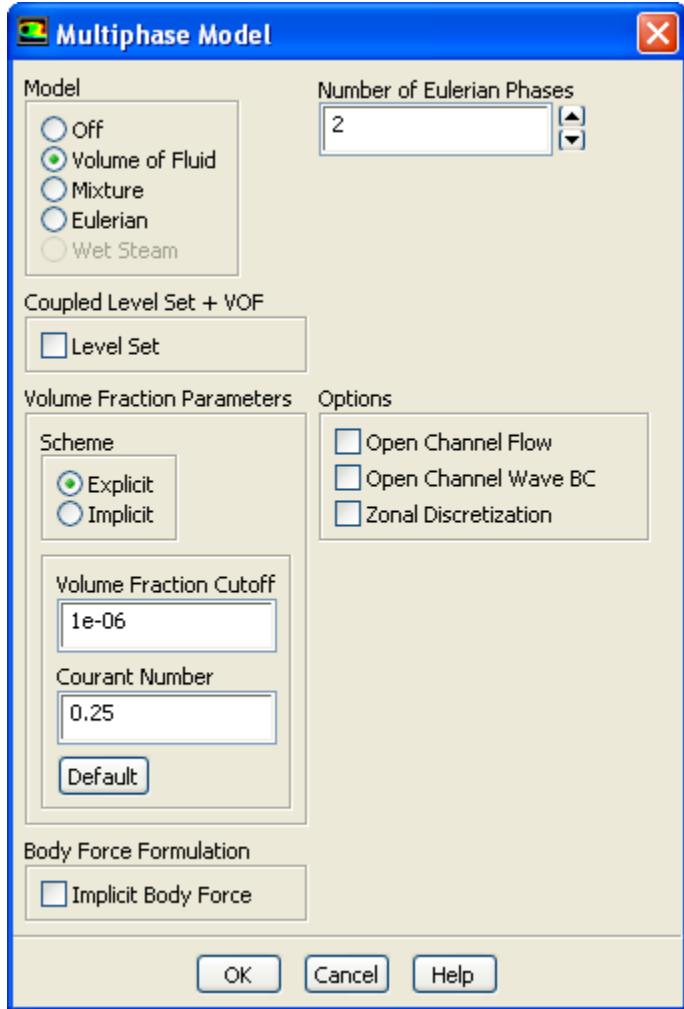

Information is presented in the following subsections:

- 26.2.1. Enabling the Multiphase Model
- 26.2.2. Choosing a Volume Fraction Formulation
- 26.2.3. Solving a Homogeneous Multiphase Flow
- 26.2.4. Defining the Phases
- 26.2.5. Including Body Forces
- 26.2.6. Modeling Multiphase Species Transport
- 26.2.7. Specifying Heterogeneous Reactions
- 26.2.8. Including Mass Transfer Effects
- 26.2.9. Defining Multiphase Cell Zone and Boundary Conditions

26.2.1. Enabling the Multiphase Model

To enable the VOF, mixture, or Eulerian multiphase model, select **Volume of Fluid, Mixture, or Eulerian** as the **Model** in the [Multiphase Model Dialog Box \(p. 1774\)](#) ([Figure 26.1 \(p. 1176\)](#)).

 **Models →  Multiphase → Edit...**

Figure 26.1 The Multiphase Model Dialog Box

The dialog box will expand to show the relevant inputs for the selected multiphase model.

If you selected the volume of fluid (VOF) model, the inputs are as follows:

- number of phases
- (optional) coupled level set with VOF (see [Coupled Level-Set and VOF Model](#) in the [Theory Guide](#))
- volume fraction scheme (explicit or implicit) (see [Choosing a Volume Fraction Formulation \(p. 1177\)](#))
- (optional) inclusion of open channel flow
- (optional) inclusion of open channel wave boundary conditions
- (optional) inclusion of zonal discretization for applications such as diffused interface modeling in one zone and sharp interface modeling in another zone
- (optional) inclusion of the implicit body force formulation (see [Including Body Forces \(p. 1180\)](#))

If you selected the mixture model, the inputs are as follows:

- number of phases
- (optional) inclusion of slip velocities (see [Solving a Homogeneous Multiphase Flow \(p. 1179\)](#))
- (optional) inclusion of the implicit body force formulation (see [Including Body Forces \(p. 1180\)](#))

If you selected the Eulerian model, the inputs are as follows:

- number of phases
- volume fraction scheme (explicit or implicit) (see [Choosing a Volume Fraction Formulation \(p. 1177\)](#))
- (optional) including the dense discrete phase model
- (optional) including the boiling model
- (optional) including the multi-fluid VOF model
- (optional) including zonal discretization for applications such as diffused interface modeling in one zone and sharp interface modeling in another zone. This is only available if the **Multi-Fluid VOF Model** is enabled.

To specify the number of phases for the multiphase calculation, enter the appropriate value in the **Number of Eulerian Phases** field. You can specify up to 20 phases.

26.2.2. Choosing a Volume Fraction Formulation

To specify the volume fraction formulation to be used for the VOF and Eulerian multiphase models, select the appropriate **Scheme** under **Volume Fraction Parameters** in the **Multiphase Model** dialog box.

The schemes that are available in ANSYS FLUENT are **Explicit** and **Implicit**. Whether you enable the VOF or the Eulerian multiphase model, you can specify a **Volume Fraction Cutoff** value. This value is described in more detail in [Volume Fraction Limits \(p. 1179\)](#).

26.2.2.1. Explicit Schemes

Explicit schemes are time-dependent and offer you the following options for **Volume Fraction** spatial discretization schemes, which are available in the **Solution Methods** task page:

- **First Order Upwind** (Eulerian Multiphase model only)
- **Geo-Reconstruct** (VOF model and Eulerian Multiphase with Multi-Fluid VOF enabled)
- **CICSAM** (VOF model and Eulerian Multiphase with Multi-Fluid VOF enabled)
- **Compressive**
- **Modified HRIC**
- **QUICK**

While the **Modified HRIC**, **Compressive**, and **CICSAM** schemes are less computationally expensive than the **Geo-Reconstruct** scheme, the interface between phases will not be as sharp as that predicted with the geometric reconstruction scheme. The geometric reconstruction interpolation scheme is typically used whenever you are interested in the time-accurate transient behavior of the VOF solution.

Donor-Acceptor is another spatial discretization scheme that can be used under certain circumstances for quad or hex meshes. Initially, **Donor-Acceptor** is not available in the **Solution Methods** task page GUI. To make it available, use the following text command:

```
solve → set → expert
```

You will be asked a series of questions, one of which is

```
Allow selection of all applicable discretization schemes? [no]
```

If your response is yes, then many more discretization schemes will be available for your selection.

Important

For the geometric reconstruction and donor-acceptor schemes, if you are using a conformal mesh (i.e., if the mesh node locations are identical at the boundaries where two subdomains meet), you must ensure that there are no two-sided (zero-thickness) walls within the domain. If there are, you will need to slit them, as described in [Slitting Face Zones \(p. 196\)](#).

In general, **Geo-Reconstruct**, **Modified HRIC**, **Compressive**, and **CICSAM** are applied to cases with sharp interfaces, while **First Order Upwind** and **QUICK** are applied when the phases are interpenetrating. Note that the **Geo-Reconstruct** and **CICSAM** schemes become available in the interface when the VOF model is used, or when the Eulerian multiphase model is selected with the **Multi-Fluid VOF Model** option enabled. **First Order Upwind** is not available when the volume fraction explicit scheme is used and the **Multi-Fluid VOF Model** is enabled for the Eulerian multiphase model. However, it can be made available in the GUI when the solve/set/expert text command is invoked:

```
/solve/set> expert  
Allow selection of all applicable discretization schemes? [Yes]
```

In summary, when the **Eulerian** model is used with the **Explicit** scheme and the **Multi-Fluid VOF Model** is disabled, you can apply **First Order Upwind**, **QUICK**, **Modified HRIC**, and **Compressive**. If the **Multi-Fluid VOF Model** is enabled, you can apply **Geo-Reconstruct**, **CICSAM**, **Compressive**, **QUICK**, and **Modified HRIC**.

26.2.2.2. Implicit Schemes

Implicit schemes take on the following forms:

- Time-dependent with the implicit interpolation scheme: This formulation can be used if you are looking for a steady-state solution and you are not interested in the intermediate transient flow behavior, *but* the final steady-state solution is dependent on the initial flow conditions and/or you do not have a distinct inflow boundary for each phase.

To use this formulation, select **Implicit** as the volume fraction **Scheme** in the [Multiphase Model Dialog Box \(p. 1774\)](#), and enable a **Transient** calculation in the **General** task page.

- Steady-state with the implicit interpolation scheme: This formulation can be used if you are looking for a steady-state solution, you are not interested in the intermediate transient flow behavior, *and* the final steady-state solution is not affected by the initial flow conditions and there is a distinct inflow boundary for each phase. Note that the implicit modified HRIC scheme can be used as a robust alternative to the explicit geometric reconstruction scheme.

To specify the formulation when using the VOF multiphase model, select **Implicit** as the volume fraction **Scheme** in the [Multiphase Model Dialog Box \(p. 1774\)](#), then select **First Order Upwind**, **Second Order Upwind**, **Compressive**, **Modified HRIC**, **BGM** (available only for the steady state solver), or **QUICK** as the **Volume Fraction Spatial Discretization** in the **Solution Methods** task page. When using the Eulerian multiphase model, select **First Order Upwind**, **QUICK**, or **Modified HRIC** as the **Volume Fraction Spatial Discretization** in the **Solution Methods** task page.

When the **Eulerian** model is used with the **Implicit** scheme and the **Multi-Fluid VOF Model** is enabled, you can apply **First Order Upwind**, **Compressive**, **QUICK**, and **Modified HRIC**. If the **Multi-Fluid VOF Model** is disabled, you can apply **First Order Upwind**, **QUICK**, **Modified HRIC**. Note that you can make the **Modified HRIC**, **Compressive**, **Phase Localized Compressive Scheme**,

and **Zonal Discretization** schemes available in the GUI for the Eulerian multiphase and Mixture multiphase models when the `solve/set/expert` text command is invoked for the selection of all applicable discretization schemes.

```
/solve/set> expert
Allow selection of all applicable discretization schemes? [Yes]
```

26.2.2.2.1. Examples

To help you determine the best formulation to use for your problem, some examples that use different formulations are listed below:

- jet breakup

Use the explicit scheme (time-dependent with the geometric reconstruction scheme or the donor-acceptor if problems occur with the geometric reconstruction scheme).

- shape of the liquid interface in a centrifuge

Use the time-dependent solver with the implicit interpolation scheme.

- flow around a ship's hull

Use the steady-state solver with the implicit interpolation scheme.

26.2.2.3. Volume Fraction Limits

The **Volume Fraction Cutoff** allows you to specify a cutoff limit for the volume fraction values. The value that you provide is used as the lower cutoff for the volume fraction. All volume fraction values in the domain below this cutoff value are set to zero. The upper cutoff is calculated as (1.0 - lower cutoff). All volume fraction values above the upper cutoff value are set to 1.0. The default value is 1e-6, which is the recommended value. Using a higher value may lead to a higher volume imbalance.

Important

The **Volume Fraction Cutoff** value can be specified when using the VOF model, or when using the Eulerian Multiphase model with the **Explicit** scheme.

Note

For the **Implicit** scheme, the minimum value allowed is 0 and the maximum allowable value is 1e-6. For the **Explicit** scheme, the minimum value allowed is 0 and the maximum allowable value is 1e-4. A higher cutoff value is available with the **Explicit** scheme because it allows for the local redistribution procedure of partially filled cells, which accounts for volume loss. This treatment is not available with the **Implicit** scheme.

26.2.3. Solving a Homogeneous Multiphase Flow

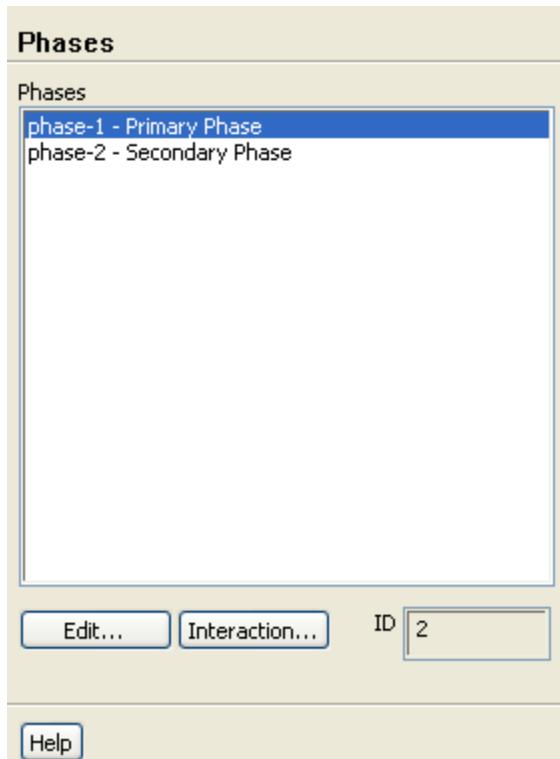

If you are using the mixture model, you have the option to disable the calculation of slip velocities and solve a homogeneous multiphase flow (i.e., one in which the phases all move at the same velocity). By default, ANSYS FLUENT will compute the slip velocities for the secondary phases, as described in [Relative \(Slip\) Velocity and the Drift Velocity](#) in the [Theory Guide](#). If you want to solve a homogeneous multiphase flow, turn off **Slip Velocity** under **Mixture Parameters**.

26.2.4. Defining the Phases

To define the phases (including their material properties) and any interphase interaction (e.g., surface tension and wall adhesion for the VOF model, slip velocity for the mixture model, drag functions for the mixture and the Eulerian models), ([Figure 26.2 \(p. 1180\)](#)).

Figure 26.2 The Phases Task Page

Each item in the **Phases** list in this task page is one of two types: a **Primary-Phase** indicates that the selected item is the primary phase, and **Secondary-Phase** indicates that the selected item is a secondary phase. To specify any interaction between the phases, click the **Interaction...** button.

Instructions for defining the phases and interaction are provided in [Defining the Phases for the VOF Model \(p. 1219\)](#), [Defining the Phases for the Mixture Model \(p. 1230\)](#), and [Defining the Phases for the Eulerian Model \(p. 1240\)](#) for the VOF, mixture, and Eulerian models, respectively.

26.2.5. Including Body Forces

When large body forces (e.g., gravity or surface tension forces) exist in multiphase flows, the body force and pressure gradient terms in the momentum equation are almost in equilibrium, with the contributions of convective and viscous terms small in comparison. Segregated algorithms converge poorly unless partial equilibrium of pressure gradient and body forces is taken into account. ANSYS FLUENT provides an optional “implicit body force” treatment that can account for this effect, making the solution more robust.

The basic procedure involves augmenting the correction equation for the face flow rate, [Equation 20–50](#) in the [Theory Guide](#), with an additional term involving corrections to the body force. This results in

extra body force correction terms in [Equation 20–48](#) in the [Theory Guide](#), and allows the flow to achieve a realistic pressure field very early in the iterative process.

To include this body force, enable **Gravity** in the [Operating Conditions Dialog Box](#) (p. 1952) and specify the **Gravitational Acceleration**.

 **Cell Zone Conditions** → **Operating Conditions...**

For VOF calculations, you should also enable the **Specified Operating Density** option in the [Operating Conditions](#) dialog box, and set the **Operating Density** to be the density of the lightest phase. (This excludes the buildup of hydrostatic pressure within the lightest phase, improving the round-off accuracy for the momentum balance.) If any of the phases is compressible, set the **Operating Density** to zero.

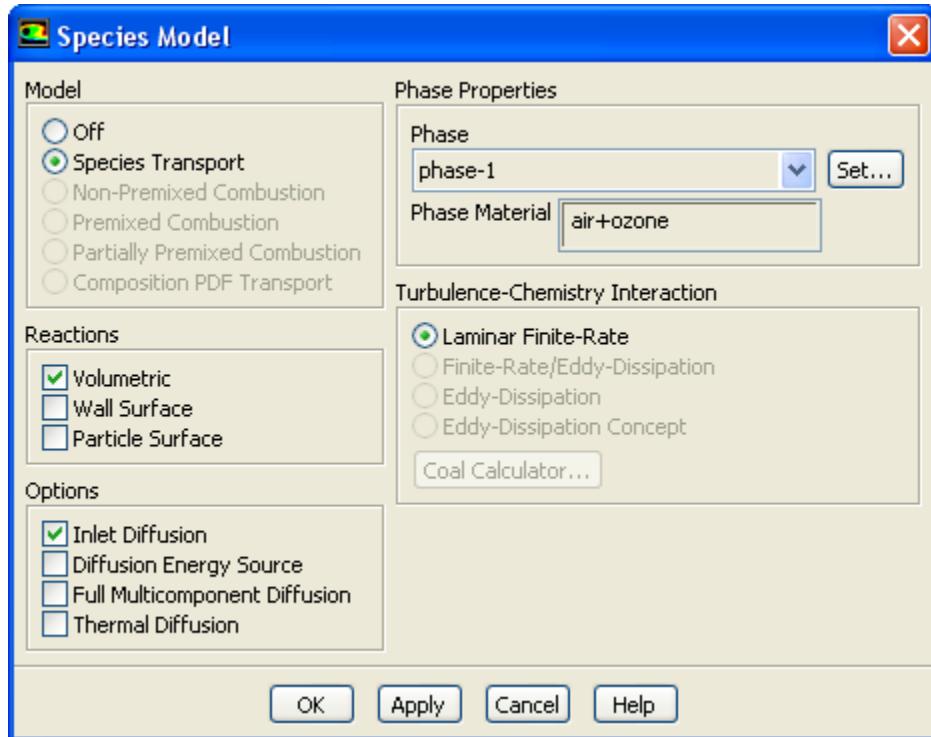

Important

For VOF and mixture calculations involving body forces, it is recommended that you also enable the **Implicit Body Force** treatment for the **Body Force Formulation** in the [Multiphase Model](#) dialog box. This treatment improves solution convergence by accounting for the partial equilibrium of the pressure gradient and body forces in the momentum equations. See [Including Body Forces](#) (p. 1180) for details.

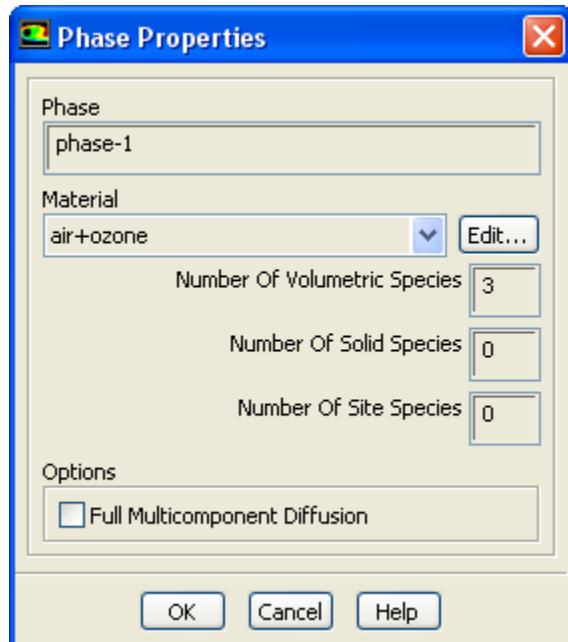

26.2.6. Modeling Multiphase Species Transport

ANSYS FLUENT lets you describe a multiphase species transport and volumetric reaction ([Modeling Species Transport in Multiphase Flows](#) in the [Theory Guide](#)) in a fashion that is similar to setting up a single-phase chemical reaction using the **Species Model** dialog box (e.g., [Figure 26.3](#) (p. 1182)).

 **Models** →  **Species** → **Edit...**

Figure 26.3 The Species Model Dialog Box with a Multiphase Model Enabled

1. Select **Species Transport** under **Model**.
2. Enable **Volumetric** under **Reactions**.
3. Select a specific phase using the **Phase** drop-down list under **Phase Properties**.
4. Click the **Set...** button to display the **Phase Properties** dialog box (*Figure 26.4 (p. 1182)*).

Figure 26.4 The Phase Properties Dialog Box

In the **Phase Properties** dialog box, the material for each phase is listed in the **Material** drop-down list. From this list, you can choose the material that you want to use for a specific phase. The drop-down list contains all of the materials, then open the **Edit Material** dialog box by clicking the **Edit...** (or **View...**) button next to the **Material** drop-down list.

5. In the **Species Model** dialog box, choose the **Turbulence-Chemistry Interaction** model. Three models are available:

Laminar Finite-Rate

computes only the Arrhenius rate (see [Equation 7–8](#) in the [Theory Guide](#)) and neglects turbulence-chemistry interaction.

Eddy-Dissipation

(for turbulent flows) computes only the mixing rate (see [Equation 7–25](#) and [Equation 7–26](#) in the [Theory Guide](#)).

Finite-Rate/Eddy-Dissipation

(for turbulent flows) computes both the Arrhenius rate and the mixing rate and uses the smaller of the two.

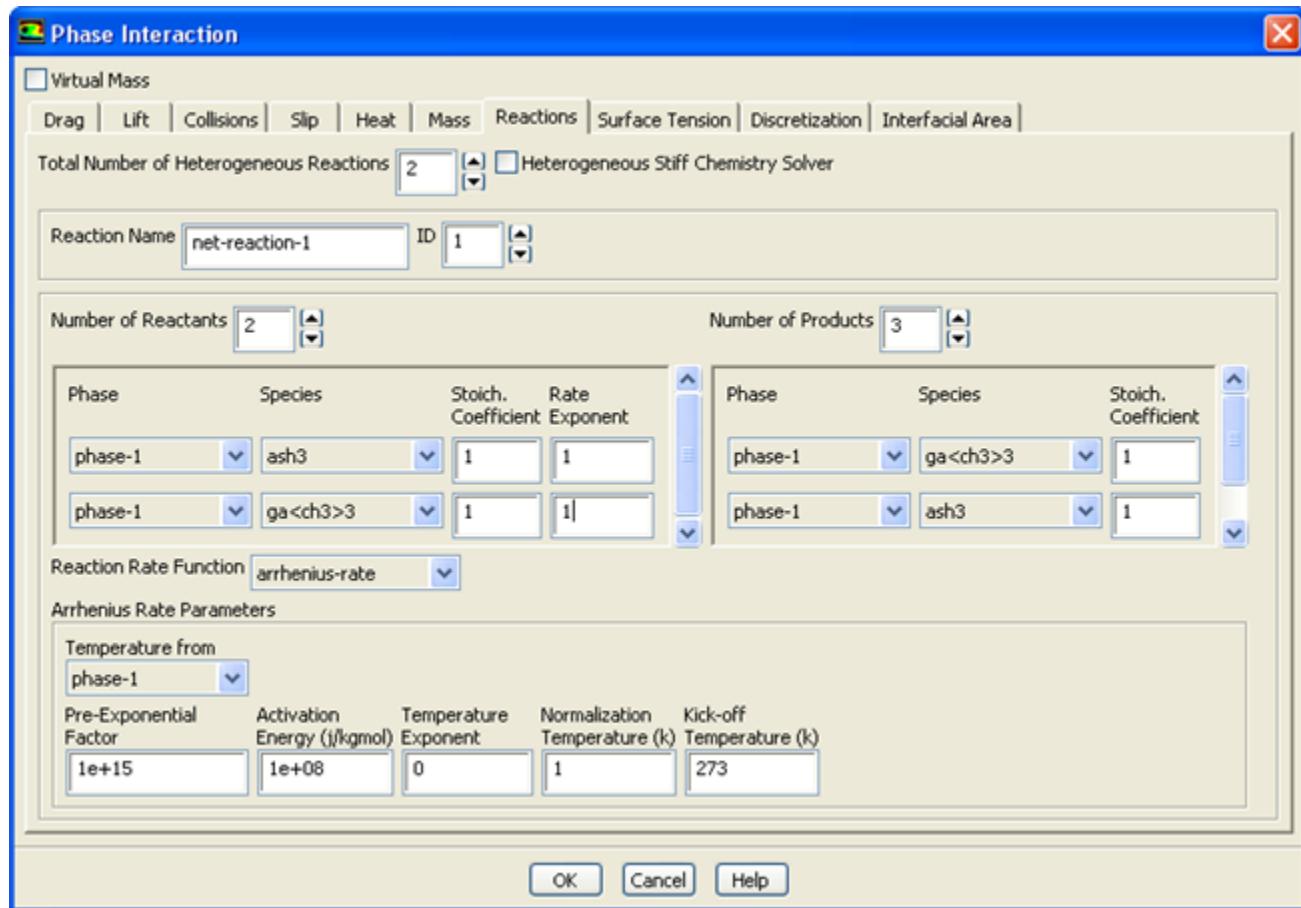

When modeling multiphase species transport, additional inputs may also be required depending on your modeling needs. See, for example, [Specifying Heterogeneous Reactions \(p. 1183\)](#) for more information defining heterogeneous reactions, or [Including Mass Transfer Effects \(p. 1186\)](#) for more information on mass transfer effects.

26.2.7. Specifying Heterogeneous Reactions

You can use ANSYS FLUENT to define multiple heterogeneous reactions and stoichiometry using the **Phase Interaction** dialog box (e.g., [Figure 26.5 \(p. 1184\)](#)).

1. In the **Phases** task page ([Figure 26.2 \(p. 1180\)](#)), click the **Interaction...** button to open the **Phase Interaction** dialog box.

Figure 26.5 The Phase Interaction Dialog Box for Heterogeneous Reactions

2. Click the **Reactions** tab in the **Phase Interaction** dialog box.
3. Set the total number of reactions (volumetric reactions, wall surface reactions, and particle surface reactions) in the **Total Number of Heterogeneous Reactions** field. (Use the arrows to change the value, or type in the value and press <Enter>.)
4. Enable the **Heterogeneous Stiff Chemistry Solver** option if your inter-phase reaction mechanism contains numerically stiff reactions. This option can improve convergence and is available for transient Eulerian multiphase simulations. When this option is enabled, ANSYS FLUENT uses a fractional step algorithm where the flow is advanced without reaction sources for a time-step, and then the chemistry is integrated point-by-point for the same time-step. The stiff chemistry scheme solves all species in all phases coupled. Note that it is possible to include homogeneous (intra-phase) reactions along with the heterogeneous reactions in the **(Phase Interaction** dialog box (instead of in the reaction mechanism in the **Create/Edit Materials** dialog box), and these reactions will be solved with the stiff solver. The stiff ODE solver tolerances can be set using the following text command:

```
solve → set → heterogeneous-stiff-chemistry
```

5. Specify the **Reaction Name** of each reaction that you want to define.
6. Set the **ID** of each reaction you want to define. (Again, if you type in the value be sure to press Enter.)
7. For each reaction, specify how many reactants and products are involved in the reaction by increasing the value of the **Number of Reactants** and the **Number of Products**. Select each reactant or product in the **Reaction** tab and then set its stoichiometric coefficient in the **Stoich. Coefficient** field. (The stoichiometric coefficient is the constant $v'_{i,r}$ or $v''_{i,r}$ in [Equation 7-6](#) in the [Theory Guide](#).)

8. For each reaction, indicate the **Phase** and **Species** and the stoichiometric coefficient for each of your reactants and products.
9. For each reaction, use the **Reaction Rate Function** drop-down list to select one of the following:

none

if you do not want to include a reaction rate

population-balance

is the mass transfer due to nucleation and growth. If neither the primary phase or secondary phase has species associated with it, then the mass transfer is modeled as unidirectional. If the mass transfer process involves reactions or species, the problem must be set up as one involving heterogeneous reaction/mass transfer.

Important

The **population-balance** option for **Reaction Rate Function** should not be used if there are multiple reactions leading to the formation of the secondary phase. In this case, the reaction rate functions should be specified either through the standard dialog boxes or UDFs and the growth rate function should be a sum of the individual reaction rates. This would ensure consistency between the individual reaction rates and the total mass transfer from the primary to the secondary phase.

You can always use `DEFINE_MASS_TRANSFER` or `DEFINE_HET_RXN_RATE` UDF types instead of the **population-balance** option to specify mass transfer rates. However, the growth rate function and the mass transfer rates returned from the UDFs need to be consistent with each other.

arrhenius-rate

to specify rate exponents for an Arrhenius-type reaction (see [Heterogeneous Phase Interaction](#) in the [Theory Guide](#) for more information)

Important

This simple form of the Arrhenius rate option may only be used for devolatilization reactions only. Char combustion reaction may be more involved and complicated to be simply casted in this form. Additional diffusion rate formulations may be needed to formulate a complete char (or solid phase) reaction system.

Important

Note that you can also specify the heterogeneous reaction rates using a user-defined function. A UDF is available for an Arrhenius-type reaction with rate exponents that are equivalent to the stoichiometric coefficients. For more information, see [DEFINE_HET_RXN_RATE](#) in the [UDF Manual](#).

Important

ANSYS FLUENT assumes that the reactants are mixed thoroughly *before* reacting together, thus the heat and momentum transfer is based on this assumption. This assumption can be deactivated using a text command. For more information, contact your ANSYS FLUENT support engineer.

26.2.8. Including Mass Transfer Effects

As discussed in [Modeling Mass Transfer in Multiphase Flows](#) in the [Theory Guide](#), mass transfer effects in the framework of ANSYS FLUENT's general multiphase models (i.e., Eulerian multiphase, mixture multiphase, or VOF multiphase) can be modeled in one of three ways:

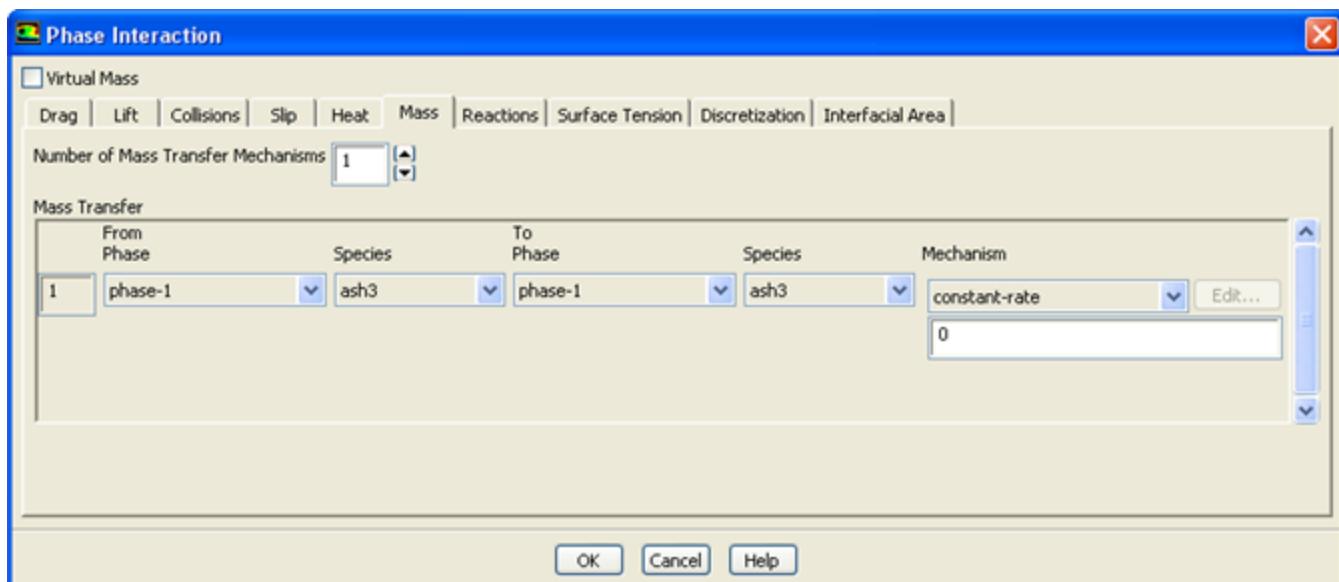

- Unidirectional constant rate mass transfer (not available for VOF calculations)
- UDF-prescribed mass transfer
- mass transfer through cavitation, evaporation-condensation, or boiling

Because of the different procedures and limitations involved, defining mass transfer through the Singhal et al. cavitation model is described separately in [Including Cavitation Effects](#) (p. 1239).

To define mass transfer in a multiphase simulation, as unidirectional constant, using a UDF, through population balance, cavitation, or evaporation and condensation, you will need to use the **Phase Interaction** dialog box (e.g., [Figure 26.6](#) (p. 1186)).

↳ **Phases → Interaction...**

Figure 26.6 The Phase Interaction Dialog Box for Mass Transfer

1. Click the **Mass** tab in the **Phase Interaction** dialog box.
2. Specify the **Number of Mass Transfer Mechanisms**. You can include any number of mass transfer mechanisms in your simulation. Note also that the same pair of phases can have multiple mass transfer mechanisms and you have the ability to activate and deactivate the mechanisms of your choice.

3. For each mechanism, specify the phase of the source material under **From Phase**. Note that the phase you select for **From Phase** must be a liquid if you plan to select **cavitation**, **evaporation-condensation**, or **boiling** from the **Mechanism** drop-down menu (see Step 7.).
4. If species transport is part of the simulation, and the source phase is composed of a mixture material, then specify the species of the source phase mixture material in the corresponding **Species** drop-down list.
5. For each mechanism, specify the phase of the destination material phase under **To Phase**. Note that the phase you select for **To Phase** must be a vapor if you plan to select **cavitation**, **evaporation-condensation**, or **boiling** from the **Mechanism** drop-down menu (see Step 7.).
6. If species transport is part of the simulation, and the destination phase is composed of a mixture material, then specify the species of the destination phase mixture material in the corresponding **Species** drop-down list.
7. For each mass transfer mechanism, select the desired mass transfer correlation under **Mechanism**. The following choices are available:

constant-rate

enables a constant, unidirectional mass transfer.

user-defined

allows you to implement a correlation reflecting a model of your choice, through a user-defined function.

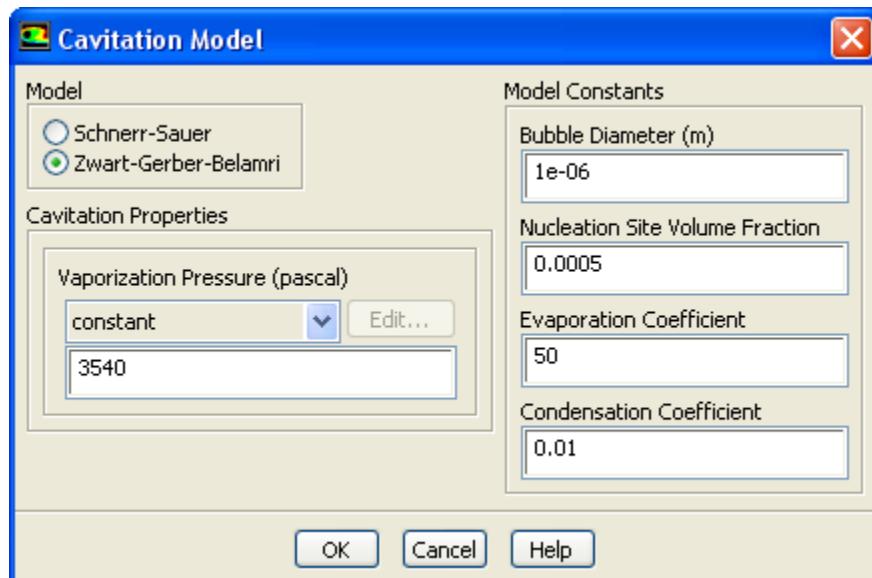

population-balance

allows you to model flow where a number density function is introduced to account for the particle population. With the aid of particle properties (e.g., particle size, porosity, composition, etc.), different particles in the population can be distinguished and their behavior can be described. For a comprehensive understanding of this option, please refer to the Population Balance Module Manual.

cavitation

provides you with two model options: **Schnerr-Sauer** and **Zwart-Gerber-Belamri**. To open the **Cavitation Model** dialog box, select **cavitation** from the **Mechanism** drop-down list. For information about the cavitation models, refer to [Cavitation Models](#) in the [Theory Guide](#).

Figure 26.7 The Cavitation Model Dialog Box

- Select **Schnerr-Sauer** and specify the **Bubble Number Density** under **Model Constants** and the **Vaporization Pressure** under **Cavitation Properties**.
- Select **Zwart-Gerber-Belamri** and specify the **BubbleDiameter**, the **Nucleation Site Volume Fraction**, the **Evaporation Coefficient**, and the **Condensation Coefficient** under **Model Constants**. Enter the **Vaporization Pressure** under **Cavitation Properties**. It is advisable to use the default values for all the model constants in both the **Schnerr-Sauer** and **Zwart-Gerber-Belamri** models. For the **Vaporization Pressure**, you have the choice of **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or **user-defined**.

Important

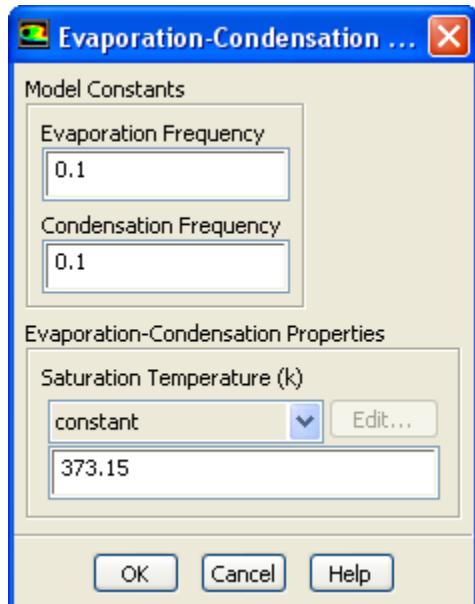

If the **Mixture** multiphase model is enabled, then the Singhal et al. cavitation model can be enabled using the solve/set/expert text command and responding yes to use Singhal-et-al cavitation model?. The **Singhal-Et-Al Cavitation Model** option will now be visible in the **Phase Interaction** dialog box, under the **Mass** tab. Enable this option to include the Singhal et al. cavitation model. Refer to [Including Cavitation Effects \(p. 1239\)](#) for information about setting the cavitation parameters. Also refer to [Cavitation Models](#) in the [Theory Guide](#) for information about the Singhal et al. model.

To disable this model, first deselect the **Singhal-Et-Al Cavitation Model** option in the **Phase Interaction** dialog box, then type the solve/set/expert text command again and enter no when asked if you want to use Singhal-et-al cavitation model?

evaporation-condensation

enables you to apply the evaporation-condensation model as the mass transfer mechanism. This model is available with the mixture and Eulerian multiphase models. Refer to [Evaporation-Condensation Model](#) in the [Theory Guide](#) for a theoretical discussion about this model.

Figure 26.8 The Evaporation-Condensation Model Dialog Box

- Enter the **Evaporation Frequency** and **Condensation Frequency** model constants. Those values are 0.1 by default. Note that the bubble diameter and accommodation coefficient are

usually not very well known, which is why the coefficient *coeff* ([Equation 17–406 in the Theory Guide](#)) can be fine tuned to match experimental data.

- Specify the **Saturation Temperature** for your flow regime.

boiling

enables you to apply the boiling model as the mass transfer mechanism. This model is only available with the Eulerian multiphase model (when **Boiling** is enabled in the **Multiphase Model** dialog box). For information about the inputs in [Figure 26.44 \(p. 1263\)](#), please refer to [Including the Boiling Model \(p. 1258\)](#).

ANSYS FLUENT will automatically include the terms needed to model mass transfer in all relevant conservation equations. Another option to model mass transfer between phases is through the use of user-defined sources and their inclusion in the relevant conservation equations. This approach is more involved, but more powerful, allowing you to split the source terms according to a model of your choice.

Important

Momentum, energy, and turbulence are also transported with the mass that is transferred. ANSYS FLUENT assumes that the reactants are mixed thoroughly *before* reacting together, thus the heat and momentum transfer is based on this assumption. This assumption can be deactivated using a text command. For more information, contact your ANSYS FLUENT support engineer.

When your model involves the transport of multiphase species, you can define a mass transfer mechanism between species from different phases. If a particular phase does not have a species associated with it, then the mass transfer throughout the system will be performed by the bulk fluid material.

Important

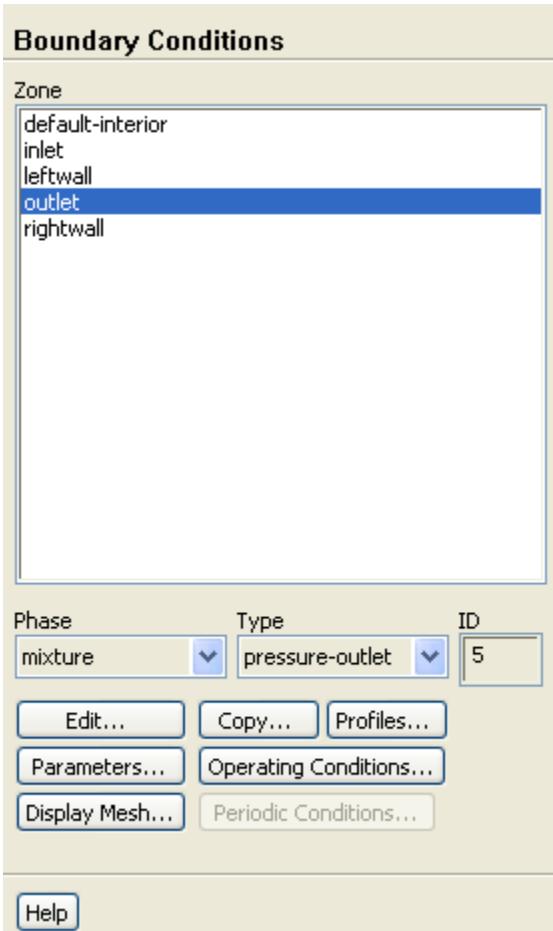

Including species transport effects in the mass transport of multiphase simulation requires that **Species Transport** be selected in the **Species Model** dialog box.

26.2.9. Defining Multiphase Cell Zone and Boundary Conditions

The procedure for setting multiphase boundary conditions is slightly different than for single-phase models. You will need to set some conditions separately for individual phases, while other conditions are shared by all phases (i.e., the mixture), as described in detail below ([Figure 26.9 \(p. 1190\)](#)).

Figure 26.9 The Boundary Conditions Task Page

26.2.9.1. Boundary Conditions for the Mixture and the Individual Phases

The conditions you need to specify for the mixture and those you need to specify for the individual phases will depend on which of the three multiphase models you are using. Details for each model are provided below.

26.2.9.1.1. VOF Model

If you are using the VOF model, the conditions you need to specify for each type of zone are listed below and summarized in *Table 26.1: Phase-Specific and Mixture Conditions for the VOF Model* (p. 1191).

- For an exhaust fan, inlet vent, intake fan, outlet vent, pressure inlet, pressure outlet, or velocity inlet, there are no conditions to be specified for the primary phase. For each secondary phase, you will need to set the backflow volume fraction as a constant, a profile (see *Profiles* (p. 382)), or a user-defined function (see the *UDF Manual*). All other conditions are specified for the mixture.
- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. All other conditions are specified for the mixture.

Important

Note that if you read a VOF case that was set up in a version of ANSYS FLUENT prior to 6.1, you will need to redefine the conditions at the mass flow inlets.

- For an axis, fan, outflow, periodic, porous jump, radiator, solid, symmetry, or wall zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases.
- For a wall zone, you can specify the contact angle for the mixture if the wall adhesion option is enabled.
- For a fluid zone, mass sources are specified for the individual phases, and all other sources are specified for the mixture.
 - If the fluid zone is not porous, all other conditions are specified for the mixture.
 - If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See *User Inputs for Porous Media* (p. 235) for the mixture.
 - If **Zonal Discretization** was enabled in the **Multiphase Model** dialog box, then you can specify the **Compressive Scheme Slope Limiter** in the **Multiphase** tab of the **Fluid** dialog box. Depending on the value of the slope limiter, you can select either diffused or sharp interface behavior in different cell zones. The slope limiter in Equation 17–12 in the *Theory Guide* ranges from 0 to 2. For example, a **Compressive Scheme Slope Limiter** of 0 corresponds to first order upwind behavior, a value of 1 corresponds to second order upwind, and a value of 2 applies the compressive scheme (see *The Compressive and Zonal Discretization Schemes* in the *Theory Guide*).
 - If **Open Channel Flow** and/or **Open Channel Wave BC** is/are enabled in the **Multiphase Model** dialog box, then the **Numerical Beach** option becomes available under the **Multiphase** tab of the **Fluid** dialog box. To learn how to include numerical beach in your simulation, please refer to *Numerical Beach Treatment for Open Channels* (p. 1216).

See *Cell Zone and Boundary Conditions* (p. 211) for details about the relevant conditions for each type of boundary. Note that the pressure far-field boundary is not available with the VOF model.

Table 26.1 Phase-Specific and Mixture Conditions for the VOF Model

Type	Primary Phase	Secondary Phase	Mixture
exhaust fan; inlet vent; intake fan; outlet vent; pressure inlet; pressure outlet; velocity inlet	nothing	volume fraction	all others
mass flow inlet	mass flow/flux	mass flow/flux	all others
axis; fan; outflow; periodic; porous jump; radiator; solid; symmetry; wall	nothing	nothing	all others
pressure far-field	not available	not available	not available
fluid	mass source; other porous inputs	mass source; other porous inputs	porous zone; porosity; all others

26.2.9.1.2. Mixture Model

If you are using the mixture model, the conditions you need to specify for each type of zone are listed below and summarized in *Table 26.2: Phase-Specific and Mixture Conditions for the Mixture Model* (p. 1192).

- For an exhaust fan, outlet vent, or pressure outlet, there are no conditions to be specified for the primary phase. For each secondary phase, you will need to set the volume fraction as a constant, a profile (see

[Profiles \(p. 382\)](#)), or a user-defined function (see the [UDF Manual](#)) and if applicable, the backflow granular temperature. All other conditions are specified for the mixture.

- For an inlet vent, intake fan, or pressure inlet, you will specify for the mixture which direction specification method will be used at this boundary (**Normal to Boundary** or **Direction Vector**). If you select the **Direction Vector** specification method, you will specify the coordinate system (3D only) and flow-direction components for the individual phases. For each secondary phase, you will need to set the volume fraction (as described above). All other conditions are specified for the mixture.
- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. All other conditions are specified for the mixture.

Important

Note that if you read a mixture multiphase case that was set up in a version of ANSYS FLUENT previous to 6.1, you will need to redefine the conditions at the mass flow inlets.

- For a velocity inlet, you will specify the velocity for the individual phases. For each secondary phase, you will need to set the volume fraction (as described above). All other conditions are specified for the mixture.
- For an axis, fan, outflow, periodic, porous jump, radiator, solid, symmetry, or wall zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases. Outflow boundary conditions are not available for the cavitation model.
- For a fluid zone, mass sources are specified for the individual phases, and all other sources are specified for the mixture.

If the fluid zone is not porous, all other conditions are specified for the mixture.

If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See [User Inputs for Porous Media \(p. 235\)](#) for details about these inputs. All other conditions are specified for the mixture.

See [Cell Zone and Boundary Conditions \(p. 211\)](#) for details about the relevant conditions for each type of boundary. Note that the pressure far-field boundary is not available with the mixture model.

Table 26.2 Phase-Specific and Mixture Conditions for the Mixture Model

Type	Primary Phase	Secondary Phase	Mixture
exhaust fan; outlet vent; pressure outlet	nothing	volume fraction	all others
inlet vent; intake fan; pressure inlet	coord. system; flow direction	coord. system; flow direction; volume fraction	dir. spec. method; all others
mass flow inlet	mass flow/flux	mass flow/flux	all others
velocity inlet	velocity	velocity; volume fraction	all others
axis; fan; outflow (n/a for cavitation model); periodic; porous jump; radiator; solid; symmetry; wall	nothing	nothing	all others

Type	Primary Phase	Secondary Phase	Mixture
pressure far-field	not available	not available	not available
fluid	mass source; other porous in- puts	mass source; other porous inputs	porous zone; porosity; all others

26.2.9.1.3. Eulerian Model

If you are using the Eulerian model, the conditions you need to specify for each type of zone are listed below and summarized in

- *Table 26.3: Phase-Specific and Mixture Conditions for the Eulerian Model (for Laminar Flow)* (p. 1196)
- *Table 26.4: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Mixture Turbulence Model)* (p. 1196)
- *Table 26.5: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Dispersed Turbulence Model)* (p. 1197)
- *Table 26.6: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Per-Phase Turbulence Model)* (p. 1198)

Note that the specification of turbulence parameters will depend on which of the three multiphase turbulence models you are using, as indicated in

- *Table 26.4: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Mixture Turbulence Model)* (p. 1196)
- *Table 26.5: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Dispersed Turbulence Model)* (p. 1197)
- *Table 26.6: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Per-Phase Turbulence Model)* (p. 1198)

See *Turbulence Models* in the Theory Guide and *Modeling Turbulence* (p. 1250) for more information about multiphase turbulence models.

- For an exhaust fan, outlet vent, or pressure outlet, there are no conditions to be specified for the primary phase if you are modeling laminar flow or using the mixture turbulence model (the default multiphase turbulence model), except for backflow total temperature if heat transfer is on.

For each secondary phase, you will need to set the backflow volume fraction as a constant, a profile (see *Profiles* (p. 382)), or a user-defined function (see the *UDF Manual*). If the phase is granular, you will also need to set its backflow granular temperature. If heat transfer is on, you will also need to set the backflow total temperature.

If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

All other conditions are specified for the mixture.

- For an inlet vent, intake fan, or pressure inlet, you will specify for the mixture which direction specification method will be used at this boundary (**Normal to Boundary** or **Direction Vector**). If you select the **Direction Vector** specification method, you will specify the coordinate system (3D only) and flow-direction

components for the individual phases. If heat transfer is on, you will also need to set the total temperature for the individual phases.

For each secondary phase, you will need to set the volume fraction (as described above). If the phase is granular, you will also need to set its granular temperature.

If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

All other conditions are specified for the mixture.

- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. You will also need to specify the temperature of each phase, since the energy equations are solved for each phase.

For mass flow inlet boundary conditions, you can specify the slip velocity between phases. When you select a mass flow inlet boundary for the secondary phase, two options will be available for the **Slip Velocity Specification Method**, as shown in *Figure 26.10* (p. 1195) :

- **Velocity Ratio**

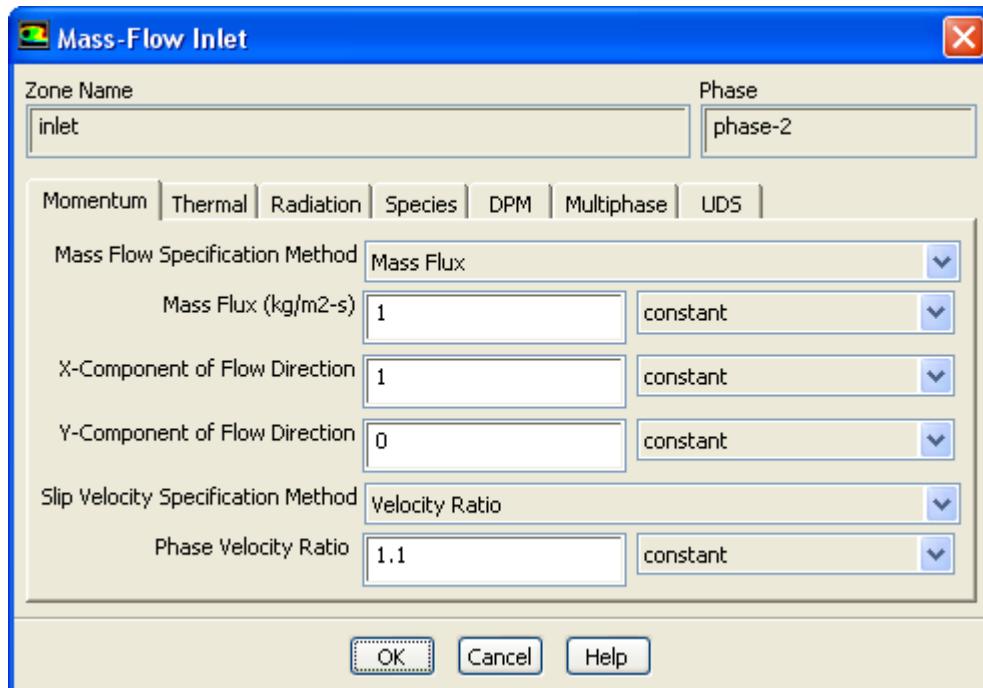

The value for the **Phase Velocity Ratio** is the secondary phase to primary phase velocity ratio. By default, it is 1.0, which means velocities are the same (no slip). By entering a ratio that is greater than 1.0, you are indicating a larger secondary phase velocity. Otherwise, you can enter a ratio that is less than 1.0 to indicate a smaller secondary phase velocity.

- **Volume Fraction**

If you specify the volume fraction at an inlet, ANSYS FLUENT will calculate the phase velocities.

Important

If a secondary phase has zero mass flux (i.e., the Eulerian model is used to run a single phase case), neither **Phase Velocity Ratio** nor **Volume Fraction** will affect the solution.

Figure 26.10 Mass-Flow Inlet Boundary Condition Dialog Box

- For a velocity inlet, you will specify the velocity for the individual phases. If heat transfer is on, you will also need to set the static temperature for the individual phases.

For each secondary phase, you will need to set the volume fraction (as described above). If the phase is granular, you will also need to set its granular temperature.

If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

All other conditions are specified for the mixture.

- For an axis, outflow, periodic, solid, or symmetry zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases.
- For a wall zone, shear conditions are specified for the individual phases. All other conditions are specified for the mixture, including thermal boundary conditions, if heat transfer is on.
- For a fluid zone, all source terms and fixed values are specified for the individual phases, *unless* you are using the mixture turbulence model or the dispersed turbulence model. If you are using the mixture turbulence model, source terms and fixed values for turbulence are specified instead for the mixture. If you are using the dispersed turbulence model, they are specified only for the primary phase.
 - If the fluid zone is not porous, all other conditions are specified for the mixture.
 - If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See [User Inputs for Porous Media \(p. 235\)](#) for details about these inputs. All other conditions are specified for the mixture.
 - If your simulation includes the **Multi-Fluid VOF Model** and **Zonal Discretization** was enabled in the **Multiphase Model** dialog box, then you can specify the **Compressive Scheme Slope Limiter** in the **Multiphase** tab of the **Fluid** dialog box. Depending on the value of the slope limiter, you can

select either diffused or sharp interface behavior in different cell zones. The slope limiter in [Equation 17–12](#) in the [Theory Guide](#) ranges from 0 to 2. For example, a, **Compressive Scheme Slope Limiter** of 0 corresponds to first order upwind behavior, a value of 1 corresponds to second order upwind, and a value of 2 applies the compressive scheme (see [The Compressive and Zonal Discretization Schemes](#) in the [Theory Guide](#)).

See [Cell Zone and Boundary Conditions](#) (p. 211) for details about the relevant conditions for each type of boundary. Note that the pressure far-field, fan, porous jump, radiator, and mass flow inlet boundaries are not available with the Eulerian model.

Table 26.3 Phase-Specific and Mixture Conditions for the Eulerian Model (for Laminar Flow)

Type	Primary Phase	Secondary Phase	Mixture
exhaust fan; outlet vent; pressure outlet	(tot. temperature)	volume fraction; gran. temperature (tot. temperature)	all others

26.2.9.2. Steps for Setting Boundary Conditions

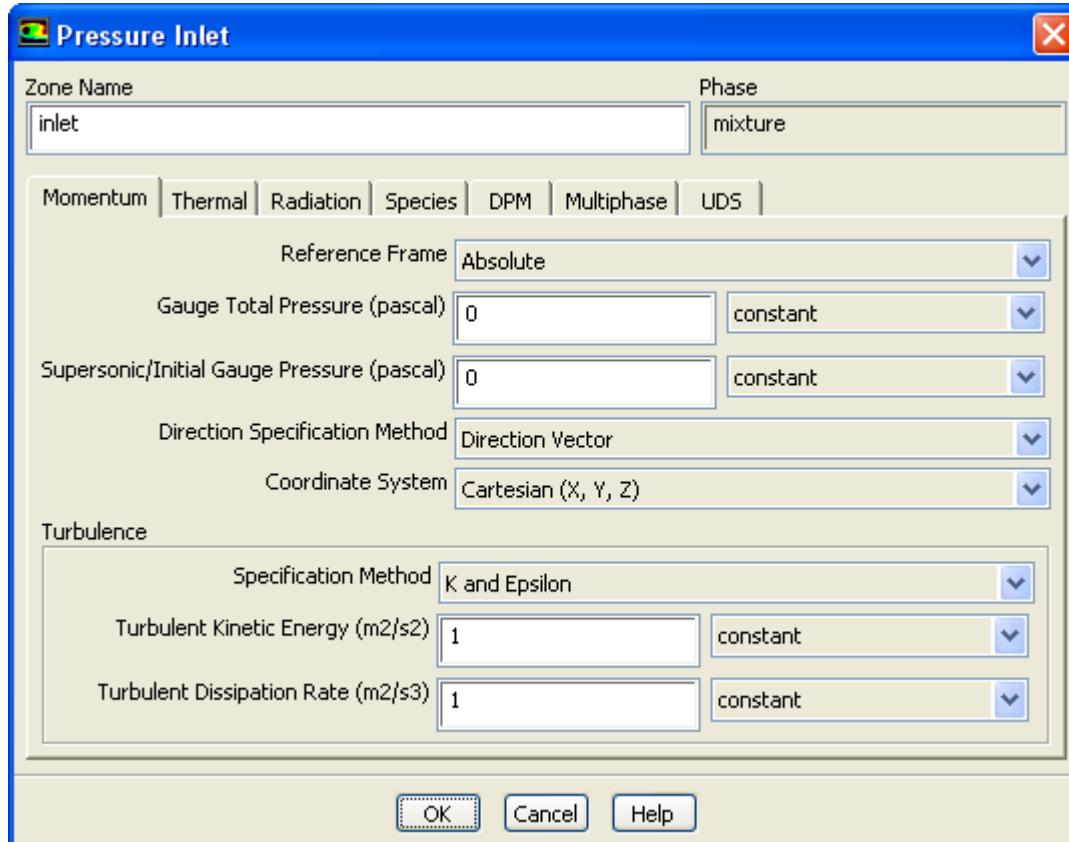

The steps you need to perform for each boundary are as follows:

1. Select the boundary in the **Zone** list in the **Boundary Conditions** task page.
2. Set the conditions for the mixture at this boundary, if necessary. (See above for information about which conditions need to be set for the mixture.)
 - a. In the **Phase** drop-down list, select **mixture**.
 - b. If the current **Type** for this zone is correct, click **Edit...** to open the corresponding dialog box (e.g., the **Pressure Inlet** dialog box); otherwise, choose the correct zone type in the **Type** drop-down

list, confirm the change (when prompted), and the corresponding dialog box will open automatically.

- In the corresponding dialog box for the zone type you have selected (e.g., the **Pressure Inlet** dialog box for the Eulerian model, shown in [Figure 26.11 \(p. 1199\)](#)), specify the mixture boundary conditions.

Figure 26.11 The Pressure Inlet Dialog Box for a Mixture

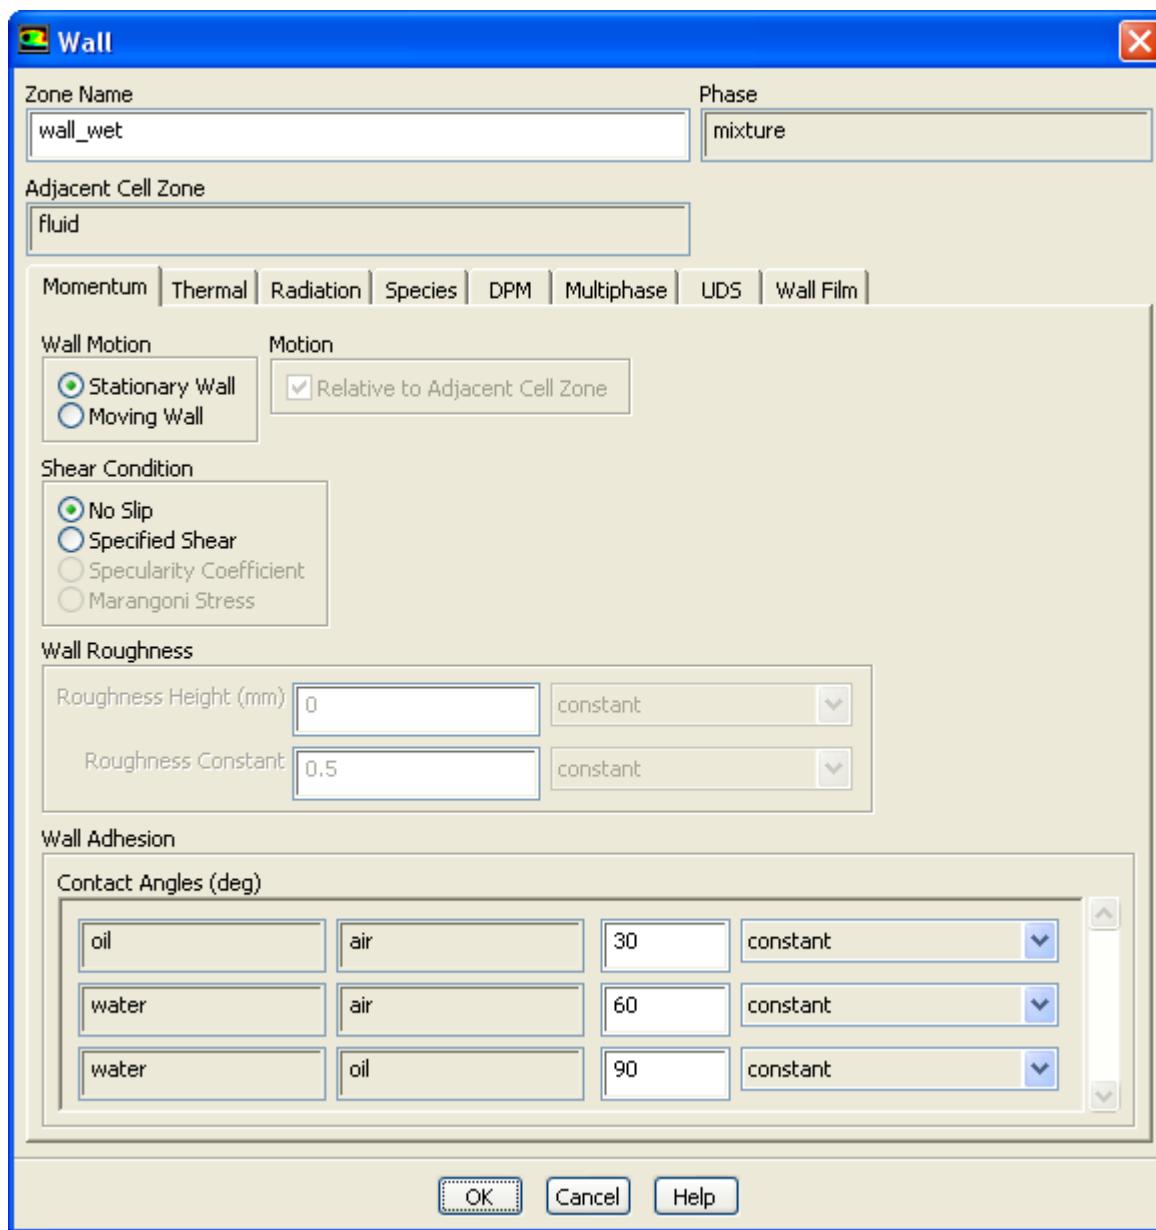

Note that only those conditions that apply to all phases, as described above, will appear in this dialog box.

Important

For a VOF and Eulerian multiphase calculation, if you enabled the **Wall Adhesion** option in the **Phase Interaction** dialog box, you can specify the contact angle at the wall for each pair of phases as a constant (as shown in [Figure 26.12 \(p. 1200\)](#)) or a UDF (see the UDF manual for more information).

The contact angle (θ_w in [Figure 26.26 \(p. 1225\)](#)) is the angle between the wall and the tangent to the interface at the wall, measured inside the phase listed in the left column under **Wall Adhesion** in the **Momentum** tab of the **Wall** dialog box. For example, if you are setting the contact angle between the oil and air phases in the **Wall** dialog box shown in [Figure 26.12 \(p. 1200\)](#), θ_w is measured inside the oil phase.

Figure 26.12 The Wall Dialog Box for a Mixture in a VOF or Eulerian Multiphase Calculation with Wall Adhesion

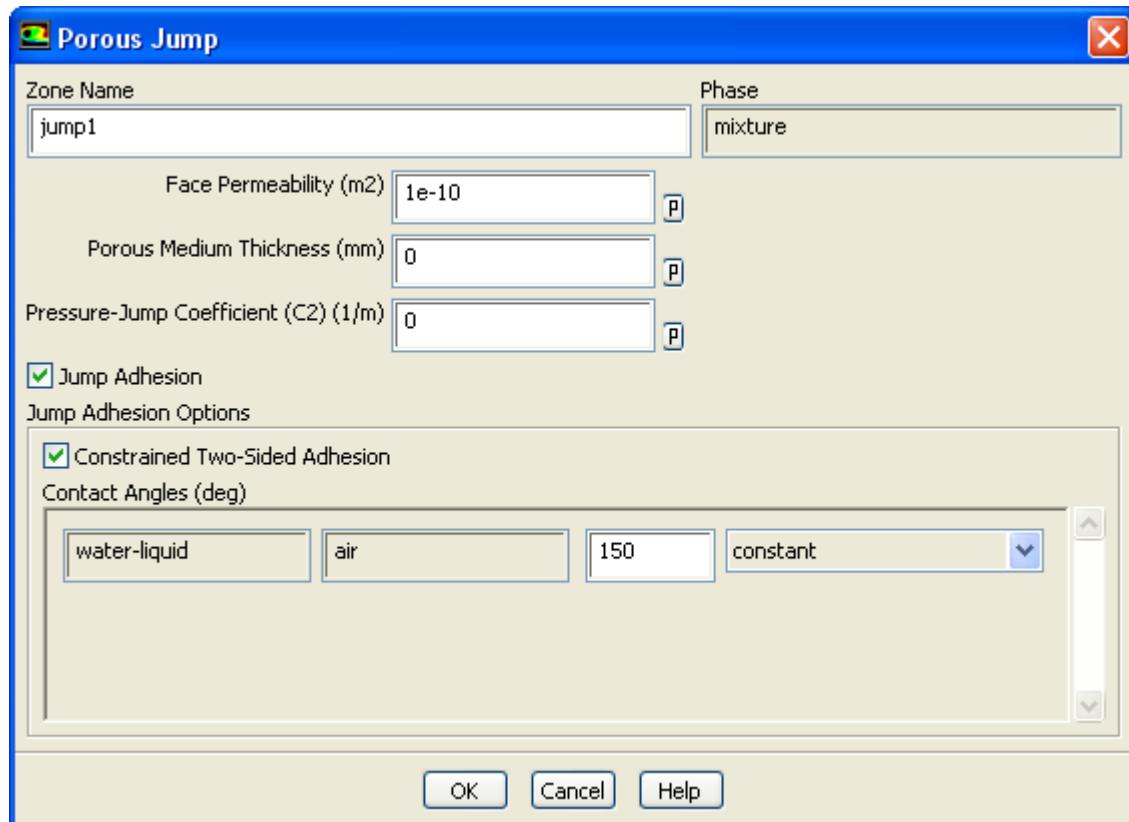

The default value for all pairs is 90 degrees, which is equivalent to no wall adhesion effects (i.e., the interface is normal to the adjacent wall). A contact angle of 45 °, for example, corresponds to water creeping up the side of a container, as is common with water in a glass.

- d. For the VOF model, if you enabled the **Jump Adhesion** option in the **Phase Interaction** dialog box, specify the contact angle at the porous jump for each pair of phases. If you enable the **Jump Adhesion** option in the **Phase Interaction** dialog box, this option becomes visible at each of the porous jump boundaries. You can enable or disable the **Jump Adhesion** option in the **Porous Jump** dialog boxes and provide the inputs for the contact angle at the desired porous jump boundary, as shown in [Figure 26.13 \(p. 1201\)](#).

The contact angle θ_w is the angle at the porous jump. To constrain the contact angle at the porous jump based on porous or non-porous fluid zones, enable the **Constrained Two-Sided**

Adhesion option. Otherwise, if it is disabled, then the forced two-sided adhesion treatment is in effect. This is described in more detail in [Jump Adhesion](#).

Figure 26.13 The Porous Jump Dialog Box Displaying Jump Adhesion

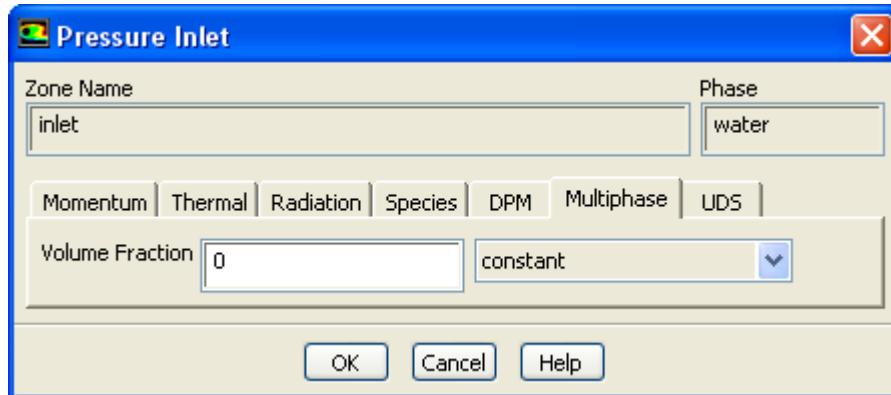

- e. Click **OK** when you are done setting the mixture boundary conditions.
3. Set the conditions for each phase at this boundary, if necessary. (See above for information about which conditions need to be set for the individual phases.)
 - a. In the **Phase** drop-down list, select the phase (e.g., **water**).

Important

Note that, when you select one of the individual phases (rather than the mixture), only one type of zone appears in the **Type** drop-down list. It is not possible to assign phase-specific zone types at a given boundary; the zone type is specified for the mixture, and it applies to all of the individual phases.

- b. Click **Edit...** to open the dialog box for this phase's conditions (e.g., the **Pressure Inlet** dialog box, shown in [Figure 26.14 \(p. 1202\)](#)).

Figure 26.14 The Pressure Inlet Dialog Box for a Phase

- c. Specify the conditions for the phase. Note that only those conditions that apply to the individual phase, as described above, will appear in this dialog box.
- d. Click **OK** when you are done setting the phase-specific boundary conditions.

26.2.9.3. Steps for Copying Cell Zone and Boundary Conditions

The steps for copying cell zone and boundary conditions for a multiphase flow are slightly different from those described in [Copying Cell Zone and Boundary Conditions \(p. 215\)](#) for a single-phase flow. The modified steps are listed below:

1. In the **Cell Zone Conditions** or **Boundary Conditions** task page, click the **Copy...** button. This will open the **Copy Conditions** dialog box.
2. In the **From Cell Zone** or **From Boundary Zone** list, select the zone that has the conditions you want to copy.
3. In the **To Cell Zones** or **To Boundary Zones** list, select the zone or zones to which you want to copy the conditions.
4. In the **Phase** drop-down list, select the phase for which you want to copy the conditions (either **mixture** or one of the individual phases).

Important

Note that copying the boundary conditions for one phase does not automatically result in the boundary conditions for the other phases and the mixture being copied as well. You need to copy the conditions for each phase on each boundary of interest.

5. Click **Copy**. ANSYS FLUENT will set *all* of the selected phase's (or mixture's) boundary conditions on the zones selected in the **To Cell Zones** or **To Boundary Zones** list to be the same as that phase's conditions on the zone selected in the **From Cell Zone** or **From Boundary Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

See [Copying Cell Zone and Boundary Conditions \(p. 215\)](#) for additional information about copying boundary conditions, including limitations.

26.3. Setting Up the VOF Model

For background information about the VOF model and the limitations that apply, refer to [Overview of the VOF Model](#) in the [Theory Guide](#).

This section is organized as follows:

- 26.3.1. Including Coupled Level Set with the VOF Model
- 26.3.2. Modeling Open Channel Flows
- 26.3.3. Modeling Open Channel Wave Boundary Conditions
- 26.3.4. Recommendations for Open Channel Initialization
- 26.3.5. Numerical Beach Treatment for Open Channels
- 26.3.6. Defining the Phases for the VOF Model
- 26.3.7. Setting Time-Dependent Parameters for the VOF Model
- 26.3.8. Modeling Compressible Flows
- 26.3.9. Modeling Solidification/Melting

26.3.1. Including Coupled Level Set with the VOF Model

When using the VOF formulation, you can couple the level set method with it to help overcome some limitations that exist in the interface tracking method of the VOF model and the level set method. To use the coupled level set method with VOF, perform the following:

1. Enable the volume of fluid model.
 - a. Open the **Multiphase Model** dialog box.

Models → Multiphase → Edit...

- b. Under **Model**, enable **Volume of Fluid**.
- c. Under **Coupled Level Set + VOF**, enable **Level Set** (see [Figure 26.1 \(p. 1176\)](#)).

After the **Level Set** option is enabled, proceed as you normally would when setting up the VOF model (described in [Setting Up the VOF Model \(p. 1203\)](#)). For theoretical information, please refer to [Coupled Level-Set and VOF Model](#).

Note

When using the **Level Set** option, the recommended scheme is the geo-reconstruct scheme (see [The Geometric Reconstruction Scheme](#)).

Important

- The level set method is only suitable for two-phase flow regime, where two fluids are not interpenetrating.
- The level set model can only be used when the VOF model is activated. No mass transfer is allowed.
- The level set method is not compatible with the dynamic mesh model.

Normally, zero flux of the level set function is set as the default for the boundary conditions. Due to the geometrical re-initialization procedure at each time step, the boundary conditions shall not have

any significant effect on the results. For more information, see [Re-initialization of the Level-set Function via the Geometrical Method](#).

26.3.2. Modeling Open Channel Flows

Using the VOF formulation, open channel flows can be modeled in ANSYS FLUENT. To start using the open channel flow boundary condition, perform the following:

1. Enable **Gravity** and set the gravitational acceleration fields.

General

2. Enable the volume of fluid model.
 - a. Open the **Multiphase Model** dialog box.

Multiphase

Edit...

- b. Under **Model**, enable **Volume of Fluid**.
- c. Under **Scheme**, select either **Implicit**, **Explicit**.
3. Under **Volume Fraction Parameters**, select **Open Channel Flow**.

Note

The default VOF formulation is set to **Implicit** after enabling the **Open Channel Flow** option. This is done to allow the usage of larger time step sizes for such applications.

In order to set specific parameters for a particular boundary for open channel flows, enable the **Open Channel** option in the **Multiphase** tab of the corresponding boundary condition dialog box.

Table 26.7: Open Channel Boundary Parameters for the VOF Model (p. 1204) summarizes the types of boundaries available to the open channel flow boundary condition, and the additional parameters needed to model open channel flow. For more information on setting boundary condition parameters, see [Cell Zone and Boundary Conditions](#) (p. 211).

Table 26.7 Open Channel Boundary Parameters for the VOF Model

Boundary Type	Parameter
pressure inlet	Inlet Group ID; Secondary Phase for Inlet; Flow Specification Method; Free Surface Level, Bottom Level; Velocity Magnitude
pressure outlet	Outlet Group ID; Pressure Specification Method; Free Surface Level; Bottom Level
mass flow inlet	Inlet Group ID; Secondary Phase for Inlet; Free Surface Level; Bottom Level
outflow	Flow Rate Weighting

26.3.2.1. Defining Inlet Groups

Open channel systems involve the flowing fluid (the secondary phase) and the fluid above it (the primary phase).

If both phases enter through the separate inlets (e.g., inlet-phase2 and inlet-phase1), these two inlets form an inlet group. This inlet group is recognized by the parameter **Inlet Group ID**, which will be same for both the inlets that make up the inlet group. On the other hand, if both the phases enter through the same inlet (e.g., inlet-combined), then the inlet itself represents the inlet group.

Important

In three-phase flows, only one secondary phase is allowed to pass through one inlet group.

26.3.2.2. Defining Outlet Groups

Outlet-groups can be defined in the same manner as the inlet groups.

Important

In three-phase flows, the outlet should represent the outlet group, i.e., separate outlets for each phase are not recommended in three-phase flows.

26.3.2.3. Setting the Inlet Group

For pressure inlets and mass flow inlets, the **Inlet Group ID** is used to identify the different inlets that are part of the same inlet group. For instance, when both phases enter through the same inlet (single face zone), then those phases are part of one inlet group and you would set the **Inlet Group ID** to 1 for that inlet (or inlet group).

In the case where the same inlet group has separate inlets (different face zones) for each phase, then the **Inlet Group ID** will be the same for each inlet of that group.

When specifying the inlet group, use the following guidelines:

- Since the **Inlet Group ID** is used to identify the inlets of the same inlet group, general information such as **Free Surface Level**, **Bottom Level**, or the mass flow rate for each phase should be the same for each inlet of the same inlet group.
- You should specify a different **Inlet Group ID** for each distinct inlet group.

For example, consider the case of two inlet groups for a particular problem. The first inlet group consists of water and air entering through the same inlet (a single face zone). In this case, you would specify an inlet group ID of 1 for that inlet (or inlet group). The second inlet group consists of oil and air entering through the same inlet group, but each uses a different inlet (oil-inlet and air-inlet) for each phase. In this case, you would specify the same **Inlet Group ID** of 2 for both of the inlets that belong to the inlet group.

26.3.2.4. Setting the Outlet Group

For pressure outlet boundaries, the **Outlet Group ID** is used to identify the different outlets that are part of the same outlet group. For instance, when both phases enter through the same outlet (single face zone), then those phases are part of one outlet group and you would set the **Outlet Group ID** to 1 for that outlet (or outlet group).

In the case where the same outlet group has separate outlets (different face zones) for each phase, then the **Outlet Group ID** will be the same for each outlet of that group.

When specifying the outlet group, use the following guidelines:

- Since the **Outlet Group ID** is used to identify the outlets of the same outlet group, general information such as **Free Surface Level** or **Bottom Level** should be the same for each outlet of the same outlet group.
- You should specify a different **Outlet Group ID** for each distinct outlet group.

For example, consider the case of two outlet groups for a particular problem. The first inlet group consists of water and air exiting from the same outlet (a single face zone). In this case, you would specify an outlet number of 1 for that outlet (or outlet group). The second outlet group consists of oil and air exiting through the same outlet group, but each uses a different outlet (oil-outlet and air-outlet) for each phase. In this case, you would specify the same **Outlet Group ID** of 2 for both of the outlets that belong to the outlet group.

Important

For three-phase flows, when all the phases are leaving through the same outlet, the outlet should consist only of a single face zone.

26.3.2.5. Determining the Free Surface Level

For the appropriate boundary, you need to specify the **Free Surface Level** value. This parameter is available for all relevant boundaries, including pressure outlet, mass flow inlet, and pressure inlet. The **Free Surface Level**, is represented by y_{local} in [Equation 17–41](#) in the [Theory Guide](#).

$$y_{local} = -(\vec{a} \cdot \hat{g}) \quad (26-1)$$

where \vec{a} is the position vector of any point on the free surface, and \hat{g} is the unit vector in the direction of the force of gravity. Here we assume a horizontal free surface that is normal to the direction of gravity.

We can simply calculate the free surface level in two steps:

1. Determine the absolute value of height from the free surface to the origin in the direction of gravity.
2. Apply the correct sign based on whether the free surface level is above or below the origin.

If the liquid's free surface level lies above the origin, then the **Free Surface Level** is positive (see [Figure 26.15 \(p. 1207\)](#)). Likewise, if the liquid's free surface level lies below the origin, then the **Free Surface Level** is negative.

26.3.2.6. Determining the Bottom Level

For the appropriate boundary, you need to specify the **Bottom Level** value. This parameter is available for all relevant boundaries, including pressure outlet, mass flow inlet, and pressure inlet. The **Bottom Level**, is represented by a relation similar to [Equation 17–41](#) in the [Theory Guide](#).

$$y_{bottom} = - (\vec{b} \cdot \hat{g}) \quad (26-2)$$

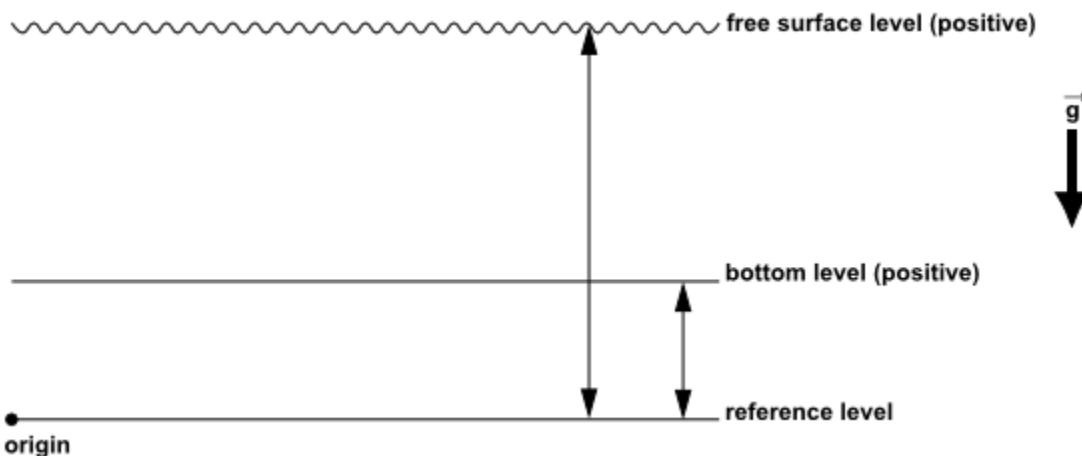

where \vec{b} is the position vector of any point on the bottom of the channel, and \hat{g} is the unit vector of gravity. Here we assume a horizontal free surface that is normal to the direction of gravity.

We can simply calculate the bottom level in two steps:

1. Determine the absolute value of depth from the bottom level to the origin in the direction of gravity.
 2. Apply the correct sign based on whether the bottom level is above or below the origin.

If the channel's bottom lies above the origin, then the **Bottom Level** is positive (see [Figure 26.15 \(p. 1207\)](#)). Likewise, if the channel's bottom lies below the origin, then the **Bottom Level** is negative.

Figure 26.15 Determining the Free Surface Level and the Bottom Level

26.3.2.7. Specifying the Total Height

The total height, along with the velocity, is used as an option for describing the flow. The total height is given as

$$y_{tot} = y_{local} + \frac{V^2}{2\sigma} \quad (26-3)$$

where V is the velocity magnitude and g is the gravity magnitude.

26.3.2.8. Determining the Velocity Magnitude

Pressure inlet boundaries require the **Velocity Magnitude** for calculating the dynamic pressure at the boundary. This is to be specified as the magnitude of the upstream inlet velocity in the flow.

26.3.2.9. Determining the Secondary Phase for the Inlet

For pressure inlets and mass flow inlets, the **Secondary Phase for Inlet** field allows you to choose the desired secondary phase in the case of three-phase flows.

Important

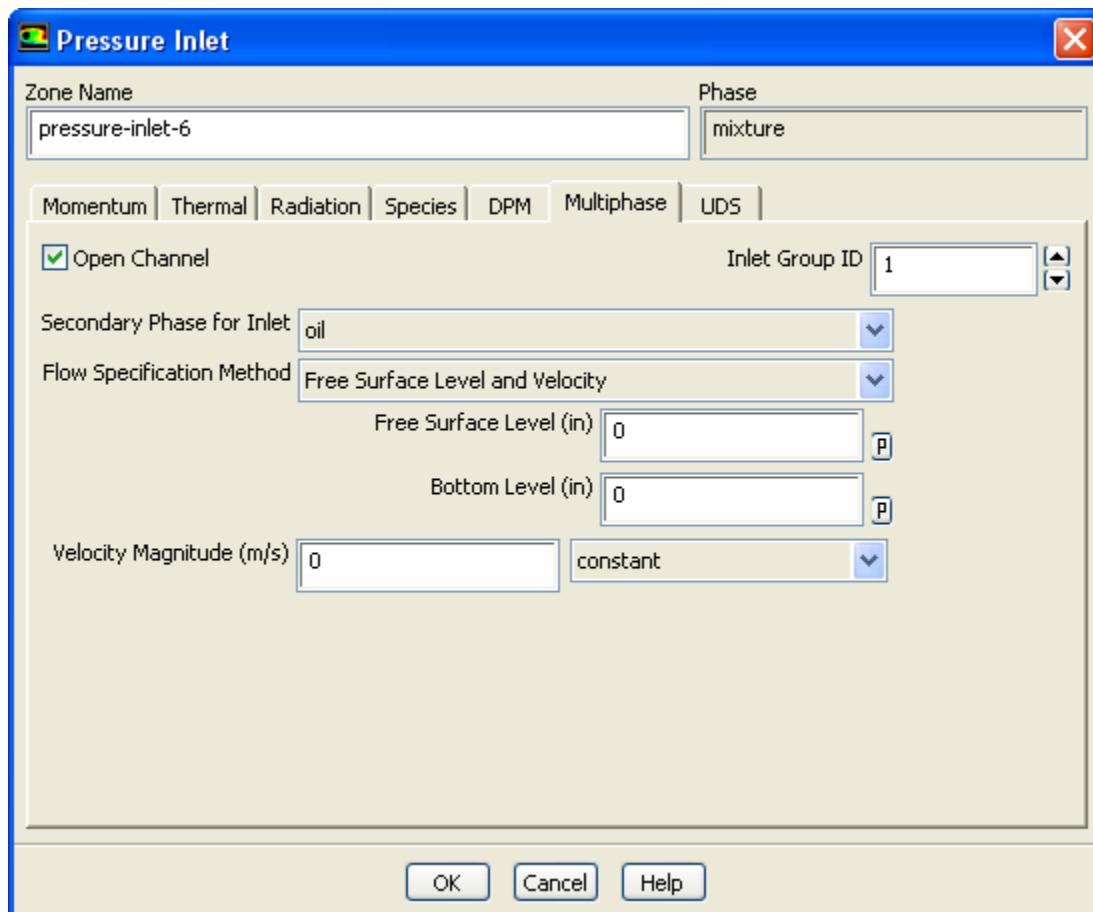

Note that only one secondary phase is allowed to pass through one inlet group.

Consider a problem involving a three-phase flow consisting of air as the primary phase, and oil and water as the secondary phases. Consider also that there are two inlet groups:

- water and air
- oil and air

For the former inlet group, you would choose water as the secondary phase. For the latter inlet group, you would choose oil as the secondary phase (as shown in [Figure 26.16 \(p. 1208\)](#)).

Figure 26.16 Pressure Inlet for Open Channel Flow

26.3.2.10. Choosing the Pressure Specification Method

For a pressure outlet boundary, the outlet pressure can be specified in one of three ways:

- by prescribing the local height, such as a hydrostatic pressure profile (available for two-phase flow only)
- by specifying the constant pressure
- by specifying the neighboring cell pressure

Note

You can also specify a hydrostatic pressure profile at the pressure outlet for axisymmetric open channel flow. However, there are certain limitations as noted in [Limitations \(p. 1209\)](#).

Important

This option is not available in the case of three-phase flows since the pressure on the boundary is taken from the neighboring cell.

26.3.2.11. Limitations

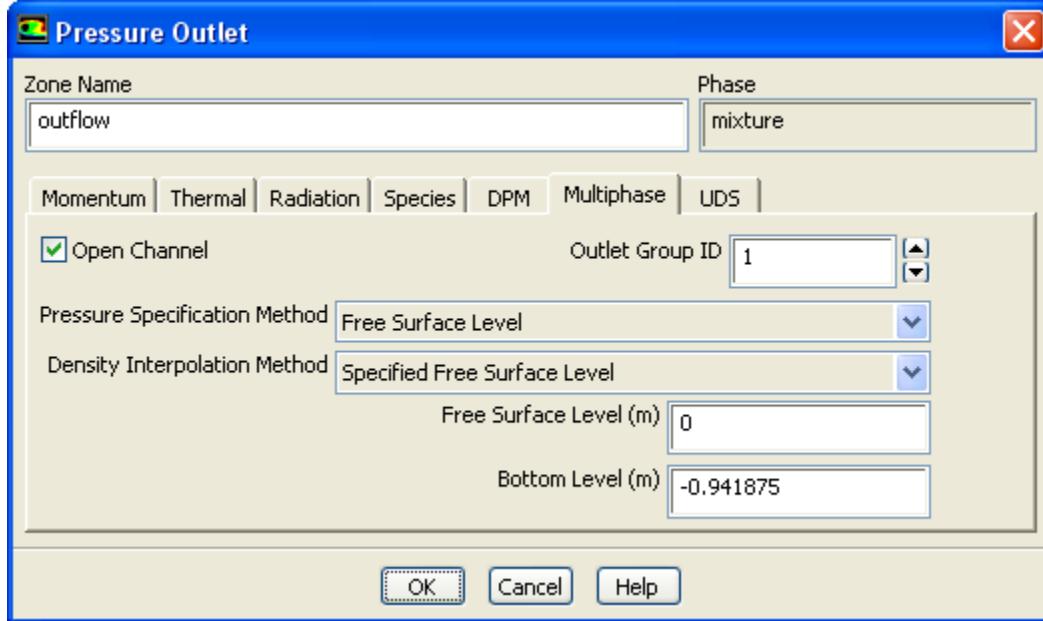

The following list summarizes some issues and limitations associated with the open channel boundary condition.

- The conservation of the Bernoulli integral does not provide the conservation of mass flow rate for the pressure boundary. In the case of a coarser mesh, there can be a significant difference in mass flow rate from the actual mass flow rate. For finer meshes, the mass flow rate comes closer to the actual value. So, for problems having constant mass flow rate, the mass flow rate boundary condition is a better option. The pressure boundary should be selected when steady and nonoscillating drag is the main objective.
- Specifying the top boundary as the pressure outlet can sometimes lead to a divergent solution. This may be due to the corner singularity at the pressure boundary in the air region or due to the inability to specify local flow direction correctly if the air enters through the top locally.
- Only the heavier phase should be selected as the secondary phase.
- In the case of three-phase flows, only one secondary phase is allowed to enter through one inlet group (i.e., the mixed inflow of different secondary phases is not allowed).
- For axisymmetric flow, pressure and mass flow inlets do not support open channel boundary conditions.
- Open channel wave boundary conditions for velocity inlets do not support cases with axisymmetric flow.
- Axisymmetric open channel flow is available for two phase flow and the pressure outlet boundary.
- For axisymmetric open channel flow, the direction of gravity must be aligned with the direction of the axis.

26.3.2.12. Choosing the Density Interpolation Method

For problems involving sub-critical flow, where the pressure specification method is the **Free Surface Level**, you can specify a **Density Interpolation Method**. Two options exist for the **Density Interpolation Method**:

- **Neighboring Cell Volume Fraction** is the default option, where the face density used in the hydrostatic profile is interpolated from the neighboring cell volume fraction.
- **Specified Free Surface Level** is the face density used in the hydrostatic profile and is interpolated from the specified free surface level.

Figure 26.17 Density Interpolation Method for the Free Surface Level

26.3.2.13. Recommendations for Setting Up an Open Channel Flow Problem

The following list represents a list of recommendations for solving problems using the open channel flow boundary condition:

- In the cases where the inlet group has a different inlet for each phase of fluid, then the parameter values (such as **Free Surface Level**, **Bottom Level**, and **Mass Flow Rate**) for each inlet should correspond to all other inlets that belong to the inlet group.
- The solution begins with an estimated pressure profile at the outlet boundary.

In general, you can start the solution by assuming that the level of liquid at the outlet corresponds to the level of liquid at the inlet. The convergence and solution time is very dependent on the initial conditions. When the flow is completely subcritical (upstream and downstream), in marine applications for instance, the above approach is recommended.

If the final conditions of the flow can be predicted by other means, the solution time can be significantly reduced by using the proper boundary condition.

- In the case of super-critical flow at the outlet, you can use the **From Neighboring Cell** option at the outlet, as it may provide better convergence.
- The initialization procedure is very critical in the open channel analysis. Please refer to *Recommendations for Open Channel Initialization* (p. 1213).
- For the initial stability of the solution, a smaller time step is recommended. You can increase the time step once the solution becomes more stable.

26.3.3. Modeling Open Channel Wave Boundary Conditions

When modeling open channel wave boundary conditions, many of the variables that are used in open channel flow, also exist for open channel wave boundary conditions. You may have to refer to *Modeling Open Channel Flows* (p. 1204) for information about some of the settings.

To use the open channel wave boundary condition, perform the following:

1. Enable **Gravity** and set the gravitational acceleration fields.

 **General**

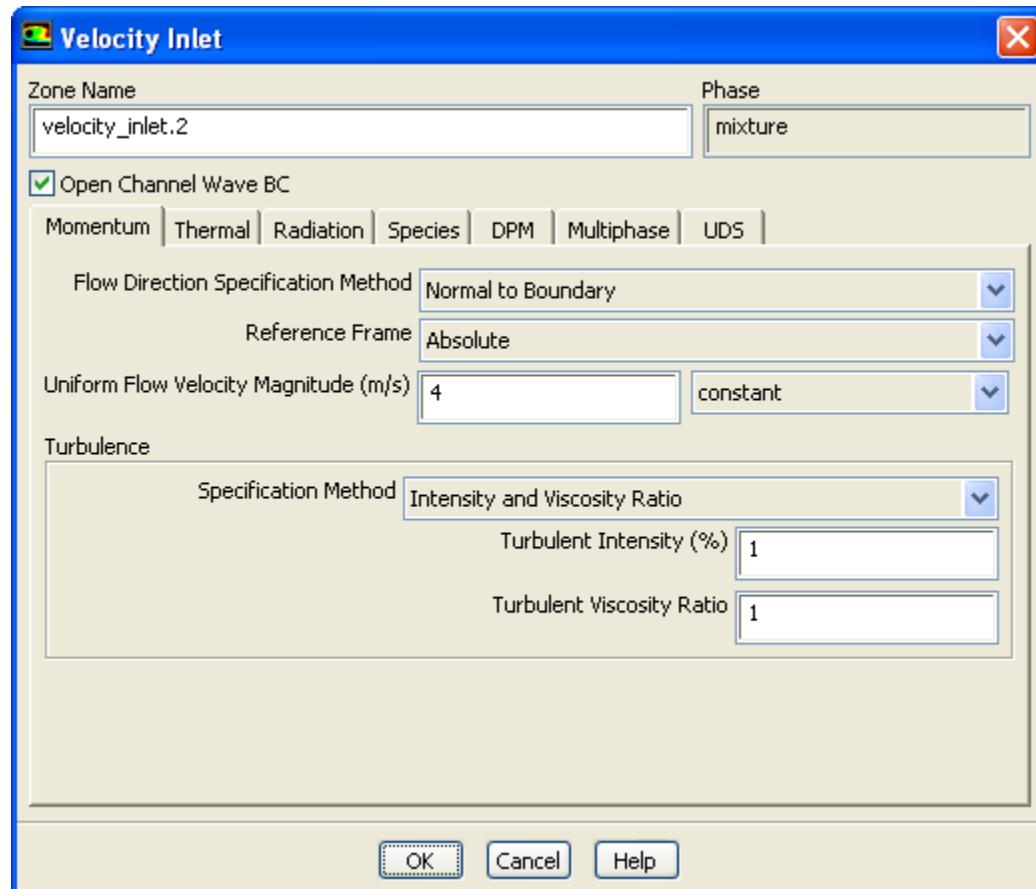

2. Enable the **Volume of Fluid** model in the **Multiphase Model** dialog box.

 **Models** →  **Multiphase** → **Edit...**

3. Under **Scheme**, select either **Implicit** or **Explicit**.
4. Under **Volume Fraction Parameters**, select **Open Channel Wave BC**.

In order to set specific parameters for a particular boundary for open channel wave boundaries, enable the **Open Channel Wave BC** option in the **Velocity Inlet** boundary condition dialog box ([Figure 26.18 \(p. 1211\)](#)).

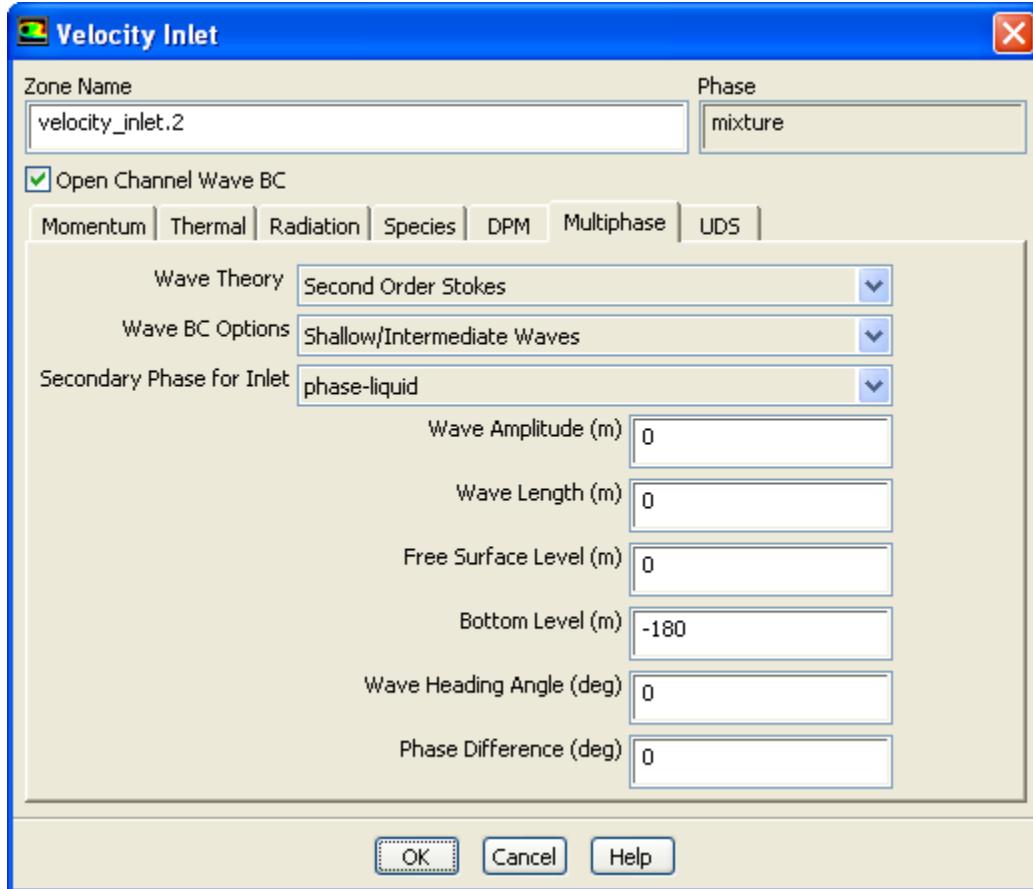

Figure 26.18 The Velocity Inlet for Open Channel Wave BC

In the **Momentum** tab of the **Velocity Inlet** dialog box, enter the following wave specific variables:

- **Flow Direction Specification Method** which can be **Direction Vector** or **Normal to Boundary**.
- **Uniform Flow Velocity Magnitude** which can be specified as a **Constant** or a **New Input Parameter....**

In the **Multiphase** tab ([Figure 26.19 \(p. 1212\)](#)), you will specify the following:

Figure 26.19 The Velocity Inlet for Open Channel Wave BC

- **Wave Theory** of which you have a choice of **First Order Airy** (the default), **Second Order Stokes**, **Third Order Stokes**, **Fourth Order Stokes**, and **Fifth Order Stokes**. Information about the types of wave theory is available in [Open Channel Wave Boundary Conditions](#) in the [Theory Guide](#).
- **Wave BC Options** of which you have a choice of **Shallow/Intermediate Waves** or **Short Gravity Waves**. Information about the two types of waves is available in [Open Channel Wave Boundary Conditions](#) in the [Theory Guide](#). Note that the short gravity waves expression is derived under the assumption of infinite liquid height.
- **Secondary Phase for Inlet** is where the specified parameters are valid only for one secondary phase. In case of a three-phase flow, select the corresponding secondary phase from this list.
- **Wave Amplitude** is the amplitude of the shallow or short gravity waves.
- **Wave Length** is the wavelength of the shallow or short gravity waves.
- **Free Surface Level** is the same definition as for open channel flow, see [Modeling Open Channel Flows](#) (p. 1204).
- **Bottom Level** is the same definition as for open channel flow, see [Modeling Open Channel Flows](#) (p. 1204), and is valid only for shallow waves. The bottom level is used for calculating the liquid height.
- **Wave Heading Angle** is the angle between the wave front and the flow direction, in the plane of the flow direction and cross-flow direction.
- **Phase Difference** is the phase angle by which one periodic disturbance or wave front lags behind or precedes another in time or space.

A useful text command used to print out a summary of the open channel wave boundary condition settings is `define/boundary-conditions/open-channel-wave-settings`. Below is a sample of the output displayed in the text user interface:

```
/define/boundary-conditions> open-channel-wave-settings

Wave Input Analysis for Velocity Inlet : Thread ID = 4
*****
Current Settings :
-----
Second Order Stokes, Shallow/Intermediate Waves
Wave Amplitude (A) = 7.3711, Wave Length (L) = 189.2780, Depth (h) = 180.0000
Wave Height (H) = 14.7422, Wave Steepness (H/L) = 0.0779
Ursell Number (Ur = H*L*L/(h*h*h)) = 0.0906

Checking parameters within wave breaking limit :
-----
Wave Height/Depth ratio
H/h = 0.0819, Max limit = 0.78
H/h ratio within wave breaking limit

Wave_Height/Wave_Length ratio
H/L = 0.0779, Max limit = 0.1420
H/L ratio within wave breaking limit

Checking Stability Criterion based on Ursell number
-----
Ursell number = 0.0906, Max Limit = 26.0000
Ursell number within stability limit

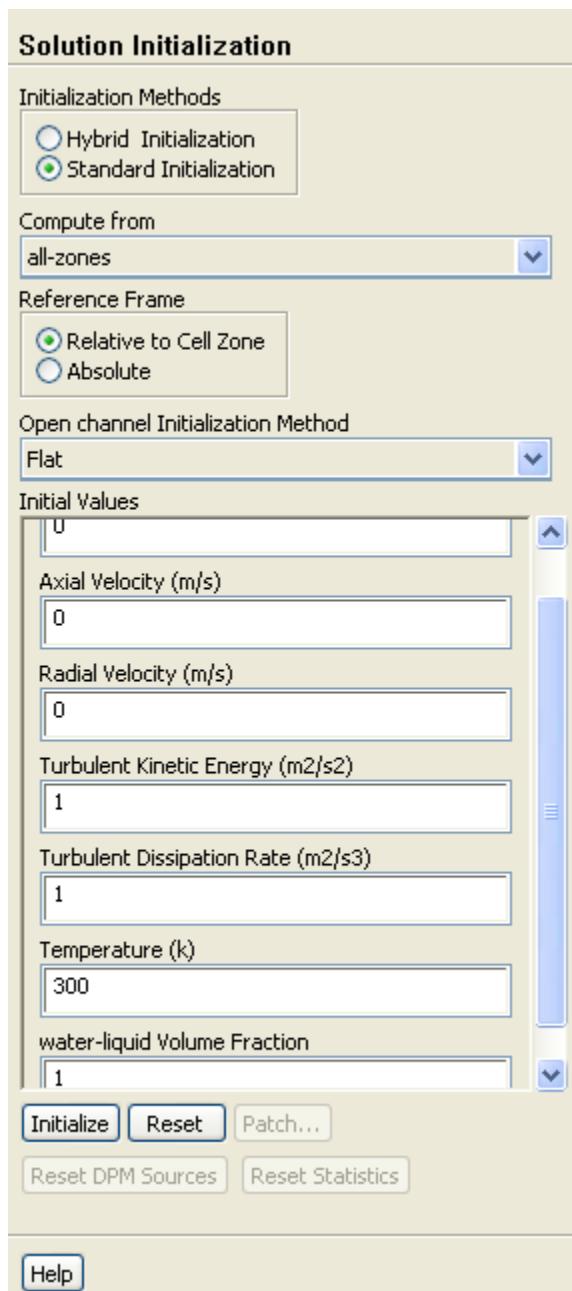

Summary :
-----
Checks successful

Recommendations :
-----
Preferred Wave theories : 3rd to 5th Order Stokes
```

26.3.4. Recommendations for Open Channel Initialization

Once you have selected either the **Open Channel Flow** or the **Open Channel Wave BC** option in the **Multiphase Model** dialog box, then the **Open Channel Initialization Method** drop-down list appears in the **Solution Initialization** task page.

Figure 26.20 The Solution Initialization Task Page

Select an inlet zone from the **Compute from** drop-down list. You can now make your selection from the **Open Channel Initialization Method** drop-down list. If only the **Open Channel Flow** option was enabled, then you only have a choice of **None** or **Flat**. If you enabled **Open Channel Wave BC**, then your choices are **None**, **Flat**, or **Wavy**. The default initialization method is **None**.

If you initialize the solution using **None**, it has no effect as it does not use any open channel information from the selected zone. The **Open Channel Initialization Method** comes into effect when you select either **Flat** or **Wavy**.

Important

This initialization is only valid for pressure-inlets, pressure outlets, and mass-flow inlets for open channel flow and velocity inlets for open channel wave boundary conditions. If the selected inlet zone does not have either open channel flow or open channel wave boundary conditions, ANSYS FLUENT will report an error message after you initialize the flow with open channel initialization method of **Flat** or **Wavy**.

For open channel initialization from the pressure outlet boundary, the hydrostatic pressure profile based on the **Free Surface Level** is patched in the domain. The volume fraction in the domain is patched based on **Free Surface Level** provided at the pressure outlet boundary. To patch velocity and other variables, the values in the **Solution Initialization** task page will be used.

Important

- Open channel initialization from the pressure outlet boundary is only supported for two phase flow.
- The pressure specification methods, with the exception of **Free Surface Level**, are not supported for open channel initialization from the pressure outlet boundary.

Initialization will result in the volume fraction, X, Y, and Z velocities, and pressure being patched in the domain. The volume fraction will be patched in the domain based on the free surface level of the selected zone from the **Compute from** list. The velocities in the domain will be patched assuming the constant value provided for the velocity magnitude in the selected zone.

Important

If you specify a profile for the velocity magnitude or direction vectors, the initialization will select the value for the velocity magnitude and direction vectors from only one face. Therefore the initialization may be inaccurate. However, generally, open channel inputs for velocity magnitude and direction vectors are constant.

The pressure which is patched is the hydrostatic pressure based on the free surface level specified in the selected zone.

You can use the following text command for open channel automatic initialization:

```
solve → initialize → open-channel-auto-init
```

When prompted, set up the following parameters:

boundary thread id

Enter the thread id for the boundary to be selected for open channel automatic initialization.

flat free surface initialization

This option is available for both open channel flow and open channel wave boundary conditions.

wavy free surface initialization

This option appears only for open channel wave boundary conditions, when flat free surface initialization is not selected.

The steps to be followed for open channel automatic initialization are

1. Compute defaults based on valid open channel boundary thread. This step is required for better initialization of turbulence parameters based on uniform velocity magnitude.
`solve → initialize → compute defaults`
2. This would provide information about the selected boundary and type of initialization.
`solve → initialize → open-channel-auto-init`
3. Initialize
`solve → initialize → initialize`

26.3.5. Numerical Beach Treatment for Open Channels

In certain applications, it is desirable to suppress numerical reflection near the outlet boundary for wave dampening. To understand the theory involved in this application, please refer to [Numerical Beach Treatment](#)

To include numerical beach in your simulation, perform the following:

1. Enable **Gravity** and set the gravitational acceleration fields.

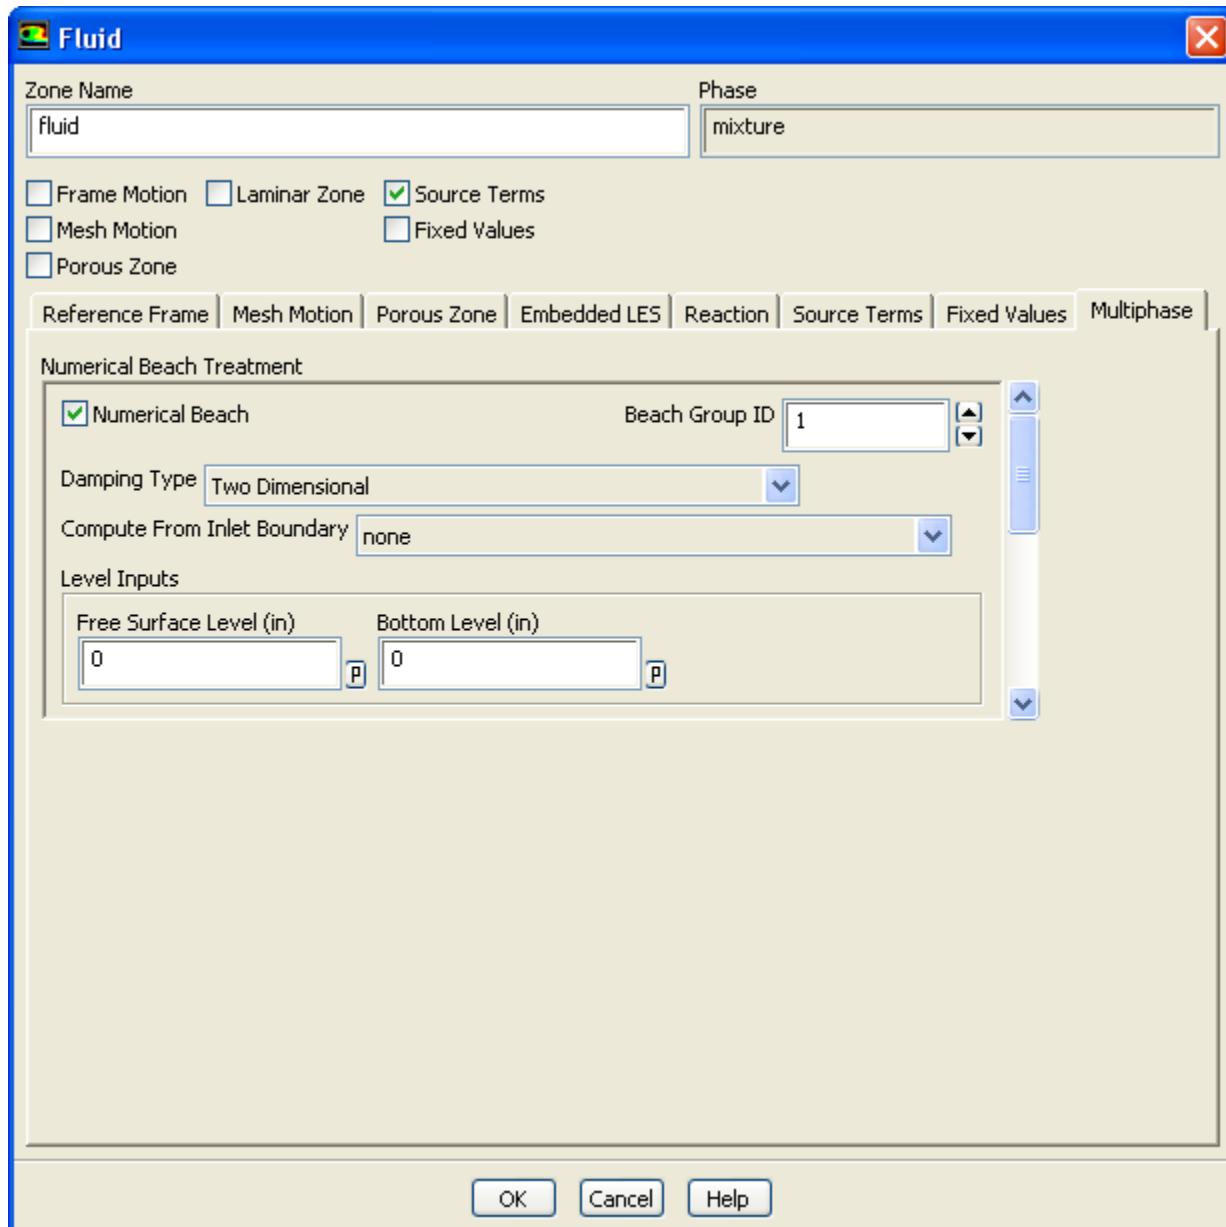

2. Enable the **Volume of Fluid** model in the **Multiphase Model** dialog box.

3. Under **Scheme**, select either **Implicit** or **Explicit**.
4. Select **Open Channel Flow** and/or **Open Channel Wave BC**.

In order to set the numerical beach parameters for a fluid zone, go to the **Fluid** dialog box ([Figure 26.21 \(p. 1217\)](#)).

Figure 26.21 The Fluid Dialog Box Displaying Numerical Beach

In the **Multiphase** tab of the **Fluid** dialog box, enable the **Numerical Beach** option and enter the following:

- **Beach Group ID** represents the cell zones sharing the damping length containing the same input parameters.
- **Damping Type** allows you to choose between **Two Dimensional** and **One Dimensional**.
 - **Two Dimensional** is the damping treatment in the flow and gravity direction.
 - **One dimensional** is the damping treatment in the flow direction.
- **Compute from Inlet Boundary** is set to **none** by default. If there are available open channel boundaries (velocity-inlet, pressure-inlet, and mass-flow-inlet), boundary names are added to the drop-down list. If you select a boundary from the list, the **Level Inputs** and the **Damping Length Inputs in Flow Direction** will be updated in the interface. You have the option to overwrite the updated inputs with values that are more applicable to your simulation.

- **Level Inputs** is only available for the **Two Dimensional** damping type.
 - **Free Surface Level** is the same definition as for open channel flow, see *Modeling Open Channel Flows* (p. 1204).
 - **Bottom Level** is the same definition as for open channel flow, see *Modeling Open Channel Flows* (p. 1204). During the automatic calculation from the velocity inlet boundary for short gravity waves, this parameter is updated under some assumptions, as noted in *Solution Strategies* (p. 1218). The bottom level is used for calculating the liquid height.
- **Flow Direction** is the X, Y, and Z (for 3D) components.
- **Damping Length Inputs in Flow Direction** are required to calculate the start and end points of the damping length in the flow direction.
 - **Damping Length Specification** is only available if **Open Channel Wave BC** is enabled in the **Multiphase Model** dialog box. There are two options you can choose from:
 - **End Point and Wave Lengths** is the default option.
 - **End and Start Points** are the limits of the damping zone.
 - **End Point** is the end point of the damping zone. **End Point** is updated automatically if the boundary is selected from the **Compute from Inlet Boundary** drop-down list.

Note

The calculated value is assumed based on the domain extents for all the cell zones, and you should enter your own value if needed.

The end point is calculated by taking the dot product of the flow direction $x_e = \vec{X}_e \cdot \hat{x}$

Here, x_e is the end point and \vec{X}_e is the position vector in the plane perpendicular to the flow direction \hat{x} .

- **Start Point** is the starting point in the flow direction.

The start point is calculated by taking the dot product of the flow direction $x_s = \vec{X}_s \cdot \hat{x}$

Here, x_s is the start point and \vec{X}_s is the position vector in the plane perpendicular to the flow direction \hat{x} .

- **Wave Length** is updated automatically if the boundary is selected from the **Compute from Inlet Boundary** drop-down list.
- **Number Of Wave Lengths** is set to 2 by default for the calculation of the damping length.
- **Damping Resistance** is the resistance per unit length.

26.3.5.1. Solution Strategies

Below are some helpful key points when using the **Numerical Beach** option:

1. The **Compute from Inlet Boundary** drop-down list is a convenient feature as it provides automatic inputs, which you should check to make sure the values are reasonable. Some of the provided values are calculated under certain assumptions:

- a. The bottom level, in the case of short gravity waves, is selected in the velocity inlet dialog box for open channel wave boundary conditions. Since there is no user input for this parameter, ANSYS FLUENT calculates the bottom level as the value of the free surface level less 2.5 times the wave length. The assumption is that the liquid height is 2.5 times the wave length.
 - b. The end point domain extents in the flow direction and includes all the cell zones.
2. For manual inputs of start and end points, you should verify that these points are calculated correctly in the flow direction. To check for their validity, subtracting the start point from the end point should give you a positive value.
 3. For manual inputs of **Free Surface Level** and **Bottom Level**, you should verify that these points are calculated correctly in the direction opposite to gravity. To check for their validity, subtracting the bottom level from the free surface level should give you a positive value.
 4. In case you create separate damping zones, but the damping length is not sufficient to suppress the waves, clubbing of the beach could be done by selecting the same beach ID for other cell zones. In this case, both the cell zones would share the same information.
 5. In case of separate damping zones (without clubbing), you should verify that the damping length is more than or equal to the specified number of wave lengths for the calculation of the start point.
 6. Damping resistance should be chosen accordingly: too much or too little damping could affect the wave profiles in a no-damping zone. For higher order waves, a default value of 10 was satisfactory, but this value is case specific and should be tuned to get better results with minimal reflection.
 7. Steep damping at the beginning of the damping zone could affect the wave profile just before the damping zone.
 8. It is recommended to use a coarse mesh in the damping zone with increased coarseness towards the end of the damping zone.

26.3.6. Defining the Phases for the VOF Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction in a VOF calculation are provided below.

Important

In general, you can specify the primary and secondary phases whichever way you prefer. It is a good idea, especially in more complicated problems, to consider how your choice will affect the ease of problem setup. For example, if you are planning to patch an initial volume fraction of 1 for one phase in a portion of the domain, it may be more convenient to make that phase a secondary phase. Also, if one of the phases is a compressible ideal gas, it is recommended that you specify it as the primary phase to improve solution stability.

Important

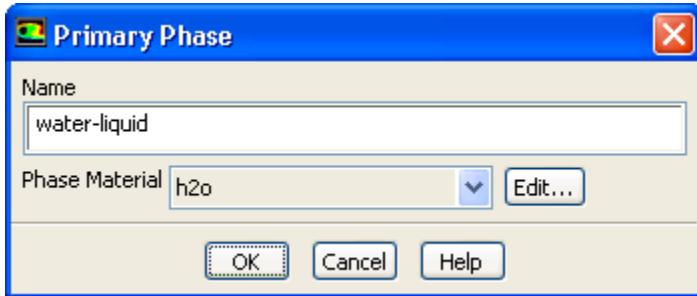

Recall that only one of the phases can be a compressible ideal gas. Be sure that you do not select a compressible ideal gas material (i.e., a material that uses the compressible ideal gas law for density) for more than one of the phases. See [Modeling Compressible Flows](#) (p. 1230) and [Modeling Compressible Flows](#) (p. 1239) for details.

26.3.6.1. Defining the Primary Phase

To define the primary phase in a VOF calculation, perform the following steps:

1. Select **phase-1** in the **Phases** list.
2. Click **Edit...** to open the **Primary Phase** dialog box (*Figure 26.22 (p. 1220)*).

Figure 26.22 The Primary Phase Dialog Box

3. In the **Primary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**.
 - a. Click **Edit...**, and the **Edit Material** dialog box will open.
 - b. In the **Edit Material** dialog box, check the properties, and modify them if necessary. (See *Physical Properties* (p. 403) for general information about setting material properties, *Modeling Compressible Flows* (p. 1230) for specific information related to compressible VOF calculations, and *Modeling Solidification/Melting* (p. 1230) for specific information related to melting/solidification VOF calculations.)

Important

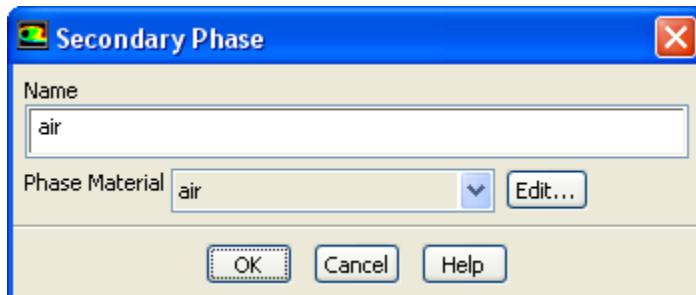

If you make changes to the properties, remember to click **Change** before closing the **Edit Material** dialog box.

6. Click **OK** in the **Primary Phase** dialog box.

26.3.6.2. Defining a Secondary Phase

To define a secondary phase in a VOF calculation, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the **Secondary Phase** dialog box (*Figure 26.23 (p. 1221)*).

Figure 26.23 The Secondary Phase Dialog Box for the VOF Model

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**, following the procedure outlined above for setting the material properties for the primary phase.
6. Click **OK** in the **Secondary Phase** dialog box.

26.3.6.3. Including Surface Tension and Adhesion Effects

As discussed in [When Surface Tension Effects Are Important](#) in the [Theory Guide](#), the importance of surface tension effects depends on the value of the capillary number, Ca (defined by [Equation 17-31](#) in the [Theory Guide](#)), or the Weber number, We (defined by [Equation 17-32](#) in the [Theory Guide](#)). Surface tension effects can be neglected if $Ca \gg 1$ or $We \gg 1$.

Several surface tension options are provided through the text user interface (TUI) using the `solve/set/surface-tension` command :

`solve → set → surface-tension`

The `surface-tension` command prompts you for the following information:

- whether you require node-based smoothing

The default value is `yes`, indicating that node-based smoothing will be used. Note that if you are reading in a case that was created in versions prior to ANSYS FLUENT 13, then cell-based smoothing will be used by default for the VOF calculations.

- the number of smoothings

The default value is 1. A higher value can be used in case of tetrahedral and triangular meshes in order to reduce any spurious velocities.

- the smoothing relaxation factor

The default is 1. This is useful in the cases where VOF smoothing causes a problem (e.g., liquid enters through the inlet with wall adhesion on).

- whether you want to use VOF gradients at the nodes for curvature calculations

With this option, ANSYS FLUENT uses VOF gradients directly from the nodes to calculate the curvature for surface tension forces. The default is `yes` which produces better results with surface tension compared to gradients that are calculated at the cell centers.

Important

Note that the calculation of surface tension effects will be more accurate if you use a quadrilateral or hexahedral mesh in the area(s) of the computational domain where surface tension is significant. If you cannot use a quadrilateral or hexahedral mesh for the entire domain, then you should use a hybrid mesh, with quadrilaterals or hexahedra in the affected areas.

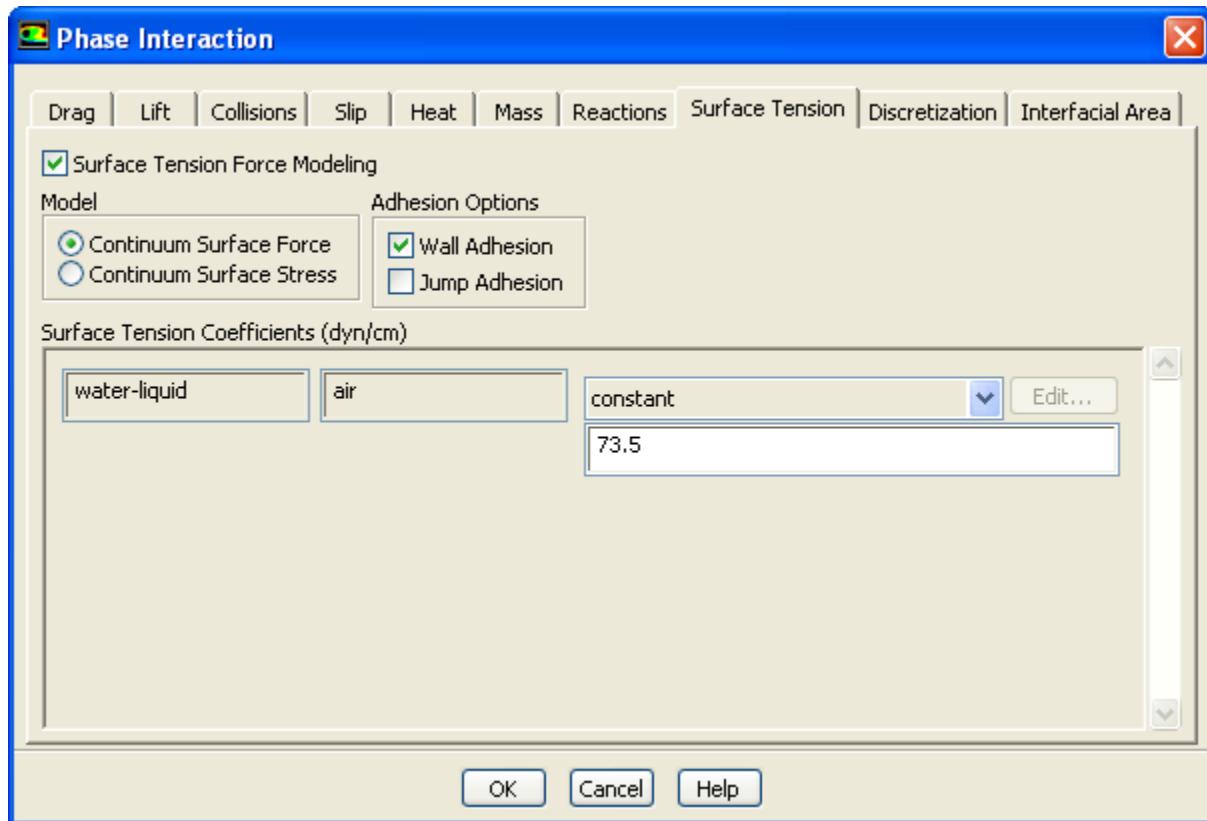

ANSYS FLUENT uses node based smoothing for smoothed volume fraction and node based gradients for smoothed curvature calculation to provide better accuracy and robustness.

Important

Pressure jump caused by the surface tension is discontinuous in nature, and also it acts locally at the interface. These numerical difficulties are overcome in an approximate manner by considering the smoothed distribution of the volume fraction field within the finite interfacial width. Smoothing procedures, in general, are mesh dependent. Therefore, the amount and nature of the smoothing procedure could have a significant effect on the results for surface tension cases.

If you want to include the effects of surface tension along the interface between one or more pairs of phases, as described in [Surface Tension and Adhesion](#) in the [Theory Guide](#), click **Interaction...** to open the [Phase Interaction Dialog Box \(p. 1937\)](#) (*Figure 26.24 (p. 1222)*).

Figure 26.24 The Phase Interaction Dialog Box for the VOF Model (Surface Tension Tab)

Perform the following steps to model surface tension (and, if appropriate, include adhesion) effects along the interface between one or more pairs of phases:

1. Click the **Surface Tension** tab.
2. Enable the **Surface Tension Force Modeling** option to include the surface tension method.

Note

Make sure you specify the **Surface Tension Coefficients** as **constant** or **user-defined**. If **none** is selected, then **Surface Tension Force Modeling** will automatically be disabled.

3. Select the surface tension method that is most applicable to your case. You can choose between **Continuum Surface Force** and **Continuum Surface Stress**. Information about each of the methods is described in **Surface Tension** in the [Theory Guide](#).
4. For each pair of phases between which you want to include the effects of surface tension, specify a constant surface tension coefficient. Alternatively you can specify a temperature dependent, polynomial, piecewise polynomial, piecewise linear, or a user-defined surface tension coefficient. See [Surface Tension and Adhesion](#) in the [Theory Guide](#) for more information on surface tension, and the [UDF Manual](#) for more information on user-defined functions. All surface tension coefficients are equal to 0 by default, representing no surface tension effects along the interface between the two phases.

Important

For calculations involving surface tension, it is recommended that you also turn on the **Implicit Body Force** treatment for the **Body Force Formulation** in the **Multiphase Model** dialog box. This treatment improves solution convergence by accounting for the partial equilibrium of the pressure gradient and surface tension forces in the momentum equations. See [Including Body Forces](#) (p. 1180) for details.

5. If you want to include wall adhesion, enable the **Wall Adhesion** option. When **Wall Adhesion** is enabled, you will need to specify the contact angle at each wall as a boundary condition (as described in [Defining Multiphase Cell Zone and Boundary Conditions](#) (p. 1189)).

The contact angle θ_w is the angle between the wall and the tangent to the interface at the wall, measured inside the *phase listed in the left column* under **Wall Adhesion** in the **Momentum** tab of the **Wall** dialog box. For example, if you are setting the contact angle between the oil and air phases in the **Wall** dialog box shown in [Figure 26.25](#) (p. 1224), θ_w is measured inside the oil phase, as seen in [Figure 26.26](#) (p. 1225). For more information, refer to [Wall Adhesion](#) in the [Theory Guide](#).

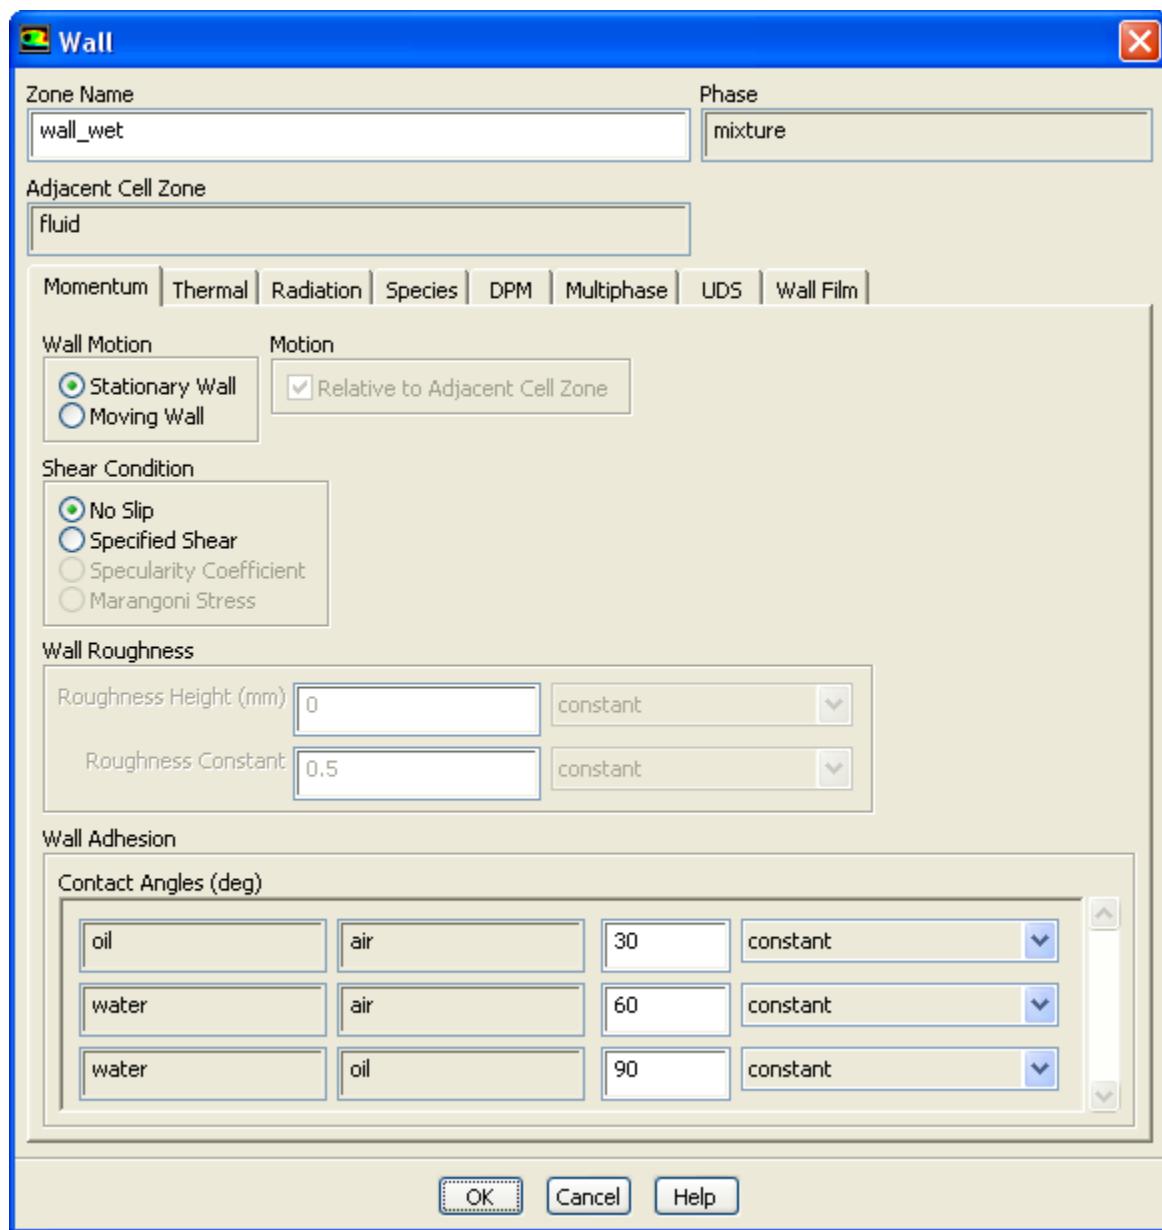

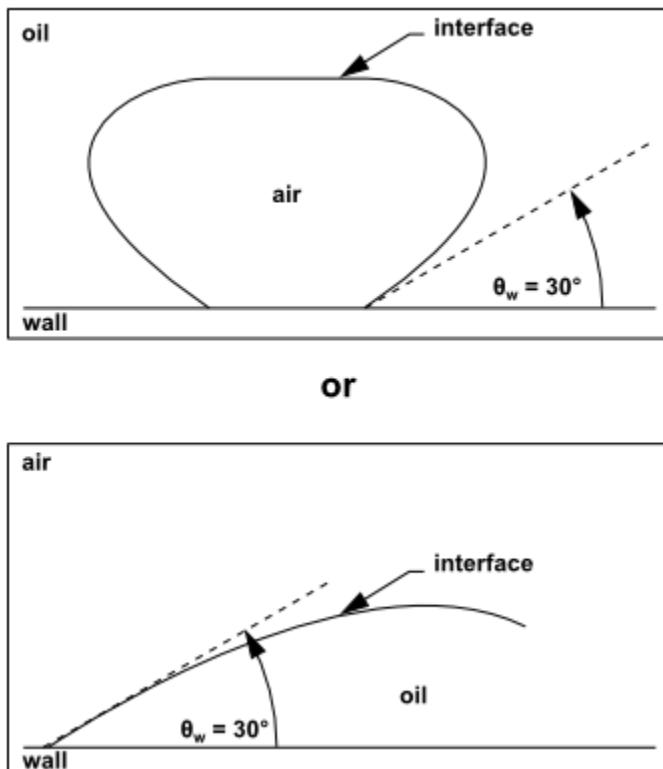

Figure 26.25 The Wall Dialog Box for a Mixture in a VOF Calculation with Wall Adhesion

Figure 26.26 Measuring the Contact Angle

6. If you want to include jump adhesion, enable the **Jump Adhesion** option. When **Jump Adhesion** is enabled, you will need to specify the contact angle at the porous jump in the **Porous Jump** dialog box (as described in [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#)). The contact angle specification and measurement for jump adhesion is similar to that of wall adhesion (as explained in step 3 above).

Important

Jump adhesion only supports the cell based smoothing option for surface tension. When the **Jump Adhesion** option is enabled in the **Phase Interaction** dialog box, the correct settings are automatically set for surface tension. To view the surface tension settings, use the `solve/set/surface-tension` text command.

Note

The following limitations exist:

- When the **Wall Adhesion** and **Jump Adhesion** options are enabled, you must specify a non-zero surface tension coefficient.
- **Jump Adhesion** is not available with the **Continuum Surface Stress** model.
- The **Continuum Surface Stress** model and the **Jump Adhesion** option are not available with the **Level Set** option.

26.3.6.4. Discretizing Using the Phase Localized Compressive Scheme

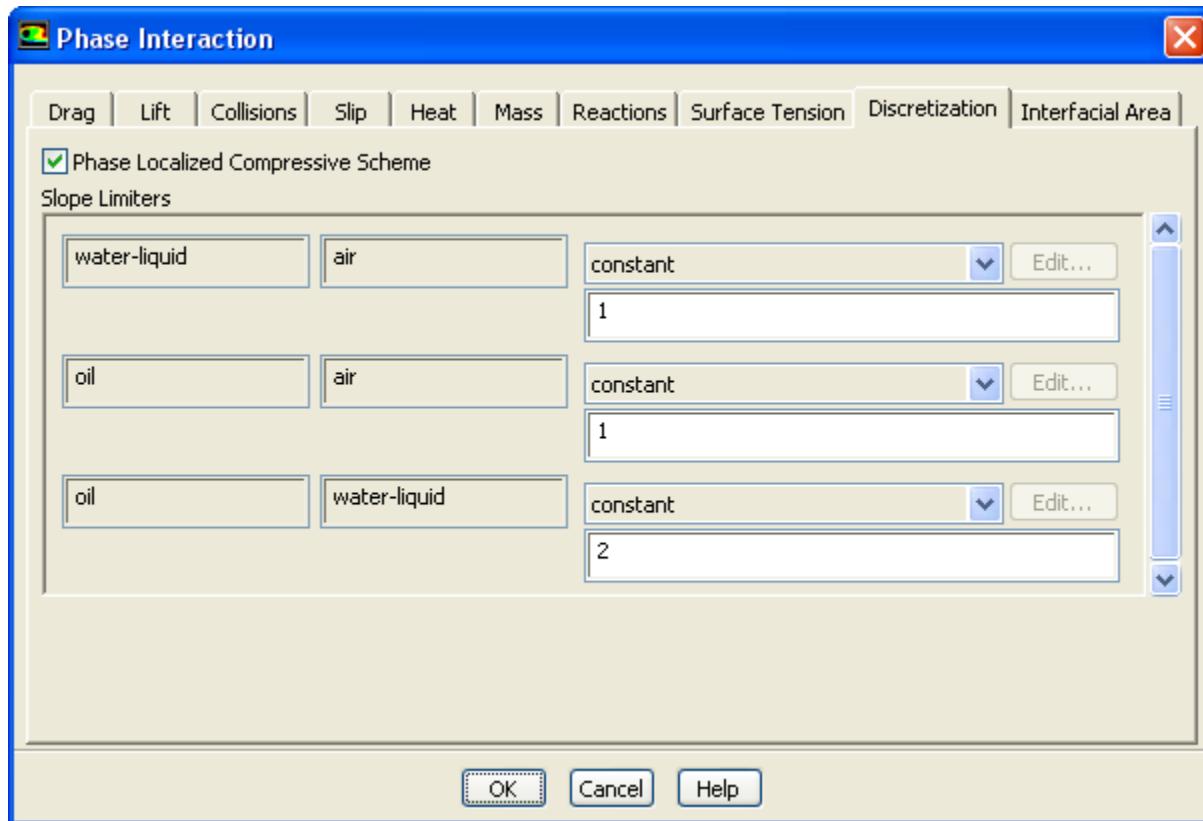

Most of the interface capturing or tracking schemes, which are common in literature, can simulate either diffused interface modeling or sharp interface modeling. There are a number of applications where you may be interested in modeling diffused *and* sharp interfaces in different regimes, which results in the need for a unique discretization procedure to handle such applications.

Below are some examples of such applications:

- **Air bubble rise in water-solid slurry:** Diffused interface modeling is required for the water and solid, and sharp interface modeling for the air bubble is desirable. A sharpening scheme would cause undesirable effects for the modeling of the diffused interface between water and solids and a diffusive scheme would not be able to maintain the sharp interface for bubble rising in the slurry.
- **Evaporation/condensation in a tank partially filled with water and being heated at the bottom:** Diffused interface modeling is required for the liquid-vapor and sharp interface modeling for the water-air regime is desirable. A sharpening scheme, would not be able to simulate the diffused phenomena of evaporation/condensation for the liquid- vapor phase and a diffusive scheme would not be able to maintain the sharp interface between water and air.
- **Air jet penetrating through layer of liquids:** You may be interested in diffused jet modeling and sharp interface modeling between the liquid layers. A sharpening scheme would not be able to maintain the continuous air stream and a diffusive scheme would not be able to maintain the sharp interfaces between the layers of liquids.

Using the Modified HRIC and Compressive schemes for such applications would result in the HRIC scheme producing undesirable sharpening of the dispersed phases and undesirable diffusion of the continuous phases, whereas the Compressive scheme would produce undesirable sharpening of the dispersed phases.

Therefore, the phase localized compressive scheme is particularly useful in cases where the desirable behavior is such that you have diffused modeling of dispersed phases and sharp modeling of continuous phases. In ANSYS FLUENT, diffusive and anti-diffusive discretization procedures can be used across the distinct interfaces, which share a pair of phases. This functionality is provided through the compressive discretization scheme, where the degree of diffusion or sharpness is controlled through the value of the slope limiters. The theory used is described in [The Compressive and Zonal Discretization Schemes](#).

Figure 26.27 The Phase Interaction Dialog Box for the VOF Model (Discretization Tab)

To use the phase localized compressive scheme, perform the following steps:

1. Click the **Discretization** tab.

Note

The **Discretization** tab is only available if the VOF model is enabled, or if the Eulerian multiphase model is selected with the explicit scheme.

2. Enable **Phase Localized Compressive Scheme**.

Important

When this option is enabled, the **Compressive** spatial discretization scheme is automatically selected for the **Volume Fraction** in the **Solution Methods** dialog box.

3. For each pair of phases, specify the value of the slope limiter. You can enter a value of 0, 1, or 2, or any value between 0 and 2. Please refer to [Table 26.8: Slope Limiter Discretization Scheme \(p. 1228\)](#) to equate each value of the slope limiter with a discretization scheme.

Table 26.8 Slope Limiter Discretization Scheme

Slope Limiter Value β	Scheme
0	first order upwind
1	second order reconstruction bounded by the global minimum/maximum of the volume fraction
2	compressive
$0 < \beta < 1$ and $1 < \beta < 2$	blended: where a value between 0 and 1 means blending of the first order and second order and a value between 1 and 2 means blending of the second order and compressive scheme

When using the **Phase Localized Compressive Scheme**, please keep in mind the following:

- The minimum limit for the slope limiter is 0, whereas the maximum is 2.
- The slope limiter can be interpreted as the degree of compression/anti-diffusion, where 0 demonstrates the minimum compression and 2 demonstrates the maximum compression.
- For interfaces sharing the diffused phases, a slope limiter value of 2 should not be used. A value between 0 and 1 is recommended.
- For interfaces sharing the continuous phases, any value between 0 and 2 can be used depending on the application.
- For interfaces sharing the continuous and diffused phases, any value between 0 and 2 can be used based on the application.
- If you want variable discretization behavior for an interface between two phases, you can do so via the `DEFINE_PROPERTY UDF`.

Note

- If the interface has a transition from sharp to diffused modeling, you should not experience any problems.
- If the interface has a transition from diffused to sharp modeling, this transition should be smooth by gradually varying the value of the slope limiter within some transition zone.

26.3.7. Setting Time-Dependent Parameters for the VOF Model

If you are using the time-dependent volume fraction formulation in ANSYS FLUENT, an explicit solution for the volume fraction is obtained either once each time step or once each iteration, depending upon your inputs to the model. You also have control over the time step used for the volume fraction calculation.

To compute a time-dependent VOF solution, you will need to enable the **Transient** option in the **General** task page (and choose the appropriate **Transient Formulation** in the **Solution Methods** task page, as discussed in [User Inputs for Time-Dependent Problems \(p. 1366\)](#)).

There are two inputs for the time-dependent calculation for the VOF model:

- By default, ANSYS FLUENT will solve the volume fraction equation(s) once for each time step. This means that the convective flux coefficients appearing in the other transport equations will not be completely updated each iteration, since the volume fraction fields will not change from iteration to iteration.

If you want ANSYS FLUENT to solve the volume fraction equation(s) at every iteration within a time step, first make sure that you have selected **Volume of Fluid** from the **Model** list in the **Multiphase Model** dialog box, and then enter the following text command in the console:

```
define → models → multiphase → volume-fraction-parameters
```

When prompted to `solvevofevery iteration?`, enter yes.

When ANSYS FLUENT solves these equations every iteration, the convective flux coefficients in the other transport equations will be updated based on the updated volume fractions at each iteration. This choice is the less stable of the two, and requires more computational effort per time step than the default choice.

Important

If you are using sliding meshes, or dynamic meshes with layering and/or remeshing, using the `solve vof every iteration?` option will yield more accurate results, although at a greater computational cost.

- When ANSYS FLUENT performs a time-dependent VOF calculation, the time step used for the volume fraction calculation will not be the same as the time step used for the rest of the transport equations. ANSYS FLUENT will refine the time step for VOF automatically, based on your input for the maximum **Courant Number** allowed near the free surface. The Courant number is a dimensionless number that compares the time step in a calculation to the characteristic time of transit of a fluid element across a control volume:

$$\frac{\Delta t}{\Delta x_{cell}/v_{fluid}} \quad (26-4)$$

In the region near the fluid interface, ANSYS FLUENT divides the volume of each cell by the sum of the outgoing fluxes. The resulting time represents the time it would take for the fluid to empty out of the cell. The smallest such time is used as the characteristic time of transit for a fluid element across a control volume, as described above. Based upon this time and your input for the maximum allowed **Courant Number** in the [Multiphase Model Dialog Box \(p. 1774\)](#), a time step is computed for use in the VOF calculation. For example, if the maximum allowed Courant number is 0.25 (the default), the time step will be chosen to be at most one-fourth the minimum transit time for any cell near the interface.

Note that these inputs are not required when the implicit scheme is used.

26.3.8. Modeling Compressible Flows

If you are using the VOF model for a compressible flow, note the following:

- Only one of the phases can be defined as a compressible ideal gas (i.e., you can select the ideal gas law for the density of only one phase's material). There is no limitation on using compressible liquids using user-defined functions.
- When using the VOF model, for stability reasons, it is better (although not required) if the primary phase is a compressible ideal gas.
- If you specify the total pressure at a boundary (e.g., for a pressure inlet or intake fan) the specified value for temperature at that boundary will be used as total temperature for the compressible phase, and as static temperature for the other phases (which are incompressible).
- For each mass flow inlet, you will need to specify mass flow or mass flux for each individual phase.

Important

Note that if you read a case file that was set up in a version of ANSYS FLUENT previous to 6.1, you will need to redefine the conditions at the mass flow inlets. See [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#) for more information on defining conditions for a mass flow inlet in VOF multiphase calculations.

See [Compressible Flows \(p. 525\)](#) for more information about compressible flows.

26.3.9. Modeling Solidification/Melting

If you are including melting or solidification in your VOF calculation, note the following:

- It is possible to model melting or solidification in a single phase or in multiple phases.
- For phases that are *not* melting or solidifying, you must set the latent heat (L), liquidus temperature ($T_{liquidus}$), and solidus temperature ($T_{solidus}$) to zero.

See [Modeling Solidification and Melting \(p. 1297\)](#) for more information about melting and solidification.

26.4. Setting Up the Mixture Model

For background information about the mixture model and the limitations that apply, refer to [Overview](#) in the [Theory Guide](#).

For additional information, please see the following sections:

- [26.4.1. Defining the Phases for the Mixture Model](#)
- [26.4.2. Including Cavitation Effects](#)
- [26.4.3. Modeling Compressible Flows](#)

26.4.1. Defining the Phases for the Mixture Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction for a mixture model calculation are provided below.

Important

Recall that only one of the phases can be a compressible ideal gas. Be sure that you do not select a compressible ideal gas material (i.e., a material that uses the compressible ideal gas law for density) for more than one of the phases. See [Modeling Compressible Flows \(p. 1239\)](#) for details.

26.4.1.1. Defining the Primary Phase

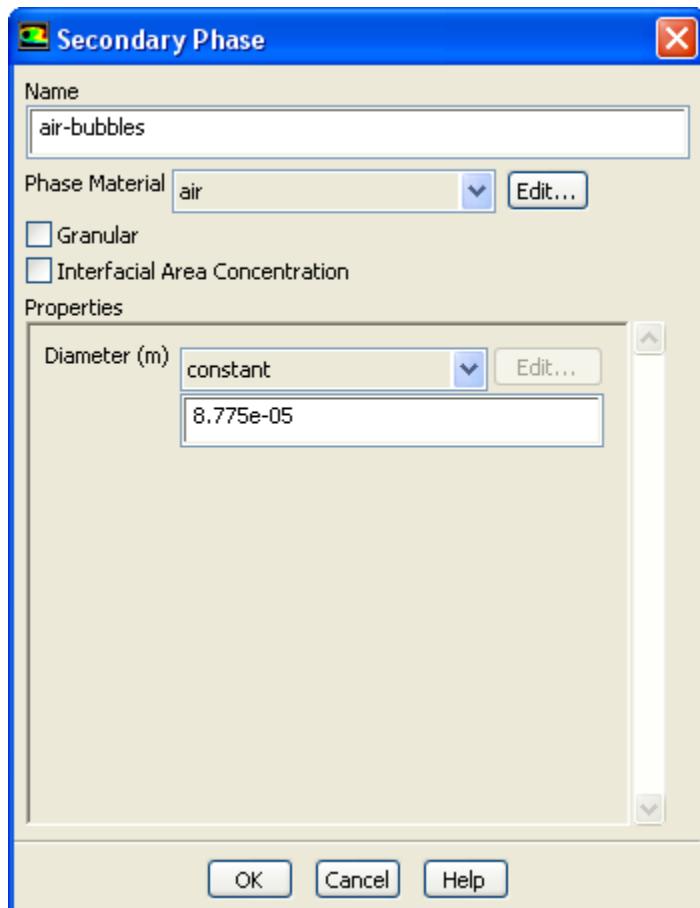

The procedure for defining the primary phase in a mixture model calculation is the same as for a VOF calculation. See [Defining the Primary Phase \(p. 1220\)](#) for details.

26.4.1.2. Defining a Nongranular Secondary Phase

To define a nongranular (i.e., liquid or vapor) secondary phase in a mixture multiphase calculation, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.28 (p. 1231)*).

Figure 26.28 The Secondary Phase Dialog Box for the Mixture Model

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

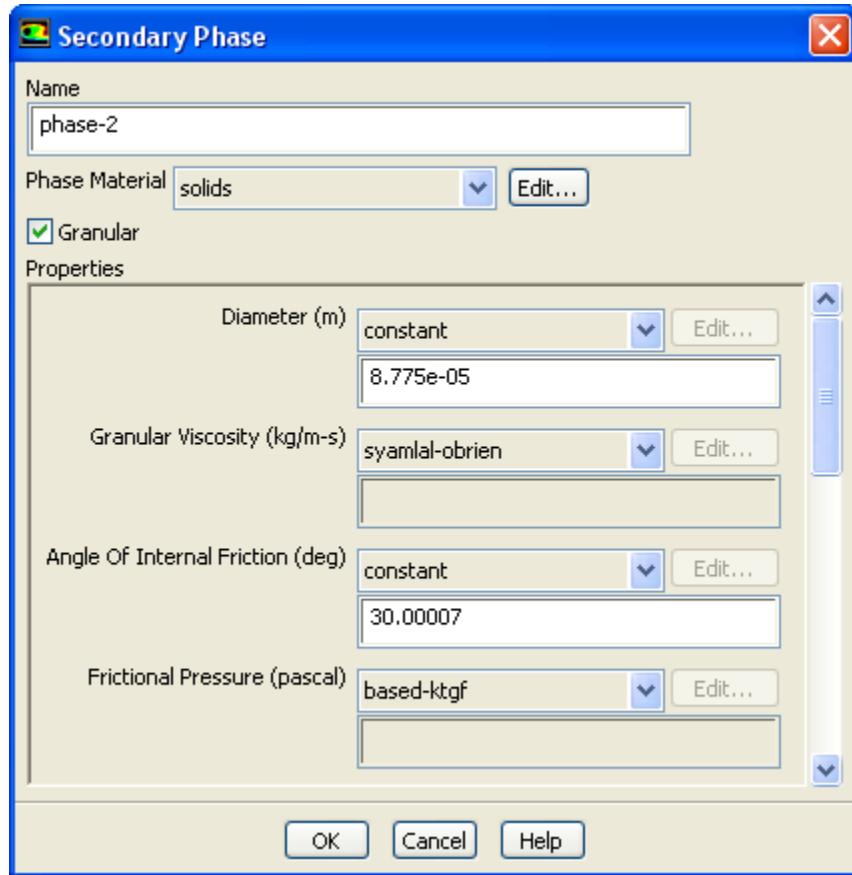

5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see *Defining the Primary Phase* (p. 1220)). For a particulate phase (which must be placed in the fluid materials category, as mentioned in *Steps for Using a Multiphase Model* (p. 1173)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.
6. In the **Secondary Phase** dialog box, specify the **Diameter** of the bubbles, droplets, or particles of this phase (d_p in *Equation 17–95* in the *Theory Guide*). You can specify a constant value, or use a user-defined function. See the *UDF Manual* for details about user-defined functions. Note that when you are using the mixture model without slip velocity, this input is not necessary, and it will not be available to you.
7. Click **OK** in the **Secondary Phase** dialog box.

26.4.1.3. Defining a Granular Secondary Phase

To define a granular (i.e., particulate) secondary phase in a mixture model multiphase calculation, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.29* (p. 1232)).

Figure 26.29 The Secondary Phase Dialog Box for a Granular Phase Using the Mixture Model

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see [Defining the Primary Phase \(p. 1220\)](#)). For a granular phase (which must be placed in the fluid materials category, as mentioned in [Steps for Using a Multiphase Model \(p. 1173\)](#)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.

Important

Note that all properties for granular flows can utilize user-defined functions (UDFs).

- See the [UDF Manual](#) for details about user-defined functions.
6. Enable the **Granular** option.
 7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

Diameter

specifies the diameter of the particles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the [UDF Manual](#) for details about user-defined functions.

Granular Viscosity

specifies the kinetic part of the granular viscosity of the particles ($\mu_{s,kin}$ in [Equation 17–103](#) in the [Theory Guide](#)). You can select **constant** (the default) in the drop-down list and specify a constant value, select **syamlal-obrien** to compute the value using [Equation 17–105](#) in the [Theory Guide](#), select **gidaspow** to compute the value using [Equation 17–106](#) in the [Theory Guide](#), or select **user-defined** to use a user-defined function.

Frictional Pressure

specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johson-et-al** to apply [Equation 17–226](#) in the [Theory Guide](#), **syamlal-obrien** to apply [Equation 17–162](#) in the [Theory Guide](#), **based-ktgtf**, where the frictional pressure is defined by the kinetic theory [20] (p. 2368). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You must hook a user-defined function when selecting the **user-defined** option. See the UDF manual for information on hooking a UDF.

Frictional Modulus

is defined as

$$G = \frac{\partial P_{friction}}{\partial \alpha_{friction}} \quad (26-5)$$

with $G \geq 0$, which is the **derived** option. You can also specify a **user-defined** function for the frictional modulus.

Friction Packing Limit

specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5. This is only a general rule of thumb as there may be other factors involved.

Granular Temperature

specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles. Choose either the **algebraic**, the **constant**, or the **user-defined** option.

Solids Pressure

specifies the pressure gradient term, ∇p_s , in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, or the **user-defined** option.

Radial Distribution

specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastoopour**, or a **user-defined** option.

Elasticity Modulus

is defined as

$$G = \frac{\partial P_s}{\partial \alpha_s} \quad (26-6)$$

with $G \geq 0$.

Choose either the **derived** or **user-defined** options.

Packing Limit

specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres, the packing limit is about 0.63, which is the default value in ANSYS FLUENT. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

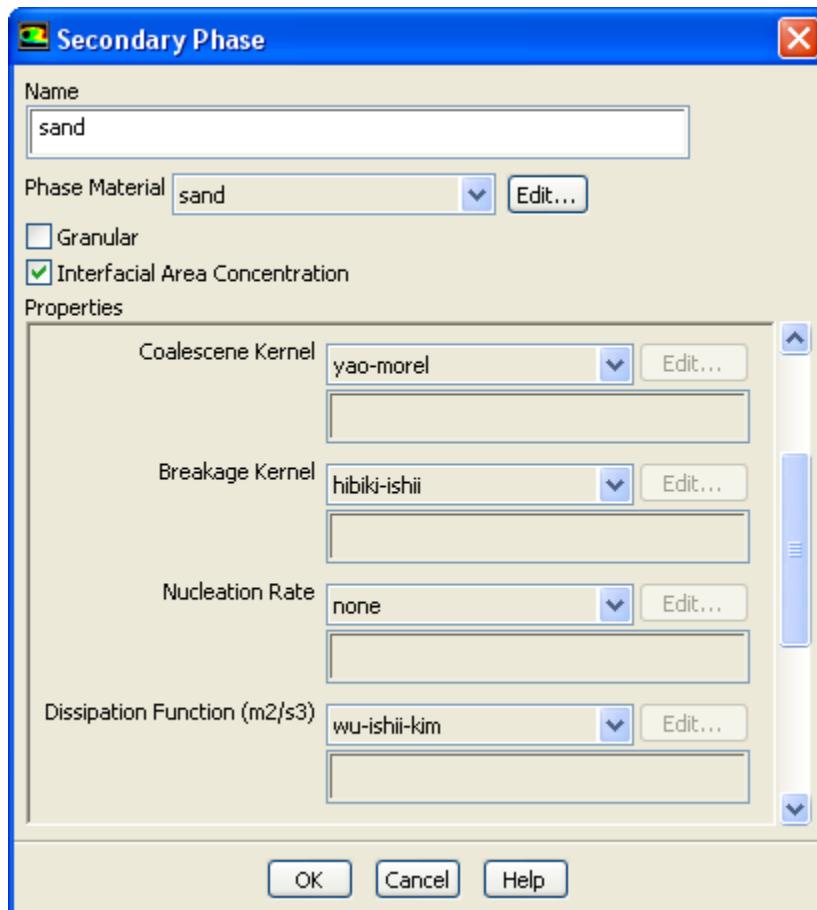

8. Click **OK** in the **Secondary Phase** dialog box.

26.4.1.4. Defining the Interfacial Area Concentration

To define the interfacial area concentration on the secondary phase in the mixture model, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.30* (p. 1235)).

Figure 26.30 The Secondary Phase Dialog Box Displaying the Interfacial Area Concentration Settings

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**.
6. Enable the **Interfacial Area Concentration** option. Make sure the **Granular** option is disabled for the **Interfacial Area Concentration** option to be visible in the interface.
7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

Diameter

specifies the diameter of the particles or bubbles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the [UDF Manual](#) for details about user-defined functions. The **Diameter** recommended setting is **sauter-mean**, allowing for the effects of the interfacial area concentration values to be considered for mass, momentum and heat transfer across the interface between phases.

Surface Tension

specifies the surface tension at the liquid-air interface. You can select either the **hibiki-ishii** or the **ishii-kim** model.

Coalescence Kernel and Breakage Kernel

allows you to specify the coalescence and breakage kernels. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim** and **yao-morel** are described in detail in [Interfacial Area Concentration](#) in the [Theory Guide](#).

In addition to specifying the **hibiki-ishii**, **ishii-kim**, and **yao-morel** as the coalescence and breakage kernels, you can also tune the properties of the three models by using the /define/phases/iac-expert/hibiki-ishii-model, /define/phases/iac-expert/ishii-kim-model, and /define/phases/iac-expert/yao-morel-model text commands.

For each of the three models you can specify the parameters listed in *Table 26.9: Parameters for the Coalescence and Breakage Kernels* (p. 1236)

Table 26.9 Parameters for the Coalescence and Breakage Kernels

Hibiki-Ishii Model	Ishii-Kim Model	Yao-Morel Model
Coefficient Gamma_c	Coefficient Crc	Coefficient K_c1
Coefficient K_c	Coefficient Cwe	Coefficient K_c3
Coefficient Gamma_b	Coefficient C	Coefficient K_b1
Coefficient K_b	Coefficient Cti	alpha_max
alpha_max	alpha_max	

These values are discussed in greater detail in [Interfacial Area Concentration](#) in the [Theory Guide](#).

Nucleation Rate

is a source term for the interfacial area concentration which models the rate of formation of the dispersed phase. You can choose from **constant** or **user-defined**.

Critical Weber Number

will need to be specified if you selected **ishii-kim** or **yao-morel** for the **Breakage Kernel**.

Dissipation Function

gives you the option to choose the formula which calculates the dissipation rate used in the **hibiki-ishii** and **ishii-kim** models. You can choose amongst **constant**, **wu-ishii-kim**, **fluent-ke**, and **user-defined** for the dissipation function.

The **wu-ishii-kim** option uses a simple algebraic correlation for ε :

$$\varepsilon = f_{TW} (1/2D_h) v_m^3 \quad (26-7)$$

where

$$f_{TW} = \frac{0.316}{[(1-\alpha) Re_m]^{0.25}}$$

and

$$Re_m = \frac{\rho_m v_m D_h}{\mu_m}$$

where ρ_m , v_m , μ_m , and D_h are the mixture density, mixture velocity, mixture molecular viscosity, and hydraulic diameter of the flow path.

When you select the **wu-ishii-kim** model, you will set an additional input for **Hydraulic Diameter**.

Hydraulic Diameter

is the value used in *Equation 26–7* (p. 1236), should you use the **wu-ishii-kim** formulation.

Min/Max Diameter

are the limits of the bubble diameters.

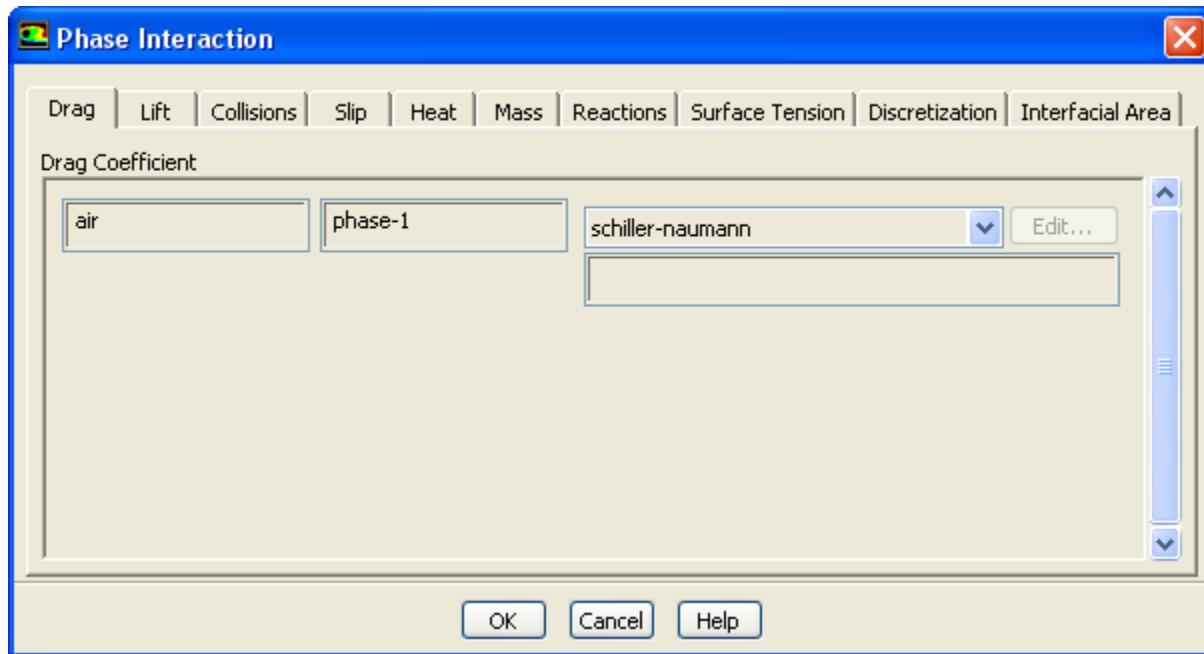

Note

When solving a steady state problem, the preferred setting for the **Under-Relaxation Factor** is 1.0, as the interfacial area equation for the boiling models is currently under-relaxed using a locally defined pseudo-time step. If you want extra explicit under-relaxation, you may set the value of the **Under-Relaxation Factor** to less than one, this may be done only in case of serious convergence problems with the interfacial area transport equation. To improve convergence you can switch to a pseudo-time step for the interfacial area concentration only, using the **define/phases/iac-expert/iac-pseudo-time-step** text command and set the local pseudo-time to less than 1.

26.4.1.5. Defining Drag Between Phases

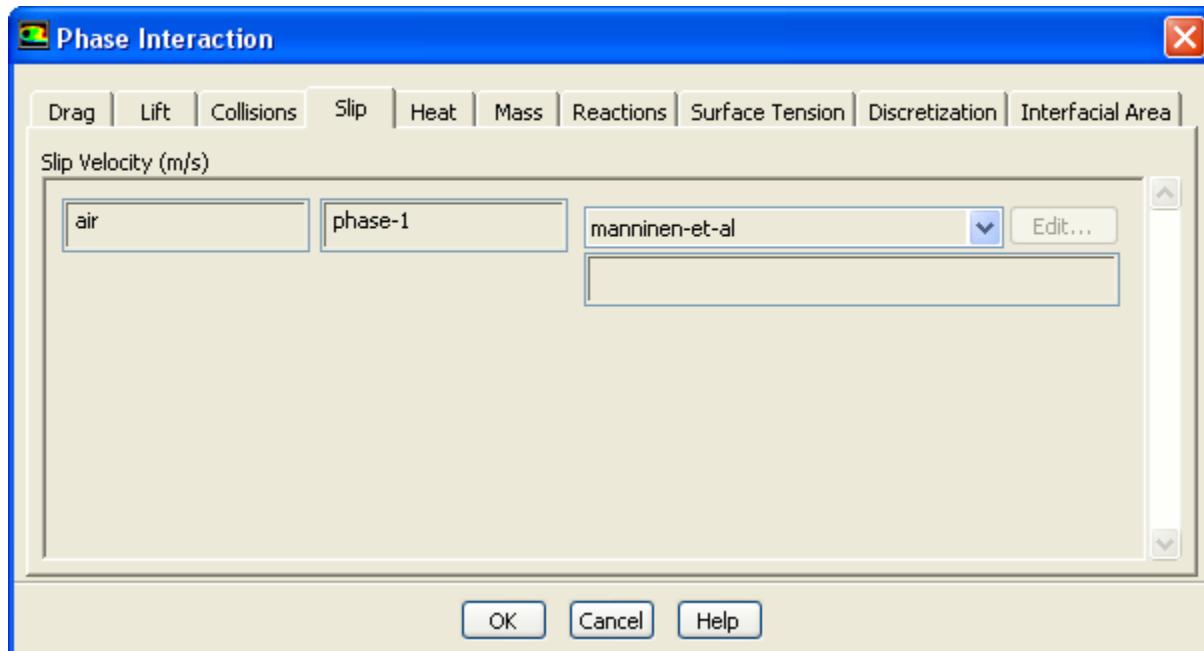

For mixture multiphase flows with slip velocity, you can specify the drag function to be used in the calculation. The functions available here are a subset of those discussed in *Defining the Phases for the Eulerian Model* (p. 1240). See *Relative (Slip) Velocity and the Drift Velocity* in the Theory Guide for more information.

To specify drag laws, click **Interaction...** to open the *Phase Interaction Dialog Box* (p. 1937) (*Figure 26.31* (p. 1238)), and then click the **Drag** tab.

Figure 26.31 The Phase Interaction Dialog Box for the Mixture Model (Drag Tab)

26.4.1.6. Defining the Slip Velocity

If you are solving for slip velocities during the mixture calculation, and you want to modify the slip velocity definition, click **Interaction...** to open the *Phase Interaction Dialog Box* (p. 1937) (*Figure 26.32* (p. 1238)), and then click the **Slip** tab.

Figure 26.32 The Phase Interaction Dialog Box for the Mixture Model Slip Tab

Under **Slip Velocity**, you can specify the slip velocity function for each secondary phase with respect to the primary phase by choosing the appropriate item in the adjacent drop-down list.

- Select **maninnen-et-al** (the default) to use the algebraic slip method of Manninen et al. [50] (p. 2369), described in [Relative \(Slip\) Velocity and the Drift Velocity](#) in the [Theory Guide](#).
- Select **none** if the secondary phase has the same velocity as the primary phase (i.e., no slip velocity).
- Select **user-defined** to use a user-defined function for the slip velocity. See the [UDF Manual](#) for details.

26.4.2. Including Cavitation Effects

For mixture model calculations, it is possible to include the effects of cavitation, using ANSYS FLUENT's cavitation models described in [Cavitation Models](#) in the [Theory Guide](#).

To enable the Singhal et al. cavitation model, use the `solve/set/expert` text command and answer yes to use Singhal-et-al cavitation model?. The **Singhal-Et-Al Cavitation Model** option will now be visible in the **Phase Interaction** dialog box, under the **Mass** tab. Enable this option to include the Singhal et al. cavitation model.

You will specify three parameters to be used in the calculation of mass transfer due to cavitation. Set the **Vaporization Pressure**, the **Surface Tension Coefficient**, and the **Non-Condensable Gas Mass Fraction**. The default value of p_{sat} is 3540 Pa, the vaporization pressure for water at ambient temperature.

Note that p_{sat} and the surface tension are properties of the liquid, depending mainly on temperature.

Non-Condensable Gas Mass Fraction is the mass fraction of dissolved gases, which depends on the purity of the liquid.

When multiple species are included in one or more secondary phases, or the heat transfer due to phase change needs to be taken into account, the mass transfer mechanism must be defined *before* activating the cavitation model. It may be noted, however, that for cavitation problems, at least two mass transfer mechanisms are defined:

- mass transfer from liquid to vapor.
- mass transfer from vapor to liquid.

To enable and set up the **Schnerr-Sauer** and **Zwart-Gerber-Belamri** cavitation models, refer to [Including Mass Transfer Effects](#) (p. 1186).

26.4.3. Modeling Compressible Flows

If you are using the mixture model for a compressible flow, note the following:

- Only one of the phases can be defined as a compressible ideal gas (i.e., you can select the ideal gas law for the density of only one phase's material). There is no limitation on using compressible liquids using user-defined functions.
- If you specify the total pressure at a boundary (e.g., for a pressure inlet or intake fan) the specified value for temperature at that boundary will be used as total temperature for the compressible phase, and as static temperature for the other phases (which are incompressible).
- For each mass flow inlet, you will need to specify mass flow or mass flux for each individual phase.

Important

Note that if you read a case file that was set up in a version of ANSYS FLUENT previous to 6.1, you will need to redefine the conditions at the mass flow inlets. See [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#) for more information on defining conditions for a mass flow inlet in mixture multiphase calculations.

See [Compressible Flows \(p. 525\)](#) for more information about compressible flows.

26.5. Setting Up the Eulerian Model

For background information about the Eulerian model and the limitations that apply, refer to [Overview of the Eulerian Model](#) in the Theory Guide.

For additional information, please see the following sections:

- [26.5.1. Additional Guidelines for Eulerian Multiphase Simulations](#)
- [26.5.2. Defining the Phases for the Eulerian Model](#)
- [26.5.3. Setting Time-Dependent Parameters for the Explicit Volume Fraction Scheme](#)
- [26.5.4. Modeling Turbulence](#)
- [26.5.5. Including Heat Transfer Effects](#)
- [26.5.6. Modeling Compressible Flows](#)
- [26.5.7. Including the Dense Discrete Phase Model](#)
- [26.5.8. Including the Boiling Model](#)
- [26.5.9. Including the Multi-Fluid VOF Model](#)

26.5.1. Additional Guidelines for Eulerian Multiphase Simulations

Once you have determined that the Eulerian multiphase model is appropriate for your problem (as described in [Choosing a General Multiphase Model](#) in the Theory Guide), you should consider the computational effort required to solve your multiphase problem. The required computational effort depends strongly on the number of transport equations being solved and the degree of coupling. For the Eulerian multiphase model, which has a large number of highly coupled transport equations, computational expense will be high. Before setting up your problem, try to reduce the problem statement to the simplest form possible.

Instead of trying to solve your multiphase flow in all of its complexity on your first solution attempt, you can start with simple approximations and work your way up to the final form of the problem definition. Some suggestions for simplifying a multiphase flow problem are listed below:

- Use a hexahedral or quadrilateral mesh (instead of a tetrahedral or triangular mesh).
- Reduce the number of phases.

You may find that even a very simple approximation will provide you with useful information about your problem.

See [Eulerian Model \(p. 1288\)](#) for more solution strategies for Eulerian multiphase calculations.

26.5.2. Defining the Phases for the Eulerian Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction for an Eulerian multiphase calculation are provided below.

26.5.2.1. Defining the Primary Phase

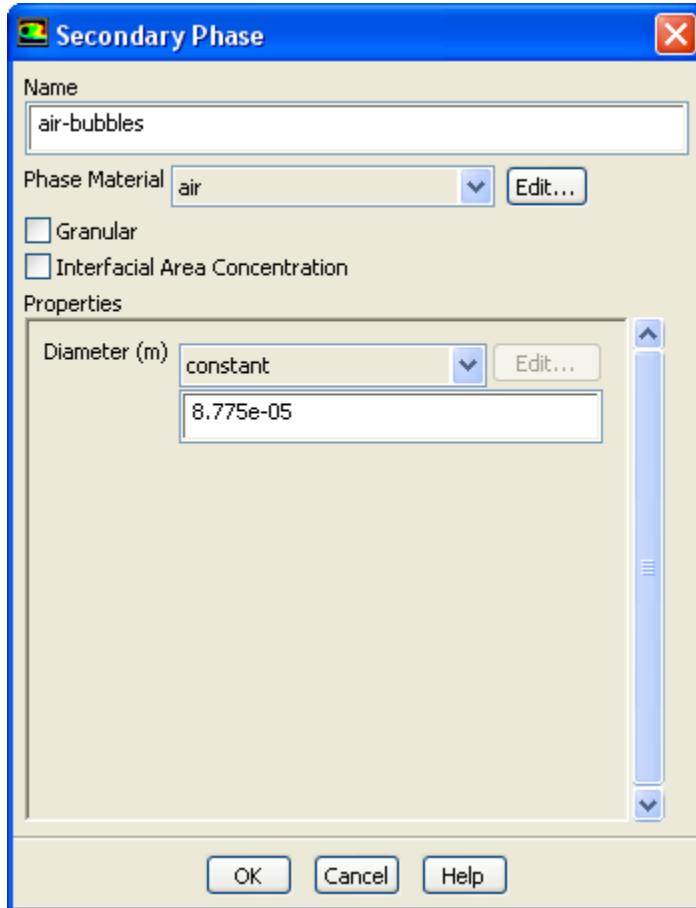

The procedure for defining the primary phase in an Eulerian multiphase calculation is the same as for a VOF calculation. See [Defining the Primary Phase \(p. 1220\)](#) for details.

26.5.2.2. Defining a Nongranular Secondary Phase

To define a nongranular (i.e., liquid or vapor) secondary phase in an Eulerian multiphase calculation, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.33 (p. 1241)*).

Figure 26.33 The Secondary Phase Dialog Box for a Nongranular Phase

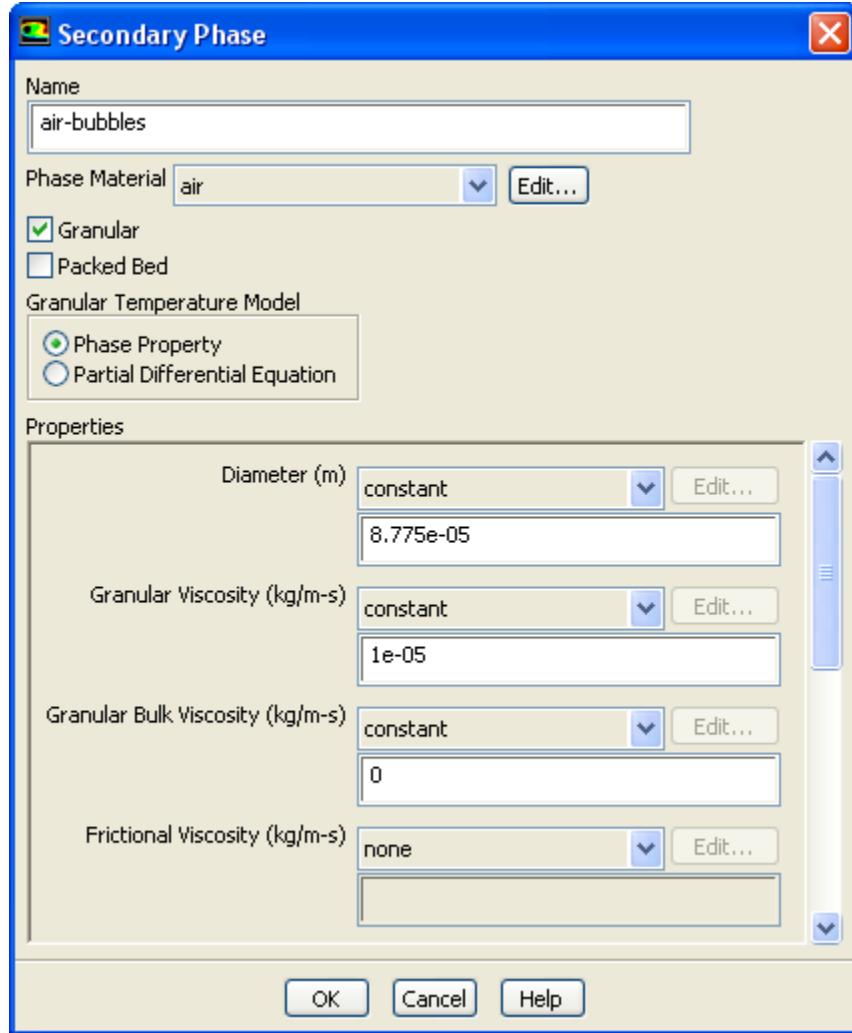

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see [Defining the Primary Phase \(p. 1220\)](#)).
6. In the **Secondary Phase** dialog box, specify the **Diameter** of the bubbles or droplets of this phase. You can specify a constant value, or use a user-defined function. See the [UDF Manual](#) for details about user-defined functions.
7. Click **OK** in the **Secondary Phase** dialog box.

26.5.2.3. Defining a Granular Secondary Phase

To define a granular (i.e., particulate) secondary phase in an Eulerian multiphase calculation, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.34* (p. 1242)).

Figure 26.34 The Secondary Phase Dialog Box for a Granular Phase

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see *Defining the Primary Phase* (p. 1220)). For a granular phase (which must be placed in the fluid materials category, as mentioned in *Steps for Using a Multiphase Model* (p. 1173)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.

Important

Note that all properties for granular flows can utilize user-defined functions (UDFs).

See the [UDF Manual](#) for details about user-defined functions.

6. Enable the **Granular** option.
7. (optional) Enable the **Packed Bed** option if you want to freeze the velocity field for the granular phase. Note that when you select the packed bed option for a phase, you should also use the fixed velocity option with a value of zero for all velocity components for all interior cell zones for that phase. Using fixed velocity in radial direction as a constant value (other than zero) does not ensure continuity. With the fixed velocity option, both velocity and pressure are fixed in a zone. Since face area in the radial direction is a function of radial distance from the axis, it will result in a mass conservation problem due to flux imbalance.

Using zero fixed velocity in the radial direction does not cause any problems related to mass conservation.

8. Specify the **Granular Temperature Model**. Choose either the default **Phase Property** option or the **Partial Differential Equation** option. See [Granular Temperature](#) in the [Theory Guide](#) for details.
9. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

Diameter

specifies the diameter of the particles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the [UDF Manual](#) for details about user-defined functions.

Granular Viscosity

specifies the kinetic part of the granular viscosity of the particles ($\mu_{s,kin}$ in [Equation 17–216](#) in the [Theory Guide](#)). You can select **constant** (the default) in the drop-down list and specify a constant value, select **syamlal-obrien** to compute the value using [Equation 17–218](#) in the [Theory Guide](#), select **gidaspow** to compute the value using [Equation 17–219](#) in the [Theory Guide](#), or select **user-defined** to use a user-defined function.

Granular Bulk Viscosity

specifies the solids bulk viscosity (λ_q in [Equation 17–135](#) in the [Theory Guide](#)). You can select **constant** (the default) in the drop-down list and specify a constant value, select **lun-et-al** to compute the value using [Equation 17–220](#) in the [Theory Guide](#), or select **user-defined** to use a user-defined function.

Frictional Viscosity

specifies a shear viscosity based on the viscous-plastic flow ($\mu_{s,fr}$ in [Equation 17–216](#) in the [Theory Guide](#)). By default, the frictional viscosity is neglected, as indicated by the default selection of **none** in the drop-down list. If you want to include the frictional viscosity, you can select **constant** and specify a constant value, select **schaeffer** to compute the value using [Equation 17–221](#) in the [Theory Guide](#), select **johson-et-al** to compute the value using [Equation 17–226](#) in the [Theory Guide](#), or select **user-defined** to use a user-defined function.

Angle of Internal Friction

specifies a constant value for the angle ϕ used in Schaeffer's expression for frictional viscosity ([Equation 17–221](#) in the [Theory Guide](#)). This parameter is relevant only if you have selected **schaeffer** or **user-defined** for the **Frictional Viscosity**.

Frictional Pressure

specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johson-et-al** to apply [Equation 17–226](#) in the [Theory Guide](#), **syamlal-obrien** to apply [Equation 17–162](#) in the [Theory Guide](#), **based-ktgtf**, where the frictional pressure is defined by the kinetic theory [20] (p. 2368). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You must hook a user-defined function when selecting the **user-defined** option. See the UDF manual for information on hooking a UDF.

Frictional Modulus

is defined as

$$G = \frac{\partial P_{friction}}{\partial \alpha_{friction}} \quad (26-8)$$

with $G \geq 0$, which is the **derived** option. You can also specify a **user-defined** function for the frictional modulus.

Friction Packing Limit

specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5. This is only a general rule of thumb as there may be other factors involved.

Granular Conductivity

specifies the solids granular conductivity ($k_{\mathcal{O}_s}$ in [Equation 17–229](#) in the [Theory Guide](#)). You can select **syamlal-obrien** to compute the value using [Equation 17–230](#) in the [Theory Guide](#), select **gidaspow** to compute the value using [Equation 17–231](#) in the [Theory Guide](#), or select **user-defined** to use a user-defined function. Note that in the algebraic model, shown in [Figure 26.34](#) (p. 1242), the granular conductivity is not required in the computation of the granular temperature. This has been obtained by neglecting convection and diffusion in the transport equation, [Equation 17–229](#) in the [Theory Guide](#) [88] (p. 2371).

Granular Temperature

specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles. Choose either the **algebraic**, the **constant**, or **user-defined** option.

Solids Pressure

specifies the pressure gradient term, ∇p_s , in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, **none**, or a **user-defined** option.

Radial Distribution

specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastoopour**, or a **user-defined** option.

Elasticity Modulus

is defined as

$$G = \frac{\partial P_s}{\partial \alpha_s} \quad (26-9)$$

with $G \geq 0$.

Packing Limit

specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres, the packing limit is about 0.63, which is the default value in ANSYS FLUENT. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

10. Click **OK** in the **Secondary Phase** dialog box.

26.5.2.4. Defining the Interfacial Area Concentration

To define the interfacial area concentration on the secondary phase in the Eulerian model, perform the following steps:

1. Select the phase (e.g., **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the *Secondary Phase Dialog Box* (p. 1931) (*Figure 26.30* (p. 1235)).
3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.
4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.
5. Define the material properties for the **Phase Material**.
6. Enable the **Interfacial Area Concentration** option. Make sure the **Granular** option is disabled for the **Interfacial Area Concentration** option to be visible in the interface.
7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

Diameter

specifies the diameter of the particles or bubbles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the [UDF Manual](#) for details about user-defined functions. The **Diameter** recommended setting is **sauter-mean**, allowing for the effects of the interfacial area concentration values to be considered for mass, momentum and heat transfer across the interface between phases.

Coalescence Kernel and Breakage Kernel

allows you to specify the coalescence and breakage kernels. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim** and **yao-morel** are described in detail in [Interfacial Area Concentration](#) in the [Theory Guide](#).

In addition to specifying the **hibiki-ishii**, **ishii-kim**, and **yao-morel** as the coalescence and breakage kernels, you can also tune the properties of the three models by using the `/define/phases/iac-expert/hibiki-ishii-model`, `/define/phases/iac-expert/ishii-kim-model`, and `/define/phases/iac-expert/yao-morel-model` text commands.

For each of the three models you can specify the parameters listed in [Table 26.10: Parameters for the Coalescence and Breakage Kernels](#) (p. 1245)

Table 26.10 Parameters for the Coalescence and Breakage Kernels

Hibiki-Ishii Model	Ishii-Kim Model	Yao-Morel Model
Coefficient Gamma_c	Coefficient Crc	Coefficient K_c1
Coefficient K_c	Coefficient Cwe	Coefficient K_c3

Hibiki-Ishii Model	Ishii-Kim Model	Yao-Morel Model
Coefficient Gamma_b	Coefficient C	Coefficient K_b1
Coefficient K_b	Coefficient Cti	alpha_max
alpha_max	alpha_max	

These values are discussed in greater detail in [Interfacial Area Concentration](#) in the [Theory Guide](#).

Nucleation Rate

is a source term for the interfacial area concentration which models the rate of formation of the dispersed phase. You can choose from **constant** or **user-defined**. If the **Boiling Model** option is enabled , you can also select **yao-morel**. The **yao-morel** option is described in [Yao-Morel Model](#) in the [Theory Guide](#).

Critical Weber Number

will need to be specified if you selected **ishii-kim** or **yao-morel** for the **Breakage Kernel**.

Dissipation Function

gives you the option to choose the formula which calculates the dissipation rate used in the **hibiki-
ishii** and **ishii-kim** models. You can choose amongst **constant**, **wu-
ishii-kim**, **fluent-ke**, and **user-
defined** for the dissipation function.

The **wu-
ishii-kim** option uses a simple algebraic correlation for ε :

$$\varepsilon = f_{TW} (1/2D_h) v_m^3 \quad (26-10)$$

where

$$f_{TW} = \frac{0.316}{[(1 - \alpha) Re_m]^{0.25}}$$

and

$$Re_m = \frac{\rho_m v_m D_h}{\mu_m}$$

where ρ_m , v_m , μ_m , and D_h are the mixture density, mixture velocity, mixture molecular viscosity, and hydraulic diameter of the flow path.

When you select the **wu-
ishii-kim** model, you will set an additional input for **Hydraulic Dia-
meter**.

Hydraulic Diameter

is the value used in [Equation 26-10](#) (p. 1246), should you use the **wu-
ishii-kim** formulation.

Min/Max Diameter

allow you to specify the minimum and maximum diameters of the secondary phase to which the interfacial area concentration model is applied, preventing some computing anomalies to spread beyond control.

Note

When solving a steady state problem, the preferred setting for the **Under-Relaxation Factor** is 1.0, as the interfacial area equation for the boiling models is currently under-relaxed using a locally defined pseudo-time step. If you want extra explicit under-relaxation, you may set the value of the **Under-Relaxation Factor** to less than one, this may be done only in case of serious convergence problems with the interfacial area transport equation. To improve convergence you can switch to a pseudo-time step for the interfacial area concentration only, using the **define/phases/iac-expert/iac-pseudo-time-step** text command and set the local pseudo-time to less than 1.

26.5.2.5. Defining the Interaction Between Phases

For both granular and nongranular flows, you will need to specify the drag function to be used in the calculation of the momentum exchange coefficients. For granular flows, you will also need to specify the restitution coefficient(s) for particle collisions. It is also possible to include an optional lift force and/or virtual mass force (described below) for both granular and nongranular flows.

To specify these parameters, click **Interaction...** to open the *Phase Interaction Dialog Box* (p. 1937) and visit the **Drag**, **Collisions**, and **Lift** tabs.

 **Phases** → **Interaction...**

26.5.2.5.1. Specifying the Drag Function

ANSYS FLUENT allows you to specify a drag function for each pair of phases. Perform the following steps:

1. Click the **Drag** tab.
2. For each pair of phases, select the appropriate drag function from the corresponding drop-down list.
 - Select **boiling-ishii** to use the fluid-fluid drag function described by [Equation 17–302](#) in the [Theory Guide](#). This option is available when the boiling model is enabled.
 - Select **schiller-naumann** to use the fluid-fluid drag function described by [Equation 17–147](#) in the [Theory Guide](#). The Schiller and Naumann model is the default method, and it is acceptable for general use in all fluid-fluid multiphase calculations.
 - Select **morsi-alexander** to use the fluid-fluid drag function described by [Equation 17–151](#) in the [Theory Guide](#). The Morsi and Alexander model is the most complete, adjusting the function definition frequently over a large range of Reynolds numbers, but calculations with this model may be less stable than with the other models.
 - Select **symmetric** to use the fluid-fluid drag function described by [Equation 17–157](#) in the [Theory Guide](#). The symmetric model is recommended for flows in which the secondary (dispersed) phase in one region of the domain becomes the primary (continuous) phase in another. For example, if air is injected into the bottom of a container filled halfway with water, the air is the dispersed phase in the bottom half of the container; in the top half of the container, the air is the continuous phase. The **symmetric** drag law is the default method for the **Multi-Fluid VOF Model**, which is available with Eulerian multiphase model.
 - Select **anisotropic** to use the fluid-fluid drag function described in [Multi-Fluid VOF Model](#) in the [Theory Guide](#). The **anisotropic** drag law is recommended for free surface modeling. It is based on

higher drag in the normal direction to the interface and lower drag in the tangential direction to the interface.

- Select **universal-drag** for bubble-liquid and/or droplet-gas flow when the characteristic length of the flow domain is much greater than the averaged size of the particles. The universal drag law is described using [Equation 17-180](#) in the [Theory Guide](#). When **universal-drag** is selected, you will need to set a value for the surface tension coefficient, under the **Surface Tension** tab, in the **Phase Interaction** dialog box. This value will apply to the primary phase and the secondary phase.
- Select **wen-yu** to use the fluid-solid drag function described by [Equation 17-171](#) in the [Theory Guide](#). The Wen and Yu model is applicable for dilute phase flows, in which the total secondary phase volume fraction is significantly lower than that of the primary phase.
- Select **gidaspow** to use the fluid-solid drag function described by [Equation 17-173](#) in the [Theory Guide](#). The Gidaspow model is recommended for dense fluidized beds.
- Select **syamlal-obrien** to use the fluid-solid drag function described by [Equation 17-163](#) in the [Theory Guide](#). The Syamlal-O'Brien model is recommended for use in conjunction with the Syamlal-O'Brien model for granular viscosity.
- Select **syamlal-obrien-symmetric** to use the solid-solid drag function described by [Equation 17-179](#) in the [Theory Guide](#). The symmetric Syamlal-O'Brien model is appropriate for a pair of solid phases.
- Select **huilin-gidaspow** to use the fluid-solid drag function described by [Equation 17-175](#) in the [Theory Guide](#). This option provides a better blending function for the Gidaspow model when moving from the dense packing limit to the dilute flow limit.
- Select **gibilaro** to use the fluid-solid drag function described by [Equation 17-177](#) in the [Theory Guide](#). This option is used for circulating fluidized beds
- Select **constant** to specify a constant value for the drag function, and then specify the value in the text field.
- Select **user-defined** to use a user-defined function for the drag function (see the [UDF Manual](#) for details).
- If you want to temporarily ignore the interaction between two phases, select **none**.

26.5.2.5.2. Specifying the Restitution Coefficients (Granular Flow Only)

For granular flows, you need to specify the coefficients of restitution for collisions between particles (e_{ls} in [Equation 17-179](#) and e_{ss} in [Equation 17-199](#) in the [Theory Guide](#)). In addition to specifying the restitution coefficient for collisions between each pair of granular phases, you will also specify the restitution coefficient for collisions between particles of the same phase.

Perform the following steps:

1. Click the **Collisions** tab to display the **Restitution Coefficient** inputs.
2. For each pair of phases, specify a constant restitution coefficient. All restitution coefficients are equal to 0.9 by default.

26.5.2.6. Including the Lift Force

For both granular and nongranular flows, it is possible to include the effect of lift forces (\vec{F}_{lift} in [Equation 17-137](#) in the [Theory Guide](#)) on the secondary phase particles, droplets, or bubbles. These lift forces act on a particle, droplet, or bubble mainly due to velocity gradients in the primary-phase flow field. In most cases, the lift force is insignificant compared to the drag force, so there is no reason to

include it. If the lift force is significant (e.g., if the phases separate quickly), you may want to include this effect.

Important

Note that the lift force will be more significant for larger particles, but the ANSYS FLUENT model assumes that the particle diameter is much smaller than the interparticle spacing. Thus, the inclusion of lift forces is not appropriate for closely packed particles or for very small particles.

To include the effect of lift forces, perform the following steps:

1. Click the **Lift** tab to display the **Lift Coefficient** inputs.
2. For each pair of phases, select the appropriate specification method from the corresponding drop-down list. Note that, since the lift forces for a particle, droplet, or bubble are due mainly to velocity gradients in the primary-phase flow field, you will not specify lift coefficients for pairs consisting of two secondary phases; lift coefficients are specified only for pairs consisting of a secondary phase and the primary phase.
 - Select **boiling-moraga** if you have the boiling model option enabled in the **Multiphase Model** dialog box. Information about this option is found in [Interfacial Lift Force](#) in the [Theory Guide](#).
 - Select **boiling-tomiyama-et-al** if you have the boiling model option enabled in the **Multiphase Model** dialog box. Information about this option is found in [Interfacial Lift Force](#) in the [Theory Guide](#).
 - Select **none** (the default) to ignore the effect of lift forces.
 - Select **constant** to specify a constant lift coefficient, and then specify the value in the text field.
 - Select **user-defined** to use a user-defined function for the lift coefficient (see the [UDF Manual](#) for details).

26.5.2.7. Including Surface Tension and Wall Adhesion Effects

As discussed in [When Surface Tension Effects Are Important](#) in the [Theory Guide](#), the importance of surface tension effects depends on the value of the capillary number, Ca (defined by [Equation 17-31](#) in the [Theory Guide](#)), or the Weber number, We (defined by [Equation 17-32](#) in the [Theory Guide](#)). Surface tension effects can be neglected if $Ca \gg 1$ or $We \gg 1$.

Important

Note that the calculation of surface tension effects will be more accurate if you use a quadrilateral or hexahedral mesh in the area(s) of the computational domain where surface tension is significant. If you cannot use a quadrilateral or hexahedral mesh for the entire domain, then you should use a hybrid mesh, with quadrilaterals or hexahedra in the affected areas. ANSYS FLUENT also offers an option to use VOF gradients at the nodes for curvature calculations on meshes when more accuracy is desired. For more information, see [Surface Tension and Adhesion](#) in the [Theory Guide](#).

If you want to include the effects of surface tension along the interface between one or more pairs of phases, as described in [Surface Tension and Adhesion](#) in the [Theory Guide](#), please refer to [Including Surface Tension and Adhesion Effects](#) (p. 1221).

26.5.2.7.1. Including the Virtual Mass Force

For both granular and nongranular flows, it is possible to include the “virtual mass force” (\vec{F}_{vm} in [Equation 17–138](#) in the **Theory Guide**) that is present when a secondary phase accelerates relative to the primary phase. The virtual mass effect is significant when the secondary phase density is much smaller than the primary phase density (e.g., for a transient bubble column).

To include the effect of the virtual mass force, turn on the **Virtual Mass** option in the **Phase Interaction** dialog box. The virtual mass effect will be included for all secondary phases; it is not possible to enable it just for a particular phase.

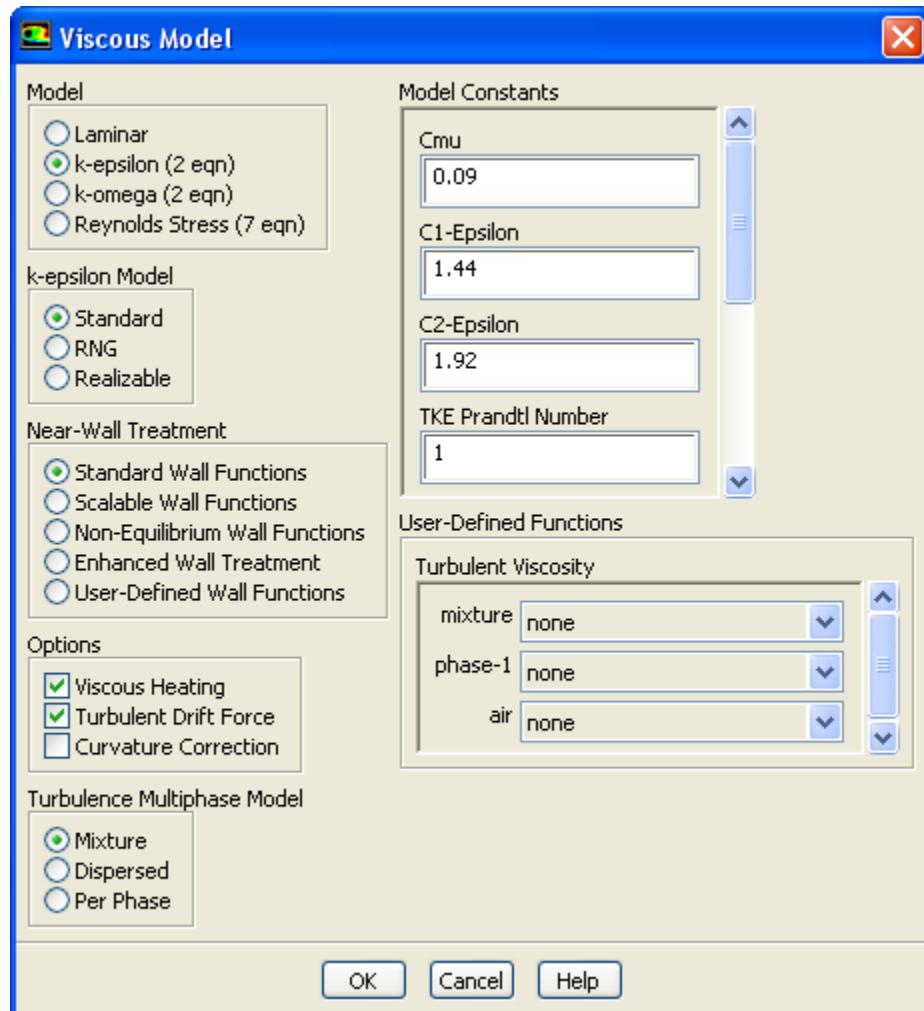

26.5.3. Setting Time-Dependent Parameters for the Explicit Volume Fraction Scheme

If you are using the time-dependent volume fraction formulation in ANSYS FLUENT, an explicit solution for the volume fraction is obtained either once each time step or once each iteration, depending upon your inputs to the model. By default, ANSYS FLUENT will solve the volume fraction equation(s) once for each time step, except for the first time step. This means that the convective flux coefficients appearing in the other transport equations will not be completely updated each iteration, since the volume fraction fields will not change from iteration to iteration.

This formulation also applies to the VOF model, and is discussed in greater detail in [Setting Time-Dependent Parameters for the VOF Model](#) (p. 1228).

26.5.4. Modeling Turbulence

If you are using the Eulerian model to solve a turbulent flow, you will need to choose one of turbulence models described in [Turbulence Models](#) in the **Theory Guide** in the [Viscous Model Dialog Box](#) (p. 1778) ([Figure 26.35](#) (p. 1251)).

Figure 26.35 The Viscous Model Dialog Box for an Eulerian Multiphase Calculation

The procedure is as follows:

1. Select **k-epsilon**, **k-omega**, or **Reynolds Stress** under **Model**.
2. Select the desired **k-epsilon Model**, **k-omega Model**, or **Reynolds-Stress Model** and any other related parameters, as described for single-phase calculations in *Steps in Using a Turbulence Model* (p. 696).
3. Under **Turbulence Multiphase Model** or **RSM Multiphase Model**, indicate the desired multiphase turbulence model (see *Turbulence Models* in the *Theory Guide* for details about each):
 - Select **Mixture** to use the mixture turbulence model. This is the default model.
 - Select **Dispersed** to use the dispersed turbulence model. This model is applicable when there is clearly one primary continuous phase and the rest are dispersed dilute secondary phases.
 - Select **Per Phase** to use a $k-\varepsilon$ or $k-\omega$ turbulence model for each phase. This model is appropriate when the turbulence transfer among the phases plays a dominant role.

You can include the effect of drift velocity by enabling **Turbulent Drift Force** under **Options**.

Important

This option is only available if either the **Eulerian** multiphase model is selected, or the **Mixture** model with **Slip Velocity** is enabled in the **Multiphase Model** dialog box.

However, you can also allow for drift velocity by performing the following:

1. If it is not already done, set the **Turbulence Multiphase Model** to **Mixture, Dispersed**, or **Per Phase** in the **Viscous Model** dialog box.
2. Enter the `multiphase-options` text command in the console.

```
define → models → viscous → multiphase-turbulence → multiphase-options  
/define/models/viscous/multiphase-turbulence> multiphase-options  
Enable dispersion force in momentum? [no] yes  
Enable interphase turbulence source? [no] yes
```

The effect of the drift velocity is influenced both by the momentum equation and, to a lesser extent, the turbulence equation. Therefore, you should answer **yes** to both questions to take into account the effect of drift velocity.

Important

Anisotropic drag applicable to free surface modeling is only compatible with the **Mixture** turbulence model.

26.5.4.1. Including Source Terms

By default, the interphase momentum, k , and ε sources are not included in the calculation. If you want to include any of these source terms, you can enable them using the `multiphase-options` command in the `define/models/viscous/multiphase-turbulence/` text menu. Note that the inclusion of these terms can slow down convergence noticeably. If you are looking for additional accuracy, you may want to compute a solution first without these sources, and then continue the calculation with these terms included. In most cases these terms can be neglected.

26.5.4.2. Customizing the k - ε Multiphase Turbulent Viscosity

If you are using the k - ε multiphase turbulence model, a user-defined function can be used to customize the turbulent viscosity for each phase. This option will enable you to modify μ_t in the k - ε model. For more information, see the [UDF Manual](#).

In the **Viscous Model** dialog box, under **User-Defined Functions**, select the appropriate user-defined function in the **Turbulent Viscosity** drop-down list.

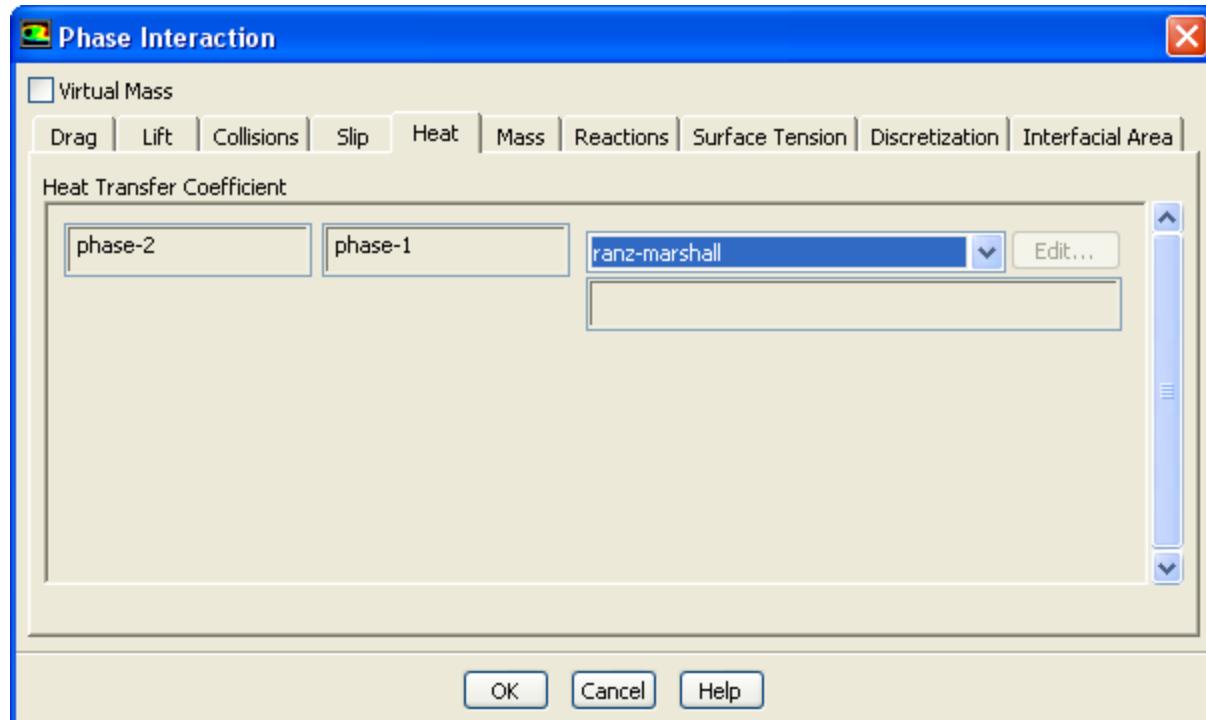

26.5.5. Including Heat Transfer Effects

To define heat transfer in a multiphase Eulerian simulation, you will need to visit the **Phase Interaction** dialog box, after you have enabled the energy equation in the **Energy** dialog box.

◀ Phases → Interaction...

1. Click the **Interaction...** button to open the **Phase Interaction** dialog box (e.g., *Figure 26.36 (p. 1253)*).

Figure 26.36 The Phase Interaction Dialog Box for Heat Transfer

2. Click on the **Heat** tab in the **Phase Interaction** dialog box.
3. Select the desired correlation for the **Heat Transfer Coefficient**. Note the following regarding the available choices:
 - gunn**
is frequently used for Eulerian multiphase simulations involving a granular phase.
 - ranz-marshall**
is frequently used for Eulerian multiphase simulations not involving a granular phase.
 - none**
allows you to ignore the effects of heat transfer between the two phases
 - user-defined**
allows you to implement a correlation reflecting a model of your choice, through a user-defined function.
4. Set the appropriate thermal boundary conditions. You will specify the thermal boundary conditions for each individual phase on most boundaries, and for the mixture on some boundaries. See *Cell Zone and Boundary Conditions (p. 211)* for more information on boundary conditions, and *Eulerian Model (p. 1193)* for more information on specifying boundary conditions for a Eulerian multiphase calculation.

See *Description of Heat Transfer* in the *Theory Guide* for more information on heat transfer in the framework of a Eulerian multiphase simulation.

26.5.6. Modeling Compressible Flows

You can model compressible multiphase flows, and can use it in conjunction with the energy multiphase equations and available multiphase turbulence models. When using the Eulerian multiphase model for a compressible flow, note the following:

- While you can specify both compressible gas phases and compressible liquid phases, you can only define one of the phases as a compressible ideal gas (i.e., you can select the **ideal-gas** for the density in the **Create/Edit Materials** dialog box of only one phase's material). There is no limitation on using compressible liquids using user-defined functions.
- You can define only one compressible fluid phase.
- For each mass flow inlet, you will need to specify mass flow or mass flux for each individual phase.
- If you specify the total pressure at a boundary (e.g., for a pressure inlet or intake fan), ANSYS FLUENT will use the specified value for temperature at that boundary as total temperature for the compressible phase, and as static temperature for the other phases (which are incompressible).

Important

Note that if you read a case file that was set up in a version of ANSYS FLUENT previous to 6.1, you will need to redefine the conditions at the mass flow inlets. See [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#) for more information on defining conditions for a mass flow inlet in Eulerian multiphase calculations.

See [Compressible Flows \(p. 525\)](#) for more information about compressible flows.

26.5.7. Including the Dense Discrete Phase Model

If you are using the Eulerian multiphase model ([Setting Up the Eulerian Model \(p. 1240\)](#)), you have the option of including the **Dense Discrete Phase Model** (Dense Discrete Phase Model in the Theory Guide).

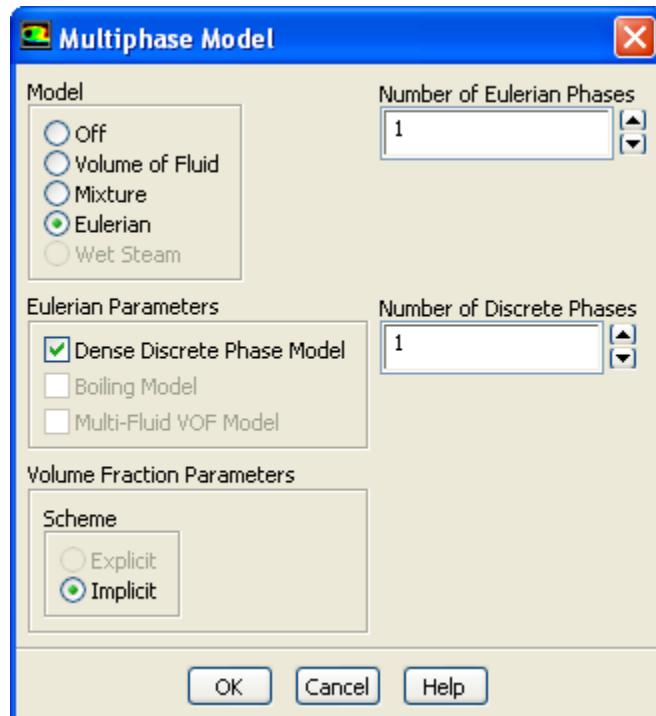

Important

- This model is only available with the **Eulerian** multiphase model.
- Enabling this model automatically enables the DPM model. You will notice that **Interaction with Continuous Phase** in the **Discrete Phase Model** dialog box is enabled.

The required work flow when using the dense discrete phase model is as follows:

1. Set up the **Multiphase Model** dialog box ([Figure 26.37 \(p. 1255\)](#)) to include the dense discrete phase model parameters.

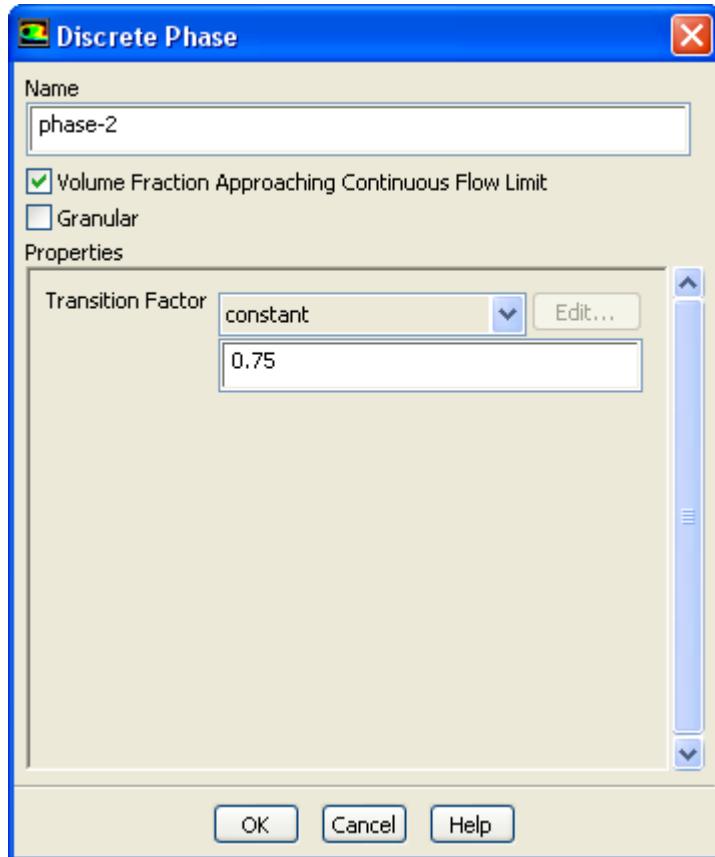

Figure 26.37 The Dense Discrete Phase Model

- a. Enable **Dense Discrete Phase Model** under **Eulerian Parameters**.
- b. Set the **Number of Discrete Phases** that are present in your case.
2. Open the **Phases** task page, in order to define the phases.

◆ Phases

- a. Define the discrete phase, by selecting the phase from the **Phases** selection list that is labeled **Discrete Phase** and clicking the **Edit...** button. Then set up the properties in the **Discrete Phase** dialog box that opens, as shown in [Figure 26.38 \(p. 1256\)](#).

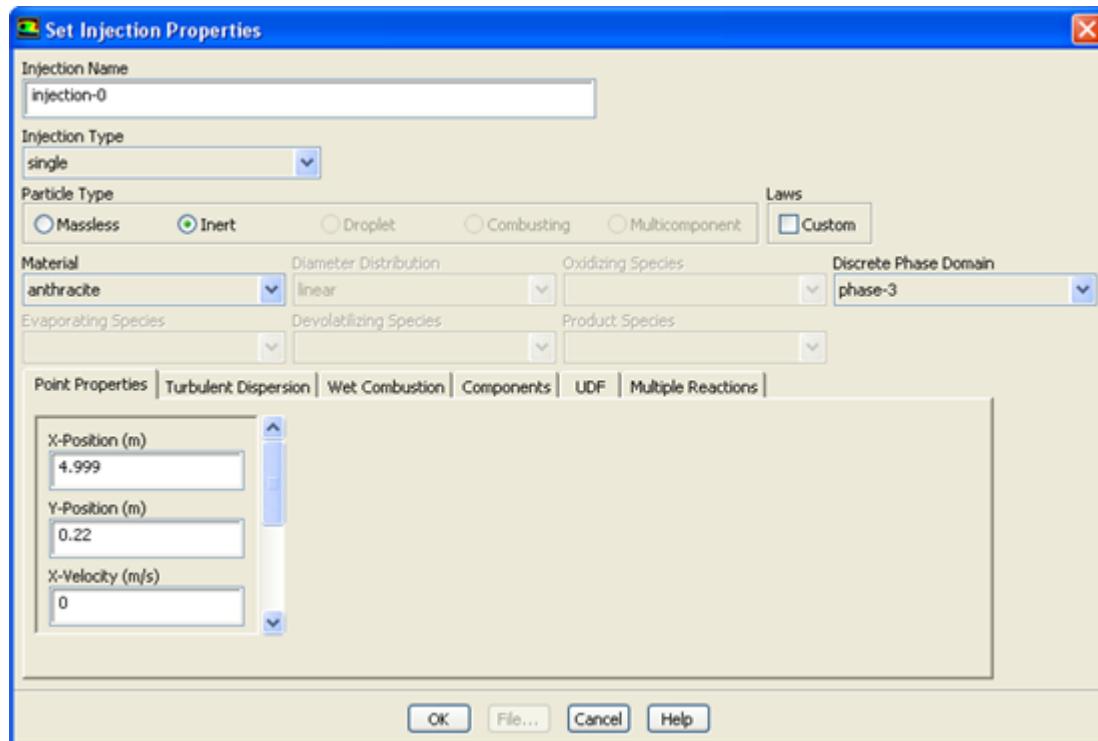

Figure 26.38 The Discrete Phase Dialog Box

Note that for nongranular flow, no additional inputs are required here (since the material is set automatically in the background, and the diameter is part of the solution).

- b. Enable **Volume Fraction Approaching Continuous Flow Limit** to specify a **Transition Factor**. The default value is assumed to be 0.75, which corresponds to the closest sphere packing for monosized spheres (a factor of $4/3$). The transition volume fraction here will be 0.5625 ($0.75 * 4/3$). Note that this factor is not limited to a range between 0 and 1. In other words, you can specify values outside this range. For example, a value of 1.2 will give a transition volume fraction of 0.9. You can also specify locally variable values using the **DEFINE_PROPERTY** user-defined macro, depending on the local particle size distribution, as an example.
- See **DEFINE_PROPERTY UDFs** in the **UDF Manual** for information about the **DEFINE_PROPERTY**.
- c. Define the primary and secondary phases, as described in *Defining the Phases for the Eulerian Model* (p. 1240).
3. Define the injections using the **Injections** dialog box.

Define → Injections...

- a. Create a new injection by clicking the **Create** button in the **Injections** dialog box, or edit an existing injection by selecting the injection from the **Injections** list and clicking the **Set...** button. The **Set Injection Properties** dialog box will open (*Figure 26.39* (p. 1257)).

Figure 26.39 The Set Injection Properties Dialog Box

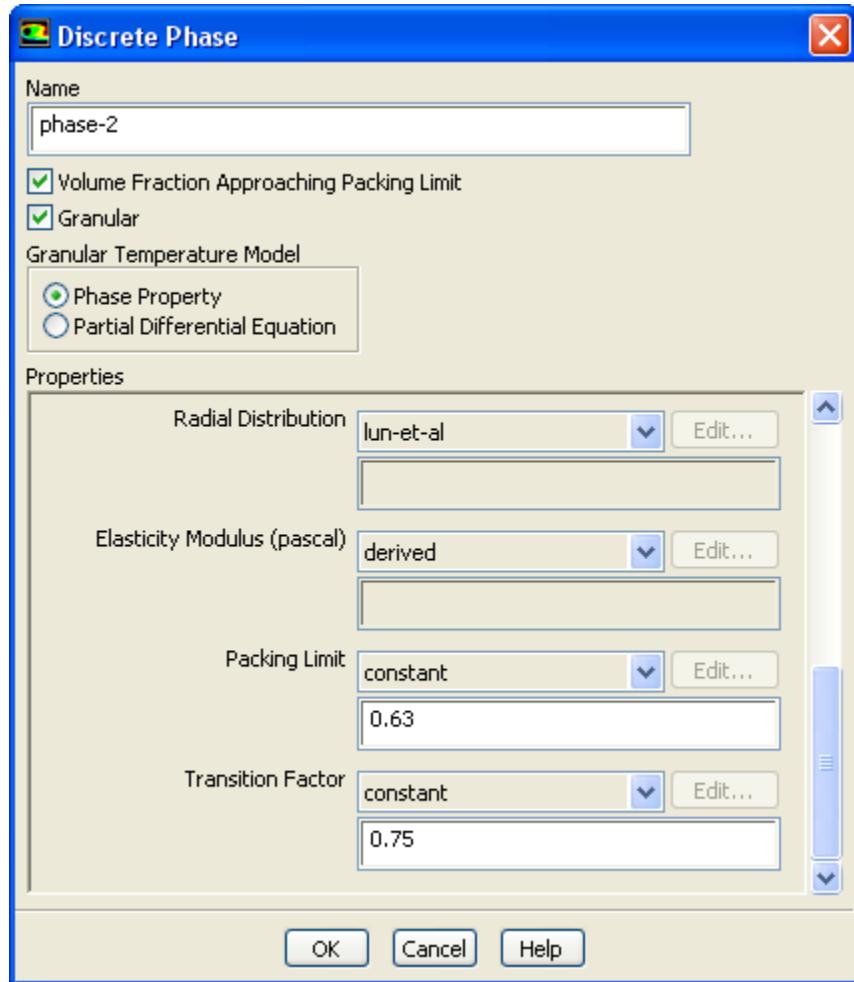

- b. Select the discrete phase from the **Discrete Phase Domain** drop-down list.
4. Define the material properties for each injection.

Materials

26.5.7.1. Defining a Granular Discrete Phase

To define a granular (i.e., particulate) discrete phase in an Eulerian multiphase calculation, perform the following steps:

1. Select the phase (e.g., **Discrete Phase**) in the **Phases** list.
2. Click **Edit...** to open the **Discrete Phase** dialog box (*Figure 26.40* (p. 1258)).

Figure 26.40 The Discrete Phase Dialog Box for a Granular Phase

3. In the **Discrete Phase** dialog box, enter a **Name** for the phase.
4. Enable the **Granular** option.
5. Enable **Volume Fraction Approaching Packing Limit** to prevent the unlimited accumulation of particles, which are operating at packing limit conditions.
6. Specify the **Transition Factor** as either a **constant** or a **user-defined** function. The default value for the **Transition Factor** is 0.75. The transition criterion is based on the local particle volume fraction of the given discrete phase and is specified as a factor multiplied by the maximum packing limit (also a user specified value). In other words, For a typical granular phase with a maximum packing limit of 0.63, the transition volume fraction is the product of 0.75 and 0.63 which is equal to 0.4725.

You can now define all other fields of the discrete phase in a similar manner to that described in [Defining a Granular Secondary Phase \(p. 1242\)](#).

26.5.8. Including the Boiling Model

If you are using the Eulerian multiphase model ([Setting Up the Eulerian Model \(p. 1240\)](#)), you have the option of including the **Boiling Model** (see [Wall Boiling Models](#) in the Theory Guide).

Important

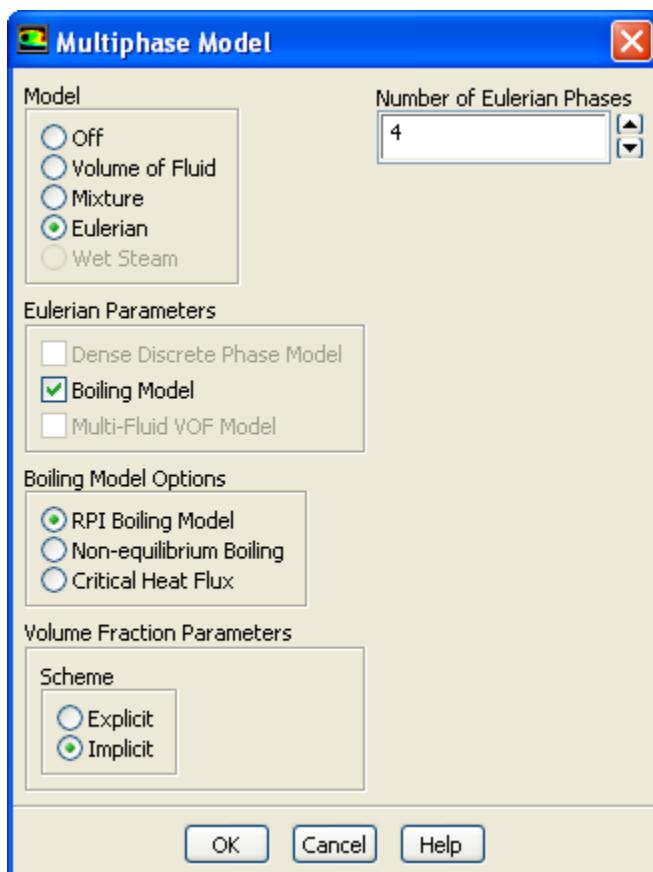

- This model is only available with the **Eulerian** multiphase model.
- This model is only available with the **Pressure-Based** solver.

The required work flow when using the boiling model is as follows:

1. Open the **Multiphase Model** dialog box (*Figure 26.41* (p. 1259)).

↳ **Models** → **Multiphase** → **Edit...**

Figure 26.41 The Boiling Model

- a. Enable **Boiling Model** under **Eulerian Parameters**.
 - b. Select **RPI Boiling Model**, **Non-equilibrium Boiling**, or **Critical Heat Flux** as the boiling model option. Information about the three options is available in [RPI Model](#), [Non-equilibrium Subcooled Boiling](#), and [Critical Heat Flux](#) in the [Theory Guide](#).
 - c. Set the total **Number of Eulerian Phases** that are present in your case. This can consist of two phases: liquid and vapor, which are directly involved in boiling mass transfer; or it can include "non-boiling phases" or "species". If a system consists of three phases: liquid, vapor, and air, then the **Number of Eulerian Phases** will be 3, where air is the non-boiling phase.
2. Make sure the energy option is enabled.

Note

The energy option will be automatically turned on when the boiling model is enabled.

3. Enable **Gravity** and set the **Operating Pressure** in the **Operating Conditions** dialog box.
-

Important

Make sure gravity is included when the boiling model is used.

4. Choose one of the turbulence models that is available with the Eulerian multiphase model and enable **Turbulent Drift Force**.

**Important**

The turbulent drift force is an important force in the boiling model and should generally be included.

5. Open the **Create/Edit Materials** dialog box and specify the material properties for the liquid, vapor, solid, and any other phases that may exist.

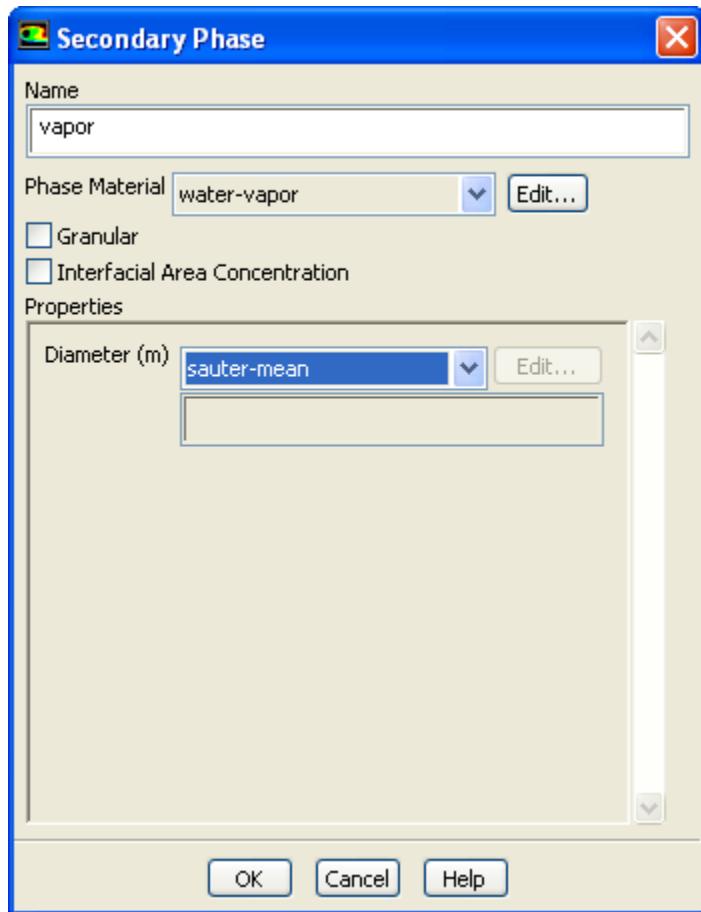

**Important**

For the liquid and vapor phases, the **Standard State Enthalpy** must be specified, as it is used in the computation of the **Latent Heat**.

6. Open the **Phases** task page, in order to define the phases.

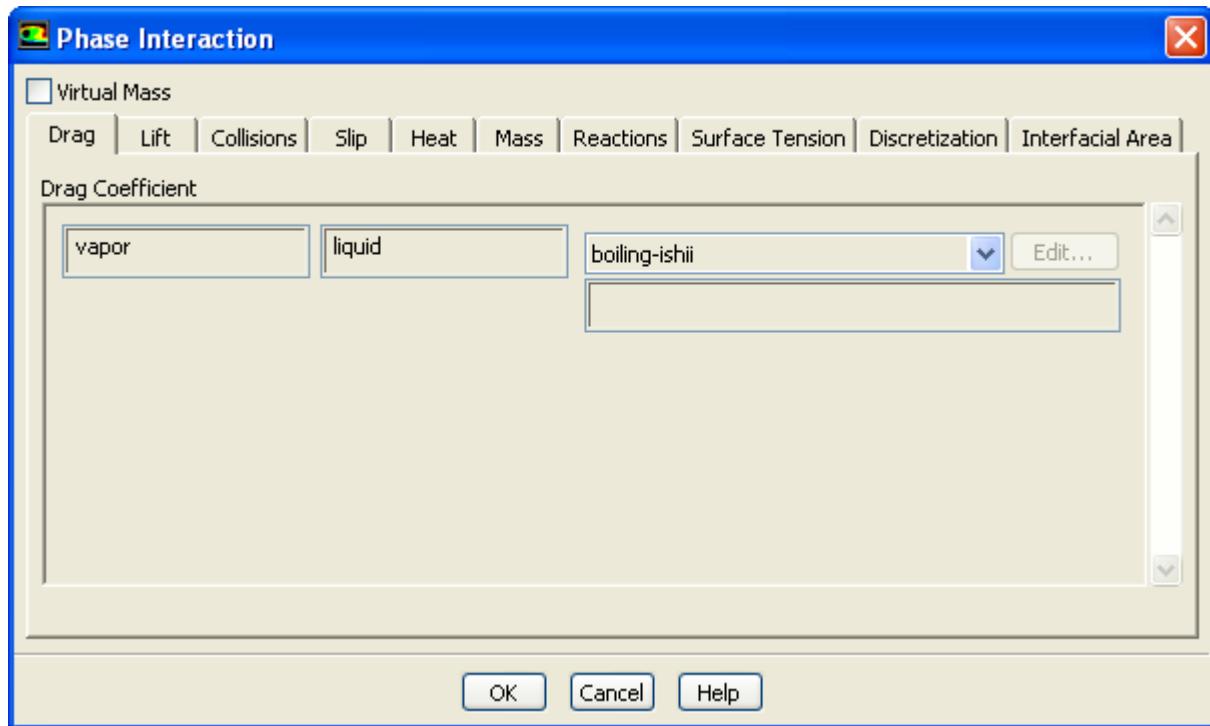

Define the liquid as the primary phase by selecting the phase from the **Phases** selection list that is labeled **Primary Phase** and clicking the **Edit...** button. Define the vapor as the secondary phase. In the **Secondary Phase** dialog box, the **Diameter** is set to **sauter-mean** by default, but you have the option of setting it up as a **constant** value or a **user-defined** function, as shown in [Figure 26.42 \(p. 1261\)](#).

Figure 26.42 The Secondary Phase Dialog Box

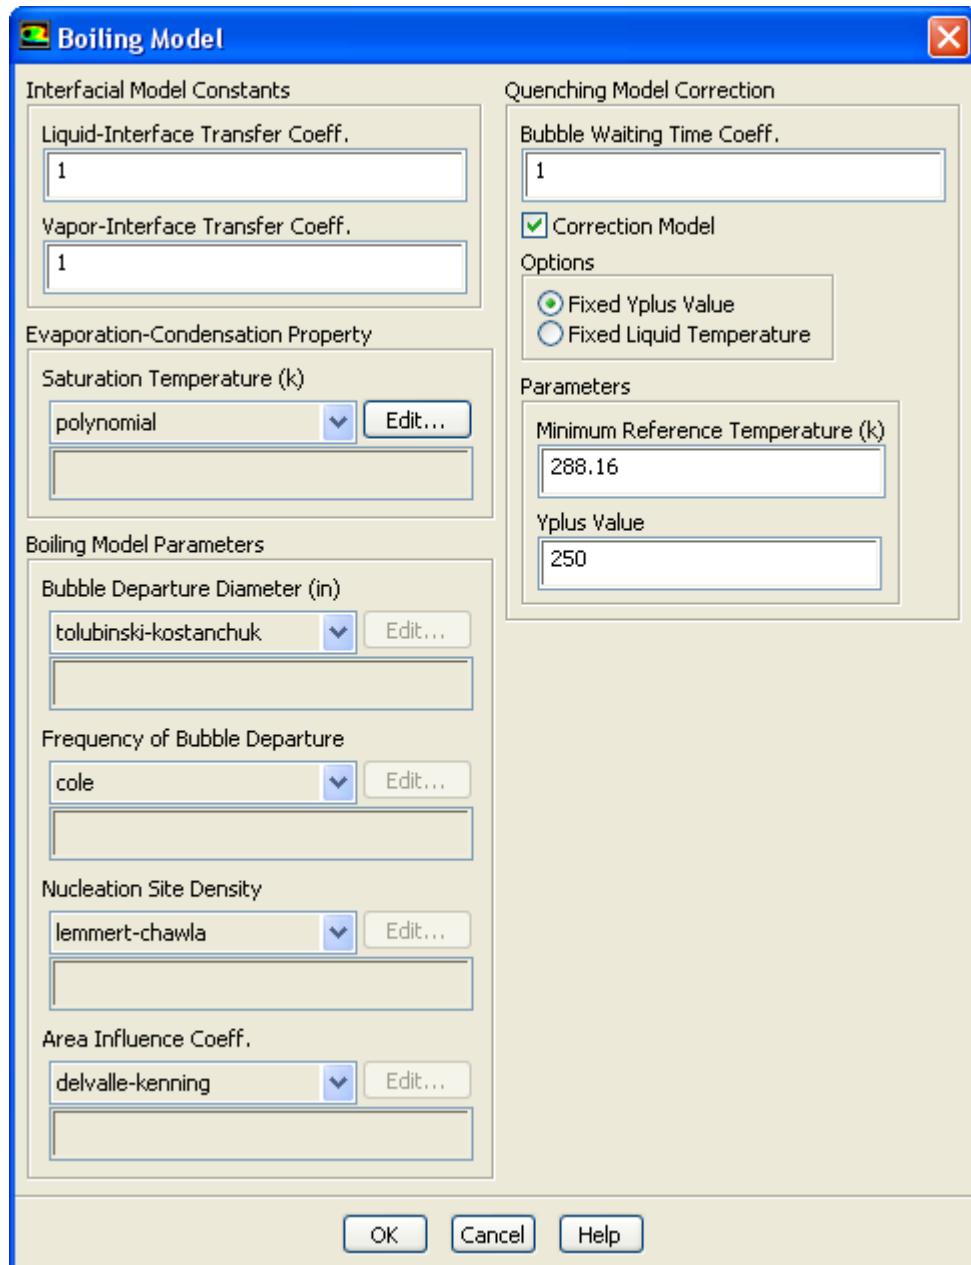

7. Open the **Phase Interaction** dialog box.

◆ Phases → Liquid → Interaction...

- In the **Drag** tab, you have a choice of **boiling-ishii**, **universal-drag**, **schiller-naumann**, **symmetric**, **morsi-alexander**, or **user-defined**. See *Specifying the Drag Function* (p. 1247) for definitions of the drag options.

Figure 26.43 The Phase Interaction Dialog Box

- b. In the **Lift** tab, select **boiling-moraga**, **boiling-tomiyama-et-al**, or **user-defined**.
- c. In the **Heat** tab, select **ranz-marshall** or **user-defined**.
- d. In the **Surface Tension** tab, select **constant** and enter the desired value.
- e. In the **Interfacial Area** tab, you have four formulations available from which to select:
 - **ia-symmetric** (default) (see [Equation 17-319 in the Theory Guide](#))
 - **ia-particle** (see [Equation 17-318 in the Theory Guide](#))
 - **ia-ishii** (see [Equation 17-320 in the Theory Guide](#))
 - **user-defined** (see [Example 3 - Custom Interfacial Area in the UDF Manual](#))
- f. In the **Mass** tab, set the **Number of Mass Transfer Mechanisms** to 1 and make sure the transfer is always from the liquid to the vapor phase. Select **boiling** under **Mechanism**. The **Boiling Model** dialog box will open ([Figure 26.44 \(p. 1263\)](#)), where you will set the boiling model parameters and the quenching model corrections.

Figure 26.44 The Boiling Model Dialog Box

- i. Specify the **Interfacial Model Constants** and the **Saturation Temperature**. The default values for the liquid and vapor interface transfer coefficients are 1.

Note

If you selected the **RPI Boiling Model** in the **Multiphase Model** dialog box, then you will not need to specify the **Vapor-Interface Transfer Coeff.**, since the vapor phase temperature is fixed to the saturation temperature.

- ii. Under the **Boiling Model Parameters**, select the **Bubble Departure Diameter** that best describes your model. Five options exist: **tolubinski-kostanchuk** (the default setting), **unal**, **kocamustafaogullari-ishii**, **constant**, and **user-defined**. The **tolubinski-kostanchuk** formulation is described in [Equation 17–304](#) in the **Theory Guide**, the **unal** formulation is described

in [Equation 17–306](#) in the [Theory Guide](#) and the **kocamustafaogullari-Ishii** formulation is described in [Equation 17–302](#) in the [Theory Guide](#).

- iii. Specify the **Frequency of Bubble Departure**. You can choose the **cole** option (which is the default), or enter a **constant** value. The **cole** formulation is described in [Equation 17–300](#) in the [Theory Guide](#).
- iv. Specify the **Nucleation Site Density**. You can choose between **lemmert-chawla** (which is the default), **kocamustafaogullari-ishii**, and **user-defined**. This quantity is usually represented by a correlation based on the wall superheat, described in [Equation 17–301](#) in the [Theory Guide](#).

Note

It is recommended that when using the **kocamustafaogullari-ishii** option, it should be used for both the **Bubble Departure Diameter** and **Nucleation Site Density**.

- v. Specify the **Area Influence Coeff**. The area of influence is based on the bubble departure diameter and the nucleate site density, as defined in [Equation 17–297](#) in the [Theory Guide](#). You have a choice of three options when modeling the area of influence coefficient: **delvalle-k彭ning** (which is the default and defined in [Equation 17–298](#) in the [Theory Guide](#)), **constant**, and **user-defined**.
- vi. The **Quenching Correction Model** addresses the quenching term in the wall heat flux partition (described in [Wall Heat Flux Partition](#) in the [Theory Guide](#)). The quenching term in the wall heat flux partition models the cyclic averaged transient energy transfer related to liquid filling the wall vicinity after the bubble detachment with a period T and it is expressed as:

$$\dot{q}_q = C_{wt} \frac{2k_l}{\sqrt{\pi\gamma_l T}} (T_w - T_l) A_b \quad (26-11)$$

where k_l is the liquid heat conductivity, T is the periodic time, and $\gamma_l = k_l / (\rho_l c_{pl})$ is the liquid phase diffusivity. The **Bubble Waiting Time Coefficient**, C_{wt} , is a coefficient introduced to correct the waiting time between departures of consecutive bubbles. The default value is 1, however you can modify this value as needed, but it can only be specified as a constant.

From [Equation 26–11 \(p. 1264\)](#), you can see that the quenching model is strongly dependent on T_l , which results in grid-dependent solutions. To remedy this, two approaches have been adopted in ANSYS FLUENT: **Fixed Yplus Value** and **Fixed Liquid Temperature**.

- vii. Enable the **Correction Model** if you want to achieve a certain level of grid-independence in your solution. If this option is disabled, [Equation 26–11 \(p. 1264\)](#) calculates the quench flux term without corrections.
- viii. Select **Fixed Yplus Value** if you want to use the logarithmic form of the wall functions to estimate the liquid temperature T_l at a fixed Yplus value of 250, as proposed by Egorov and Mentor [115] (p. 2373), instead of using the liquid temperature values in the near-wall cells. Enter the **Minimum Reference Temperature**, which limits the lowest value of the liquid temperature. It should not be lower than the liquid inlet temperature. Specify a **Yplus Value**. It is by default set to 250.

- ix. If you select **Fixed Liquid Temperature**, you can choose from **standard**, **constant**, or **user-defined** for the **Liquid Reference Temperature**. You will also need to enter the **Minimum Reference Temperature**. The liquid temperature used to compute the quenching flux should usually be between the inlet liquid temperature and the saturation temperature.

Note

To learn how to hook boiling parameter UDFs, please refer to [DEFINE_BOILING_PROPERTY](#) in the [UDF Manual](#)

8. Set up the conditions at inlets, outlets, and thermal conditions for walls.

Boundary Conditions

For the quenching wall heat flux, Koncar et al [114] (p. 2373) have suggested that in order to avoid grid dependence when calculating the quenching heat transfer, a factor that relates the temperature at a fixed normalized distance ($y+ = 250$) to the temperature at the near wall cell needs to be applied. Please contact a technical support engineer for more information.

The wall boiling models are compatible with three different wall boundaries: isothermal wall, specified heat flux, and specified heat transfer coefficient (coupled wall boundary).

Note

The boiling models do not apply to thin walls.

9. Choose **Coupled** as the pressure-velocity coupling scheme.

Solution Methods

Note

Although **Phase Coupled SIMPLE** is also available, it is generally less robust and is not recommended for use in steady cases involving boiling or mass transfer.

10. The following solution strategies are recommended for boiling model simulations:

Solution Controls

- **Courant Number:** use a value between 1 and 20 is recommended. As a first try, use a value of 10.
- **Explicit Relaxation Factors:** use the default values of 1 for **Momentum** and **Pressure**.
- **Vaporization Mass:** use an under-relaxation factor between 0.5 and 1 is recommended. As a first try, use a value of 1.
- **Volume Fraction:** use an under-relaxation factor between 0.3 and 0.5 is recommended.
- **Turbulent Kinetic Energy :** use an under-relaxation factor between 0.3 and 0.8 is recommended.
- **Turbulent Viscosity :** use an under-relaxation factor between 0.5 and 1.0 is recommended.

- **Energy** : use an under-relaxation factor between 0.5 and 0.8 is recommended.

26.5.9. Including the Multi-Fluid VOF Model

After you have selected the Eulerian multiphase model ([Setting Up the Eulerian Model \(p. 1240\)](#)), you can enable the **Multi-Fluid VOF Model** ([Multi-Fluid VOF Model](#) in the Theory Guide).

Important

- This model is only available with the **Eulerian** multiphase model.
- You cannot use this model with the **Dense Discrete Phase Model**.
- After selecting this model, VOF sharpening schemes such as **Geo-Reconstruct** and **CICSAM** become available for the Eulerian multiphase model. The default scheme with this model is **Geo-Reconstruct**.
- You can use the following drag laws with this model: **symmetric**, **anisotropic-drag**, **user-defined**, and **none**. The Default drag law with this model is **symmetric**.
- The anisotropic drag law is only compatible with the Eulerian multiphase model with the **Multi-Fluid VOF Model** enabled.
- Anisotropic drag applicable to free surface modeling is only compatible with the **Mixture** turbulence model.

Important

The multi-fluid VOF model for the Eulerian multiphase allows you to use the sharpening schemes Geo-Reconstruct, compressive, and CICSAM with the **Explicit** VOF option. This model should be enabled only for the cases requiring sharp interface treatment between phases.

If you want to use the anisotropic drag law, perform the following steps:

1. Define the drag law in the **Phase Interaction** dialog box.
 **Phases** → **Interaction...**
2. Click the **Drag** tab to display the **Drag Coefficient** inputs.
3. For each pair of phases, select the appropriate drag law from the corresponding drop-down list.
 - Select **anisotropic-drag** when there is higher drag in the normal direction to the interface and lower drag in the tangential direction to the interface. For details about this drag law, refer to [Multi-Fluid VOF Model](#) in the Theory Guide.

To specify the input parameters for anisotropic drag, you will need to use the `/solve/set/mp-mfluid-aniso-drag` text command. The options for an Anisotropic Drag Method of 0 (which is based on the symmetric drag), are as follows:

```
Anisotropic Drag Method  
[0]
```

```
Normal Interfacial Drag Friction Factor  
[1000000]
```

```
Tangential Interfacial Drag Friction Factor
```

[10]

Length scale
[0.0001]

The options for an Anisotropic Drag Method of 1 are as follows:

Anisotropic Drag Method
[0] 1

Viscosity option
[2]

Normal Interfacial Drag Friction Factor
[1000000]

Tangential Interfacial Drag Friction Factor
[10]

Length scale
[0.0001]

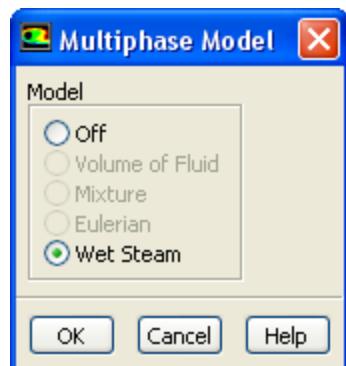

- Click the **Discretization** tab to enable the use of the **Phase Localized Compressive Scheme**. For information about applying the various schemes, please refer to *Discretizing Using the Phase Localized Compressive Scheme* (p. 1226).

26.6. Setting Up the Wet Steam Model

After you have enabled the density-based solver in ANSYS FLUENT, you can activate the wet steam model (see [Wet Steam Model Theory](#) in the [Theory Guide](#)) by opening the **Multiphase Model** dialog box and selecting the **Wet Steam** option.

Models →  Multiphase → Edit...

Figure 26.45 The Multiphase Model Dialog Box with the Wet Steam Model Activated

This section includes information about using your own property functions and data with the wet steam model. Solution settings and strategies for the wet steam model can be found in [Wet Steam Model](#) (p. 1290). Postprocessing variables are described in [Model-Specific Variables](#) (p. 1291).

This section is organized as follows:

- 26.6.1. Using User-Defined Thermodynamic Wet Steam Properties
- 26.6.2. Writing the User-Defined Wet Steam Property Functions (UDWSPF)
- 26.6.3. Compiling Your UDWSPF and Building a Shared Library File
- 26.6.4. Loading the UDWSPF Shared Library File

26.6.5. UDWSPF Example

26.6.1. Using User-Defined Thermodynamic Wet Steam Properties

ANSYS FLUENT allows you to use your own property functions and data with the wet steam model. This is achieved with user-defined wet steam property functions (UDWSPF).

These user-defined functions are written in the C programming language and there is a certain programming format that must be used so that you can build a successful library that can be loaded into the ANSYS FLUENT code.

The following is the procedure for using the user-defined wet steam property functions (UDWSPF):

1. Define the wet steam equation of state and all related thermodynamic and transport property equations.
2. Create a C source code file that conforms to the format defined in this section.
3. Start ANSYS FLUENT and set up your case file in the usual way.
4. Turn on the wet steam model.
5. Compile your UDWSPF C functions and build a shared library file using the text user interface.

```
define → models → multiphase → wet-steam → compile-user-defined-wetsteam-
functions
```

6. Load your newly created UDWSPF library using the text user interface.

```
define → models → multiphase → wet-steam → load-unload-user-defined-
wetsteam-library
```

7. Run your calculation.

Important

Note that the UDWSPF can only be used when the wet steam model is activated. Therefore, the UDWSPF are available for use with the density-based solver only.

26.6.2. Writing the User-Defined Wet Steam Property Functions (UDWSPF)

Creating a UDWSPF C function library is reasonably straightforward:

- The code must contain the `udf.h` file inclusion directive at the beginning of the source code. This allows the definitions for `DEFINE` macros and other ANSYS FLUENT functions to be accessible during the compilation process.
- The code must include at least one in the UDF's `DEFINE` functions (i.e. `DEFINE_ON_DEMAND`) to be able to use the compiled UDFs utility.
- Any values that are passed to the solver by the UDWSPF or returned by the solver to the UDWSPF are assumed to be in SI units.
- You must use the principle set of user-defined wet steam property functions in your UDWSPF library, as described in the list that follows. These functions are the mechanism by which your thermodynamic property data is transferred to the ANSYS FLUENT solver.

The following lists the user-defined wet steam property function names and arguments, as well as a short description of their functions. Function inputs from the ANSYS FLUENT solver consist of one or more of the following variables: T = temperature (K), P = pressure (Pa), and ρ = vapor-phase density (kg/m^3).

- `void wetst_init(Domain *domain)`

This will be called when you load the UDWSPF. You use it to initialize wet steam model constants or your own model constants. It returns nothing.

- `real wetst_satP(real T)`

This is the saturated pressure function, which takes on temperature in K and returns saturation pressure in Pa.

- `real wetst_satT(real P, real T)`

This is the saturated temperature function, which takes on pressure in Pa and a starting guess temperature in K and returns saturation temperature in K.

- `real wetst_eosP(real rho, real T)`

This is the equation of state, which takes on vapor density in kg/m^3 and Temperature in K and returns pressure in Pa.

- `real wetst_eosRHO(real P, real T)`

This is the equation of state, which takes on pressure in Pa and temperature in K and returns vapor density in kg/m^3 .

- `real wetst_cpv(real T, real rho)`

This is the vapor specific heat at constant pressure, which takes on temperature in K and vapor density in kg/m^3 and returns specific heat at constant pressure in J/kg/K.

- `real wetst_cvv(real T, real rho)`

This is the vapor specific heat at constant volume, which takes on temperature in K and vapor density in kg/m^3 and returns specific heat at constant volume in J/kg/K.

- `real wetst_hv(real T, real rho)`

This is the vapor specific enthalpy, which takes on temperature in K and vapor density in kg/m^3 and returns specific enthalpy in J/Kg.

- `real wetst_sv(real T, real rho)`

This is the vapor specific entropy, which takes on temperature in K and vapor density in kg/m^3 and returns specific entropy in J/Kg/K.

- `real wetst_muv(real T, real rho)`

This is the vapor dynamic viscosity, which takes on temperature in K and vapor density in kg/m^3 and returns viscosity in kg/m/s.

- `real wetst_ktv(real T, real rho)`

This is the vapor thermal conductivity, which takes on temperature in K and vapor density in kg/m^3 and returns thermal conductivity in W/m/K.

- `real wetst_rhol(real T)`

This is the saturated liquid density, which takes on temperature in K and returns liquid density in kg/m^3 .

- `real wetst_cpl(real T)`

This is the saturated liquid specific heat at constant pressure, which takes on temperature in K and returns liquid specific heat in J/kg/K.

- `real wetst_mul(real T)`

This is the liquid dynamic viscosity, which takes on Temperature in K and returns dynamic viscosity in kg/m/s.

- `real wetst_ktl(real T)`

This is the liquid thermal conductivity, which takes on temperature in K and returns thermal conductivity in W/m/K.

- `real wetst_surft(real T)`

This is the liquid surface tension, which takes on Temperature in K and returns surface tension N/m.

At the end of the code you must define a structure of type `WS_Functions` whose members are pointers to the principle functions listed previously. The structure is of type `WS_Functions` and its name is `WetSteamFunctionList`.

```
UDF_EXPORT WS_Functions WetSteamFunctionList =
{
    wetst_init,      /*initialization function*/
    wetst_satP,      /*Saturation pressure*/
    wetst_satT,      /*Saturation temperature*/
    wetst_eosP,      /*equation of state*/
    wetst_eosRHO,    /*equation of state*/
    wetst_hv,        /*vapor enthalpy*/
    wetst_sv,        /*vapor entropy*/
    wetst_cpv,       /*vapor isobaric specific heat*/
    wetst_cvv,       /*vapor isochoric specific heat*/
    wetst_muv,       /*vapor dynamic viscosity*/
    wetst_ktv,       /*vapor thermal conductivity*/
    wetst_rhol,      /*sat. liquid density*/
    wetst_cpl,       /*sat. liquid specific heat*/
    wetst_mul,       /*sat. liquid viscosity*/
    wetst_ktl,       /*sat. liquid thermal conductivity*/
    wetst_surft     /*liquid surface tension*/
};
```

26.6.3. Compiling Your UDWSPF and Building a Shared Library File

This section presents the steps you will need to follow to compile your UDWSPF C code and build a shared library file. This process requires the use of a C compiler. Most Linux operating systems provide a C compiler as a standard feature. If you are using a PC, you will need to ensure that a C++ compiler is installed before you can proceed (e.g., Microsoft Visual C++, v6.0 or higher).

Important

To use the UDWSPF you will need to first build the UDWSPF library by compiling your UDWSPF C code and then loading the library into the ANSYS FLUENT code.

The UDWSPF shared library is built in the same way that the ANSYS FLUENT executable itself is built. Internally, a script called `Makefile` is used to invoke the system C compiler to build an object code library that contains the native machine language translation of your higher-level C source code. This shared library is then loaded into ANSYS FLUENT (either at runtime or automatically when a case file is read) by a process called *dynamic loading*. The object libraries are specific to the computer architecture being used, as well as to the particular version of the ANSYS FLUENT executable being run. The libraries must, therefore, be rebuilt any time ANSYS FLUENT is upgraded, when the computer's operating system level changes, or when the job is run on a different type of computer.

The general procedure for compiling UDWSPF C code is as follows:

- Place the UDWSPF C code in your working directory (i.e., where your case file resides).
- Launch ANSYS FLUENT.
- Read your case file into ANSYS FLUENT.
- You can now compile your UDWSPF C code and build a shared library file using the commands provided in the text command interface (TUI):
 - Select the `define/models/multiphase/wet-steam` menu item.

`define → models → multiphase → wet-steam`

- Select the `compile-user-defined-wetsteam-functions` option.
- Enter the compiled UDWSPF library name.

The name given here is the name of the directory where the shared library (e.g., `libudf`) will reside. For example, if you hit <Enter> then a directory should exist with the name `libudf`, and this directory will contain library file called `libudf`. If, however, you type a new library name such as `mywetsteam`, then a directory called `mywetsteam` will be created and it will contain the library `libudf`.

- Continue on with the procedure when prompted.
- Enter the C source file names.

Important

Ideally you should place all of your functions into a single file. However, you can split them into separate files if desired.

- Enter the header file names, if applicable. If you do not have an extra header file, then press <Enter> when prompted.

ANSYS FLUENT will then start compiling the UDWSPF C code and put it in the appropriate architecture directory.

26.6.4. Loading the UDWSPF Shared Library File

To load the UDWSPF library, perform the following steps:

- Go to the `define/models/multiphase/wet-steam` menu item in the text user interface.
`define → models → multiphase → wet-steam`
- Select the `load-unload-user-defined-wetsteam-library` option and follow the procedure when prompted.

If the loading of the UDWSPF library is successful, you will see a message similar to the following:

```
Opening user-defined wet steam library "libudf"...
Library "libudf/lnamd64/2d/libudf.so" opened

Setting material properties to Wet-Steam...

Initializing user defined material properties...
```

26.6.5. UDWSPF Example

This section describe a simple UDWSPF. You can use this example as a the basis for your own UDWSPF code. For approximate calculations at low pressure, the simple ideal-gas equation of state and constant isobaric specific heat is assumed and used. The properties at the saturated liquid line and the saturated vapor line used in this example are similar to the one used by ANSYS FLUENT.

```

26.7. Solution Strategies for Multiphase Modeling

For additional information, please see the following sections:

- 26.7.1. Coupled Solution for Eulerian Multiphase Flows
- 26.7.2. Coupled Solution for VOF and Mixture Multiphase Flows
- 26.7.3. Selecting the Pressure-Velocity Coupling Method
- 26.7.4. Controlling the Volume Fraction Coupled Solution
- 26.7.5. Setting Initial Volume Fractions
- 26.7.6. VOF Model
- 26.7.7. Mixture Model
- 26.7.8. Eulerian Model
- 26.7.9. Wet Steam Model

26.7.1. Coupled Solution for Eulerian Multiphase Flows

In multiphase flow, the phasic momentum equations, the shared pressure, and the phasic volume fraction equations are highly coupled. Traditionally, these equations have been solved in a segregated fashion using some variation of the SIMPLE algorithm to couple the shared pressure with the momentum equations. This is attained by effectively transforming the total continuity into a shared pressure. The ANSYS FLUENT **Phase Coupled SIMPLE** algorithm has been successfully implemented and solves a wide range of multiphase flows. However, coupling the linearized system of equations in an implicit manner would offer a more robust alternative to the segregated approach.

One of the fundamental problems is that the resulting matrix is not symmetric and that the continuity constraint may contribute to a zero diagonal block, making the solution difficult to obtain. One way to circumvent this problem is to use direct solvers, but these are too expensive for large industrial cases. In addition, we need to avoid a zero diagonal, resulting from the continuity constraint, and like the segregated solver, we need to construct a pressure correction equation. In multiphase, we also have the additional problem of the vanishing phase, which for the coupled solver is important to ensure some continuity in the coefficients. Like the **Phase Coupled**, we use a Rhee and Chow type of scheme to calculate volume fluxes and to provide proper coupling between velocity and pressure, thus avoiding unphysical oscillations.

Consider a single-phase system and let us denote the velocity correction components in the three Cartesian directions by u' , v' , and w' with p' denoting the shared pressure correction. These are discrete variables and can be expressed in the form (p', U') . The linear system that is generated by the single-phase coupled solver is of the form

$$\begin{pmatrix} A_p & C_U \\ B_U & A_U \end{pmatrix} \begin{pmatrix} p' \\ U' \end{pmatrix} = \begin{pmatrix} S_p \\ S_U \end{pmatrix} \quad (26-12)$$

For a notation in component form (p', u', v', w')

$$\begin{pmatrix} A_{pp} & C_u & C_v & C_w \\ B_u & A_{uu} & A_{uv} & A_{uw} \\ B_v & A_{vu} & A_{vv} & A_{vw} \\ B_w & A_{wu} & A_{wv} & A_{ww} \end{pmatrix} \begin{pmatrix} p' \\ u' \\ v' \\ w' \end{pmatrix} = \begin{pmatrix} S_p \\ S_u \\ S_v \\ S_w \end{pmatrix} \quad (26-13)$$

Now let us consider a multiphase system of n -phases and denote the phasic velocity correction components in the three Cartesian directions by u'_k , v'_k , and w'_k where the subscript k represents the phase notation, p' denotes the shared pressure correction and α'_k denotes the volume fraction correction (ANSYS FLUENT can solve in both correction form for velocity and volume fraction and noncorrection form). For simplicity the matrix will be shown for two phases. The vector solution is of the form $(p', u'_1, v'_1, w'_1, u'_2, v'_2, w'_2, \alpha'_2)$ or in a shorter notation $(p', U'_1, U'_2, \alpha'_2)$. The linear system would be an extension of the one generated by the coupled solver shown by [Equation 26-12 \(p. 1277\)](#).

$$\begin{pmatrix} A_p & C_{U1} & C_{U2} & D_{\alpha 2} \\ B_{U1} & A_{U1} & A_{U12} & D_{U1} \\ B_{U2} & A_{U21} & A_{U2} & D_{U2} \\ E_p & E_{U1} & E_{U2} & A_{\alpha 2} \end{pmatrix} \begin{pmatrix} p' \\ U'_1 \\ U'_2 \\ \alpha'_2 \end{pmatrix} = \begin{pmatrix} S_p \\ S_{U1} \\ S_{U2} \\ S_{\alpha 2} \end{pmatrix} \quad (26-14)$$

This system can be easily generalized to n phases. The components of this matrix are also matrices.

For large problems we need to resort to iterative solvers. The ANSYS FLUENT AMG Coupled solver with an ILU smoother has proved to be a robust method. Most coupled solvers also need a pseudo stepping method, adding more diagonal dominance to the matrix. Our method here is to use under-relaxation factors for momentum, which is equivalent to time stepping in steady flows. Similar to that of the single phase, we have introduced a steady Courant Number instead of an under-relaxation for velocities. Having this control is important when using second order numerical schemes in the convective terms.

For the sake of simplicity, input parameters for the **Coupled** solver are similar to the single-phase solver. We have the options for solving the whole system including volume fraction, or to treat the volume fraction solution in a segregated manner while preserving the pressure-velocity coupling for all phases.

Important

Equations in multiphase are more strongly linked than single phase and generally may need more under-relaxation, hence using the same values as single phase may not be ideal. A low Courant number would stabilize the solution.

See [Selecting the Pressure-Velocity Coupling Method \(p. 1280\)](#) for information about applying the various algorithms.

26.7.2. Coupled Solution for VOF and Mixture Multiphase Flows

We have the option of solving the multiphase system for VOF and mixture multiphase models in the following ways:

- Solving the continuity and momentum equations in a coupled manner (see [Coupled Algorithm](#) in the [Theory Guide](#)) and solving the volume fraction equation in a segregated manner.
- Solving the volume fraction equation in a coupled manner along with the continuity and momentum equations.

Solving the volume fraction equation in a coupled manner requires discretization of the volume fraction equation in the correction form along with the discretization of the continuity and momentum equation, as discussed in [Coupled Algorithm](#) in the [Theory Guide](#).

The volume fraction equation could be represented in the discretized form as

$$\sum_k \sum_j a_{ij}^{\alpha u_k} u_{kj} + \sum_j a_{ij}^{\alpha p} p_j + \sum_j a_{ij}^{\alpha \alpha} \alpha_j = b_i^\alpha \quad (26-15)$$

The overall system of equations after being transformed to the correction form could be represented as

$$\sum_j [A]_{ij} \vec{X}_j = \vec{B}_i \quad (26-16)$$

For a 2D case and two-phase flow, the system could be expanded as follows:

$$A_{ij} = \begin{bmatrix} a_{ij}^{pp} & a_{ij}^{pu} & a_{ij}^{pv} & a_{ij}^{p\alpha} \\ a_{ij}^{up} & a_{ij}^{uu} & a_{ij}^{uv} & a_{ij}^{u\alpha} \\ a_{ij}^{vp} & a_{ij}^{vu} & a_{ij}^{vv} & a_{ij}^{v\alpha} \\ a_{ij}^{ap} & a_{ij}^{au} & a_{ij}^{av} & a_{ij}^{a\alpha} \end{bmatrix} \quad (26-17)$$

and the unknown and residual vectors have the form

$$\vec{X}_j = \begin{bmatrix} p'_i \\ u'_i \\ v'_i \\ \alpha'_i \end{bmatrix} \quad (26-18)$$

$$\vec{B}_i = \begin{bmatrix} -r_i^p \\ -r_i^u \\ -r_i^v \\ -r_i^\alpha \end{bmatrix} \quad (26-19)$$

where

A_{ij} = coefficient matrix

\vec{X}_j = solution vector

\vec{B}_i = residual vector

p' = pressure correction

u', v' = velocity corrections

α' = volume fraction correction

26.7.3. Selecting the Pressure-Velocity Coupling Method

The options that are available in the **Solution Methods** task page (see [Figure 26.46 \(p. 1281\)](#)) for solving the coupled system of equations arising in multiphase flows are:

- **Phase Coupled SIMPLE** (Eulerian multiphase)
- **PISO** (VOF and mixture)
- **SIMPLE** (VOF and mixture)
- **SIMPLEC** (VOF and mixture)
- **Coupled** (all multiphase models)
- **Coupled with Volume Fractions** (all multiphase models except drift-flux)

The **PISO**, **SIMPLE**, and **SIMPLEC** schemes apply to the VOF and mixture models and are discussed in **Pressure-Velocity Coupling** in the [Theory Guide](#).

The **Phase Coupled SIMPLE** (PC-SIMPLE) is an extension of the SIMPLE algorithm [\[61\] \(p. 2370\)](#) to multiphase flows. The velocities are solved coupled by phases in a segregated fashion. Fluxes are reconstructed at the faces of the control volume and then a pressure correction equation is built based on total continuity. The coefficients of the pressure correction equations come from the coupled per phase momentum equations. This method has proven to be robust and it is the only method available for all previous versions of ANSYS FLUENT.

The **Coupled** scheme (also known as **Multiphase Coupled** in previous ANSYS FLUENT versions) solves all equations for phase velocity corrections and shared pressure correction simultaneously [\[25\] \(p. 2368\)](#). These methods incorporate the lift forces and the mass transfer terms implicitly into the general matrix. This method works very efficiently in steady state situations, or for transient problems when larger time steps are required.

The **Coupled with Volume Fractions** option (also known as **Full Multiphase Coupled** in previous ANSYS FLUENT versions) couples velocity corrections, shared pressure corrections, and the correction for volume fraction simultaneously. Theoretically, it should be more efficient, however it may have some drawbacks in robustness and CPU time usage. The robustness issue stems from the lack of control of the solution of the volume fraction equation. The continuity constraint (sum of all volume fractions equals 1, and individual values limited between zero and one) cannot be enforced exactly during inner solver iterations, and slight variations from the physical limits may lead to divergence. Research is ongoing in this area to improve the method. The method is advantageous for heterogeneous mass transfer when a low Courant number is given; it also works well in dilute situations.

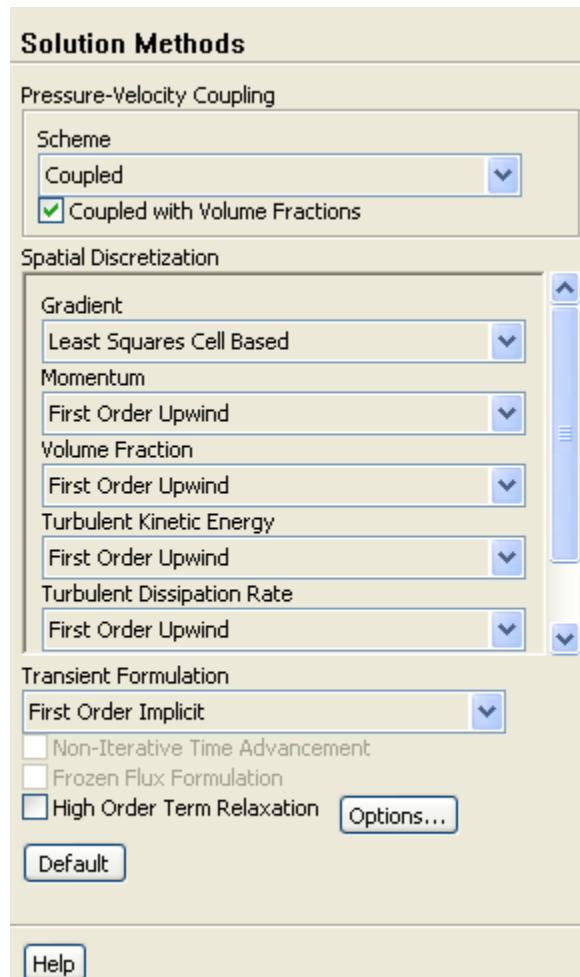

The Volume Fraction Coupling Method aims to achieve a faster steady state solution compared to the segregated method of solving equations. It may not be a suitable option for transient applications due to the significant overhead in CPU time compared to the segregated method, unless it is run with a larger time step size.

Note

The **Coupled with Volume Fractions** option is available in the interface after you have selected **Coupled** from the **Scheme** drop-down list for **Pressure-Velocity Coupling**.

For steady state cases, the **Pseudo Transient** option will be enabled automatically when you activate the **Coupled with Volume Fractions** option for the VOF and mixture models.

Figure 26.46 The Solution Methods Task Page Displaying The Pressure-Velocity Coupling Options

26.7.3.1. Limitations and Recommendations of the Coupled with Volume Fraction Options for the VOF and Mixture Models

The coupled with volume fractions option has the following limitations:

- It is not available when **Slip Velocity** is enabled for the **Mixture** multiphase model.
- It is not supported when using the Singhal-Et-Al cavitation model.
- It is not supported when the **Explicit** scheme for volume fraction is selected.

Recommended uses of the coupled with volume fractions option:

- The Pseudo-transient solver is recommended for steady state calculations.
- It is recommended that you use lower under-relaxation factors for momentum for higher order schemes.
- For marine applications, it is recommended that you use a low-order variant or hybrid treatment for the Rhee-chow face flux interpolation (see [High-Order Rhee-Chow Face Flux Interpolation \(p. 1286\)](#)).
- It is recommended that you use the expert text command options `solve/set/coupled-vof-expert` for better stability when using the VOF model (see "solve/" in the [Text Command List](#)).

26.7.4. Controlling the Volume Fraction Coupled Solution

When using the **Coupled with Volume Fractions** scheme, you will need to specify the following in the **Solution Controls** task page (see [Figure 26.47](#) (p. 1283)):

- **VOF and Mixture Multiphase Model:**
 - For steady state cases using the pseudo transient solver, specify the **Volume Fraction Courant Number**, and the **Pseudo Transient Explicit Relaxation Factors**. The **Pseudo Transient Explicit Relaxation Factors** are described in [Setting Pseudo Transient Explicit Relaxation Factors](#) (p. 1360).

Note

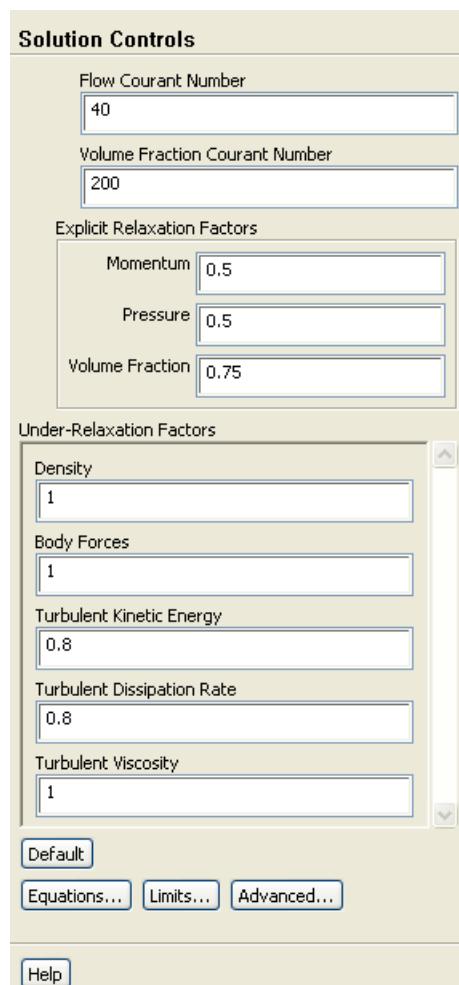

The **Pseudo Transient Explicit Relaxation Factors** for the **Volume Fraction** is set to 0.5 by default.

- For transient cases or steady state cases not involving the pseudo transient solver, enter the **Flow Courant Number**, the **Volume Fraction Courant Number**, **Explicit Relaxation Factors**, and the **Under-Relaxations Factors**.

Note

The **Volume Fraction** is set as an **Explicit Relaxation Factor** and is 0.75 by default.

Figure 26.47 The Solution Controls Task Page Displaying the Coupled Volume Fraction Method for the VOF and Mixture Models

- **Eulerian Multiphase Model:**

- For steady state cases using the pseudo transient solver, specify the **Pseudo Transient Explicit Relaxation Factors** as described in *Setting Pseudo Transient Explicit Relaxation Factors* (p. 1360).

Note

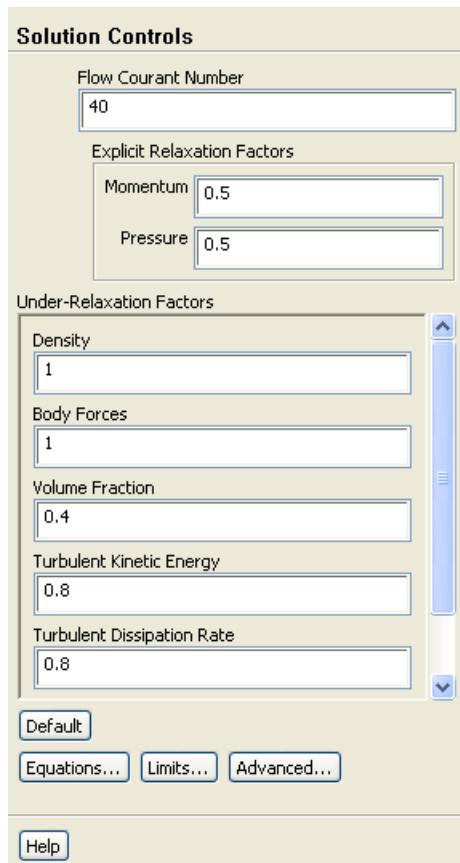

The **Pseudo Transient Explicit Relaxation Factors** for the **Volume Fraction** is set to 0.5 by default.

- For transient cases or steady state cases not involving the pseudo transient solver, enter the **Flow Courant Number**, the **Explicit Relaxation Factors**, and the **Under-Relaxations Factors**.

Note

The under-relaxation for **Volume Fraction** is set by using an implicit **Under-Relaxation Factor**, rather than a **Volume Fraction Courant Number**, and is 0.5 by default.

Figure 26.48 The Solution Controls Task Page Displaying the Coupled Volume Fraction Method for the Eulerian Multiphase Model

26.7.5. Setting Initial Volume Fractions

Once you have initialized the flow (as described in [Initializing the Solution \(p. 1348\)](#)), you can define the initial distribution of the phases. For a transient simulation, this distribution will serve as the initial condition at $t = 0$; for a steady-state simulation, setting an initial distribution can provide added stability in the early stages of the calculation.

You can patch an initial volume fraction for each secondary phase using the [Patch Dialog Box \(p. 2090\)](#).

◀ Solution Initialization → Patch...

If the region in which you want to patch the volume fraction is defined as a separate cell zone, you can simply patch the value there. Otherwise, you can create a cell “register” that contains the appropriate cells and patch the value in the register. See [Patching Values in Selected Cells \(p. 1351\)](#) for details.

Solution strategies for the VOF, mixture, and Eulerian models are provided in [VOF Model \(p. 1284\)](#), [Mixture Model \(p. 1287\)](#), and [Eulerian Model \(p. 1288\)](#), respectively.

26.7.6. VOF Model

Several recommendations for improving the accuracy and convergence of the VOF solution are presented here.

26.7.6.1. Setting the Reference Pressure Location

The site of the reference pressure can be moved to a location that will result in less round-off in the pressure calculation. By default, the reference pressure location is the center of the cell at or closest to the point (0,0,0). You can move this location by specifying a new **Reference Pressure Location** in the *Operating Conditions Dialog Box* (p. 1952).

◆ Cell Zone Conditions → Operating Conditions...

The position that you choose should be in a region that will always contain the least dense of the fluids (e.g., the gas phase, if you have a gas phase and one or more liquid phases). This is because variations in the static pressure are larger in a more dense fluid than in a less dense fluid, given the same velocity distribution. If the zero of the relative pressure field is in a region where the pressure variations are small, less round-off will occur than if the variations occur in a field of large nonzero values. Thus in systems containing air and water, for example, it is important that the reference pressure location be in the portion of the domain filled with air rather than that filled with water.

26.7.6.2. Pressure Interpolation Scheme

For all VOF calculations, you should use the body-force-weighted pressure interpolation scheme or the PRESTO! scheme.

◆ Solution Controls

26.7.6.3. Discretization Scheme Selection for the Implicit and Explicit Formulations

When the implicit scheme is used, the available options for **Volume Fraction** are

◆ Solution Methods

- **First Order Upwind**
- **Second Order upwind**
- **Compressive** (available exclusively when **Zonal Discretization** is enabled in the **Multiphase Model** dialog box)
- **Modified HRIC**
- **BGM** (steady state only)
- **QUICK**

When the explicit scheme is used, the available options for **Volume Fraction** are

- **Geo-Reconstruct**
- **CICSAM**
- **Compressive** (available exclusively when **Zonal Discretization** is enabled in the **Multiphase Model** dialog box)
- **Modified HRIC**
- **QUICK**

When using the explicit scheme, **First Order Upwind**, **Second Order upwind**, and **Donor-Acceptor** can be made available under **Volume Fraction** by using the following text command:

solve → set → expert

You will be asked a series of questions, one of which is

```
Allow selection of all applicable discretization schemes? [no]
```

to which you will respond yes.

Important

You are encouraged to use the CICSAM scheme, as it gives a sharper interface than the modified HRIC scheme.

When using the **Compressive** spatial discretization scheme, it is recommended that you use step-wise sharpening after the flow transitions from the diffused zone to the sharpening zone. In other words, you would want to transition from first order to second order, followed by a transition from second order to compressive. You would want to take this approach if the flow has a smooth transition from a sharp interfacial zone to a diffused interfacial zone. However, if the flow has a nonuniform transition from a diffused interfacial zone to a sharp interfacial zone, this might create unphysical sharpening of the interface if not handled properly, especially for transient cases. For example, transitioning from a slope limiter of 2 (compressive) to a slope limiter of 0 or 1 (first order or second order) might be acceptable, but a first order to compressive transition might create unphysical sharpening of the interface.

Important

The **BGM** scheme produces a sharp interface, which may result in poor convergence in some cases. In such situations, we recommend you use a low value for the VOF under-relaxation. In addition, you can start with the **Compressive** or **Modified HRIC** scheme and then switch to the **BGM** scheme.

26.7.6.4. High-Order Rhie-Chow Face Flux Interpolation

In VOF modeling, using a high-order discretization scheme for the momentum transport equations may reduce the stability of the solution compared to cases using first-order discretization. In such situations, there are a couple of recommendations:

1. Use a low-order variant of the Rhie-Chow face flux interpolation. This is enabled using the following text command:

solve → set → numerics

You will be asked

```
disable high order Rhie-Chow flux? [no]
```

to which you will respond yes.

2. Use a hybrid treatment of high-order Rhie-Chow face flux interpolation. This is enabled using the following text command:

solve → set → vof-numerics

You will be asked

```
Use hybrid treatment for high order Rhie-Chow flux? [no]
```

to which you will respond yes.

Hybrid treatment allows you to use a high-order variant of the Rhie-Chow face flux interpolation everywhere inside the domain, except in the vicinity of the interface where a low-order variant is used for the interpolation of the face flux. This treatment could be helpful to get better convergence without compromising much of the accuracy.

26.7.6.5. Pressure-Velocity Coupling and Under-Relaxation for the Time-dependent Formulations

Another change that you should make to the solver settings is in the pressure-velocity coupling scheme and under-relaxation factors that you use. The PISO scheme is recommended for transient calculations in general. Using PISO allows for increased values on all under-relaxation factors, without a loss of solution stability. You can generally increase the under-relaxation factors for all variables to 1 and expect stability and a rapid rate of convergence (in the form of few iterations required per time step). For calculations on tetrahedral or triangular meshes, an under-relaxation factor of 0.7–0.8 for pressure is recommended for improved stability with the PISO scheme.

Solution Controls

As with any ANSYS FLUENT simulation, the under-relaxation factors will need to be decreased if the solution exhibits unstable, divergent behavior with the under-relaxation factors set to 1. Reducing the time step is another way to improve the stability.

26.7.6.6. Under-Relaxation for the Steady-State Formulation

If you are using the steady-state implicit VOF scheme, the under-relaxation factors for all variables should be set to values between 0.2 and 0.5 for improved stability.

26.7.7. Mixture Model

26.7.7.1. Setting the Under-Relaxation Factor for the Slip Velocity

You should begin the mixture calculation with a low under-relaxation factor for the slip velocity. A value of 0.2 or less is recommended. If the solution shows good convergence behavior, you can increase this value gradually.

26.7.7.2. Calculating an Initial Solution

For some cases (e.g., cyclone separation), you may be able to obtain a solution more quickly if you compute an initial solution without solving the volume fraction and slip velocity equations. Once you have set up the mixture model, you can temporarily disable these equations and compute an initial solution.

Solution Controls

In the [Equations Dialog Box](#) (p. 2054), deselect **Volume Fraction** and **Slip Velocity** in the **Equations** list. You can then compute the initial flow field. Once a converged flow field is obtained, turn the **Volume Fraction** and **Slip Velocity** equations back on again, and compute the mixture solution.

26.7.7.3. Discretization Scheme Selection for the Mixture Model

The available spatial discretization schemes for **Volume Fraction** are

- **First Order Upwind**
- **QUICK**

Second Order upwind, Modified HRIC, and Compressive can be made available under **Volume Fraction** by using the following text command:

`solve → set → expert`

You will be asked a series of questions, one of which is

Allow selection of all applicable discretization schemes? [no]

to which you will respond yes.

26.7.8. Eulerian Model

26.7.8.1. Calculating an Initial Solution

To improve convergence behavior, you may want to compute an initial solution before solving the complete Eulerian multiphase model. There are three methods you can use to obtain an initial solution for an Eulerian multiphase calculation:

- Set up and solve the problem using the mixture model (with slip velocities) instead of the Eulerian model. You can then enable the Eulerian model, complete the setup, and continue the calculation using the mixture-model solution as a starting point.
- Set up the Eulerian multiphase calculation as usual, but compute the flow for only the primary phase. To do this, deselect **Volume Fraction** in the **Equations** list in the *Equations Dialog Box* (p. 2054). Once you have obtained an initial solution for the primary phase, turn the volume fraction equations back on and continue the calculation for all phases.
- Use the mass flow inlet boundary condition to initialize the flow conditions. It is recommended that you set the value of the volume fraction close to the value of the volume fraction at the inlet.
- At the beginning of the solution, a lower time step is recommended to obtain convergence.
- If using the volume fraction explicit scheme, do not start with a large Courant number at the beginning of your run.
- If using the volume fraction explicit scheme, start a run with a lower time step and then increase the time step size. Alternatively, this could be done by using variable time stepping, which would increase the time step size based on the input parameters.
- For problems involving a free surface or sharp interfaces between the phases, it is recommended that you use the **symmetric** drag law, available in the *Phase Interaction Dialog Box* (p. 1937).
- Variable time stepping is not recommended for compressible flows.

Important

You should *not* try to use a single-phase solution obtained without the mixture or Eulerian model as a starting point for an Eulerian multiphase calculation. Doing so will not improve convergence, and may make it even more difficult for the flow to converge.

26.7.8.2. Temporarily Ignoring Lift and Virtual Mass Forces

If you are planning to include the effects of lift and/or virtual mass forces in a steady-state Eulerian multiphase simulation, you can often reduce stability problems that sometimes occur in the early stages of the calculation by temporarily ignoring the action of the lift and the virtual mass forces. Once the solution without these forces starts to converge, you can interrupt the calculation, define these forces appropriately, and continue the calculation.

26.7.8.3. Discretization Scheme Selection for the Implicit and Explicit Formulations

When the implicit scheme is used, the available options for **Volume Fraction** are

- **First Order Upwind**
- **Compressive** (available exclusively when the **Multi-Fluid VOF Model** and **Zonal Discretization** is enabled in the **Multiphase Model** dialog box)
- **QUICK**
- **Modified HRIC**

When the explicit scheme is used, the available options for **Volume Fraction** are

- **First Order Upwind**
- **Geo-Reconstruct**
- **CICSAM**
- **Compressive**
- **Modified HRIC**
- **QUICK**

When using the explicit scheme **Second Order upwind**, and **Donor-Acceptor** can be made available under **Volume Fraction** by using the following text command:

`solve → set → expert`

You will be asked a series of questions, one of which is

`Allow selection of all applicable discretization schemes? [no]`

to which you will respond **yes**.

26.7.8.4. Using W-Cycle Multigrid

For problems involving a packed-bed granular phase with very small particle sizes (on the order of 10 μm), convergence can be obtained by using the W-cycle multigrid for the pressure. In the **Multigrid** tab, under **Fixed Cycle Parameters** in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#), you may need to use higher values for **Pre-Sweeps**, **Post-Sweeps**, and **Max Cycles**. When you are choosing the values for these parameters, you should also increase the **Verbosity** to 1 in order to monitor the AMG performance; i.e., to make sure that the pressure equation is solved to a desired level of convergence within the AMG solver during each global iteration. See [Defining the Phases for the Eulerian Model \(p. 1240\)](#) for more information about granular phases, and [The V and W Cycles](#) in the [Theory Guide](#) and [Modifying Algebraic Multigrid Parameters \(p. 1432\)](#) for details about multigrid cycles.

26.7.8.5. Including the Anisotropic Drag Law

When using the anisotropic drag law ([Including the Multi-Fluid VOF Model \(p. 1266\)](#)), it is recommended that you start the solution with a lower anisotropy ratio. After you let your solution run for some time, you can then increase the ratio by reducing the friction factor in the tangential direction. Note that You can also start the solution with the symmetric drag law, then change to the anisotropic drag law.

Using a smaller under-relaxation for pressure and momentum may also help in convergence for cases with a higher anisotropy ratio.

If the flow for a particular phase is important in both directions (normal and tangential to the interface), use a lower anisotropy ratio, between 100-1000. A higher anisotropy ratio might cause an unstable solution for such cases. For a higher anisotropy ratio of more than 1000, a smaller under-relaxation for pressure and momentum is recommended. When using the coupled multiphase solver, if the solution is unstable with a higher anisotropy ratio, then reducing the courant number may be beneficial. Anisotropic Drag Method [1], with Viscosity option [2] is recommended for a higher viscosity ratio.

26.7.9. Wet Steam Model

26.7.9.1. Boundary Conditions, Initialization, and Patching

When you use the wet steam model (described in [Wet Steam Model Theory](#) in the [Theory Guide](#), and [Setting Up the Wet Steam Model \(p. 1267\)](#)), the following two field variables will show up in the inflow, outflow boundary dialog boxes, and in the **Solution Initialization** task page and **Patch** dialog boxes.

- **Liquid Mass Fraction** (or the wetness factor)

In general, for dry steam entering flow boundaries the wetness factor is zero.

- **Log10 (Droplets Per Unit Volume)**

In general this value is set to zero, indicating zero droplets entering the domain.

26.7.9.2. Solution Limits for the Wet Steam Model

When you activate the wet steam model for the first time, a message is displayed indicating that the **Minimum Static Temperature** should be adjusted to 273 K since the accuracy of the built-in steam data is not guaranteed below a value of 273 K. If you use your own steam property functions, you can adjust this limit to whatever is permissible for your data.

To adjust the temperature limits, go to the **Solution Limits** dialog box.

 **Solution Controls** → **Limits...**

The default maximum wetness factor or liquid mass fraction (β) is set to 0.1. In general, during the convergence process, it is common that this limit will be reached, but eventually the wetness factor will drop below the value of 0.1. However, in cases where the limit must be adjusted, you can do so using the text user interface.

define → models → multiphase → wet-steam → set → max-liquid-mass-fraction

Important

Note that the maximum wetness factor should not be set beyond 0.2 since the present model assumes a low wetness factor. When the wetness factor is greater than 0.1, the solution tends to be less stable due to the large source terms in the transport equations. Thus, the maximum wetness factor has been set to a default value of 0.1, which corresponds to the fact that most nozzle and turbine flows will have a wetness factor less than 0.1.

26.7.9.3. Solution Strategies for the Wet Steam Model

If you face convergence difficulties while solving wet steam flow, try to initially lower the CFL value and use first-order discretization schemes for the solution. If you are still unable to obtain a converged solution, then try the following solver settings:

1. Lower the under-relaxation factor for the wet steam equation below the current set value. The under-relaxation factor can be found in the **Solution Controls** task page.

Solution Controls

2. Solve for an initial solution with no condensation. Once you have obtained a proper initial solution, turn on the condensation.

To turn condensation on or off, go to the **Solution Controls** task page.

Solution Controls

In the **Equations** dialog box, deselect **Wet Steam** in the **Equations** list. When doing so, you are preventing condensation from taking place while still computing the flow based on steam properties. Once a converged flow field is obtained, turn the **Wet Steam** equation back on again and compute the mixture solution.

26.8. Postprocessing for Multiphase Modeling

Each of the three general multiphase models provides a number of additional field functions that you can plot or report. You can also report flow rates for individual phases for all three models, and display velocity vectors for the individual phases in a mixture or Eulerian calculation.

Information about these postprocessing topics is provided in the following subsections:

- 26.8.1. Model-Specific Variables
- 26.8.2. Displaying Velocity Vectors
- 26.8.3. Reporting Fluxes
- 26.8.4. Reporting Forces on Walls
- 26.8.5. Reporting Flow Rates

26.8.1. Model-Specific Variables

When you use one of the general multiphase models, some additional field functions will be available for postprocessing, as listed in this section. Most field functions that are available in single phase calculations will be available for either the mixture or each individual phase, as appropriate for the general multiphase model and specific options that you are using. See *Field Function Definitions* (p. 1653) for a complete list of field functions and their definitions. *Displaying Graphics* (p. 1499) and *Reporting Alphanumeric Data* (p. 1633) explain how to generate graphics displays and reports of data.

26.8.1.1. VOF Model

For VOF calculations you can generate graphical plots or alphanumeric reports of the following additional item:

- **Volume fraction** (in the **Phases...** category)

This item is available for each phase.

The variables that are not phase specific are available (e.g., variables in the **Pressure...** and **Velocity...** categories) and represent mixture quantities. Thermal quantities will be available only for calculations that include the energy equation.

26.8.1.2. Mixture Model

For calculations with the mixture model, you can generate graphical plots or alphanumeric reports of the following additional items:

- **Diameter** (in the **Properties...** category)

This item is available only for secondary phases.

- **Volume fraction** (in the **Phases...** category)

This item is available only for secondary phases.

- **Interfacial Area Concentration** (in the **Interfacial Area Concentration...** category)

This item is available only for secondary phases.

The variables that are not phase specific are available (e.g., variables in the **Pressure...** category) represent mixture quantities. Thermal quantities will be available only for calculations that include the energy equation.

26.8.1.3. Eulerian Model

For Eulerian multiphase calculations you can generate graphical plots or alphanumeric reports of the following additional items:

- **Diameter** (in the **Properties...** category)

This item is available only for secondary phases.

- **Granular Conductivity** (in the **Properties...** category)

This item is available only for granular phases.

- **Granular Pressure** (in the **Granular Pressure...** category)

This item is available only for granular phases.

- **Granular Temperature** (in the **Granular Temperature...** category)

This item is available only for granular phases.

- **Volume fraction** (in the **Phases...** category)

This item is available only for secondary phases.

- **Interfacial Area Concentration** (in the **Interfacial Area Concentration...** category)

This item is available only for secondary phases.

The availability of turbulence quantities will depend on which multiphase turbulence model you used in the calculation. Thermal quantities will be available (on a per-phase basis) only for calculations that include the energy equation.

More advanced options for the mixture phase are available under the **Phases...** category, allowing you to select from a list of variables to postprocess. To access the entire list in the GUI, type the following text command:

```
solve → set → expert
```

Retain most of the default settings, except when asked to Keep temporary solver memory from being freed?. Answering yes to this question will expose a list under the **Phases** category for the mixture phase, one of which will be the **Phase ID**. Selecting this option allows you to plot contours of phase IDs for the volume fraction, which will facilitate phase distribution display when more than two phases are present for free surface calculations.

Note

The expert option for not freeing temporary solver memory is incompatible with dynamic adaption in parallel.

Important

This option is available for all the multiphase models. However, note that only cell values should be plotted for this option. Make sure that the **Node Values** option is not selected as it will show the wrong phase ID contours at the interface.

26.8.1.4. Multiphase Species Transport

For calculations using species transport with either of the multiphase models, you can generate graphical plots or alphanumeric reports of the following additional items:

- **Mass Fraction of species-n** (in the **Species...** category)

This item is available for each species.

- **Mole Fraction of species-n** (in the **Species...** category)

This item is available for each species.

- **Molar Concentration of species-n** (in the **Species...** category)

This item is available for each species.

- **Lam. Diff Coeff of species-n** (in the **Species...** category)

This item is available for each species.

- **Eff. Diff. Coeff. of species-n** (in the **Species...** category)

This item is available for each species.

- **Enthalpy of species-n** (in the **Species...** category)
This item is available for each species.
- **Relative Humidity** (in the **Species...** category).
- **Turbulent Rate of Reaction-n** (in the **Reactions...** category)

- This item is available for each species.
- **Rate of Reaction** (in the **Reactions...** category).
 - **Mass Transfer Rate n** (in the **Phase Interaction...** category)

This item is available for each mass transfer mechanism that you defined.

Thermal quantities will be available only for calculations that include the energy equation.

26.8.1.5. Wet Steam Model

ANSYS FLUENT provides a wide range of postprocessing information related to the wet steam model.

The wet steam related items can be found in **Wet Steam....** category of the variable selection drop-down list that appears in the postprocessing dialog boxes.

- **Liquid Mass Fraction**
- **Liquid Mass Generation Rate**
- **Log10 (Droplets Per Unit Volume)**
- **Log10 (Droplets Nucleation Rate)**
- **Steam Density (Gas-Phase)**
- **Liquid Density (Liquid-Phase)**
- **Mixture Density**
- **Saturation Ratio**
- **Saturation Pressure**
- **Saturation Temperature**
- **Subcooled Vapor Temperature**
- **Droplet Surface Tension**
- **Droplet Critical Radius (microns)**
- **Droplet Average Radius (microns)**
- **Droplet Growth Rate (microns/s)**

26.8.1.6. Dense Discrete Phase Model

For postprocessing, both the DPM and the Eulerian multiphase capabilities are retained. In addition to usual DPM postprocessing ([Postprocessing for the Discrete Phase \(p. 1142\)](#)), you can display, for example, vector plots of the particle's velocity field. Make sure to select the discrete phase from the **Phase** drop-down list. For transient simulations which include the dense discrete phase model, you can display the following when the **Unsteady Statistics...** category is selected:

- **Mean Velocity**

- **Mean Volume Fraction**
 - **Mean Phase Diameter**
 - **RMS Velocity**
 - **RMS Volume Fraction**
 - **RMS Phase Diameter**
-

Important

For the **Unsteady Statistics...** category to appear in the postprocessing dialog boxes, make sure that **Data Sampling for Time Statistics** is enabled in the **Run Calculation** task page, and that you have performed the calculation.

26.8.2. Displaying Velocity Vectors

For mixture and Eulerian calculations, it is possible to display velocity vectors for the individual phases using the **Vectors** dialog box.

Graphics and Animations → **Vectors** → **Set Up...**

To display the velocity of a particular phase, select **Velocity** in the **Vectors of** drop-down list, and then select the desired phase in the **Phase** drop-down list. You can also choose **Relative Velocity** to display the phase velocity relative to a moving reference frame. To display the mixture velocity \vec{V}_m (relevant for mixture model calculations only), select **Velocity** (or **Relative Velocity** for the mixture velocity relative to a moving reference frame), and **mixture** as the **Phase**. Note that you can color vectors by values of any available variable, for any phase you defined. To do so, make the appropriate selections in the **Color by** and following **Phase** drop-down lists.

26.8.3. Reporting Fluxes

When you use the **Flux Reports** dialog box to compute fluxes through boundaries, you will be able to specify whether the report is for the mixture or for an individual phase.

Reports → **Fluxes** → **Set Up...**

Select **mixture** in the **Phase** drop-down list at the bottom of the dialog box to report fluxes for the mixture, or select the name of a phase to report fluxes just for that phase.

26.8.4. Reporting Forces on Walls

For Eulerian calculations, when you use the **Force Reports** dialog box to compute forces or moments on wall boundaries, you will be able to specify the individual phase for which you want to compute the forces.

Reports → **Forces** → **Set Up...**

Select the name of the desired phase in the **Phase** drop-down list on the left side of the dialog box.

26.8.5. Reporting Flow Rates

You can obtain a report of mass flow rate for each phase (and the mixture) through each flow boundary using the `report/fluxes/mass-flow` text command:

```
report → fluxes → mass-flow
```

When you specify the phase of interest (the mixture or an individual phase), ANSYS FLUENT will give you the option to list each zone, followed by a summary of the mass flow rate through that zone for the specified phase, or will summarize the mass flow rate for all zones. An example is shown below, demonstrating how to list the mass flow rate for all zones.

```
/report/fluxes> mf
(mixture water air)
domain id/name [mixture] air
all boundary/interior zones [yes]
Write to File? [no]

          air
Mass Flow Rate      (kg/s)
-----
spiral-press-outlet      -1.2330244
pressure-outlet           -9.7560663
spiral-vel-inlet           0.6150589
walls                      0
velocity-inlet            4.9132133
-----
Net                  -5.4608185
```

Chapter 27: Modeling Solidification and Melting

This chapter describes how you can model solidification and melting in ANSYS FLUENT. For information about the theory behind the model, see "Solidification and Melting" in the [Theory Guide](#). Information about using the model is organized into the following sections:

- 27.1. Setup Procedure
- 27.2. Procedures for Modeling Continuous Casting
- 27.3. Modeling Thermal and Solutal Buoyancy
- 27.4. Solution Procedure
- 27.5. Postprocessing

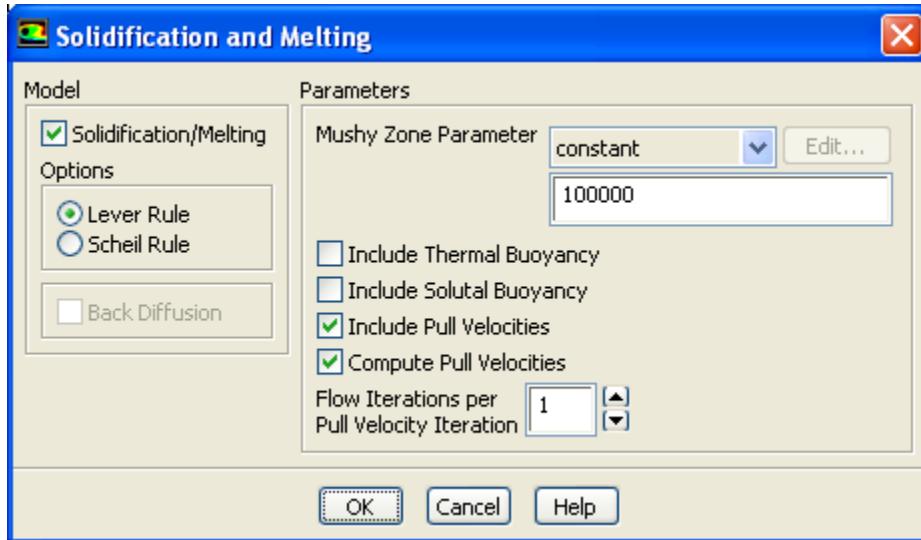

27.1. Setup Procedure

The procedure for setting up a solidification/melting problem is described below. (Note that this procedure includes only those steps necessary for the solidification/melting model itself; you will need to set up other models, boundary conditions, etc. as usual.)

1. To activate the solidification/melting model, enable the **Solidification/Melting** option in the **Solidification and Melting** dialog box ([Figure 27.1 \(p. 1297\)](#)).

Models → Solidification & Melting → Edit...

Figure 27.1 The Solidification and Melting Dialog Box

ANSYS FLUENT will automatically enable the energy equation, so you do not have to visit the **Energy** dialog box before turning on the solidification/melting model.

2. Under **Parameters**, specify the value of the **Mushy Zone Parameter** (A_{mush} in [Equation 18–6](#)) as a **constant**, or as a **user-defined** function. Please refer to [DEFINE_SOLIDIFICATION_PARAMS](#) in the UDF Manual for detailed information about the user-defined function.

Values between 10^4 and 10^7 are recommended for most computations. The higher the value of the **Mushy Zone Parameter**, the steeper the damping curve becomes, and the faster the velocity drops to zero as the material solidifies. Very large values may cause the solution to oscillate as control volumes alternately solidify and melt with minor perturbations in liquid volume fraction.

3. If you want to include the pull velocity in your simulation (as described in [Momentum Equations](#) and [Pull Velocity for Continuous Casting](#) in the [Theory Guide](#)), enable the **Include Pull Velocities** option under **Parameters**.
4. If you are including pull velocities and you want ANSYS FLUENT to compute them (using [Equation 18–22](#)) based on the specified velocity boundary conditions, as described in [Pull Velocity for Continuous Casting](#) in the Theory Guide, enable the **Compute Pull Velocities** option and specify the number of **Flow Iterations Per Pull Velocity Iteration**.

Important

It is not necessary to have ANSYS FLUENT compute the pull velocities. See [Procedures for Modeling Continuous Casting \(p. 1300\)](#) for information about other approaches.

The default value of 1 for the **Flow Iterations Per Pull Velocity Iteration** indicates that the pull velocity equations will be solved after each iteration of the solver. If you increase this value, the pull velocity equations will be solved less frequently. You may want to increase the number of **Flow Iterations Per Pull Velocity Iteration** if the liquid fraction equation is almost converged (i.e., the position of the liquid-solid interface is not changing very much). This will speed up the calculation, although the residuals may jump when the pull velocities are updated.

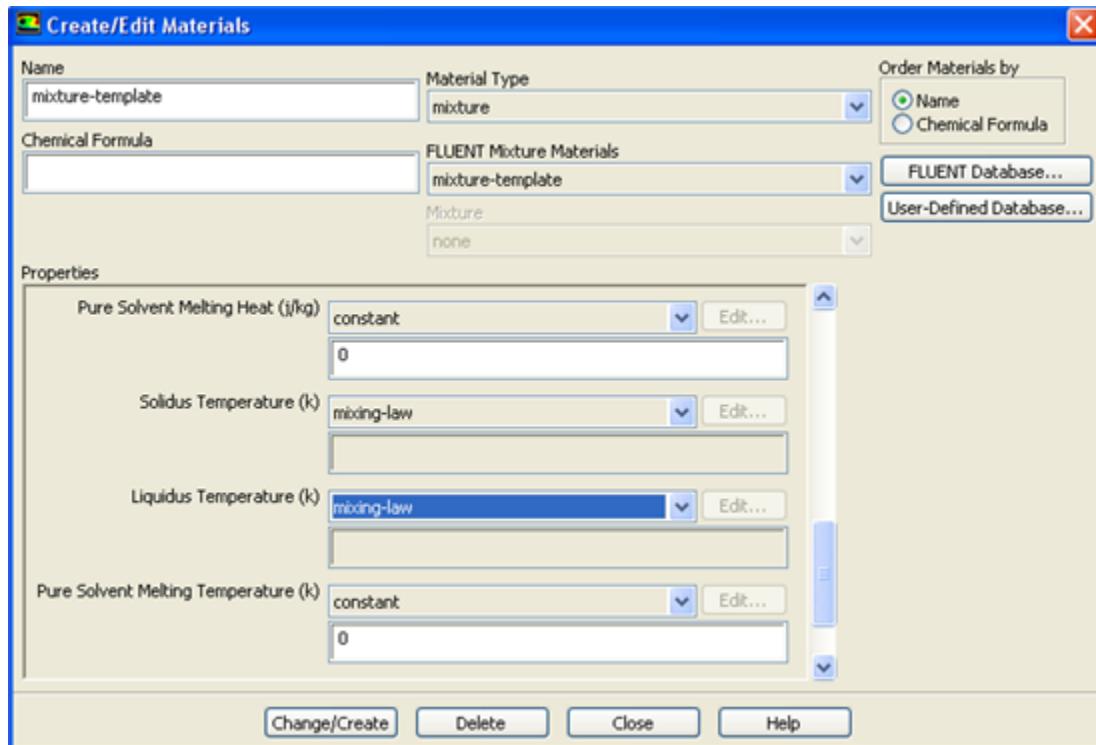

5. Under **Options**, select either **Lever Rule** or **Scheil Rule**. See [Species Equations](#) in the [Theory Guide](#) for details.

Important

The **Lever Rule** and **Scheil Rule** options are available only when **Species Transport** is enabled in the **Species Model** dialog box.

6. If you select **Scheil Rule**, then you can enable **Back Diffusion**. Enter either a **constant** or a **user-defined** function to specify the value of the **Back Diffusion Parameter** (γ in [Equation 18–19](#)). Please refer to [DEFINE_SOLIDIFICATION_PARAMS](#) in the UDF Manual for detailed information about the user-defined function. Note that the value for the **Back Diffusion Parameter** must be between 0 and 1.
7. In the [Create/Edit Materials Dialog Box \(p. 1882\)](#) ([Figure 27.2 \(p. 1299\)](#)), specify the **Pure Solvent Melting Heat** (L in [Equation 18–4](#)), **Solidus Temperature** ($T_{solidus}$ in [Equation 18–3](#)), and **Liquidus Temperature** ($T_{liquidus}$ in [Equation 18–3](#)) for the material being used in your model.

 **Materials**

Figure 27.2 The Create/Edit Materials Dialog Box for Melting and Solidification

If you are solving for species transport, you need to specify properties for the mixture, including the method by which the **Solidus Temperature** and the **Liquidus Temperature** are calculated. The default method is the **mixing-law** (Equation 18–8 and Equation 18–9 in the [Theory Guide](#)), in which the solidus temperature and the liquidus temperature are calculated from the parameters provided for each solute (such as the slope of the liquidus line or partition coefficient). However, a **user-defined** function of type `DEFINE_PROPERTY` can be used to specify both of these temperatures. See the [UDF Manual](#) for examples of `DEFINE_PROPERTY`.

Important

It is highly recommended that you use the same method for specifying the **Solidus Temperature** and the **Liquidus Temperature**.

When defining the mixture, you will also specify the **Mass Diffusivity** ($D_{i,m,\text{liq}}$ in Equation 18–15 and Equation 18–18) and the **Eutectic Temperature** (T_{Eut} in Equation 18–10), as well as the **Pure Solvent Melting Heat** (L in Equation 18–4) and the **Pure Solvent Melting Temperature** (T_{melt} in Equation 18–8 and Equation 18–9). Note that the solvent is the last species listed under **Selected Species** in the **Species** dialog box.

For each solute, you have to specify the **Slope of Liquidus Line** (m_i in Equation 18–8 and Equation 18–9 in the [Theory Guide](#)) with respect to the concentration of the solute, the **Partition Coefficient** (K_i in Equation 18–8), the **Eutectic Mass Fraction** ($Y_{i,\text{Eut}}$ in Equation 18–10), and, if **Lever Rule** is selected in the **Solidification and Melting** dialog box, the coefficient for **Diffusion in Solid** ($D_{i,m,\text{sol}}$ in Equation 18–15). It is not necessary to specify m_i , K_i , $Y_{i,\text{Eut}}$, and $D_{i,m,\text{sol}}$ for the solvent.

8. Set the boundary conditions.

Boundary Conditions...

In addition to the usual boundary conditions, consider the following:

- If you want to account for the presence of an air gap between a wall and an adjacent solidified region (as described in [Contact Resistance at Walls](#) in the Theory Guide), specify a nonzero value, a profile, or a user-defined function for **Contact Resistance** (R_c in [Equation 18–23](#)) under **Thermal Conditions** in the [Wall Dialog Box](#) (p. 2011).
- If you want to specify the gradient of the surface tension with respect to the temperature at a wall boundary, you can use the **Marangoni Stress** option for the wall **Shear Condition**. See [Marangoni Stress](#) (p. 318) for details.
- If you want ANSYS FLUENT to compute the pull velocities during the calculation, note how your specified velocity conditions are used in this calculation (see [Pull Velocity for Continuous Casting](#) in the Theory Guide).

[Procedures for Modeling Continuous Casting](#) (p. 1300) contains additional information about modeling continuous casting. See [Solution Procedure](#) (p. 1302) and [Postprocessing](#) (p. 1302) for information about solving a solidification/melting model and postprocessing the results.

27.2. Procedures for Modeling Continuous Casting

As described in [Momentum Equations](#) and [Pull Velocity for Continuous Casting](#) in the Theory Guide, you can include the pull velocities in your solidification/melting calculation to model continuous casting. There are three approaches to modeling continuous casting in ANSYS FLUENT:

- Specify constant or variable pull velocities.

To use this approach (the default), do not enable the **Compute Pull Velocities** option.

If you use this approach, you will need to patch constant values or custom field functions for the pull velocities, after you initialize the solution.

Solution Initialization → Patch...

See [Patching Values in Selected Cells](#) (p. 1351) for details about patching values. Note that it is acceptable to patch values for the pull velocities in the entire domain, because the patched values will be used only if the liquid fraction, β , is less than 1.

- Have ANSYS FLUENT compute the pull velocities (using [Equation 18–22](#)) during the calculation, based on the specified velocity boundary conditions.

To use this approach, enable the **Compute Pull Velocities** option. This method is computationally expensive, and is recommended only if the pull velocities are strongly dependent on the location of the liquid-solid interface.

If you have ANSYS FLUENT compute the pull velocities, then there are no additional inputs or setup procedures beyond those presented in [Setup Procedure](#) (p. 1297).

- Have ANSYS FLUENT compute the pull velocities just once, and then use those values for the remainder of the calculation.

To use this approach, perform one iteration with ANSYS FLUENT computing the pull velocities, and then turn off the **Compute Pull Velocities** option and continue the calculation. For the remainder

of the calculation, ANSYS FLUENT will use the values computed for the pull velocities at the first iteration.

27.3. Modeling Thermal and Solutal Buoyancy

When the effects of thermal and solutal buoyancy are present, a flow can be induced inside the domain due to the effect of gravity on the variable density of the medium. In the case of multi-component solidification problems, the density variation takes place due to temperature changes and also due to species concentration gradients near the liquid-solid interface. The flow due to buoyancy with solidification and melting can be modeled in ANSYS FLUENT using the thermal and solutal buoyancy options.

For more information on the theory behind buoyancy induced flow in solidification and melting problems, please see [Thermal and Solutal Buoyancy](#) in the [Theory Guide](#).

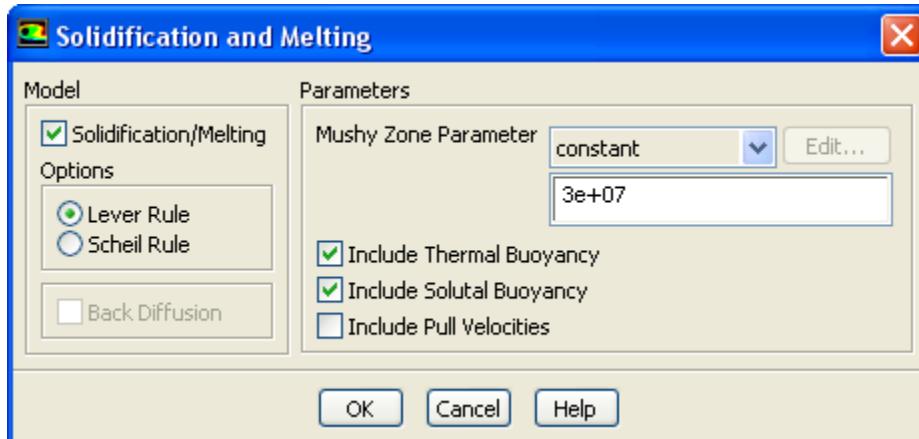

The procedure for setting up a solidification/melting problem is described in [Setup Procedure \(p. 1297\)](#). To include thermal and solutal buoyancy effects, perform the following steps:

1. Enable the **Include Thermal Buoyancy** and **Include Solutal Buoyancy** options in the **Solidification and Melting** dialog box ([Figure 27.3 \(p. 1301\)](#)).

Note

The **Include Thermal Buoyancy** and **Include Solutal Buoyancy** options are available only when solidification is modeled with species transport.

Figure 27.3 The Solidification and Melting Dialog Box

2. Define the operating conditions and properties for modeling thermal buoyancy as described in [Natural Convection and Buoyancy-Driven Flows \(p. 743\)](#).
3. To model solutal buoyancy, specify a value for the **Solutal Expansion Coefficient** for all the species except the last one in the mixture in the **Create/Edit Materials** dialog box.

Note

By default, the eutectic mass fraction of the solute is used as the reference species mass fraction of the solute for the calculation of the body force due to solutal buoyancy.

Therefore, no additional input is required. However, in certain applications, it is not always desirable to use the default values of the reference mass fraction. For such cases, the solute mass fraction values can be entered through text user interface as follows:

```
define/models/solidification-melting? yes
Include Thermal Buoyancy? yes
Include Solutal Buoyancy? yes
Use reference mass fraction of solutes? yes
Reference mass fraction of the species-i "value"
```

27.4. Solution Procedure

Before solving the coupled fluid flow and heat transfer problem, you may want to patch an initial temperature or solve the steady conduction problem as an initial condition. The coupled problem can then be solved as either steady or transient. Because of the nonlinear nature of these problems, however, in most cases a transient solution approach is preferred.

You can specify the under-relaxation factor applied to the liquid fraction equation in the [Solution Controls Task Page \(p. 2052\)](#).

Solution Controls

Specify the desired value in the **Liquid Fraction Update** field under **Under-Relaxation Factors**. This sets the value of α_β in the following equation for updating the liquid fraction from one iteration (n) to the next ($n + 1$):

$$\beta_{n+1} = \beta_n + \alpha_\beta \Delta\beta \quad (27-1)$$

where $\Delta\beta$ is the predicted change in liquid fraction.

In many cases, there is no need to change the default value of α_β . If, however, there are convergence difficulties, reducing the value may improve the solution convergence. Convergence difficulties can be expected in steady-state calculations, continuous casting simulations, simulations involving multicomponent solidification, and simulations where a large value of the mushy zone constant is used.

27.5. Postprocessing

For solidification/melting calculations, you can generate graphical plots or alphanumeric reports of the following items depending on which other models are enabled in the simulation. These quantities are available in the **Solidification/Melting...** category of the variable selection drop-down list that appears in postprocessing dialog boxes:

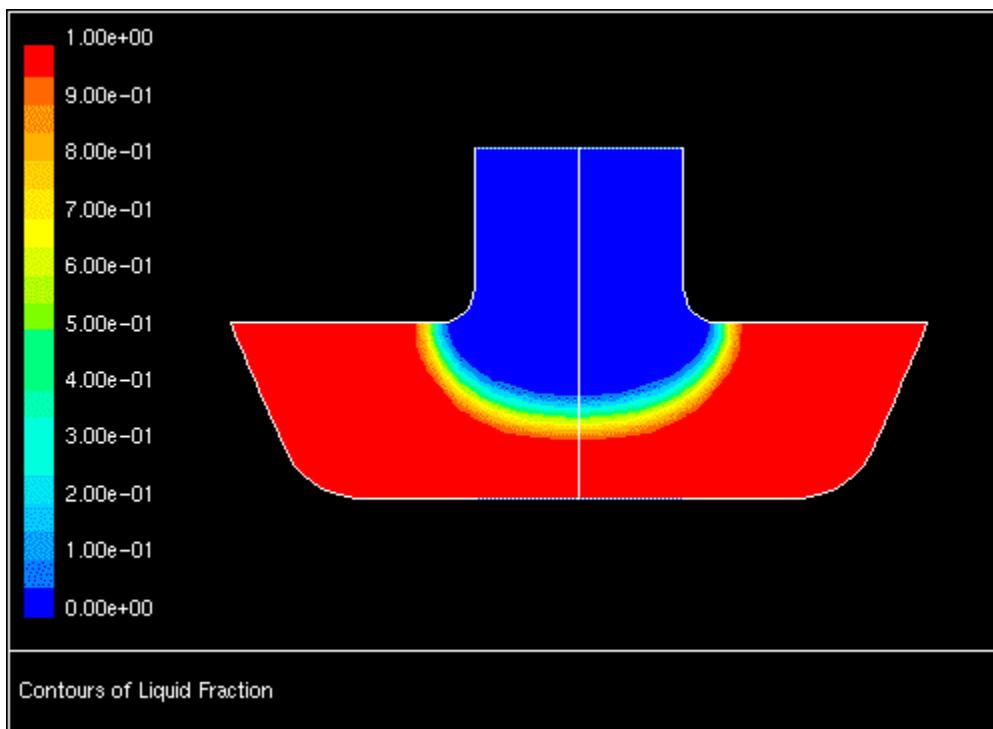

- **Liquid Fraction**
- **Contact Resistivity**
- **Pull Velocity (X, Y, Z, Axial, Radial, and Swirl components)**
- **Liquidus Temperature**

- **Solidus Temperature**

The **Liquid Fraction** and **Contact Resistivity** solution variables are available for all solidification/melting simulations. The **Pull Velocity** components are available only if you are including pull velocities (either computed or specified) in the simulation. **Liquidus Temperature** and **Solidus Temperature** are available only if the **Species** model is activated to perform a multi-component solidification/melting simulation. See *Field Function Definitions* (p. 1653) for a complete list of field functions and their definitions. *Displaying Graphics* (p. 1499) and *Reporting Alphanumeric Data* (p. 1633) explain how to generate graphics displays and reports of data.

Figure 27.4 (p. 1303) shows filled contours of liquid fraction for a continuous crystal growth simulation.

Figure 27.4 Liquid Fraction Contours for Continuous Crystal Growth

Chapter 28: Modeling Eulerian Wall Films

The Eulerian Wall Film (EWF) model can be used to predict the creation and flow of thin liquid films on the surface of walls. This chapter presents information about the basic functionality of the Eulerian Wall Film (EWF) model. Additional information about the model is provided in the following sections:

- 28.1. Limitations
- 28.2. Setting Eulerian Wall Film Model Options
- 28.3. Setting Eulerian Wall Film Solution Controls
- 28.4. Postprocessing the Eulerian Wall Film

For more information about Eulerian Wall Film model theory, see "Eulerian Wall Films" in the [Theory Guide](#). For more information about setting boundary conditions for liquid films at wall boundaries, see [.Wall Film Boundary Conditions for Walls \(p. 330\)](#)

28.1. Limitations

The following limitations exist for the Eulerian Wall Film model:

- Available for 3-D geometries only
- Compatible with stationary walls only

Many models (e.g., VOF multiphase flow or radiation) will not interact correctly with the film model without first modifying the boundary conditions using UDFs.

28.2. Setting Eulerian Wall Film Model Options

You can enable the Eulerian Wall Film model by selecting **Eulerian Wall Film** from the **Models** task page.

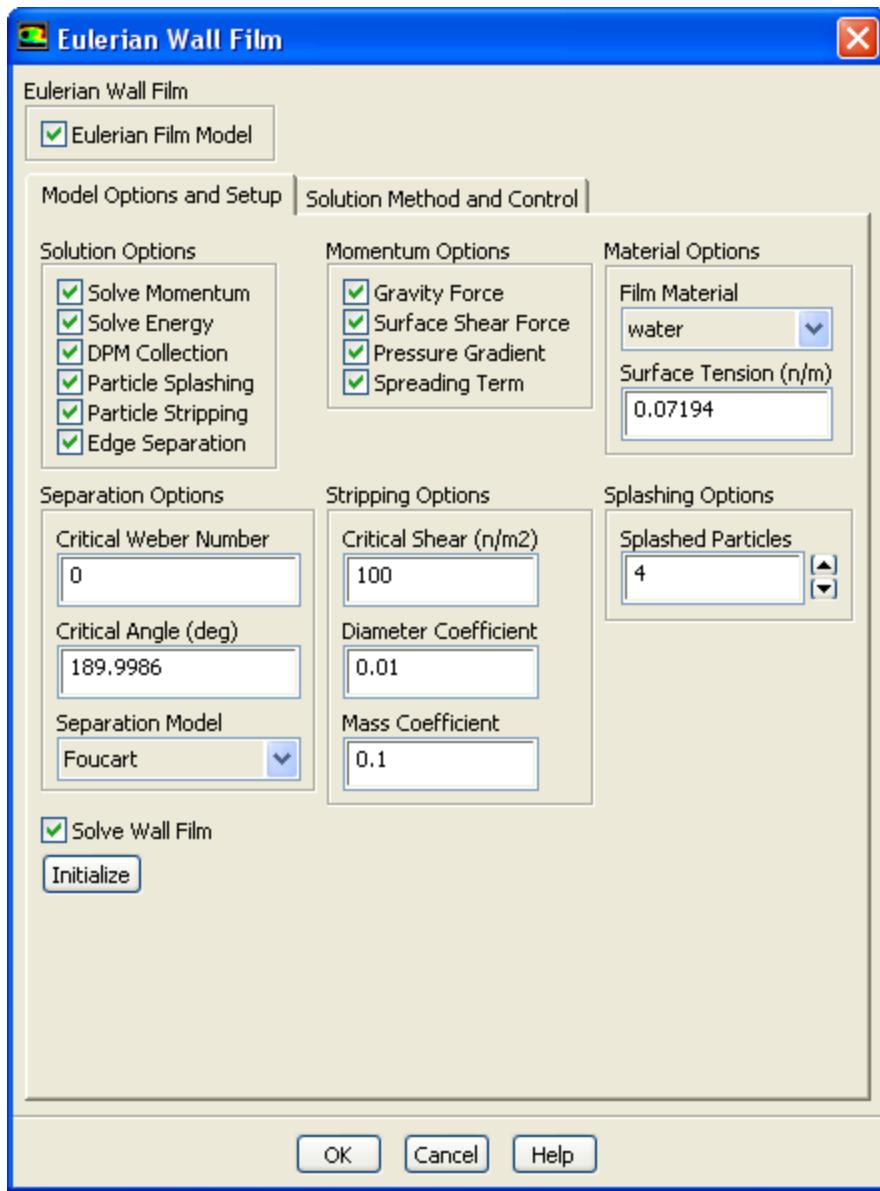

◆ **Models** →  **Eulerian Wall Film** → **Edit...**

This opens the **Eulerian Wall Film** dialog box.

Once you open the [Eulerian Wall Film Dialog Box \(p. 1876\)](#), you can select the **Eulerian Wall Film** check box to enable the model so that you can use it in your simulation. Enabling the model expands the dialog box to reveal additional model options and solution controls.

You can set general Eulerian Wall Film model options in the **Model Options and Setup** tab of the **Eulerian Wall Film** dialog box. This tab contains controls for specific solution, discrete phase model (DPM), and material options for the Eulerian Wall Film model.

In the **Model Options and Setup** tab, you can enable and disable the **Solve Momentum** option to specify whether the momentum equation (see [Equation 19–2](#) in the [Theory Guide](#)) is solved for the wall film or not. If selected, each term of the equation can be individually selected for inclusion in the calculations. In addition, under **Material Options**, you can set material properties and surface tension values for the wall film.

In addition, you can enable and disable the **Solve Energy** option to specify whether the energy equation (see [Equation 19–3](#) in the [Theory Guide](#)) is solved for the wall film or not.

If you would like to include discrete phase particles and their interaction with the film model, you can enable the **DPM Collection** option (see [DPM Collection](#) in the [Theory Guide](#)). This option allows you to choose particle splashing (see [Film Sub-Models](#) in the [Theory Guide](#)), particle stripping and/or edge separation (see [Film Separation](#) in the [Theory Guide](#)) options for your simulation.

Using the **Solve Wall Film** option allows you to skip the wall film solution during the gas phase solution, but keep the variables and setup active.

Note

The wall film cannot be solved without first initializing the wall film model (using the **Initialize** button) to initialize the wall film variables and prepare the solver for the solution procedure.

28.3. Setting Eulerian Wall Film Solution Controls

You can set solution controls for the Eulerian Wall Film model in the **Solution Method and Control** tab of the **Eulerian Wall Film** dialog box. This tab contains controls for specific temporal and spatial discretization options for the Eulerian Wall Film model.

Figure 28.1 Eulerian Wall Film Solution Controls (Steady Flow)

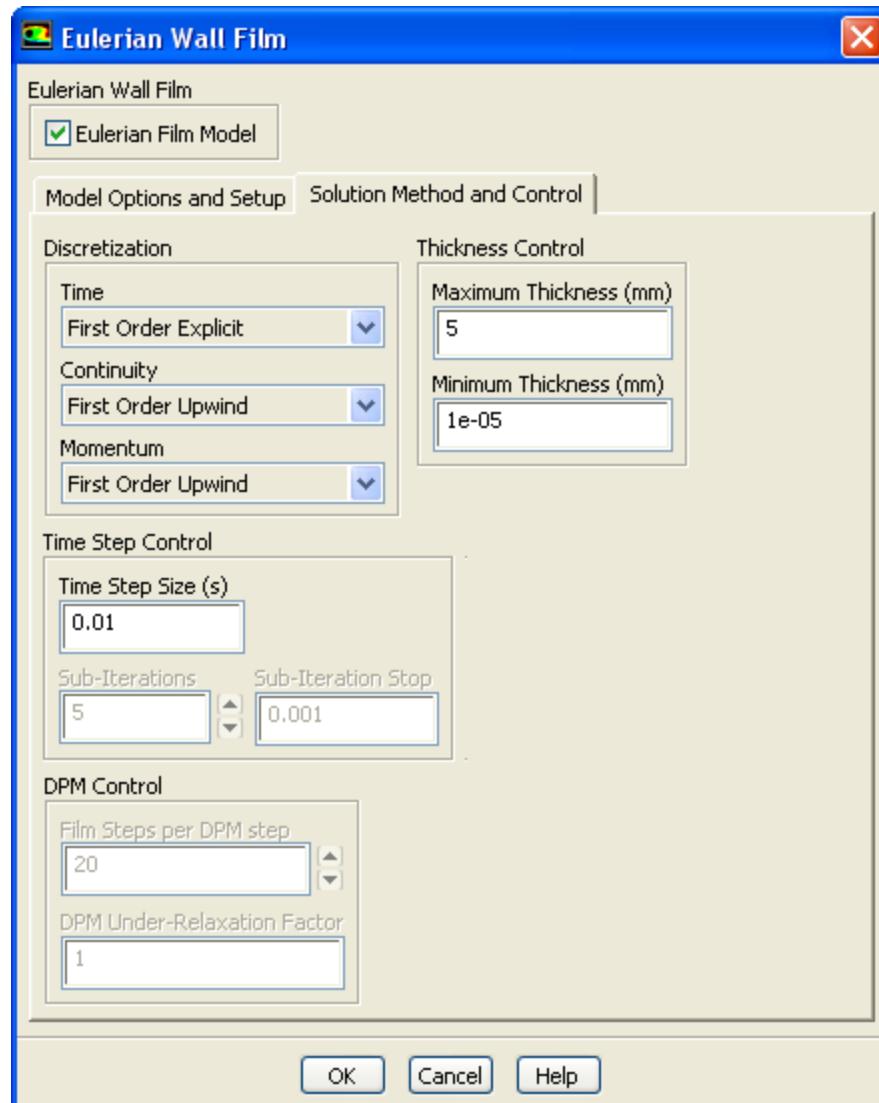

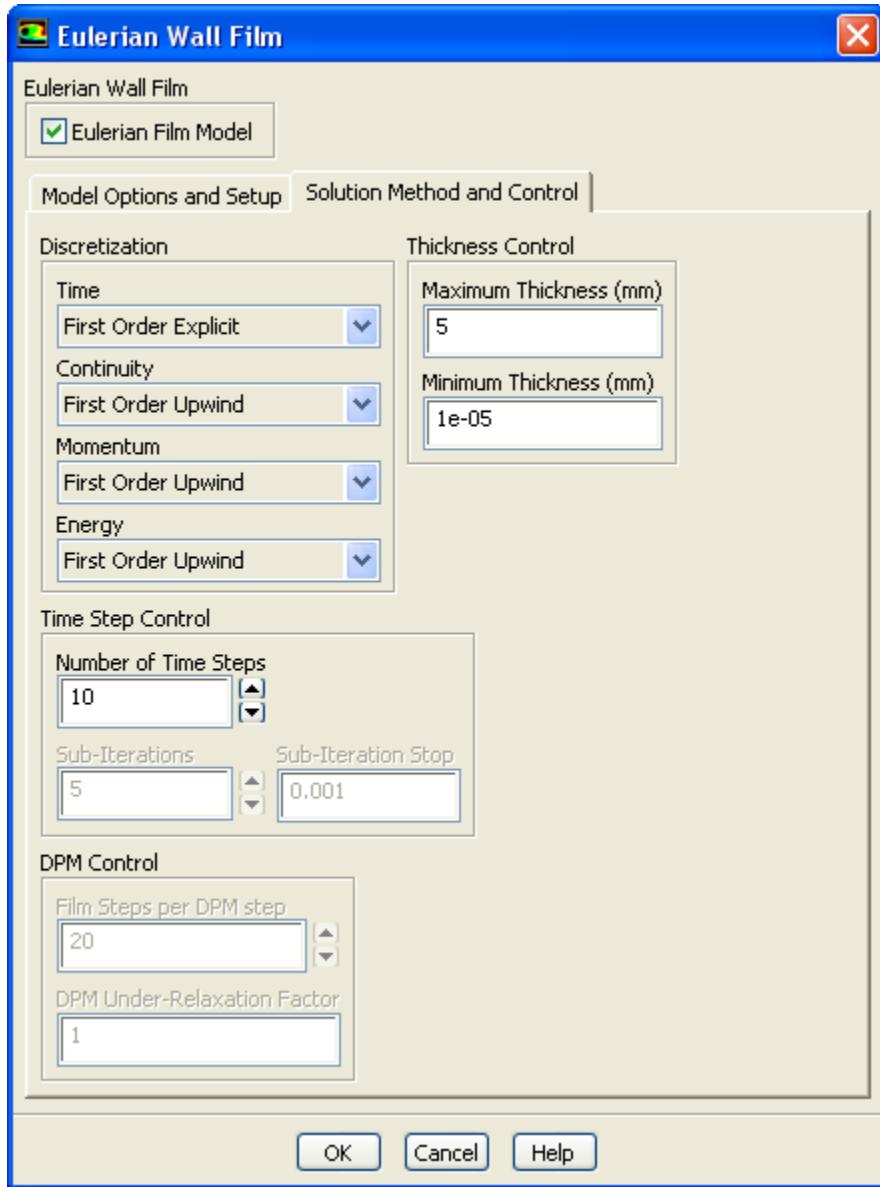

Figure 28.2 Eulerian Wall Film Solution Controls (Unsteady Flow)

In the **Solution Method and Control** tab, you can set the temporal and spatial (continuity and momentum) discretization methods under **Discretization**. In addition, you can set the **Maximum Thickness** and **Minimum Thickness** for the film. The **Maximum Thickness** setting will limit the film thickness by removing material from the film where this value is exceeded. The **Minimum Thickness** is the thickness below which the film is assumed to be stationary and have the same temperature as the wall.

For steady state calculations ([Figure 28.1 \(p. 1307\)](#)), you can specify the film model specific **Time Step Size** (the Eulerian Wall Film model is always transient). For transient cases ([Figure 28.2 \(p. 1308\)](#)), the **Number of Time Steps** per main flow time step can be specified.

For either first or second order implicit time discretization calculations, you can control the number of **Sub-Iterations** and the point at which the sub-steps are stopped when the film residual drops below the value set in the **Sub-Iteration Stop** option.

If the **DPM Collections** option is enabled in the **Model Options and Setup** tab, you can set how often the DPM phase is calculated for the film by specifying a value for the **Film Steps per DPM Step**.

28.4. Postprocessing the Eulerian Wall Film

When using the Eulerian Wall Film model, the following additional variables will be available for post-processing (see [Field Function Definitions](#) (p. 1653) for their definitions):

- **Film Thickness**
- **Film Mass**
- **Film Temperature** (when **Solve Energy** is enabled)
- **Film X-Velocity**
- **Film Y-Velocity**
- **Film Z-Velocity**
- **Film Velocity Magnitude**
- **Film Effective Pressure**
- **Film Surface X-Velocity**
- **Film Surface Y-Velocity**
- **Film Surface Z-Velocity**
- **Film Surface Velocity Magnitude**
- **Film Surface Temperature** (when **Solve Energy** is enabled)
- **Film Courant Number**
- **Film Weber Number**
- **Film Stripped Mass Source** (when **Particle Stripping** is enabled)
- **Film Stripped Diam** (when **Particle Stripping** is enabled)
- **Film DPM Mass Source** (when **DPM Collection** is enabled)
- **Film DPM Energy Source** (when **DPM Collection** and **Solve Energy** are enabled)
- **Film DPM X-Momentum Source** (when **DPM Collection** is enabled)
- **Film DPM Y-Momentum Source** (when **DPM Collection** is enabled)
- **Film DPM Z-Momentum Source** (when **DPM Collection** is enabled)
- **Film X-Momentum Source** (when **Solve Momentum** is enabled)
- **Film Y-Momentum Source** (when **Solve Momentum** is enabled)
- **Film Shed Mass** (when **Edge Separation** is enabled)

Chapter 29: Using the Solver

This chapter describes how to use the ANSYS FLUENT solver. For more information about the theory behind the ANSYS FLUENT solver, see "Solver Theory" in the [Theory Guide](#). *Choosing the Solver* (p. 1313) provides an overview, and the remaining sections provide detailed instructions.

29.1. Overview of Using the Solver

In ANSYS FLUENT, two solver technologies are available:

- pressure-based
- density-based

Both solvers can be used for a broad range of flows, but in some cases one formulation may perform better (i.e., yield a solution more quickly or resolve certain flow features better) than the other. The pressure-based and density-based approaches differ in the way that the continuity, momentum, and (where appropriate) energy and species equations are solved, as described in [Overview of Flow Solvers](#) in the [Theory Guide](#).

The pressure-based solver traditionally has been used for incompressible and mildly compressible flows. The density-based approach, on the other hand, was originally designed for high-speed compressible flows. Both approaches are now applicable to a broad range of flows (from incompressible to highly compressible), but the origins of the density-based formulation may give it an accuracy (i.e. shock resolution) advantage over the pressure-based solver for high-speed compressible flows.

Two formulations exist under the density-based solver: implicit and explicit. The density-based explicit and implicit formulations solve the equations for additional scalars (e.g., turbulence or radiation quantities) sequentially. The implicit and explicit density-based formulations differ in the way that they linearize the coupled equations. For more details about the solver formulations, see [Overview of Flow Solvers](#) in the [Theory Guide](#).

Due to broader stability characteristics of the implicit formulation, a converged steady-state solution can be obtained much faster using the implicit formulation rather than the explicit formulation. However, the implicit formulation requires more memory than the explicit formulation.

Two algorithms also exist under the pressure-based solver in ANSYS FLUENT: a segregated algorithm and a coupled algorithm. In the segregated algorithm the governing equations are solved sequentially, segregated from one another, while in the coupled algorithm the momentum equations and the pressure-based continuity equation are solved in a coupled manner. In general, the coupled algorithm significantly improves the convergence speed over the segregated algorithm, however, the memory requirement for the coupled algorithm is more than the segregated algorithm.

When selecting a solver and an algorithm you must consider the following issues:

- The model availability for a given solver.
- Solver performance for the given flow conditions.
- The size of the mesh under consideration and the available memory on your machine. This issue could be an important factor in deciding whether to use an explicit or implicit formulation when the density-based solver is selected, or to use a segregated or coupled algorithm when the pressure-based solver is selected.

The following two lists highlight the model availability for each solver:

Important

Note that the pressure-based solver provides several physical models or features that are not available with the density-based solver:

- Cavitation model
- Volume-of-fluid (VOF) model
- Multiphase mixture model
- Eulerian multiphase model
- Non-premixed combustion model
- Premixed combustion model
- Partially premixed combustion model
- Composition PDF transport model
- Soot model
- Rosseland radiation model
- Melting/solidification model
- Shell conduction model
- Floating operating pressure
- Fixed variable option

- Physical velocity formulation for porous media
- Specified mass flow rate for streamwise periodic flow

The following features are available with the density-based solver, but not with the pressure-based solver:

- Real gas models (User-defined and NIST)
- Non-reflecting boundary conditions
- Wet steam multiphase model

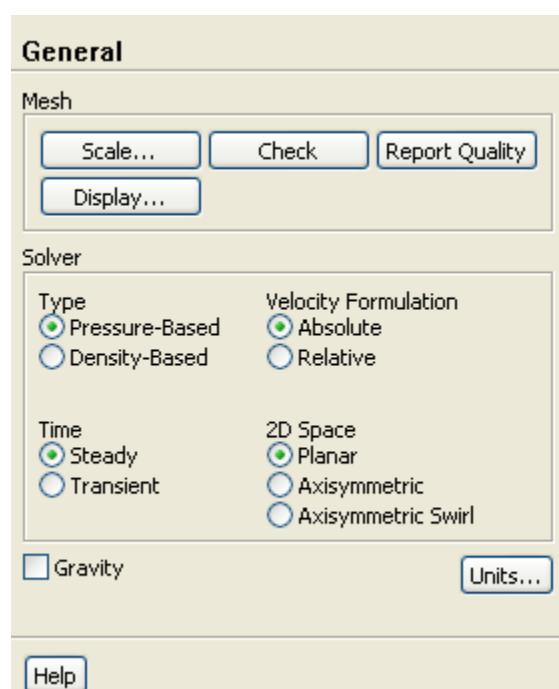

For additional information, please see the following sections:

29.1.1. Choosing the Solver

To choose one of the solvers, you will use the *General Task Page* (p. 1763) (*Figure 29.1* (p. 1313)).

Figure 29.1 The General Task Page

To use the pressure-based solver, retain the default selection of **Pressure-Based** under **Solver**.

To use the density-based solver, select **Density-Based** under **Solver**.

After you have defined your model and specified which solver you want to use, you are ready to run the solver. The following steps outline a general procedure you can follow:

1. (pressure-based solver only) Select the pressure-velocity coupling method (see *Choosing the Pressure-Velocity Coupling Method* (p. 1321)).

2. Choose the spatial discretization scheme and, for the pressure-based solver, the pressure interpolation scheme (see [Choosing the Spatial Discretization Scheme \(p. 1314\)](#)).
3. (pressure-based solver only) Select the porous media velocity method (see [Porous Media Conditions \(p. 229\)](#)).
4. Select how you want the derivatives to be evaluated by choosing a gradient option (see [Evaluation of Gradients and Derivatives](#) in the [Theory Guide](#)).
5. Set the under-relaxation factors (see [Setting Under-Relaxation Factors \(p. 1323\)](#)).
6. (density-based explicit formulation only) Set up the FAS multigrid (see [Turning On FAS Multigrid \(p. 1334\)](#)).
7. Make any additional modifications to the solver settings that are suggested in the chapters or sections that describe the models you are using.
8. Enable the appropriate solution monitors (see [Monitoring Solution Convergence \(p. 1379\)](#)).
9. Initialize the solution (see [Initializing the Solution \(p. 1348\)](#)).
10. Start calculating (see [Performing Steady-State Calculations \(p. 1358\)](#) for steady state calculations, or [Performing Time-Dependent Calculations \(p. 1365\)](#) for time-dependent calculations).
11. If you have convergence trouble, try one of the methods discussed in [Convergence and Stability \(p. 1430\)](#).

The default settings for the first three items listed above are suitable for most problems and need not be changed. The following sections outline how these and other solution parameters can be changed, and when you may wish to change them.

29.2. Choosing the Spatial Discretization Scheme

Gradients are needed not only for constructing values of a scalar at the cell faces, but also for computing secondary diffusion terms and velocity derivatives. For more information about the different gradients, see [Evaluation of Gradients and Derivatives](#) in the [Theory Guide](#).

The three gradients which are available in ANSYS FLUENT are

- **Green-Gauss Cell Based**
- **Green-Gauss Node Based**
- **Least Squares Cell Based**

The gradient options are selectable from the **Gradient** drop-down list, in the **Solution Methods** task page.

Solution Methods

In addition, ANSYS FLUENT allows you to choose the discretization scheme for the convection terms of each governing equation. (Second-order accuracy is automatically used for the viscous terms.) When the pressure-based solver is used, all equations are, by default, solved using the first-order upwind discretization for convection. When the density-based solver is used, the flow equations are solved using the second-order scheme by default, and the other equations use the first-order scheme by default. For a complete description of the discretization schemes available in ANSYS FLUENT, see [Discretization](#) in the [Theory Guide](#).

In addition, when you use the pressure-based solver, you can specify the pressure interpolation scheme. For a description of the pressure interpolation schemes available in ANSYS FLUENT, see [Pressure Interpolation Schemes](#) in the [Theory Guide](#).

For additional information, please see the following sections:

- [29.2.1. First-Order Accuracy vs. Second-Order Accuracy](#)
- [29.2.2. Other Discretization Schemes](#)
- [29.2.3. Choosing the Pressure Interpolation Scheme](#)
- [29.2.4. Choosing the Density Interpolation Scheme](#)
- [29.2.5. High Order Term Relaxation \(HOTR\)](#)
- [29.2.6. User Inputs](#)

29.2.1. First-Order Accuracy vs. Second-Order Accuracy

When the flow is aligned with the mesh (e.g., laminar flow in a rectangular duct modeled with a quadrilateral or hexahedral mesh) the first-order upwind discretization may be acceptable. When the flow is not aligned with the mesh (i.e., when it crosses the mesh lines obliquely), however, first-order convective discretization increases the numerical discretization error (numerical diffusion). For triangular and tetrahedral meshes, since the flow is never aligned with the mesh, you will generally obtain more accurate results by using the second-order discretization. For quad/hex meshes, you will also obtain better results using the second-order discretization, especially for complex flows.

In summary, while the first-order discretization generally yields better convergence than the second-order scheme, it generally will yield less accurate results, especially on tri/tet meshes. See [Convergence and Stability \(p. 1430\)](#) for information about controlling convergence.

For most cases, you will be able to use the second-order scheme from the start of the calculation. In some cases, however, you may need to start with the first-order scheme and then switch to the second-order scheme after a few iterations. For example, if you are running a high-Mach-number flow calculation that has an initial solution much different than the expected final solution, you will usually need to perform a few iterations with the first-order scheme and then turn on the second-order scheme and continue the calculation to convergence. Alternatively, full multigrid initialization is also available for some flow cases which allow you to proceed with the second-order scheme from the start.

For a simple flow that is aligned with the mesh (e.g., laminar flow in a rectangular duct modeled with a quadrilateral or hexahedral mesh), the numerical diffusion will be naturally low, so you can generally use the first-order scheme instead of the second-order scheme without any significant loss of accuracy.

Finally, if you run into convergence difficulties with the second-order scheme, you should try the first-order scheme instead.

29.2.1.1. First-to-Higher Order Blending

While the higher-order scheme may result in greater accuracy, it can also result in convergence difficulties and instabilities at certain flow conditions. On the other hand, using a first-order scheme may not provide the desired accuracy. One approach to achieving improved accuracy while maintaining good stability is to use a discretization blending factor. This feature is available for both density-based and pressure-based solvers and can be invoked using the following text command:

`solve → set → numerics`

Enter a value between 0 and 1 when asked for the blending factor: 1st-order to higher-order blending factor [min=0.0 - max=1.0]

A blending factor of 0 reduces the gradient reconstruction to a first-order discretization scheme, whereas 1 will recover high-order discretization. A blending factor of less than 1 (typically 0.75 or 0.5) will make the convective fluxes more diffusive, which in some flow conditions can stabilize a solution that is otherwise unstable when the full higher-order discretization scheme is employed.

Important

Note that in order to use this feature effectively, make sure that one of the allowed higher order discretization schemes is selected for the desired variables in the **Solution Methods** task page.

29.2.2. Other Discretization Schemes

The QUICK and third-order MUSCL discretization schemes may provide better accuracy than the second-order scheme for rotating or swirling flows. The QUICK scheme is applicable to quadrilateral or hexahedral meshes, while the MUSCL scheme is used on all types of meshes. In general, however, the second-order scheme is sufficient and the QUICK scheme will not provide significant improvements in accuracy.

Important

If QUICK is used for hybrid meshes, it will be used only for quadrilateral and hexahedral cells. Second-order upwind discretization will be applied to all other cells.

A power law scheme is also available, but it will generally yield the same accuracy as the first-order scheme.

The bounded central differencing and central differencing schemes are available only when you are using the LES and DES turbulence models, and the central differencing scheme should be used only when the mesh spacing is fine enough so that the magnitude of the local Peclet number (see [Equation 20–6](#) in the [Theory Guide](#)) is less than 1.

A modified HRIC scheme (see [Modified HRIC Scheme](#) in the [Theory Guide](#)) is also available for VOF simulations using either the implicit or explicit formulation.

29.2.3. Choosing the Pressure Interpolation Scheme

As discussed in [Pressure Interpolation Schemes](#) in the Theory Guide, a number of pressure interpolation schemes are available when the pressure-based solver is used in ANSYS FLUENT. For most cases the "standard" scheme is acceptable, but some types of models may benefit from one of the other schemes:

- For problems involving large body forces, the body-force-weighted scheme is recommended.
 - For flows with high swirl numbers, high-Rayleigh-number natural convection, high-speed rotating flows, flows involving porous media, and flows in strongly curved domains, use the PRESTO! scheme.
 - For compressible flows, the second-order scheme is recommended.
 - Use the second-order scheme for improved accuracy when one of the other schemes is not applicable.
-

Important

The second-order scheme cannot be used with porous media or porous jump.

Important

Only PRESTO! and body-force-weighted schemes are available for the VOF model.

Note that you will not specify the pressure interpolation scheme if you are using the Eulerian multiphase model. ANSYS FLUENT will use the solution method described in [Solution Method in ANSYS FLUENT](#) in the Theory Guide for Eulerian multiphase calculations.

29.2.4. Choosing the Density Interpolation Scheme

As discussed in [Density Interpolation Schemes](#) in the [Theory Guide](#), four density interpolation schemes are available when the pressure-based solver is used to solve a single-phase compressible flow.

The first-order upwind scheme (the default) provides stability for the discretization of the pressure-correction equation, and gives good results for most classes of flows. If you are calculating a compressible flow with shocks, the first-order upwind scheme may tend to smooth the shocks; you should use the second-order-upwind or QUICK scheme for such flows. For compressible flows with shocks, using the QUICK scheme for all variables, including density, is highly recommended for quadrilateral, hexahedral, or hybrid meshes. The third-order MUSCL scheme is applicable to arbitrary meshes and has the potential to improve spatial accuracy for all types of meshes by reducing numerical diffusion.

Important

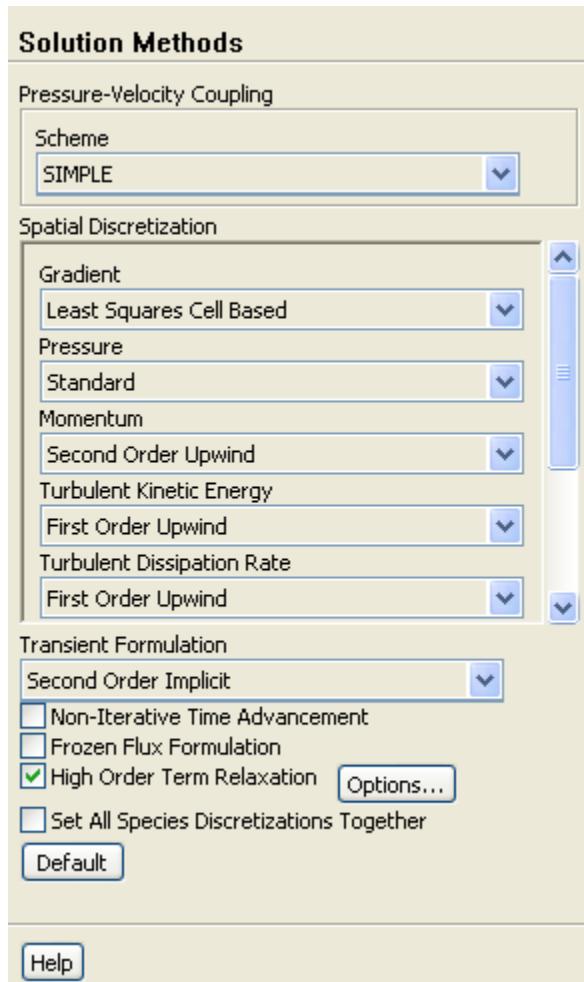

In the case of multiphase flows, the selected density scheme is applied to the compressible phase and arithmetic averaging is used for incompressible phases.

29.2.5. High Order Term Relaxation (HOTR)

The purpose of the relaxation of high order terms is to improve the startup and the general solution behavior of flow simulations when higher order spatial discretizations are used (higher than first). It has also shown to prevent convergence stalling in some cases. Such high-order terms can be of significant importance in certain cases and lead to numerical instabilities. This is particularly true at aggressive solution settings. In such cases, high order relaxation is a useful strategy to minimize your interaction during the solution. This can be an effective alternative to starting the solution first order, then switching to second order spatial discretization at a later stage.

The **High Order Term Relaxation** option can be enabled from the **Solution Methods** task page, as shown in [Figure 29.2 \(p. 1318\)](#).

Figure 29.2 The Solution Methods Task Page for the HOTR Option

Further control of **High Order Term Relaxation** can be obtained after clicking **Options...** and making the necessary selections and settings in the **Relaxation Options** dialog box ([Figure 29.3 \(p. 1318\)](#)).

Figure 29.3 The Relaxation Options Dialog Box

You have the option of selecting **All Variables** to be under-relaxed instead of only the default flow variables (**Flow Variables Only**).

- If you select **Flow Variables Only**, then the following variables will be under-relaxed:
 - Velocity components

- Pressure
- Energy
- Density
- Turbulence quantities (excluding Reynolds stresses)
- Volume fraction
- If you select **All Variables**, then relaxation is applied to each variable discretized with a higher order scheme.

The default values for the **Relaxation Factor** is 0.25 for steady state cases and 0.75 for transient cases. The same factor is applied to all equations solved.

For theoretical information about high order term relaxation, please see [High Order Term Relaxation](#) in the [Theory Guide](#).

29.2.5.1. Limitations

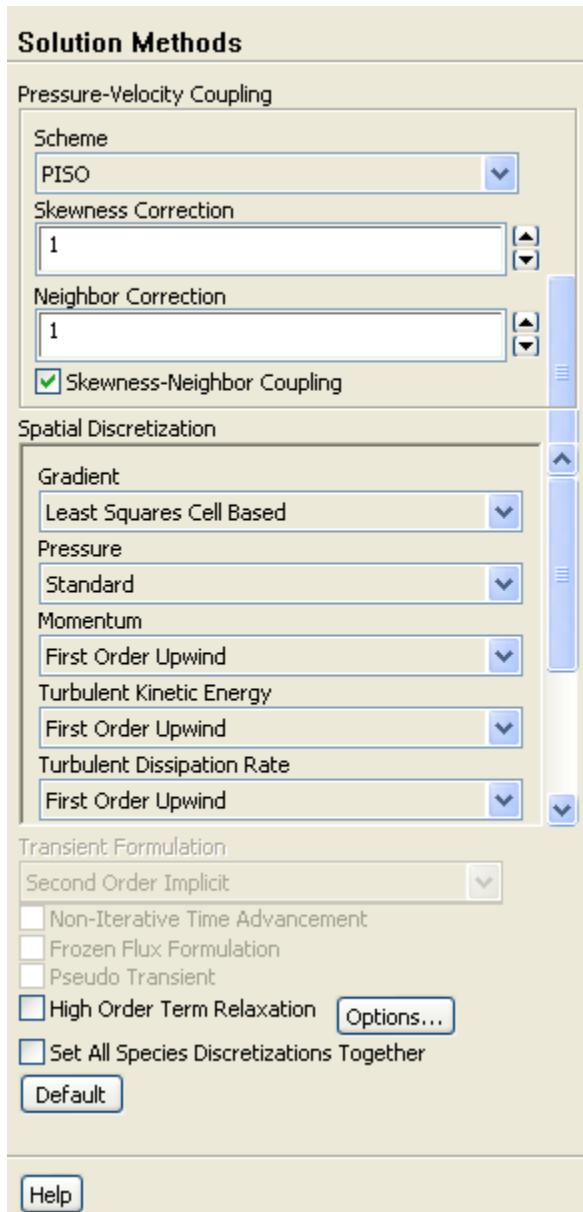

The following limitations exist when using the **High Order Term Relaxation** option:

- The **High Order Term Relaxation** option is not available when the **Non-Iterative Time Advancement** option is enabled, since the simulation would not achieve the required level of high order spatial accuracy.
- In general, high order term relaxation is available for transient flows. Nevertheless, it should be used with care. To achieve high order accuracy at convergence for each time step, you must increase the number of iterations per time step to ensure that the original convergence criteria have been met.
- When the QUICK scheme is selected for specific transport equations, no under-relaxation is applied to this equation.

29.2.6. User Inputs

You can specify the discretization scheme and, for the pressure-based solver, the pressure interpolation scheme in the [Solution Methods Task Page](#) (p. 2048) ([Figure 29.4](#) (p. 1320)).

Figure 29.4 The Solution Methods Task Page for the Pressure-Based Segregated Algorithm

For each scalar equation listed under **Spatial Discretization** (**Momentum**, **Energy**, **Turbulent Kinetic Energy**, etc. for the pressure-based solver or **Turbulent Kinetic Energy**, **Turbulent Dissipation Rate**, etc. for the density-based solver) you can choose **First Order Upwind**, **Second Order Upwind**, **Power Law**, **QUICK**, **Third-Order MUSCL**, or (if you are using the LES turbulence model) **Bounded Central Differencing** (the default) or **Central Differencing** in the adjacent drop-down list. For the density-based solver, you can choose either **First Order Upwind**, **Second Order Upwind**, or **Third-Order MUSCL** for the **Flow** equations (which include momentum and energy). Note that the task page shown in [Figure 29.4 \(p. 1320\)](#) is for the pressure-based solver.

If you are using the pressure-based solver, select the pressure interpolation scheme under **Spatial Discretization**, in the drop-down list next to **Pressure**. You can choose **Standard**, **PRESTO!**, **Linear**, **Second Order**, or **Body Force Weighted**.

Important

The low order modification of PRESTO! can be applied by disabling the high order terms for the PRESTO! scheme. This is done using the following text command:

```
solve → set → numerics
```

When asked disable high order terms for PRESTO! pressure scheme?, enter yes.

This modification can be used to stabilize the solution process when the pressure-based coupled algorithm is used and when the original PRESTO! scheme fails to converge.

If you are using the pressure-based solver and your flow is compressible (i.e., you are using the ideal gas law for density), select the density interpolation scheme under **Spatial Discretization**, in the drop-down list next to **Density**. You can choose **First Order Upwind**, **Second Order Upwind**, **QUICK** or **Third-Order MUSCL**. (Note that **Density** will not appear for incompressible flows.)

If you enable the VOF model while using the pressure-based solver, the volume fraction interpolation schemes that are available are **Geo-Reconstruct**, **CICSAM**, **Modified HRIC**, and **QUICK**.

If your case involves species transport, you can set the scheme for the individual species as **First Order Upwind**, **Second Order Upwind**, **Power Law**, **QUICK**, or **Third-Order MUSCL**. However, if you want all your species to use the same discretization scheme, then rather than setting each one individually, simply enable the **Set All Species Discretizations Together** option. Notice that you will no longer see your list of individual species, instead a **Species** field will appear with the scheme of your choice.

If you change the settings for the **Spatial Discretization**, but you then want to return to ANSYS FLUENT's default settings, you can click the **Default** button.

29.3. Pressure-Based Solver Settings

For additional information, please see the following sections:

- [29.3.1. Choosing the Pressure-Velocity Coupling Method](#)
- [29.3.2. Setting Under-Relaxation Factors](#)
- [29.3.3. Setting Solution Controls for the Non-Iterative Solver](#)

29.3.1. Choosing the Pressure-Velocity Coupling Method

ANSYS FLUENT provides four segregated types of algorithms: SIMPLE, SIMPLEC, PISO, and (for time-dependent flows using the **Non-Iterative Time Advancement** option (NITA)) Fractional Step (FSM). These schemes are referred to as the pressure-based segregated algorithm. Steady-state calculations will generally use SIMPLE or SIMPLEC, while PISO is recommended for transient calculations. PISO may also be useful for steady-state and transient calculations on highly skewed meshes. In ANSYS FLUENT, using the **Coupled** algorithm enables full pressure-velocity coupling, hence it is referred to as the pressure-based coupled algorithm.

Important

Pressure-velocity coupling is relevant only for the pressure-based solver.

29.3.1.1. SIMPLE vs. SIMPLEC

In ANSYS FLUENT, both the standard SIMPLE algorithm and the SIMPLEC (SIMPLE-Consistent) algorithm are available. SIMPLE is the default, but many problems will benefit from using SIMPLEC, particularly because of the increased under-relaxation that can be applied, as described below.

For relatively uncomplicated problems (laminar flows with no additional models activated) in which convergence is limited by the pressure-velocity coupling, you can often obtain a converged solution more quickly using SIMPLEC. With SIMPLEC, the pressure-correction under-relaxation factor is generally set to 1.0, which aids in convergence speed-up. In some problems, however, increasing the pressure-correction under-relaxation to 1.0 can lead to instability due to high mesh skewness. For such cases, you will need to use one or more skewness correction schemes, use a slightly more conservative under-relaxation value (up to 0.7), or use the SIMPLE algorithm. For complicated flows involving turbulence and/or additional physical models, SIMPLEC will improve convergence only if it is being limited by the pressure-velocity coupling. Often it will be one of the additional modeling parameters that limits convergence; in this case, SIMPLE and SIMPLEC will give similar convergence rates.

29.3.1.2. PISO

The PISO algorithm (see [PISO](#) in the [Theory Guide](#)) with neighbor correction is highly recommended for all transient flow calculations, especially when you want to use a large time step. (For problems that use the LES turbulence model, which usually requires small time steps, using PISO may result in an increased computational expense, so SIMPLE or SIMPLEC should be considered instead.) PISO can maintain a stable calculation with a larger time step and an under-relaxation factor of 1.0 for both momentum and pressure. For steady-state problems, PISO with neighbor correction does not provide any noticeable advantage over SIMPLE or SIMPLEC with optimal under-relaxation factors.

PISO with skewness correction is recommended for both steady-state and transient calculations on meshes with a high degree of distortion.

When you use PISO neighbor correction, under-relaxation factors of 1.0 or near 1.0 are recommended for all equations. If you use just the PISO skewness correction for highly-distorted meshes (without neighbor correction), set the under-relaxation factors for momentum and pressure so that they sum to 1 (e.g., 0.3 for pressure and 0.7 for momentum). If you use both PISO methods, follow the under-relaxation recommendations for PISO neighbor correction, above.

For most problems, it is not necessary to disable the default coupling between neighbor and skewness corrections. For highly distorted meshes, however, disabling the default coupling between neighbor and skewness corrections is recommended.

29.3.1.3. Fractional Step Method

The Fractional Step method (FSM), described in [Fractional-Step Method \(FSM\)](#) in the Theory Guide, is available when you choose to use the NITA scheme (i.e., the **Non-Iterative Time Advancement** option in the **Solution Methods** task page). With the NITA scheme, the FSM is slightly less computationally expensive compared to the PISO algorithm. Whether you select FSM or PISO depends on the application. For some problems (e.g., simulations that use VOF), FSM could be less stable than PISO.

In most cases, the default values for the solution methods are enough to set a robust convergence of the internal pressure correction sub-iterations due to skewness. Only very complex problems (e.g., moving deforming meshes, sliding interfaces, the VOF model) could require a reduction of relaxation for pressure up to a value of 0.7 or 0.8.

29.3.1.4. Coupled

Selecting **Coupled** from the **Pressure-Velocity Coupling** drop-down list indicates that you are using the pressure-based coupled algorithm, described in [Coupled Algorithm](#) in the Theory Guide. This solver offers some advantages over the pressure-based segregated algorithm. The pressure-based coupled algorithm obtains a more robust and efficient single phase implementation for steady-state flows. It is not available for cases using the Eulerian multiphase, NITA, and periodic mass-flow boundary conditions.

29.3.1.4.1. User Inputs

You can specify the pressure-velocity coupling method in the [Solution Methods Task Page \(p. 2048\)](#) ([Figure 29.4 \(p. 1320\)](#)).

Solution Methods

Choose **SIMPLE**, **SIMPLEC**, **PISO**, **Fractional Step**, or **Coupled** in the **Pressure-Velocity Coupling** drop-down list.

If you choose **PISO**, the task page will expand to show the additional parameters for pressure-velocity coupling. By default, the number of iterations for **Skewness Correction** and **Neighbor Correction** are set to 1. If you want to use only **Skewness Correction**, then set the number of iterations for **Neighbor Correction** to 0. Likewise, if you want to use only **Neighbor Correction**, then set the number of iterations for **Skewness Correction** to 0. For most problems, you do not need to change the default iteration values. By default, the **Skewness-Neighbor Coupling** option is enabled to allow for a more economical, but a less robust variation of the PISO algorithm.

If you choose **SIMPLEC** under **Pressure-Velocity Coupling**, you must also set the **Skewness Correction**, whose default value is 0.

If you choose **Coupled**, you will have to specify the **Courant** number in the **Solution Controls** task page, which is set at 200 by default. You will also specify the **Explicit Relaxation Factors** for **Momentum** and **Pressure**, which are set at 0.75 by default. For more information about these options, refer to [Pressure-Velocity Coupling](#) and [Steady-State Iterative Algorithm](#) in the Theory Guide.

If high-order momentum discretization is used, you may need to decrease the explicit relaxation to 0.5. For cases with very skewed meshes, the run can be stabilized by further reduction of the explicit relaxation factor to 0.25. If ANSYS FLUENT immediately diverges in the AMG solver, then the CFL number is too high and should be reduced. Reducing the CFL number below 10 is not recommended since it would be better to use the segregated algorithm for the pressure-velocity coupling.

In most transient cases, the CFL number should be set to 10^7 with an explicit relaxation of 1.0.

If you choose **Coupled** and enable the **Pseudo Transient** option, you will set the **Pseudo Transient Explicit Relaxation Factors** in the **Solution Controls** task page, as described in [Setting Pseudo Transient Explicit Relaxation Factors \(p. 1360\)](#).

29.3.2. Setting Under-Relaxation Factors

The pressure-based solver uses under-relaxation of equations to control the update of computed variables at each iteration (as described in [Under-Relaxation of Equations](#) in the Theory Guide). This means that all equations solved using the pressure-based solver, *including the non-coupled equations solved by the density-based solver* (turbulence and other scalars, as discussed in [Density-Based Solver](#) in the Theory Guide), will have under-relaxation factors associated with them.

In ANSYS FLUENT, the default under-relaxation parameters for all variables are set to values that are near optimal for the largest possible number of cases. These values are suitable for many problems, but for some particularly nonlinear problems (e.g., some turbulent flows or high-Rayleigh-number natural-convection problems) it is prudent to reduce the under-relaxation factors initially.

It is good practice to begin a calculation using the default under-relaxation factors. If the residuals continue to increase after the first 4 or 5 iterations, you should reduce the under-relaxation factors.

Occasionally, you may make changes in the under-relaxation factors and resume your calculation, only to find that the residuals begin to increase. This often results from increasing the under-relaxation factors too much. A cautious approach is to save a data file before making any changes to the under-relaxation factors, and to give the solution algorithm a few iterations to adjust to the new parameters. Typically, an increase in the under-relaxation factors brings about a slight increase in the residuals, but these increases usually disappear as the solution progresses. If the residuals jump by a few orders of magnitude, you should consider halting the calculation and returning to the last good data file saved.

Note that viscosity and density are under-relaxed from iteration to iteration. Also, if the enthalpy equation is solved directly instead of the temperature equation (i.e., for non-premixed combustion calculations), the update of temperature based on enthalpy will be under-relaxed. To see the default under-relaxation factors, you can click the **Default** button in the *Solution Controls Task Page* (p. 2052).

For most flows, the default under-relaxation factors do not usually require modification. If unstable or divergent behavior is observed, however, you need to reduce the under-relaxation factors for pressure, momentum, k , and ϵ from their default values to about 0.2, 0.5, 0.5, and 0.5. (It is usually not necessary to reduce the pressure under-relaxation for SIMPLEC.) In problems where density is strongly coupled with temperature, as in very-high-Rayleigh-number natural- or mixed-convection flows, it is wise to also under-relax the temperature equation and/or density (i.e., use an under-relaxation factor less than 1.0). Conversely, when temperature is not coupled with the momentum equations (or when it is weakly coupled), as in flows with constant density, the under-relaxation factor for temperature can be set to 1.0.

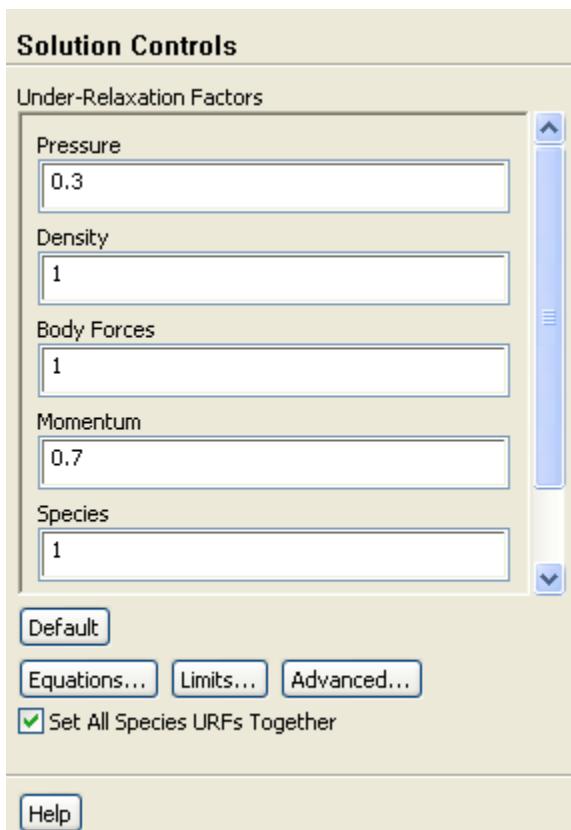

For other scalar equations (e.g., swirl, species, mixture fraction and variance) the default under-relaxation may be too aggressive for some problems, especially at the start of the calculation. You may wish to reduce the factors to 0.8 to facilitate convergence.

29.3.2.1. User Inputs

You can modify the under-relaxation factors in the *Solution Controls Task Page* (p. 2052) (*Figure 29.5* (p. 1325)).

Solution Controls

Figure 29.5 The Solution Controls Task Page for the Pressure-Based Solver

You can set the under-relaxation factor for each equation in the field next to its name under **Under-Relaxation Factors**.

Important

If you are using the pressure-based solver, all equations will have an associated under-relaxation factor (see [Under-Relaxation of Equations](#) in the [Theory Guide](#)). If you are using the density-based solver, only those equations that are solved sequentially (see [Density-Based Solver](#) in the [Theory Guide](#)) will have under-relaxation factors.

If your case involves species transport, you can set the under-relaxation factors for each of the listed species. If you want all your species to use the same under-relaxation factors, simply enable the **Set All Species URFs Together** option. Notice that you will no longer see your list of individual species, instead a **Species** field will appear where you will specify the under-relaxation factor.

If you change under-relaxation factors, but you then want to return to ANSYS FLUENT's default settings, you can click the **Default** button.

Note that with optimal settings, the convergence of the coupled pressure-velocity algorithm will be limited by the segregated solution of other scalar equations, e.g., turbulence. For optimum solver performance, you will need to increase the relaxation factors for these equations to a value greater than the default values.

29.3.3. Setting Solution Controls for the Non-Iterative Solver

You can use the non-iterative solver (see [Time-Advancement Algorithm](#) in the [Theory Guide](#)) for transient problems in order to increase the speed and efficiency of the calculations.

The settings for the non-iterative solver should provide control over the maximum number of sub-iterations for each individual equation. The criteria for convergence include the **Correction Tolerance** (defined by the overall accuracy), **Residual Tolerance** (controlling the solution of the linear equations), and the individual **Relaxation Factor**. The default control settings are optimally designed in order to get a second-order accurate solution. These controls are accessible via the **Expert** tab, in the **Advanced Solution Controls** dialog box ([Figure 29.6 \(p. 1327\)](#)).

To use ANSYS FLUENT's non-iterative transient solver in order to boost the efficiency of transient simulations:

1. Go to the **Solution Methods** task page.

 **Solution Methods**

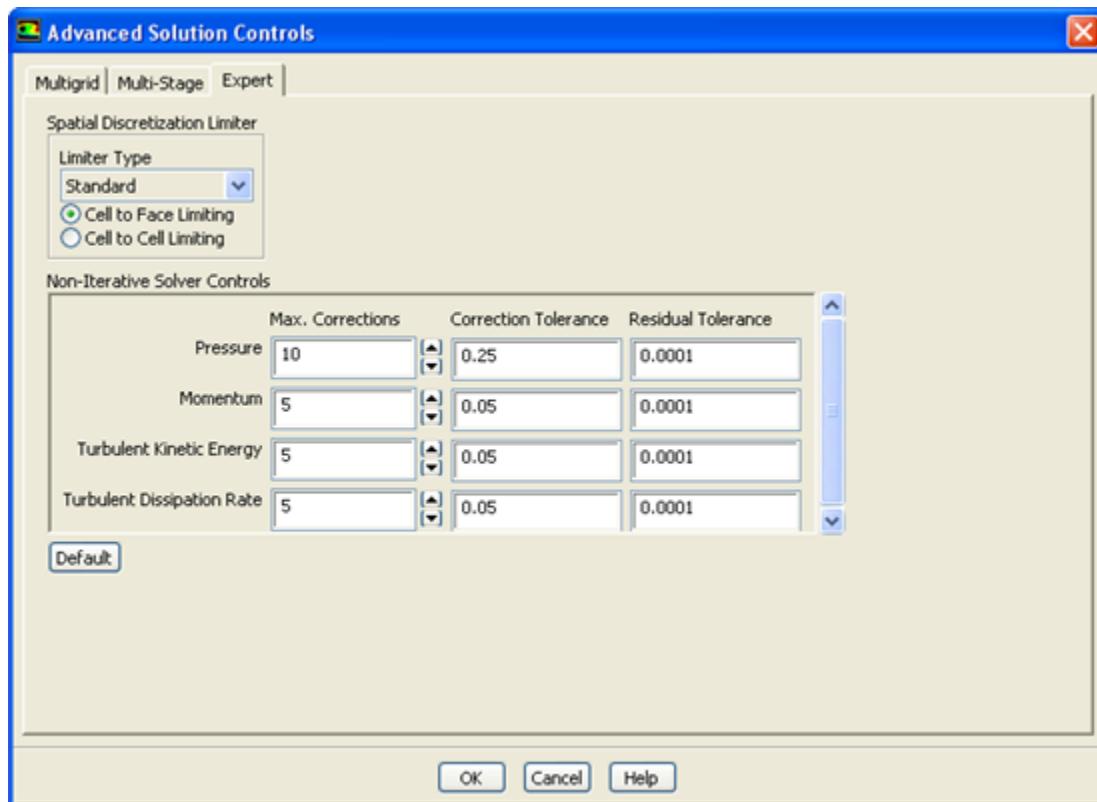

2. Enable **Non-Iterative Time-Advancement**.
3. Under **Pressure-Velocity Coupling**, you can choose either the **Fractional Step** or **PISO** scheme. Under **Non-Iterative Solver Controls** ([Figure 29.6 \(p. 1327\)](#)), you will see parameters that control the sub-iterations for individual equations (see below). When you select the PISO scheme, you can set the value for the **Neighbor Correction**. Skewness correction is performed automatically.

29.3.3.1. User Inputs

You can modify the non-iterative solution controls in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#) ([Figure 29.6 \(p. 1327\)](#)).

 **Solution Controls** → **Advanced...**

Figure 29.6 The Advanced Solution Controls Dialog Box for the Pressure-Based Segregated Non-Iterative Solver

Under **Non-Iterative Solver Controls**, there are several parameters that control the sub-iterations for the individual equations.

The sub-iterations for an equation stop when the total number of sub-iterations exceeds the value specified for **Max. Corrections**, regardless of whether or not the convergence criteria (described below) are met.

The sub-iterations for an equation end when the ratio of the residuals at the current sub-iteration and the first sub-iteration is less than the value specified in the **Correction Tolerance** field. You can monitor the details of the sub-iteration convergence by looking at the AMG solver performance (i.e., setting the **Verbosity** field in the **Multigrid** tab in the **Advanced Solution Controls** dialog box to 1). Be sure to pay attention to the residuals for the current sub-iteration (i.e., the residual for the 0-th AMG cycle at the current sub-iteration) and the initial residual of the time step (i.e., the residual for the 0-th AMG cycle of the first sub-iteration). The ratio of these two residuals is what is controlled by the **Correction Tolerance** field. These two residuals are also the residuals plotted when using the **Residual Monitor** panel and reported in the ANSYS FLUENT console at the end of a time step. Note that the residuals reported at the end of a time step can be scaled or unscaled, depending on the settings in the **Residual Monitor** dialog box. The residuals reported when monitoring the AMG solver performance are always unscaled.

For each interim sub-iteration, the AMG cycles continue until the usual AMG termination criteria (0.1 by default, and set in the **Multigrid** tab) are met. However, for the last sub-iteration (i.e., either when the maximum number of sub-iterations are reached or when the correction tolerance is satisfied), the AMG cycles continue until the ratio of the residual at the current cycle to the initial residual (the residual for the 0-th AMG cycle of the first sub-iteration of the time step) drops below the value specified for **Residual Tolerance**. You may want to adjust the **Residual Tolerance**, depending on the time step se-

lected. The default **Residual Tolerance** should be well suited for moderate time steps (i.e., for cell CFL numbers of 1 to 10). Note that you can display the cell CFL numbers for unsteady problems by selecting **Cell Courant Number** in the **Velocity...** category of all postprocessing dialog boxes. For very small time steps (cell CFL $<<1$), the diagonal dominance of the system is very high and the convergence should be driven further by reducing the **Residual Tolerance** value. For larger time steps (cell CFL $>>1$), it may be possible that the residual tolerance cannot be reached due to round-off errors, and unless the **Residual Tolerance** value is increased, AMG cycles can be wasted. Again, this can be monitored by monitoring the AMG solver performance.

The **Relaxation Factor** field defines the explicit relaxation (see [Under-Relaxation of Variables](#) in the [Theory Guide](#)) of variables between sub-iterations. The relaxation factors can be used to prevent the solution from diverging. They should be left at their default values of 1, unless divergence is detected. If the solution diverges, you should first try to stabilize the solution by lowering the relaxation factors for pressure to 0.7–0.8, and by reducing the time step.

The following is a list of models that are compatible with the non-iterative solver:

- Inviscid flow (excluding ideal gas)
- Laminar flow
- All models of turbulence (including LES and DES), except RSM
- S2S radiation model
- Heat transfer
- Non-reacting species transport
- General compressible flows (most subsonic and some transonic applications)
- VOF multiphase model (most applications)
- Phase change (solidification and melting)
- Porous media model (isotropic resistance)

The following is a list of models that are compatible with the non-iterative solver, but may result in some instabilities and inaccuracies for certain flow conditions:

- MDM
- Non-Newtonian fluids
- General compressible flows (aerospace supersonic applications)
- Floating operating pressure
- Reacting species and any type of combustion including PDF

The following is a list of models that are not compatible with the non-iterative solver:

- Eulerian multiphase (all non-VOF models)
- Radiation models (except S2S)
- DPM, spark, and crevice models
- UDS transport
- Porous jump
- Porous media model (anisotropic resistance)
- RSM turbulence model

Important

The PRESTO! pressure interpolation scheme, when used with the non-iterative time-advancement solver, is less stable than in the case of the iterative time-advancement solver. As a consequence, smaller time steps may be required.

Important

As mentioned above, the default control settings are optimally designed to obtain a second-order solution. In order to save CPU time, in cases where transient accuracy is not a main concern (i.e., first-order integration in time and space), or when NITA is used to converge toward a steady state solution, you may want to set the **Max. Corrections** value to 1 in the **Advanced Solution Controls** dialog box (**Expert** tab) for all transport equations except pressure.

29.4. Density-Based Solver Settings

To use the density-based solver you must first select the solver type, and determine if the simulation is steady-state or transient from the **General** Task Page (see [Choosing the Solver \(p. 1313\)](#)). The density based solver settings are available mainly in two task pages: the [Solution Methods Task Page \(p. 2048\)](#) and the [Solution Controls Task Page \(p. 2052\)](#).

In the **Solution Methods** task page, you can select the following:

- Solution formulation type: Implicit or Explicit
- Flux Scheme type : Roe-FDS , AUSM or (Low Diffusion Roe-FDS)
- Flow equation and model equation spatial discretization accuracy
- For the steady state solution method, you can select additional solution options to accelerate convergence
 - Pseudo transient solution method
 - Convergence acceleration for stretched meshes
- For the transient formulation you can select
 - 1st-Order implicit
 - 2nd-order implicit and for the explicit solver formulation, you can also select the explicit transient formulation

In the **Solution Controls** task page, you can select the following:

- For the density-based explicit solver, you will input the Courant number , FAS multigrid level and Residual smoothing
- For the density-based implicit solver, you will need to enter only the Courant number
- For both solver methods, you will enter the under-relaxation factors associated with other equations solved with the flow equations, such as equations of the turbulence model

The above options can be found in the following sections:

[29.4.1. Changing the Courant Number](#)

[29.4.2. Convective Flux Types](#)

[29.4.3. Convergence Acceleration for Stretched Meshes \(CASM\)](#)

29.4.4. Specifying the Explicit Relaxation

29.4.5. Turning On FAS Multigrid

29.4.1. Changing the Courant Number

For ANSYS FLUENT's density-based solver, the main control over the time-stepping scheme is the Courant number (CFL). The time step is proportional to the CFL, as defined in [Equation 20–80](#) in the Theory Guide.

Linear stability theory determines a range of permissible values for the CFL (i.e., the range of values for which a given numerical scheme will remain stable). When you specify a permissible CFL value, ANSYS FLUENT will compute an appropriate time step using [Equation 20–80](#) in the Theory Guide. In general, taking larger time steps leads to faster convergence, so it is advantageous to set the CFL as large as possible (within the permissible range).

The stability limits of the density-based implicit and explicit formulations are significantly different. The explicit formulation has a more limited range and requires lower CFL settings than does the density-based implicit formulation. Appropriate choices of CFL for the two formulations are discussed below.

29.4.1.1. Courant Numbers for the Density-Based Explicit Formulation

Linear stability analysis shows that the maximum allowable CFL for the multi-stage scheme used in the density-based explicit formulation will depend on the number of stages used and how often the dissipation and viscous terms are updated (see [Changing the Multi-Stage Scheme \(p. 1346\)](#)). But in general, you can assume that the multi-stage scheme is stable for Courant numbers up to 2.5. This stability limit is often lower in practice because of nonlinearities in the governing equations.

The default CFL for the density-based explicit formulation is 1.0, but you may be able to increase it for some 2D problems. You should generally not use a value higher than 2.0.

If your solution is diverging, i.e., if residuals are rising very rapidly, and your problem is properly set up and initialized, this is usually a good sign that the Courant number needs to be lowered. Depending on the severity of the startup conditions, you may need to decrease the CFL to a value as low as 0.1 to 0.5 to get started. Once the startup transients are reduced you can start increasing the Courant number again.

29.4.1.2. Courant Numbers for the Density-Based Implicit Formulation

Linear stability theory shows that the density-based implicit formulation is unconditionally stable. However, as with the explicit formulation, nonlinearities in the governing equations will often limit stability.

The default CFL for the density-based implicit formulation is 5.0. It is often possible to increase the CFL to 10, 20, 100, or even higher, depending on the complexity of your problem. You may find that a lower CFL is required during startup (when changes in the solution are highly nonlinear), but it can be increased as the solution progresses.

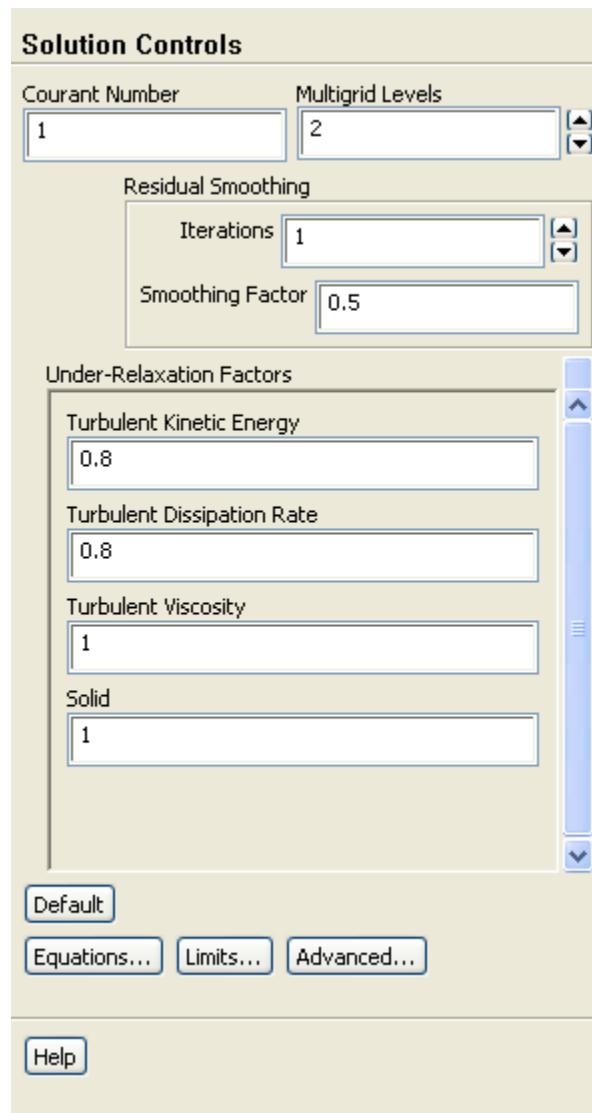

The coupled AMG solver has the capability to detect divergence of the multigrid cycles within a given iteration. If this happens, it will automatically reduce the CFL and perform the iteration again, and a message will be printed to the screen. Five attempts are made to complete the iteration successfully. Upon successful completion of the current iteration the CFL is returned to its original value and the iteration procedure proceeds as required.

29.4.1.3. User Inputs

The Courant number is set in the *Solution Controls Task Page* (p. 2052) (*Figure 29.7* (p. 1331)).

◆ Solution Controls

Figure 29.7 The Solution Controls Task Page for the Density-Based Explicit Formulation

Enter the value for **Courant Number**. (Note that the task page shown in *Figure 29.7* (p. 1331)

When you select **Explicit** from the **Formulation** drop-down list, in the *Solution Methods Task Page* (p. 2048), ANSYS FLUENT will automatically set the **Courant Number** to 1; when you select **Implicit** from the **Formulation** drop-down list, the **Courant Number** will be changed to 5 automatically.

29.4.2. Convective Flux Types

Three convective flux types exist when using the density-based solver:

- Roe flux-difference splitting (Roe-FDS)

- Advection Upstream Splitting Method (AUSM)
- Low diffusion Roe flux-difference splitting (Low Diffusion Roe-FDS)

Roe-FDS splits the fluxes in a manner that is consistent with their corresponding flux method eigenvalues. It is the default and is recommended for most cases.

AUSM provides exact resolution of contact and shock discontinuities and it is less susceptible to Carbuncle phenomena.

Low diffusion Roe-FDS is available in special circumstances when the LES viscous model is enabled and when time-implicit formulation is used in the density-based solvers. It reduces the dissipation in LES calculations. Low diffusion Roe-FDS should be used only for subsonic flows.

29.4.2.1. User Inputs

The convective fluxes are selected from the **Flux Type** drop-down list in the **Solution Methods** task page.

Solution Methods

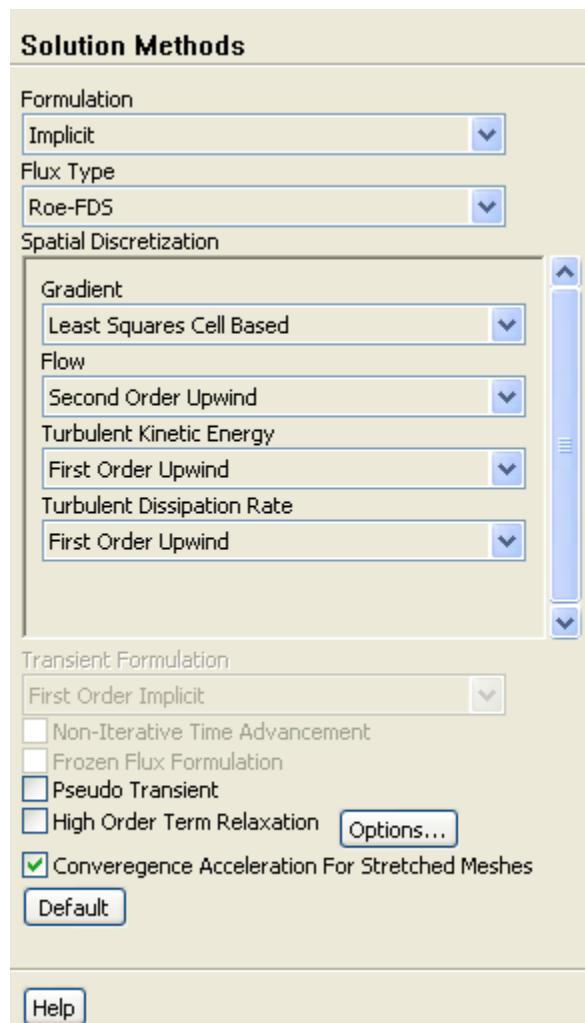

Select **Roe-FDS**, **AUSM**, or if the LES viscous model is enabled with the time-implicit formulation, **Low Diffusion Roe-FDS** will be available.

29.4.3. Convergence Acceleration for Stretched Meshes (CASM)

When using the density-based solver with the implicit solution formulation in steady-state you can accelerate the convergence of your solution on highly-stretched and anisotropic meshes (like the one used when modeling external aerodynamic problems) by selecting the **Convergence Acceleration For Stretched Meshes** in the **Solution Methods** task page. For further information and theoretical background on this solution acceleration option, see [Convergence Acceleration for Stretched Meshes](#) in the [Theory Guide](#). The **Convergence Acceleration For Stretched Meshes** option provides an optimum solution convergence of the implicit solution method.

To apply convergence acceleration for stretched meshes, perform the following:

1. Specify the solver options by selecting **Density-Based** and **Steady** in the **General** task page.
2. Select **Implicit** from the **Formulation** drop-down list and enable **Convergence Acceleration For Stretched Meshes** in the **Solution Methods** task page ([Figure 29.8 \(p. 1333\)](#)).

Figure 29.8 The Solution Methods Task Page for the Density-Based Implicit Formulation

Extra settings for CASM can be set using the following text command:

```
solve → set → convergence-acceleration-for-stretched-meshes /
```

Enter yes in response to the Use convergence acceleration for stretched meshes (CASM) ? question. You will also be asked for a cut-off on the CFL value multiplier. By default this value is set to 100. Typically, you do not need to adjust this value. But if convergence difficulties are encountered and reduction of the CFL value alone does not help improve convergence, then it is advisable to reduce this CFL multiplier cut-off to a lower value (for example from 100 to 50, 20 or 10).

The use of CASM can typically give a much faster convergence over the standard solution method. In general, when using CASM, you do not need to specify a very large CFL value as you do with the standard solution method. A CFL value between 5 and 10 is typically used for converging most flow problems. When the **Convergence Acceleration For Stretched Meshes** option is selected, the solver will run when appropriate with a variable local CFL value proportional to the cell aspect ratios. Therefore, when the cell aspect ratio nears unity (typically far from walls), the local cell CFL value will be the same as the value that you supplied. However, as the cell is stretched and the cell aspect ratio increases (near walls), the local cell CFL value will be multiplied by the cell aspect ratio value. This is true until the cell stretching is beyond the multiplier cut-off value specified using the text command. The proportional change in CFL value on highly stretched cells helps accelerate the solution especially on highly packed and stretched meshes like the one used in modeling external flow problems.

When the cell aspect ratio is selected by default, the density based implicit solver will operate with an explicit relaxation of 0.5 which can be adjusted from the **Explicit underrelaxation** value entry in **solve → set → expert**

The convergence of the solution is mainly controlled by adjusting the CFL value. Therefore, if convergence problems are encountered, lowering the CFL value will help improve the convergence. Additional solution parameters to be adjusted for more conservative solution settings are:

1. lowering the density-based implicit solver explicit relaxation (**solve → set → expert**)
2. adjusting the CFL multiplier cut-off value to a lower value (**solve → set → convergence-acceleration-for-stretched-meshes/**)

This solution convergence method is very aggressive . Therefore it is of paramount importance to start with a good initial guess especially if you start with second order spatial discretization. To get a good starting solution with the guess you provide, you are advised to use the full multi-grid initialization method (see [Full Multigrid \(FMG\) Initialization \(p. 1353\)](#)).

Note

When selecting the **Convergence Acceleration For Stretched Meshes** option then the **Pseudo-Transient** solution method will not be available. You can either use **Convergence Acceleration For Stretched Meshes** or the **Pseudo-Transient** solution method. These two options cannot be used at the same time. Both methods help in obtaining faster convergence on anisotropic meshes. But one method requires that you enter a CFL value, while the other requires that you enter a pseudo-time step value to march the solution to convergence. It is up to you to select the method with which you are most comfortable.

Convergence Acceleration For Stretched Meshes shows an advantage over the standard solution method, particularly with stretched meshes with low Y+ values (near unity). The use of **Convergence Acceleration For Stretched Meshes** results in an alteration of the numerical dissipation of the selected flux scheme. This change may slightly impact the monitored loading level if compared with the solution obtained without the use of this option.

29.4.4. Specifying the Explicit Relaxation

To improve the convergence to steady state for some flow cases when using the density-based implicit solver you can specify the explicit relaxation using the following text command:

`solve → set → expert`

Enter a value between 0 and 1 in response to the **Explicit relaxation** value prompt.

For more information about explicit relaxation, see [Under-Relaxation of Variables](#) in the [Theory Guide](#).

29.4.5. Turning On FAS Multigrid

As discussed in [Multigrid Method](#) in the [Theory Guide](#), FAS multigrid is an optional component of the density-based explicit formulation, while AMG multigrid is always on, by default for the density-based implicit formulation. Since nearly all density-based explicit calculations will benefit from the use of the FAS multigrid convergence accelerator, you should generally set a non-zero number of coarse grid levels before beginning the calculation. For most problems, this will be the only FAS multigrid parameter

you will need to set. Should you encounter convergence difficulties, consider applying one of the methods discussed in [Setting FAS Multigrid Parameters](#) (p. 1341).

Important

Note that you cannot use FAS multigrid with explicit time stepping (described in [Temporal Discretization](#) in the [Theory Guide](#)) because the coarse grid corrections will destroy the time accuracy of the fine grid solution.

29.4.5.1. Setting Coarse Grid Levels

As discussed in [Full-Approximation Storage \(FAS\) Multigrid](#) in the [Theory Guide](#), FAS multigrid solves on successively coarser grids and then transfers corrections to the solution back up to the original fine grid, thus increasing the propagation speed of the solution and speeding convergence. The most basic way you can control the multigrid solver is by specifying the number of coarse grid levels to be used.

As explained in [Full-Approximation Storage \(FAS\) Multigrid](#) in the [Theory Guide](#), the coarse grid levels are formed by agglomerating a group of adjacent “fine” cells into a single “coarse” cell. The optimal number of grid levels is therefore problem-dependent. For most problems, you can start out with 4 or 5 levels. For large 3D problems, you may want to add more levels (although memory restrictions may prevent you from using more levels, since each coarse grid level requires additional memory). If you believe that multigrid is causing convergence trouble, you can decrease the number of levels.

If ANSYS FLUENT reaches a coarse grid with one cell before creating as many levels as you requested, it will simply stop there. That is, if you request 5 levels, and level 4 has only 1 cell, ANSYS FLUENT will create only 4 levels, since levels 4 and 5 would be the same.

To specify the number of grid levels you want, set the number of **Multigrid Levels** in the [Solution Controls Task Page](#) (p. 2052) ([Figure 29.7](#) (p. 1331)).

Solution Controls

You can also set the **Max Coarse Levels** under **FAS Multigrid Controls** in the **Multigrid** tab in the [Advanced Solution Controls Dialog Box](#) (p. 2056).

Changing the number of coarse grid levels in the **Solution Controls** task page will automatically update the number shown in the **Multigrid** tab in the [Advanced Solution Controls Dialog Box](#) (p. 2056).

Coarse grid levels are created when you first begin iterating. If you want to check how many cells are in each level, request one iteration and then use the **Mesh/Info/Size** menu item (described in [Mesh Size](#) (p. 178)) to list the size of each grid level. If you are satisfied, you can continue the calculation; if not, you can change the number of coarse grid levels and check again.

For most problems, you will not need to modify any additional multigrid parameters once you have settled on an appropriate number of coarse grid levels. You can simply continue your calculation until convergence.

29.4.5.2. Using Residual Smoothing to Increase the Courant Number

In the density-based explicit formulation, implicit residual smoothing (or averaging) is a technique that can be used to reduce the time step restriction of the solver, thereby allowing the Courant number to be increased. The implicit smoothing is implemented with an iterative Jacobi method, as described in [Implicit Residual Smoothing](#) in the [Theory Guide](#). [Solution Controls Task Page](#) (p. 2052).

Solution Controls

By default, the number of **Iterations** for **Residual Smoothing** is set to zero, indicating that residual smoothing is disabled. If you increase the **Iterations** counter to 1 or more, you can enter the **Smoothing Factor**. A smoothing factor of 0.5 with 2 passes of the Jacobi smoother is usually adequate to allow the Courant number to be doubled.

29.5. Setting Algebraic Multigrid Parameters

As mentioned earlier, in most cases the multigrid solver will not require any special attention from you. If, however, you have convergence difficulties or you want to minimize the overall solution time by using more aggressive settings, you can monitor the multigrid solver and modify the parameters to improve its performance. (The instructions below assume that you have already begun calculations, since there is no need to monitor the solver if you do not fit into one of the two categories above.)

To determine whether your convergence difficulties can be alleviated by modifying the multigrid settings, you will check if the requested residual reduction is obtained on each grid level. To minimize solution time, you will check to see if switching to a more powerful cycle will result in overall reduction of work by the solver.

By default, the flexible cycle is used for all equations except pressure correction, which uses a V cycle. Typically, for a flexible cycle only a few (5–10) relaxations will be performed at the finest level and no coarse levels will be visited. In some cases one or two coarse levels may be visited. If the maximum number of fine level relaxations is not sufficient, you may want to increase the maximum number (as described in [Flexible Cycle Parameters \(p. 1340\)](#)) or switch to a V cycle (as described in [Specifying the Multigrid Cycle Type \(p. 1336\)](#)).

In the pressure-based segregated algorithm, the pressure correction uses a V cycle by default. If the maximum number of cycles (30 by default) is not sufficient, you can switch to a W cycle (using the **Multigrid** tab in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#), as described in [Specifying the Multigrid Cycle Type \(p. 1336\)](#)). Note that for the parallel solver, efficiency may deteriorate with a W cycle.

If you are using the parallel solver, you can try increasing the maximum number of cycles by increasing the value of **Max Cycles** in the **Multigrid** tab, under **Fixed Cycle Parameters**.

In the pressure-based coupled algorithm and the density-based implicit formulation, there is no pressure correction. Instead, there is a flow correction, which by default uses the F cycle. The density-based explicit formulation uses the V cycle as the default flow correction.

Solution Controls → Advanced...

For additional information, please see the following sections:

- [29.5.1. Specifying the Multigrid Cycle Type](#)
- [29.5.2. Setting the Termination and Residual Reduction Parameters](#)
- [29.5.3. Setting the AMG Method and the Stabilization Method](#)
- [29.5.4. Additional Algebraic Multigrid Parameters](#)
- [29.5.5. Setting FAS Multigrid Parameters](#)

29.5.1. Specifying the Multigrid Cycle Type

By default, the V cycle is used for the pressure equation in the pressure-based segregated algorithm and the flexible cycle is used for all other equations. In the pressure-based coupled algorithm and the density-based implicit formulation, the F cycle is default for the flow correction. The V cycle is default

for the flow correction in the density-based explicit formulation. (See [Multigrid Cycles](#) in the [Theory Guide](#) for a description of these cycles.) To change the cycle type for an equation, you will use the top portion of the **Multigrid** tab in the [Advanced Solution Controls Dialog Box](#) (p. 2056) ([Figure 29.9](#) (p. 1340)).

For each equation, you can choose **Flexible**, **V-Cycle**, **W-Cycle**, or **F-Cycle** in the adjacent drop-down list.

29.5.2. Setting the Termination and Residual Reduction Parameters

When you use the flexible cycle for an equation, you can control the multigrid performance by modifying the **Termination** and/or **Restriction** criteria for that equation at the top of the **Multigrid** tab in the [Advanced Solution Controls Dialog Box](#) (p. 2056) ([Figure 29.9](#) (p. 1340)).

 [Solution Controls](#) → [Advanced...](#)

The **Restriction** criterion is the residual reduction tolerance, β in [Equation 20–121](#) in the [Theory Guide](#). This parameter dictates when a coarser grid level must be visited (due to insufficient improvement in the solution on the current level). With a larger value of β , coarse levels will be visited less often (and vice versa). The **Termination** criterion, α in [Equation 20–122](#) in the [Theory Guide](#), governs when the solver should return to a finer grid level (i.e., when the residuals have improved sufficiently on the current level).

For the V, W, or F cycle, the **Termination** criterion determines whether or not another cycle should be performed on the finest (original) level. If the current residual on the finest level does not satisfy [Equation 20–122](#) in the [Theory Guide](#), and the maximum number of cycles has not been performed, ANSYS FLUENT will perform another multigrid cycle. (The **Restriction** parameter is not used by the V, W, and F cycles.)

29.5.3. Setting the AMG Method and the Stabilization Method

You can use the **Multigrid** tab in the [Advanced Solution Controls Dialog Box](#) (p. 2056) ([Figure 29.9](#) (p. 1340)) to choose between two AMG solvers: aggregative or selective. The aggregative AMG (AAMG) is the default solver that was used in previous versions of ANSYS FLUENT. The selective AMG (SAMG) solver is available only for scalar equations, and is not available in parallel ANSYS FLUENT. These two solvers differ in the way the grids are coarsened and in their interpolation method.

The AAMG solver [100] (p. 2372) builds coarse levels by grouping fine level cells to make coarse level cells, and uses piecewise constant interpolation. The SAMG solver [86] (p. 2371) builds coarse levels by selecting some of the fine level cells for solution on the coarse level, and tries to approximate the use of linear interpolation.

Due to its use of more accurate interpolation, SAMG has a better convergence rate than AAMG but has a more expensive setup phase. For this reason, AAMG is usually faster if you are only converging one order of magnitude, while SAMG is faster if using a tight multigrid convergence tolerance. SAMG is a good choice for multiphase granular flow problems where a tight convergence tolerance on the pressure equation can be used to avoid volume imbalance errors in the volume fraction equations.

SAMG has advantages in solving problems with strongly varying (anisotropic) diffusive coefficients, which occurs in problems with porous media, conduction with anisotropic thermal conductivities, and multiphase problems. In some cases, using SAMG allows up to a 20% reduction in the number of external iterations for unsteady water-air turbulent flow in bubble columns, and allows increasing the VOF under-relaxation factor in phase separators from 0.2 (when used with AAMG) to 1.

In the **Multigrid** tab ([Figure 29.9 \(p. 1340\)](#)), you can also choose a stabilization method. If desired, you can choose the bi-conjugate gradient stabilized method [9] ([p. 2367](#)) (**BCGSTAB**) option or recursive projection method [78] ([p. 2371](#)) (**RPM**) in order to improve the convergence of the linear solver. BCGSTAB can be preconditioned by any of the AMG solvers and provides stabilization for them whereas RPM stabilizes the AAMG solver.

ANSYS FLUENT usually builds diagonally dominant matrices for the linear solver. However, this is not always possible. A linear system with highly dominant off-diagonal coefficients may occur during discretization of complex physical models such as multiphase cavitation. Using the **BCGSTAB** or **RPM** option in such cases can be helpful. In addition, the AMG convergence in parallel can be improved using the **BCGSTAB** option with AMG.

If you are using the pressure-based segregated solver and the flow is incompressible, an additional stabilization method for the algebraic multigrid solver will appear in the **Stabilization Method** drop-down list. This is the conjugate gradient method, or **CG** [9] ([p. 2367](#)) and will be available only for the pressure equation. This method is typically used in conjunction with an AMG preconditioner (any available AMG method). The CG formulation requires a symmetric system matrix. Such matrices result from the finite volume discretization of steady or transient elliptic operators, such as the pressure correction equation in the incompressible case. The CG method provides a useful extension to BCGSTAB and RPM, since it reduces the memory requirements and the number of floating point operations, especially when compared to BCGSTAB. In addition, in transient pressure-based segregated solvers, as typically used in LES and/or NITA simulations, the solution of the pressure correction equation constitutes a significant share of the overall computational effort.

29.5.4. Additional Algebraic Multigrid Parameters

There are several additional parameters that control the algebraic multigrid solver, but there will usually be no need to modify them. These additional scalar and coupled parameters are all contained in the **Multigrid** tab in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#) ([Figure 29.9 \(p. 1340\)](#)).

[Solution Controls](#) → [Advanced...](#)

Important

When using the density-based explicit formulation or the pressure-based solver with any of the segregated algorithms, described in [Pressure-Velocity Coupling](#) in the [Theory Guide](#) and [Choosing the Pressure-Velocity Coupling Method \(p. 1321\)](#), only **Scalar Parameters** are set in the **Multigrid** tab. If you use the density-based implicit or the pressure-based coupled algorithm, described in [Coupled Algorithm](#) in the Theory Guide, then you can set the **Coupled Parameters**.

29.5.4.1. Fixed Cycle Parameters

For the fixed (V, W, and F) multigrid cycles, you can control the number of pre- and post-relaxations (β_1 and β_3 in [Multigrid Cycles](#) in the [Theory Guide](#)). **Pre-Sweeps** sets the number of relaxations to perform before moving to a coarser level. **Post-Sweeps** sets the number to be performed after coarser level corrections have been applied. Normally, under **Scalar Parameters**, one post-relaxation is performed and no pre-relaxations are done (i.e., $\beta_3 = 1$ and $\beta_1 = 0$), but in rare cases, you may need to increase the value of β_1 to 1 or 2. Under **Coupled Parameters**, three post-relaxations are performed by default with no pre-relaxations.

Important

- If you are using AMG with V-cycle to solve an energy equation with a solid conduction model presented with anisotropic or very high conductivity coefficient, there is a possibility of divergence with a default post-relaxation sweep of 1. In such cases you should increase the post-relaxation sweep (to say 2) in the AMG section for better convergence when using the pressure-based segregated algorithms.
- It is recommended that you use the Fixed F-cycle for the energy equation when running parallel ANSYS FLUENT.

29.5.4.2. Coarsening Parameters

For all multigrid cycle types, you can control the maximum number of coarse levels (**Max Coarse Levels** under **Scalar or Coupled Parameters**) that will be built by the multigrid solver.

Sets of coarser simultaneous equations are built until the maximum number of levels has been created, or the coarsest level has only 3 equations. Each level has about half as many unknowns as the previous level, so coarsening until there are only a few cells left will require about as much total coarse-level coefficient storage as was required on the fine mesh. Reducing the maximum coarse levels will reduce the memory requirements, but may require more iterations to achieve a converged solution. Setting **Max Coarse Levels** to 0 turns off the algebraic multigrid solver.

Another coarsening parameter you can control is the increase in coarseness on successive levels. The **Coarsen by** parameter specifies the number of fine grid cells that will be grouped together to create a coarse grid cell. The algorithm groups each cell with its closest neighbor, then groups the cell and its closest neighbor with the neighbor's closest neighbor, continuing until the desired coarsening is achieved. Typical values for the scalar parameters are in the range from 2 to 10, with the default value of 2 for the Gauss-Seidel smoother giving the best performance, but also the greatest memory use. For coupled parameters, a default value of 4 (for 2D) and 8 (for 3D) for the ILU smoother give the best performance. You should not adjust this parameter unless you need to reduce the memory required to run a problem.

Important

Depending on the smoother type, Gauss-Seidel or ILU, the **Coarsen by** and **Post-Sweeps** settings should be changed as follows when selecting the non-default smoother type:

ILU

: **Post-Sweeps**=3 and **Coarsen by** = 8

Gauss-Seidel

: **Post-Sweeps**=1 and **Coarsen by** = 2

29.5.4.3. Smoother Types

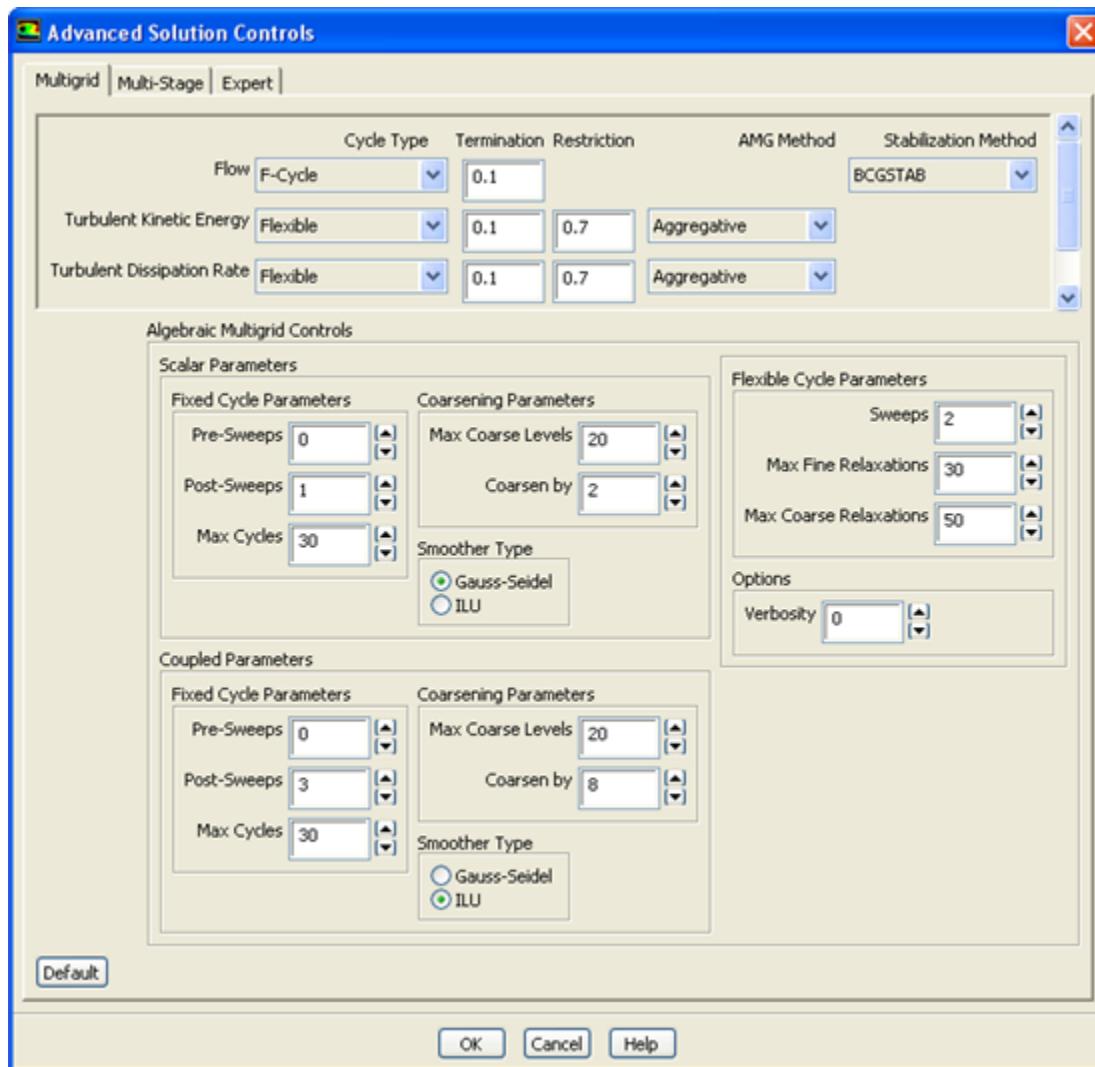

Two smoother types are available for scalar and coupled parameters. **Gauss-Seidel** is the simplest smoother type and is recommended when using the pressure-based segregated algorithm. **ILU** is more CPU intensive, but has better smoothing properties for block-coupled systems such as the pressure-based coupled solver and the density-based implicit formulation. In other words, the default scalar **Smoother Type** is **Gauss-Seidel**, while the coupled **Smoother Type** is **ILU**. For more information about the two smoother types, see [The Coupled and Scalar AMG Solvers](#) in the [Theory Guide](#).

29.5.4.4. Flexible Cycle Parameters

To change the maximum number of relaxations, increase or decrease the value of **Max Fine Relaxations** or **Max Coarse Relaxations** in the **Multigrid** tab in the *Advanced Solution Controls Dialog Box* (p. 2056) (Figure 29.9 (p. 1340)) under **Flexible Cycle Parameters**.

↳ **Solution Controls** → **Advanced...**

Figure 29.9 The Multigrid Tab for the Flexible Cycle

29.5.4.5. Setting the Verbosity

The steps for monitoring the solver are as follows:

1. Set multigrid **Verbosity** to 1 or 2 in the **Multigrid** tab in the *Advanced Solution Controls Dialog Box* (p. 2056).

↳ **Solution Controls** → **Advanced...**

2. Request a single iteration using the *Run Calculation Task Page* (p. 2107).

Run Calculation

If you set the verbosity to 2, the information printed in the ANSYS FLUENT console for each equation will include the following:

- equation name
- equation tolerance (computed by the solver using a normalization of the source vector)
- residual value after each fixed multigrid cycle or fine relaxation for the flexible cycle
- number of equations in each multigrid level, with the zeroth level being the original (finest-level) system of equations

Note that the residual printed at cycle or relaxation 0 is the initial residual before any multigrid cycles are performed.

When verbosity is set to 1, only the equation name, tolerance, and residuals are printed.

A portion of a sample printout is shown below:

```
pressure correction equation:
tol. 1.2668e-05
0 2.5336e+00
1 4.9778e-01
2 2.5863e-01
3 1.9387e-01

multigrid levels:
0 918
1 426
2 205
3 97
4 45
5 21
6 10
7 4
```

29.5.4.6. Returning to the Default Multigrid Parameters

If you change the multigrid parameters, but you then want to return to ANSYS FLUENT's default settings, you can click the **Default** button in the **Multigrid** tab. ANSYS FLUENT will change all settings to the defaults, and the **Default** button will become the **Reset** button. To get your settings back again, you can click the **Reset** button.

29.5.5. Setting FAS Multigrid Parameters

For most calculations, you will not need to modify any FAS multigrid parameters once you have set the number of coarse grid levels. If, however, you encounter convergence difficulties, you may consider the following suggested procedures.

Important

Recall that FAS multigrid is used only by the density-based explicit formulation.

29.5.5.1. Combating Convergence Trouble

Some problems may approach convergence steadily at first, but then the residuals will level off and the solution will "get stuck." In some cases (e.g., long thin ducts), this convergence trouble may be due

to multigrid's slow propagation of pressure information through the domain. In such cases, you should turn off multigrid by setting **Multigrid Levels** to 0 in the [Solution Controls Task Page \(p. 2052\)](#).

29.5.5.2. "Industrial-Strength" FAS Multigrid

In some cases, you may find that your problem is converging, but at an extremely slow rate. Such problems can often benefit from a more aggressive form of multigrid, which will speed up the propagation of the solution corrections. For such problems, you can try the "industrial-strength" multigrid settings.

Important

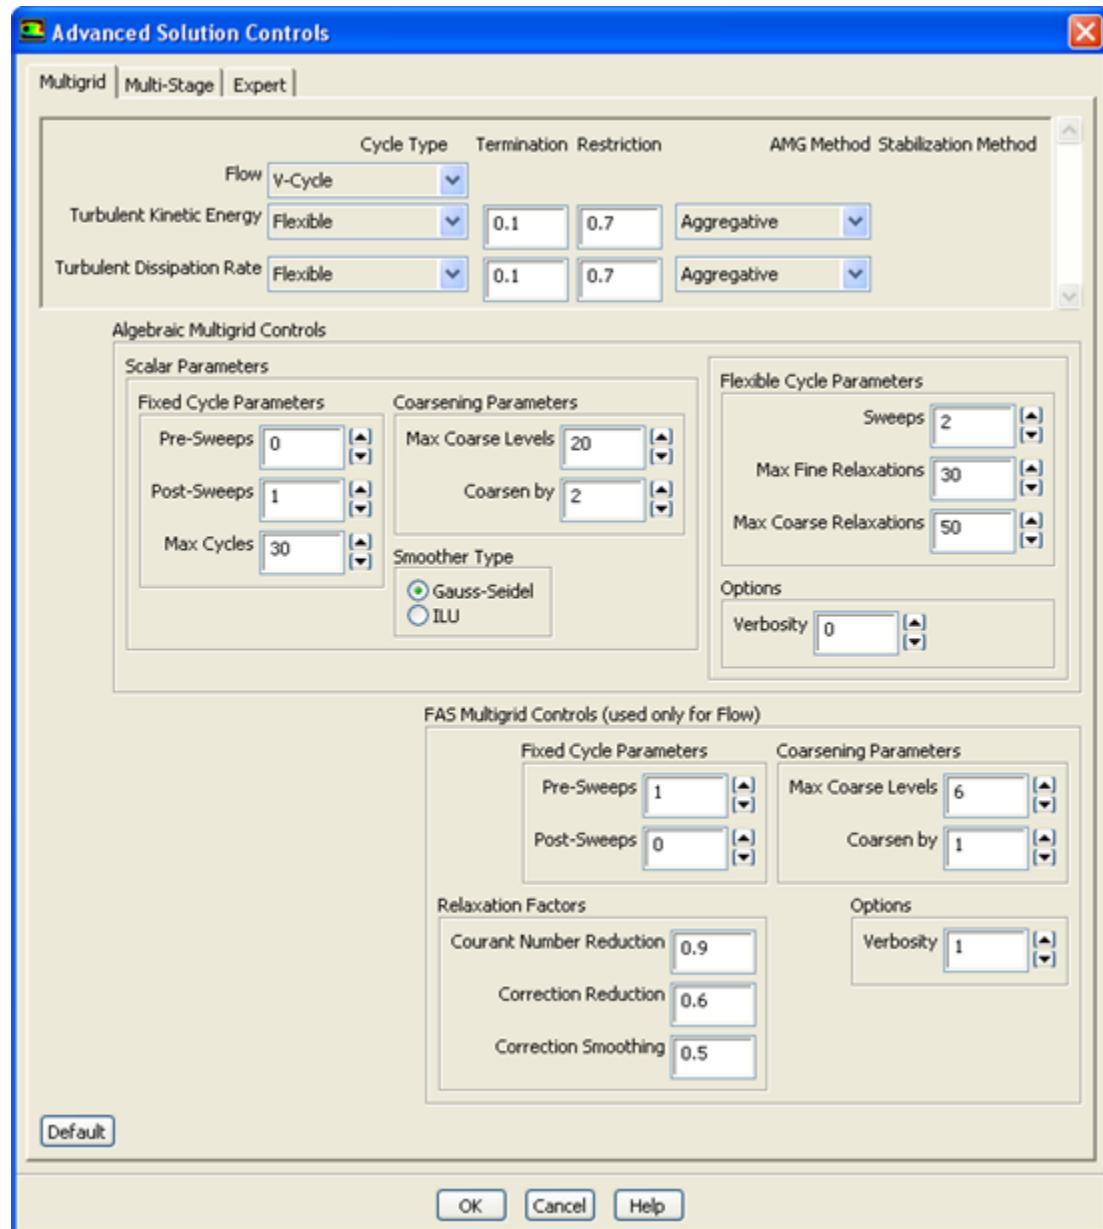

These settings are very aggressive and assume that the solution information passed through the multigrid levels is somewhat accurate. For this reason, you should only attempt the procedure described here after you have performed enough iterations that the solution is off to a good start. Using "industrial-strength" multigrid too early in the calculation process—when the solution is far from correct—will not help convergence and may cause the calculation to become unstable, as very incorrect values are propagated quickly to the original grid. Note also that while these multigrid settings will usually reduce the total number of iterations required to reach convergence, they will greatly increase the computation time for each multigrid cycle. Thus the solver will be performing fewer but longer iterations.

The strategy employed is as follows:

- Increase the number of iterations performed on each grid level before proceeding to a coarser level
- Increase the number of iterations performed on each grid level after returning from a coarser level
- Allow full correction transfer from one level to the next finer level, instead of transferring reduced values of the corrections
- Do not smooth the interpolated corrections when they are transferred from a coarser grid to a finer grid

You can set all of the parameters for this strategy under **FAS Multigrid Controls** in the **Multigrid** tab in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#) ([Figure 29.10 \(p. 1343\)](#)) and then continue the calculation.

 [Solution Controls → Advanced...](#)

Figure 29.10 The Advanced Solution Controls Dialog Box

Increasing the number of iterations performed on each grid level before proceeding to a coarser level (the value of β_1 , described in [Multigrid Cycles](#) in the [Theory Guide](#)) will improve the solution passed from each finer grid level to the next coarser grid level. Try increasing the value of **Pre-Sweeps** (under **FAS Multigrid Controls**, *not* under **Algebraic Multigrid Controls**) to 10.

Increasing the number of iterations performed on each level after returning from a coarser level will improve the corrections passed from each coarser grid level to the next finer grid level. Errors introduced on the coarser grid levels can therefore be reduced before they are passed further up the grid hierarchy to the original grid. Try increasing the value of **Post-Sweeps** (under **FAS Multigrid Controls**, *not* under **Algebraic Multigrid Controls**) to 10.

By default, the full values of the multigrid corrections are not transferred from a coarser grid to a finer grid; only 60% of the value is transferred. This prevents large errors from transferring quickly up to the original grid and causing the calculation to become unstable. It also prevents a "good" solution from

propagating quickly to the original grid. However, by increasing the **Correction Reduction** to 1, you can transfer the full values from coarser to finer grid levels, speeding the propagation of the solution and, usually, the convergence as well. The **Species Correction Reduction** sets the factor by which to reduce the magnitude of the species corrections to stabilize the multigrid calculation. This item appears only when species transport is being modeled.

When the corrections on a coarse grid are passed back to the next finer grid level, the values are, by default, interpolated and then smoothed. Disabling the smoothing so that the actual value in a coarse grid cell is assigned to the fine grid cells that comprise it can also aid convergence. To disable smoothing, set the **Correction Smoothing** to 0. Large discontinuities between cells will be smoothed out implicitly as a result of the additional **Post-Sweeps** performed.

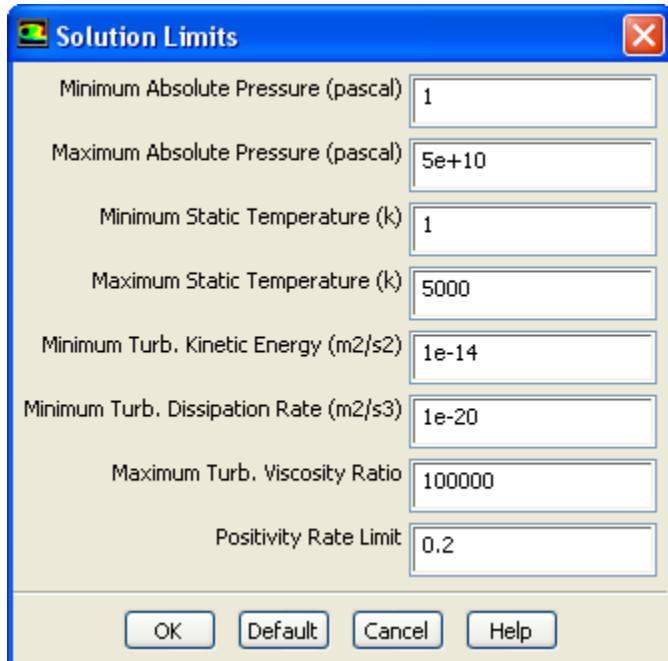

The **Courant Number Reduction** sets the factor by which to reduce the Courant number for coarse grid levels (i.e., every level except the finest). Some reduction of time step (such as the default 0.9) is typically required because the stability limit cannot be determined as precisely on the irregularly shaped coarser grid cells.

29.6. Setting Solution Limits

In order to keep the solution stable under extreme conditions, ANSYS FLUENT provides limits that keep the solution within an acceptable range. You can control these limits with the *Solution Limits Dialog Box* (p. 2054) (*Figure 29.11* (p. 1344)).

↳ **Solution Controls** → **Limits...**

Figure 29.11 The Solution Limits Dialog Box

ANSYS FLUENT applies limiting values for pressure, static temperature, and turbulence quantities. The purpose of these limits is to keep the absolute pressure or the static temperature from becoming 0, negative, or excessively large during the calculation, and to keep the turbulence quantities from becoming excessive. ANSYS FLUENT also puts a limit on the rate of reduction of static temperature to prevent it from becoming 0 or negative.

Important

Typically, you will not need to change the default solution limits. If pressure, temperature, or turbulence quantities are being reset to the limiting value repeatedly (as indicated by the appropriate warning messages in the console), you should check the dimensions, boundary conditions, and properties to be sure that the problem is set up correctly and try to determine why the variable in question is getting so close to zero or so large. You can use the “marking” feature (used to mark cells for adaption) to identify which cells have a value equal to the limit. (Use the *Iso-Value Adaption Dialog Box* (p. 2280), as described in *Isovalue Adaption* (p. 1451).) In very rare cases, you may need to change the solution limits, but only do so if you are sure that you understand the reason for the solver’s unusual behavior. (For example, you may know that the temperature in your domain will exceed 5000 K. Be sure that any temperature-dependent properties are appropriately defined for high temperatures if you increase the maximum temperature limit.)

Important

For an ideal gas, the absolute pressure and static temperature solution limits are set as described in this section. However, there are no static temperature and absolute pressure solution limits for incompressible flow.

For additional information, please see the following sections:

[29.6.1. Limiting the Values of Solution Variables](#)

[29.6.2. Adjusting the Positivity Rate Limit](#)

[29.6.3. Resetting Solution Limits](#)

29.6.1. Limiting the Values of Solution Variables

The limiting minimum and maximum values for absolute pressure are shown in the **Minimum** and **Maximum Absolute Pressure** fields. If the ANSYS FLUENT calculation predicts a value less than the **Minimum Absolute Pressure** or greater than the **Maximum Absolute Pressure**, the corresponding limiting value will be used instead. Similarly, the **Minimum** and **Maximum Temperature** are limiting values for energy calculations.

The **Maximum Turb. Viscosity Ratio** and the **Minimum Turb. Kinetic Energy** are limiting values for turbulent calculations. If the calculation predicts a k value less than the **Minimum Turb. Kinetic Energy**, the limiting value will be used instead. For the viscosity ratio limit, ANSYS FLUENT uses the limiting maximum value of turbulent viscosity ($C_\mu k^2/\varepsilon$) in the flow field relative to the laminar viscosity. If the ratio calculated by ANSYS FLUENT exceeds the limiting value, the ratio is set to the limiting value by limiting ε to the necessary value.

29.6.2. Adjusting the Positivity Rate Limit

In ANSYS FLUENT’s density-based solver, the rate of reduction of temperature is controlled by the **Positivity Rate Limit**. The default value of 0.2, for example, means that temperature is not allowed to decrease by more than 20% of its previous value from one iteration to the next. If the temperature change exceeds this limit, the time step in that cell is reduced to bring the change back into range and a “time step reduced” warning is printed. (This reduced time step will be used for the solution of all variables in the cell, not just for temperature.) Rapid reduction of temperature is an indication that the temperature may become negative. Repeated “time step reduced” warnings should alert you that

something is wrong in your problem setup. (If the warning messages stop appearing, the calculation may have “recovered” from the time-step reduction.)

Important

For high-speed flow, if your solution is diverging particularly for the energy equation, then lowering this limit to 0.05 or 0.02 might help in overcoming divergence.

29.6.3. Resetting Solution Limits

If you change and save the value of one of the solution limits, but you then want to return to the default limits set by ANSYS FLUENT, you can reopen the [Solution Limits Dialog Box \(p. 2054\)](#) and click the **Default** button. ANSYS FLUENT will change the values to the defaults and the **Default** button will become the **Reset** button. To get your values back again, you can click the **Reset** button.

29.7. Setting Multi-Stage Time-Stepping Parameters

The most common parameter you will change to control the multi-stage time-stepping scheme is the Courant number. Instructions for modifying the Courant number are presented in [Changing the Courant Number \(p. 1330\)](#). The **Multi-Stage** tab is accessible from the **Advanced Solution Controls** dialog box when using the density-based explicit formulation.

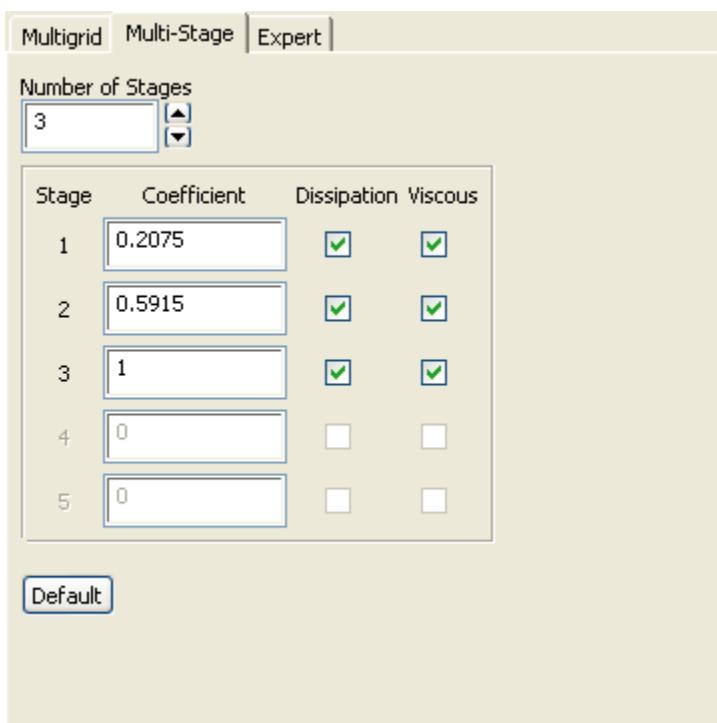

For additional information, please see the following section:

[29.7.1. Changing the Multi-Stage Scheme](#)

29.7.1. Changing the Multi-Stage Scheme

It is possible to make several changes to the multi-stage time-stepping scheme itself. You can change the number of stages and set a new multi-stage coefficient for each stage. You can also control whether or not dissipation and viscous stresses are updated at each stage. These changes are made in the **Multi-Stage** tab in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#) ([Figure 29.12 \(p. 1347\)](#)).

◀ **Solution Controls** → **Advanced...**

Figure 29.12 The Multi-Stage Tab

Important

You should not attempt to make changes to ANSYS FLUENT's multi-stage scheme unless you are very familiar with multi-stage schemes and are interested in trying a different scheme found in the literature.

29.7.1.1. Changing the Coefficients and Number of Stages

By default, the ANSYS FLUENT multi-stage scheme uses 3 stages for steady-state solutions with coefficients of 0.2075, 0.5915, and 1.0, and 4 stages for unsteady solutions with coefficients of 0.25, 0.3333, 0.5, and 1.0. You can decrease or increase the number of stages using the arrow buttons for **Number of Stages** in the **Multi-Stage** tab. (If you want to increase the number of stages beyond five, you will need to use the text-interface command `solve/set/multi-stage`.)

For each stage, you can modify the **Coefficient**. Coefficients must be greater than 0 and less than 1. The final stage should always have a coefficient of 1.

29.7.1.2. Controlling Updates to Dissipation and Viscous Stresses

For each stage, you can indicate whether or not artificial dissipation and viscous stresses are evaluated. If a **Dissipation** box is selected for a particular stage, artificial dissipation will be updated on that stage. If not selected, artificial dissipation will remain "frozen" at the value of the previous stage. If a **Viscous** box is selected for a particular stage, viscous stresses will be updated on that stage. If not selected, viscous stresses will remain "frozen" at the value of the previous stage. Viscous stresses should always be computed on the first stage, and successive evaluations will increase the "robustness" of the solution process, but will also increase the expense (i.e., increase the CPU time per iteration). For steady problems, the final solution is independent of the stages on which viscous stresses are updated.

29.7.1.3. Resetting the Multi-Stage Parameters

If you change the multi-stage parameters, but you then want to return to the default scheme set by ANSYS FLUENT, you can click the **Default** button in the **Multi-Stage** tab in the [Advanced Solution Controls Dialog Box \(p. 2056\)](#). ANSYS FLUENT will change the values to the defaults and the **Default** button will become the **Reset** button. To get your values back again, you can click the **Reset** button.

29.8. Selecting Gradient Limiters

The default gradient limiter in ANSYS FLUENT is the **Standard** limiter. Each of the limiters is described in detail in [Gradient Limiters](#) in the [Theory Guide](#). The gradient limiters are accessible from the **Expert** tab in the [Advanced Solution Controls](#) dialog box.

Solution Controls → **Advanced...**

You can select **Standard**, **Multidimensional**, or **Differentiable** from the **Spatial Discretization Limiter Type** drop-down list.

Each of these options can also be accessed using the TUI by typing the following command:

`solve → set → slope-limiter-set`

Choose from the following options:

Cri- terion	Type
0	Default (TVD) slope limiter
1	Multidimensional (TVD) slope limiter
2	Differentiable slope limiter

Note that the `Default (TVD) slope limiter` in the TUI is equivalent to the **Standard** option in the GUI.

For each of the gradient limiter methods, ANSYS FLUENT provides two limiting directions:

- **Cell to Face Limiting** is where the limited value of the reconstruction gradient is determined at cell face centers. This is the default method.
- **Cell to Cell Limiting** is where the limited value of the reconstruction gradient is determined along a scaled line between two adjacent cell centroids. On an orthogonal mesh (or when cell-to-cell direction is parallel to face area direction) this method becomes equivalent to the default cell to face method. For smooth field variation, cell to cell limiting may provide less numerical dissipation on meshes with skewed cells.

29.9. Initializing the Solution

Before starting your CFD simulation, you must provide ANSYS FLUENT with an initial “guess” for the solution flow field. In many cases, you must take extra care to provide an initial solution that will allow the desired final solution to be attained. A real-life supersonic wind tunnel, for example, will not “start” if the back pressure is simply lowered to its operating value; the flow will choke at the tunnel throat

and will not transition to supersonic. The same holds true for a numerical simulation: the flow must be initialized to a supersonic flow or it will simply choke and remain subsonic.

There are two methods for initializing the solution:

- Initialize the entire flow field (in all cells). Three methods are available:
 - Standard initialization (see [Initializing the Entire Flow Field Using Standard Initialization \(p. 1349\)](#))
 - FMG initialization (see [Full Multigrid \(FMG\) Initialization \(p. 1353\)](#))
 - Hybrid initialization (see [Hybrid Initialization \(p. 1355\)](#))
- Patch values or functions for selected flow variables in selected cell zones or “registers” of cells. (Registers are created with the same functions that are used to mark cells for adaption.)

Important

Before patching initial values in selected cells, you must first initialize the entire flow field. You can then patch the new values over the initialized values for selected variables.

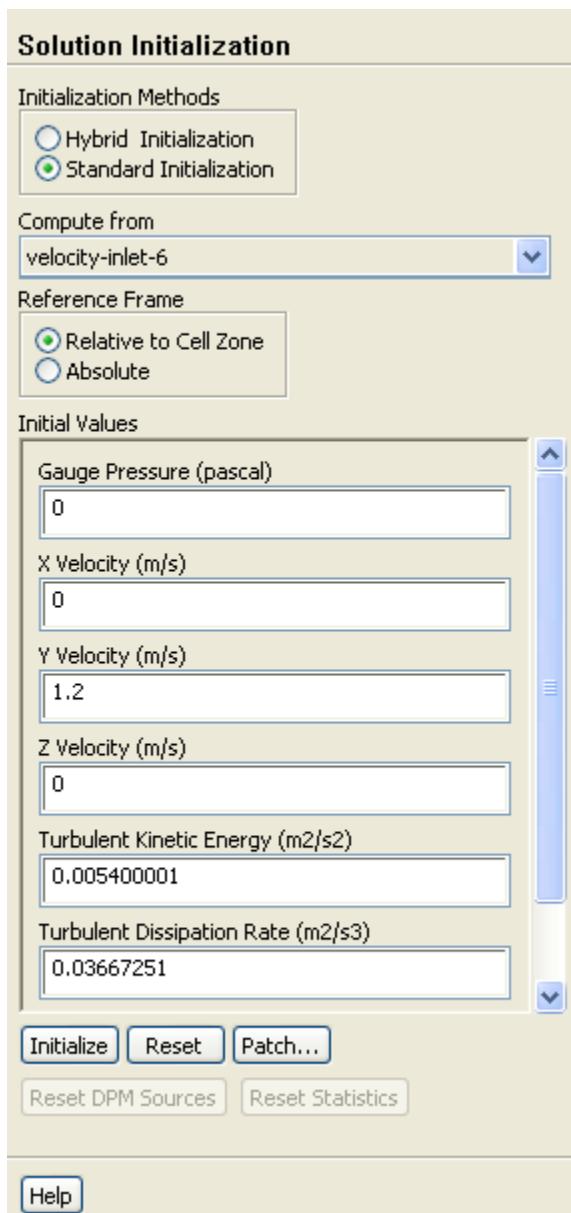

For additional information, please see the following sections:

- [29.9.1. Initializing the Entire Flow Field Using Standard Initialization](#)
- [29.9.2. Patching Values in Selected Cells](#)

29.9.1. Initializing the Entire Flow Field Using Standard Initialization

Before you start your calculations or patch initial values for selected variables in selected cells ([Patching Values in Selected Cells \(p. 1351\)](#)) you must initialize the flow field in the entire domain. The [Solution Initialization Task Page \(p. 2088\)](#) ([Figure 29.13 \(p. 1350\)](#)) allows you to set initial values for the flow variables and initialize the solution using these values.

Solution Initialization

Figure 29.13 The Solution Initialization Task Page

You can compute the values from information in a specified zone, enter them manually, or have the solver compute average values based on all zones. You can also indicate whether the specified values for velocities are absolute or relative to the velocity in each cell zone. The steps for standard initialization are as follows:

1. Select **Standard Initialization** as the **Initialization Method**.
2. Set the initial values:
 - To initialize the flow field using the values set for a particular zone, select the zone name in the **Compute from** drop-down list. All values under the **Initial Values** heading will automatically be computed and updated based on the conditions defined at the selected zone.
 - To initialize the flow field using computed average values, select **all-zones** in the **Compute from** drop-down list. ANSYS FLUENT will compute and update the **Initial Values** based on the conditions defined at all boundary zones.

- If you wish to change one or more of the values, you can enter new values manually in the fields next to the appropriate variables. If you prefer to enter all values manually, you can do so without selecting a zone in the **Compute from** list.
3. If your problem involves moving reference frames or sliding meshes, indicate whether the initial velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone** under **Reference Frame**. (If no zone motion occurs in the problem, the two options are equivalent.) The default reference frame for velocity initialization in ANSYS FLUENT is relative. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.
 4. After you are satisfied with the **Initial Values** displayed in the task page, you can click the **Initialize** button to initialize the flow field. If solution data already exist (i.e., if you have already performed some calculations or initialized the solution), you must confirm that it is OK to overwrite those data.

29.9.1.1. Saving and Resetting Initial Values

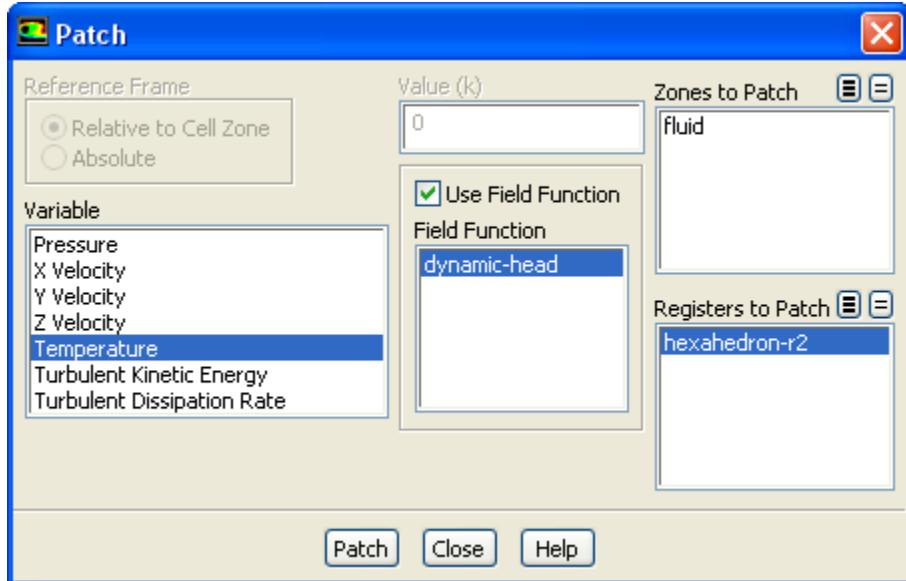

When you initialize the solution by clicking on **Initialize**, the initial values will also be saved; should you need to reinitialize the solution later, you will find the correct values in the task page when you reopen it.

If you accidentally select the wrong zone from the **Compute from** list or manually set a value incorrectly, you can use the **Reset** button to reset all fields to their “saved” values.

29.9.2. Patching Values in Selected Cells

Once you have initialized (or calculated) the entire flow field, you may patch different values for particular variables into different cells. If you have multiple fluid zones, for example, you may want to patch a different temperature in each one. You can also choose to patch a custom field function (defined using the [Custom Field Function Calculator Dialog Box \(p. 2264\)](#)) instead of a constant value. If you are patching velocities, you can indicate whether the specified values are absolute velocities or velocities relative to the cell zone’s velocity. All patching operations are performed with the [Patch Dialog Box \(p. 2090\)](#) ([Figure 29.14 \(p. 1352\)](#)).

 **Solution Initialization → Patch...**

Figure 29.14 The Patch Dialog Box

1. Select the variable to be patched in the **Variable** list.
2. In the **Zones to Patch** and/or **Registers to Patch** lists, choose the zone(s) and/or register(s) for which you want to patch a value for the selected variable.

Important

When shell conduction is enabled, the names of the **Zones to Patch** will appear as **shell:wall-name**. The wall-name is the name of the wall on which a shell conduction zone has been created.

3. If you wish to patch a constant value, simply enter that value in the **Value** field. If you want to patch a previously-defined field function, enable the **Use Field Function** option and select the appropriate function in the **Field Function** list.
4. If you selected a velocity in the **Variable** list, and your problem involves moving reference frames or sliding meshes, indicate whether the patched velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone** under **Reference Frame**. (If no zone motion occurs in the problem, the two options are equivalent.) The default reference frame for velocity patching in ANSYS FLUENT is relative. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.
5. Click the **Patch** button to update the flow-field data. (Note that patching will have no effect on the iteration or time-step count.)

Important

If you apply a patch when setting up an ANSYS FLUENT simulation from ANSYS Workbench, the patch will not be automatically performed during future automatic solution updates from Workbench. If you need to apply the patch each time the solution is updated from Workbench, you can do so by adding the text user interface (TUI) command `/solve/patch` (with appropriate arguments) to the **Original Settings** command list in the **Case Modification** tab of the **Automatic Solution Initialization and Case Modification** dialog box. See *Automatic Initialization of the Solution and Case Modification* (p. 1404) in this manual and *Case Modification Strategies with FLUENT and Workbench* in the **FLUENT in Workbench User's Guide** for more details on automatic case modification.

29.9.2.1. Using Registers

The ability to patch values in cell registers gives you the flexibility to patch different values within a single cell zone. For example, you may want to patch a certain value for temperature only in fluid cells with a particular range of concentrations for one species. You can create a cell register (basically a list of cells) using the functions that are used to mark cells for adaption. These functions allow you to mark cells based on physical location, cell volume, gradient or isovalue of a particular variable, and other parameters. See *Adapting the Mesh* (p. 1441) for information about marking cells for adaption. *Manipulating Adaption Registers* (p. 1459) provides information about manipulating different registers to create new ones. Once you have created a register, you can patch values in it as described above.

29.9.2.2. Using Field Functions

By defining your own field function using the *Custom Field Function Calculator Dialog Box* (p. 2264), you can patch a non-constant value in selected cells. For example, you may want to patch varying species mass fractions throughout a fluid region. To use this feature, simply create the function as described in *Custom Field Functions* (p. 1708), and then perform the function-patching operation in the *Patch Dialog Box* (p. 2090), as described above.

29.9.2.3. Using Patching Later in the Solution Process

Since patching affects only the variables for which you choose to change the value, leaving the rest of the flow field intact, you can use it later in the solution process without losing calculated data. (Initialization, on the other hand, resets all data to the initial values.) For example, you might want to start a combustion calculation from a cold-flow solution. You can simply read in (or calculate) the cold-flow data, patch a high temperature in the appropriate cells, and continue the calculation.

Patching can also be useful when you are solving a problem using a step-by-step technique, as described in *Step-by-Step Solution Processes* (p. 1431).

29.10. Full Multigrid (FMG) Initialization

For many complex flow problems such as those found in rotating machinery, or flows in expanding or spiral ducts, flow convergence can be accelerated if a better initial solution is used at the start of the calculation. The Full Multigrid initialization (FMG initialization) can provide this initial and approximate solution at a minimum cost to the overall computational expense.

For more information about FMG initialization, see *Overview of FMG Initialization* in the *Theory Guide*.

For additional information, please see the following sections:

29.10.1. Steps in Using FMG Initialization

29.10.2. Convergence Strategies for FMG Initialization

29.10.1. Steps in Using FMG Initialization

You can access the FMG initialization procedure using the text user interface (TUI) once the standard flow initialization is performed (see [Full-Approximation Storage \(FAS\) Multigrid](#) in the [Theory Guide](#)) or if valid flow data is available (i.e., through reading a data file).

To customize the FMG initialization, type the following command :

```
solve → initialize → set-fmg-initialization
```

You will be asked to enter:

- The number of multigrid levels for the FMG iteration (the default is 5).

Important

For small cases (100,000 cells or less), it is recommended that you lower the number of multigrid levels to 3 or 4.

- For each level of multigrid, you will be asked to enter the residual reduction (the default value is 0.001), and the number of cycles per level (the defaults at each level are 10, 10, 50, 100, 500, and 500). In general, you should perform more iterations on coarse levels than fine levels. Level 0 is the finest level, which represents the original mesh.
- FMG iteration Courant-number (the default is 0.75). This will be the CFL value that the FAS multigrid will use for the FMG initialization.
- Enabling verbose mode (the default is no). By enabling this option, you will be able to monitor the convergence at each level.

Important

If you do not customize the FMG settings, then the default values will be used.

To perform the FMG initialization, type the following command :

```
solve → initialize → fmg-initialization
```

When you are prompted to Enable FMG initialization? [no], type yes.

When verbose mode is selected and the FMG initialization is being executed, ANSYS FLUENT will first output the multigrid level information followed by convergence history for the FAS multigrid cycle on each level. The normalized residual value is printed after ten FAS cycles or when the number of FAS cycles is reached. The output will indicate when convergence is reached on each level and when the solution is being interpolated to the next level.

29.10.2. Convergence Strategies for FMG Initialization

When setting the FMG initialization parameters, you should consider performing more iterations on the coarse levels than on the fine levels. However, keep in mind that the purpose of FMG initialization is to obtain a good initial solution at a low cost. You should try to avoid unreasonable convergence tolerance that will make the FMG initialization expensive.

Turn on the verbose mode to help you determine if the flow is converging as expected during the FMG iterations. If the solution is not converging to the desired tolerance, consider increasing the number of FAS multigrid cycles at each level. If the solution is diverging during the FAS cycles, then consider lowering the FMG iteration Courant number since the default value is probably too aggressive and is likely causing the solution to diverge.

For turbulent flows, it is very important to first perform standard initialization with proper and realistic values of the turbulence variables (e.g. k and ε). This can be done by computing the average values based on the conditions defined at the inflow boundary or at all boundary zones. Then, you can proceed with FMG initialization. Unrealistic initialization of turbulence variables may cause convergence difficulties during the first few iterations on the fine mesh, thereby nullifying the benefit of FMG initialization.

29.11. Hybrid Initialization

Hybrid initialization is yet another initialization method in ANSYS FLUENT. The other initialization methods are standard initialization and FMG initialization. Hybrid initialization is a collection of recipes and boundary interpolation methods. It solves Laplace's equation to determine the velocity and pressure fields. All other variables, such as temperature, turbulence, species fractions, volume fractions, etc., will be automatically patched based on domain averaged values or a particular interpolation recipe.

For more information about hybrid initialization, see [Hybrid Initialization](#) in the [Theory Guide](#).

For additional information, please see the following sections:

[29.11.1. Steps in Using Hybrid Initialization](#)

[29.11.2. Solution Strategies for Hybrid Initialization](#)

29.11.1. Steps in Using Hybrid Initialization

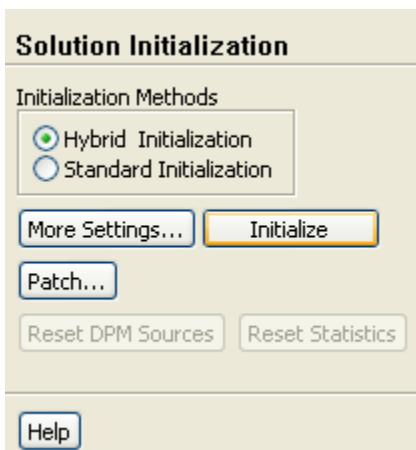

The default initialization method for single phase steady-state flows is the **Hybrid Initialization** method.

Note

For other flow types, such as multiphase or unsteady simulations, the default initialization method is the **Standard Initialization** method. However both initialization methods are available for use in all flow conditions and types.

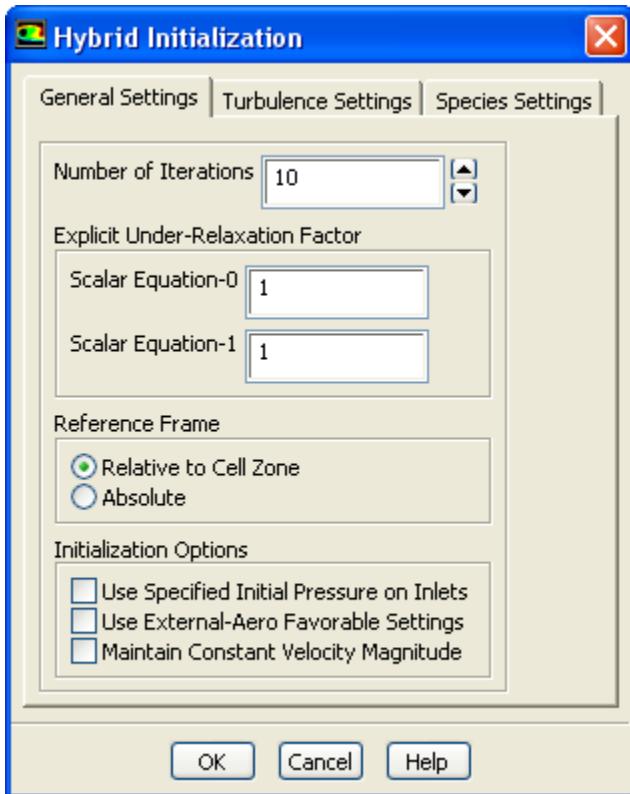

To use **Hybrid Initialization**, go to the [Solution Initialization Task Page](#) (p. 2088) ([Figure 29.15](#) (p. 1356)) where you will select **Hybrid Initialization**.

Figure 29.15 The Solution Initialization Task Page for Hybrid Initialization**Note**

In most cases, you need not do anything more than click the **Initialize** button. However, should you decide to modify the default settings for the hybrid initialization method, click **More Settings....**

If you click **More Settings...**, the **Hybrid Initialization** dialog box (*Figure 29.16 (p. 1356)*) will open. A host of settings that control the **Hybrid Initialization** strategy will be available for you to adjust.

Figure 29.16 The Hybrid Initialization Dialog Box

You can make adjustments in three different areas:

- **General Settings** tab:
 - **Number of Iterations** uses a default value of 10. This is the number of iterations that will be performed while solving the Laplace equations to initialize the velocity and pressure. In general, you do not need to change the number of iterations. However, for complex and highly curved geometries, if the default number of iterations is not enough to reach the convergence tolerance of 1e-06 and the flow fields are not to your liking, then you may want to increase the number of iterations and re-initialize the flow.
 - **Explicit Under-Relaxation Factor** uses a default value of 1. This value will be used while solving the Laplace equation to initialize the velocity and pressure. In general, you do not need to change the explicit under-relaxation factor. However, for some cases, where the scalar residuals are oscillating and showing difficulty reaching the convergence tolerance of 1e-06, you may want to re-initialize the flow by reducing the under-relaxation factor. You may also want to increase the number of iterations to produce a smooth initialization field for the velocity and pressure.
 - **Reference Frame** is set to **Relative to Cell Zone** by default. If your problem involves moving reference frames or sliding meshes, indicate whether the initial velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone**. If no zone motion occurs in the problem, the two options are equivalent. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.
 - **Initialization Options** allows you to include the following options:
 - **Use Specified Initial Pressure on Inlets** if you want the specified pressure for **Supersonic/Initialization Gauge Pressure** at the inlet boundaries to be used for solving the Laplace equation for the pressure. Otherwise, ANSYS FLUENT uses a predetermined recipe to determine the initial pressure field, as described in [Hybrid Initialization](#) of the [Theory Guide](#).
 - **Use External-Aero Favorable Settings** if you want to have the velocity potential patched with a linear value to help accelerate convergence of **Scalar Equation-0** and to obtain a better guess of the velocity field for external-aero problems, such as flow over wings, airfoils, or automobiles.
 - **Maintain Constant Velocity Magnitude** if you want to use the flow direction obtained from solving the velocity potential (**Scalar Equation-0**), while maintaining a constant velocity magnitude throughout the computational domain. This option is helpful in some incompressible external flow problems, or if there are narrow channels where large undesirable velocities can be reached.
- **Turbulence Settings** tab uses by default the domain averaged values for the turbulence parameters. If you want to use variable turbulence parameters you can deselect the **Average Turbulent Parameters** check box. When this option is disabled, then it calculates the turbulent parameters, such as kinetic energy, dissipation energy, etc., using local flow parameters.
- **Species Settings** tab will by default initialize secondary species with zero mass or mole fractions. If you want to specify the appropriate value for the species, you will need to enable **Specify Species Parameters**.

29.11.2. Solution Strategies for Hybrid Initialization

In general, you do not need to make any extra adjustments to the hybrid initialization default settings. However, if the hybrid initialization is not producing the initial field to your liking, then you can play with the various options available in the **Hybrid Initialization** dialog box (described in [Steps in Using Hybrid Initialization \(p. 1355\)](#)), or you can also use the patching option in addition to the **Hybrid Initialization**. For example, if you are solving a User Defined Scalar, then hybrid initialization will initialize them with a value of zero. However, you can specify the value with which you want to patch.

Note

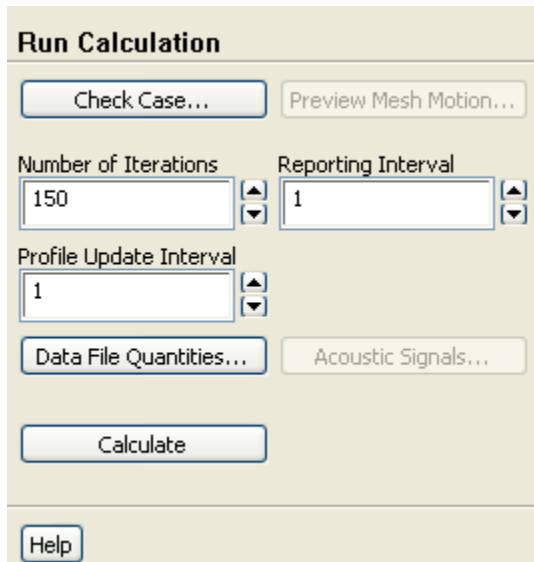

You can also use a UDF to initialize the flow or certain flow variable in conjunction with hybrid initialization.

29.12. Performing Steady-State Calculations

For steady-state calculations, you will request the start of the solution process using the [Run Calculation Task Page](#) (p. 2107) ([Figure 29.17](#) (p. 1358)).

Run Calculation

Figure 29.17 The Run Calculation Task Page

Here, you will supply the number of additional iterations to be performed in the **Number of Iterations** field. (For unsteady calculation inputs, see [User Inputs for Time-Dependent Problems](#) (p. 1366).) If no calculations have been performed yet, ANSYS FLUENT will begin calculations starting at iteration 1, using the initial solution. If you are starting from current solution data, ANSYS FLUENT will begin at the last iteration performed, using the current solution data as its starting point.

By default, ANSYS FLUENT will update the convergence monitors (described in [Monitoring Solution Convergence](#) (p. 1379)) after each iteration. If you increase the **Reporting Interval** from the default of 1 you can get reports less frequently. For example, if you set the **Reporting Interval** to 2, the monitors will print or plot reports at every other iteration. Note that the **Reporting Interval** also specifies how often ANSYS FLUENT should check if the solution is converged. For example, if your solution converges after 40 iterations, but your **Reporting Interval** is set to 50, ANSYS FLUENT will continue the calculation for an extra 10 iterations before checking for (and finding) convergence.

When you click the **Calculate** button, ANSYS FLUENT will begin to calculate. During iteration, a **Working** dialog box is displayed. Clicking the **Cancel** button or typing <Control-C> in the ANSYS FLUENT console will interrupt the iteration, as soon as it is safe to stop. (See below for more details.)

For additional information, please see the following sections:

- [29.12.1. Updating UDF Profiles](#)
- [29.12.2. Interrupting Iterations](#)

29.12.3. Resetting Data

29.12.1. Updating UDF Profiles

If you have used a user-defined function (UDF) to define any boundary conditions you can control the frequency with which the function is updated by modifying the value of the **UDF Profile Update Interval**. If **UDF Profile Update Interval** is set to n , the function will be updated after every n iterations.

By default, the **UDF Profile Update Interval** is set to 1. You might want to increase this value if your profile computation is expensive. See the [UDF Manual](#) for details about creating and using UDFs.

29.12.2. Interrupting Iterations

As mentioned above, you can interrupt the calculation by clicking the **Cancel** button in the **Working** dialog box that appears while the solver is calculating. In addition, on most, but not all, computer systems you will be able to interrupt calculations using a control sequence, usually <Control-C>. This allows you to stop the calculation process before proceeding with the remainder of the requested iterations.

29.12.3. Resetting Data

After you have performed some iterations, if you decide to start over again from the first iteration (e.g., after making some changes to the problem setup), you can reinitialize the solution using the [Solution Initialization Task Page \(p. 2088\)](#), as described in *Initializing the Entire Flow Field Using Standard Initialization (p. 1349)*.

29.13. Performing Pseudo Transient Calculations

For steady-state calculations, when using the pressure-based coupled solver or the density-based implicit solver, you have the option of solving your flow in a pseudo-transient fashion. The pseudo transient under-relaxation method is a form of implicit under-relaxation, described in [Pseudo Transient Under-Relaxation](#) in the [Theory Guide](#).

To apply the pseudo transient under-relaxation method, perform the following:

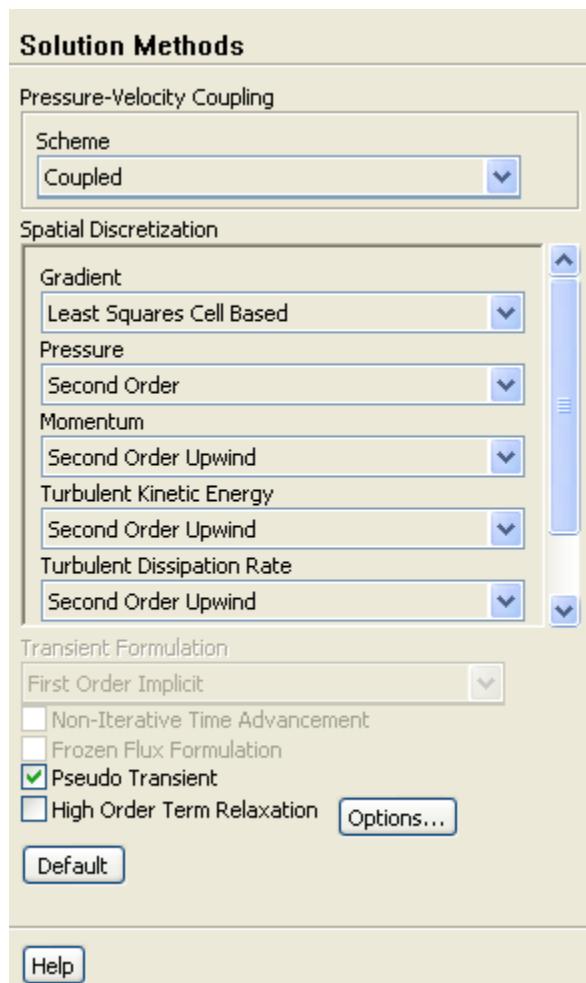

1. Select the **Density-Based** solver or the **Pressure-Based** solver.

↳ General

2. Go to the **Solution Methods** task page ([Figure 29.18 \(p. 1360\)](#)).

↳ Solution Methods

- a. If you are using the pressure-based solver, choose the **Coupled** scheme under **Pressure-Velocity Coupling**.
- b. If you are using the density-based solver, choose the **Implicit** scheme under **Formulation**.
- c. Enable the **Pseudo Transient** option.

Figure 29.18 The Solution Methods Task Page

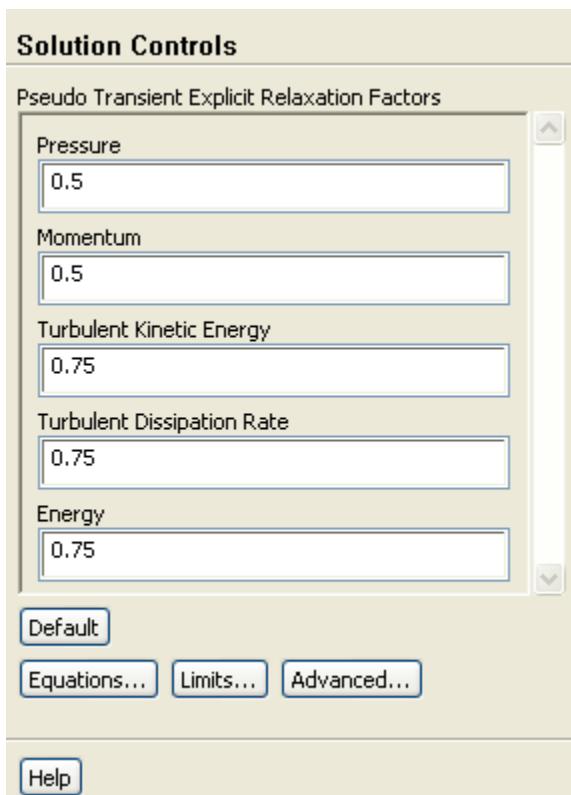

29.13.1. Setting Pseudo Transient Explicit Relaxation Factors

In addition to pseudo transient under-relaxation, you can specify an explicit under-relaxation of the equation to control the update of computed variables at each iteration (see [Pseudo Transient Under-Relaxation](#) in the Theory Guide). The default values of under-relaxation parameters for all variables are set to values that work well for most of the cases. It is good practice to start a calculation with the default under-relaxation parameters. If your case exhibits divergence or the residuals continue to increase after a few iterations, then you should reduce the under-relaxation factors.

29.13.1.1. User Inputs

You can modify the pseudo transient under-relaxation factors in the [Solution Controls Task Page](#) (p. 2052) ([Figure 29.19](#) (p. 1361)).

Solution Controls

Figure 29.19 The Solution Controls Task Page for the Pseudo Transient Runs

You can set the under-relaxation factor for each equation in the field next to its name under **Pseudo Transient Explicit Relaxation Factors**.

Important

If you are using the pressure-based solver, all equations will have an associated under-relaxation factor (see [Under-Relaxation of Equations](#) in the [Theory Guide](#)). If you are using the density-based solver, only those equations that are solved sequentially (see [Density-Based Solver](#) in the [Theory Guide](#)) will have under-relaxation factors.

If you change under-relaxation factors, but you then want to return to ANSYS FLUENT's default settings, you can click the **Default** button.

29.13.2. Setting Solution Controls for the Pseudo Transient Method

To have further control over the parameters for each individual equation, when solving a pseudo transient case, you can go to the **Expert** tab, in the **Advanced Solution Controls** dialog box ([Figure 29.20 \(p. 1362\)](#)). Note that all equations, except for flow equations (i.e. pressure and momentum) will be listed. Generally, you will not need to visit this dialog box to enter equation-specific solution parameters. However, it may help in cases where a particular equation is giving convergence problems. Here, ANSYS FLUENT allows two options to improve convergence:

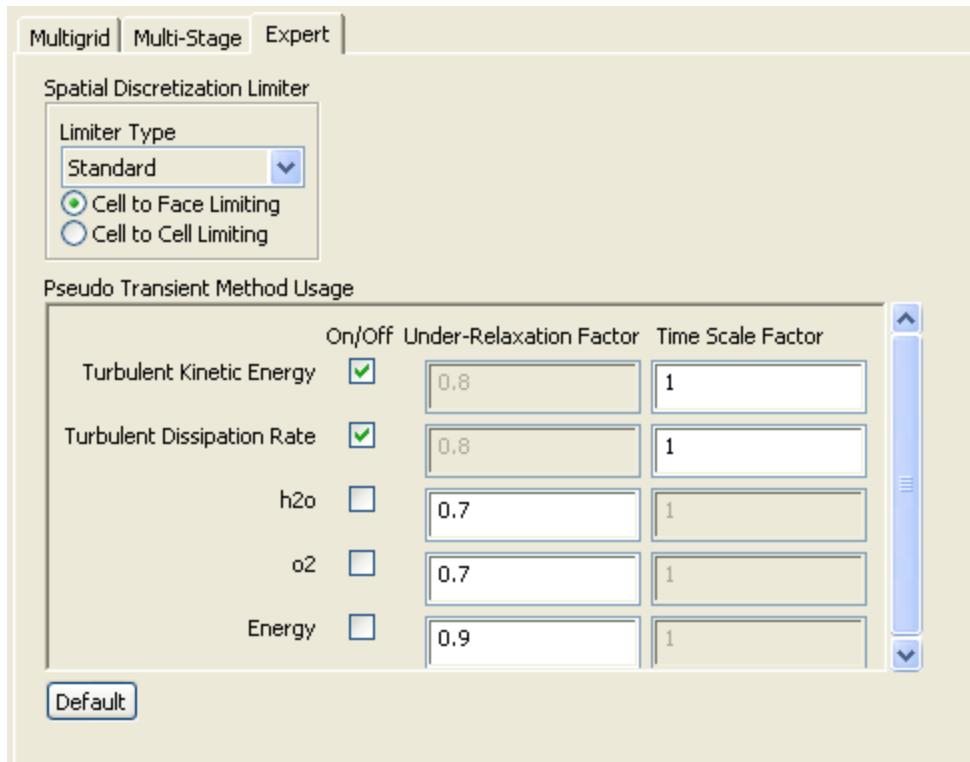

1. Specify a time scale factor for the equation specific time step in lieu of using a uniform global pseudo time step. This scaling factor scales the pseudo time step employed for the flow equations specified in the **Run Calculation** task page (see [Solving Pseudo-Transient Flow \(p. 1362\)](#)).

2. Use the standard steady state method by turning off pseudo transient for that particular equation. Here, the corresponding under-relaxation factor to be employed with that equation may be specified. The default values of under-relaxation parameters for all variables are set to values that work well for most of the cases.

The default setting will have pseudo transient method turned on for all equations with the corresponding time scale factor set to unity.

Solution Controls → Advanced...

Figure 29.20 The Advanced Solution Controls Dialog Box for the Pseudo Transient Method

Specify the equation-specific steady state solution method for a particular equation (if needed) by enabling or disabling the pseudo transient method using the **On/Off** check box next to the equation. The dialog box then allows either specification of a pseudo **Time Scale Factor** or **Under-Relaxation Factor** for that particular equation based on the check box setting.

Note

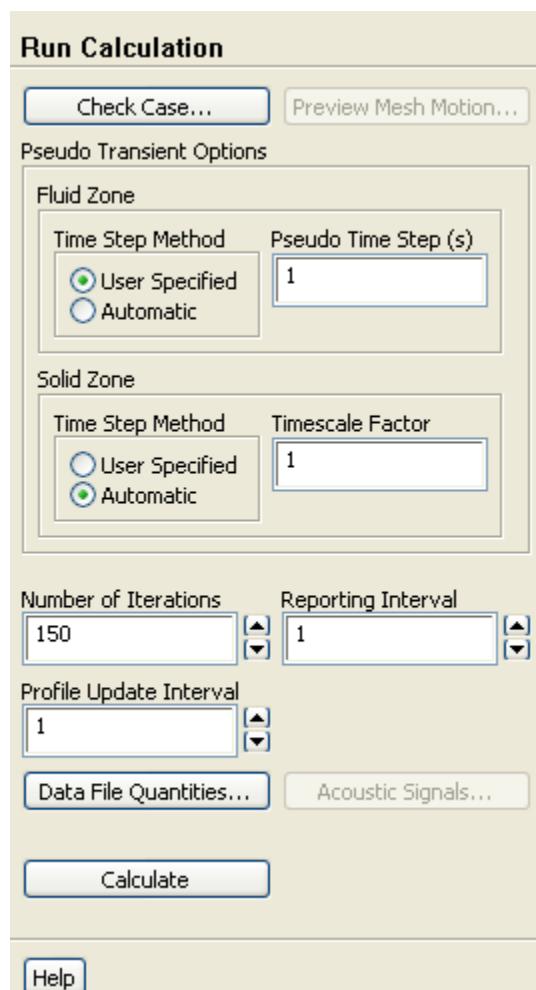

For multiphase flows, the pseudo transient expert options for the volume fraction equation are available only when it is solved in segregated fashion. It is not available when the **Coupled with Volume Fractions** option is enabled in the **Solution Methods** task page (see [Selecting the Pressure-Velocity Coupling Method \(p. 1280\)](#) for information about this setting).

29.13.3. Solving Pseudo-Transient Flow

With the **Pseudo Transient** option enabled in the **Solution Methods** task page, you can now specify the time step for the **Fluid Zone** and/or the **Solid Zone** under **Pseudo Transient Options** in the **Run Calculation** task page ([Figure 29.21 \(p. 1363\)](#)).

◆ Run Calculation

Figure 29.21 The Run Calculation Task Page for the User Specified Pseudo Transient Option

1. Select the **Time Step Method** for the **Fluid Zone**.

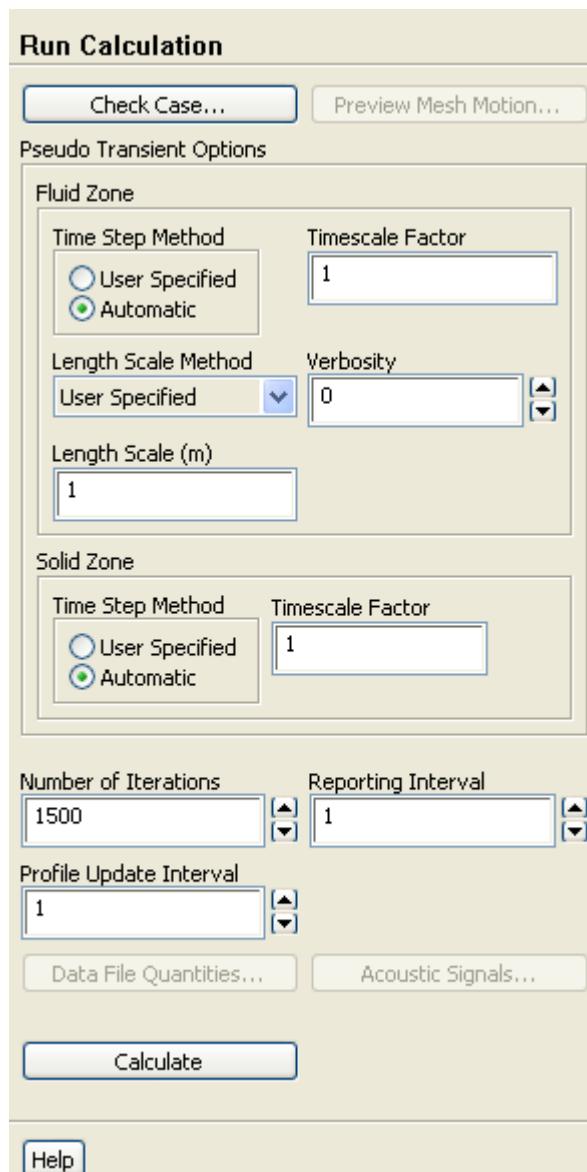

- If you choose **User Specified**, you will enter the **Pseudo Time Step**, which is used for every equation unless the equation specific time step is used for a particular equation, as mentioned in *Setting Solution Controls for the Pseudo Transient Method* (p. 1361).
- If you choose **Automatic**, which is the default method, (see *Figure 29.22* (p. 1364)), the pseudo time step is calculated internally and used for each equation listed, unless the equation has a time step specified as noted in *Setting Solution Controls for the Pseudo Transient Method* (p. 1361). For more information about the automatic time step calculation, please refer to **Automatic Pseudo Transient Time Step** in the **Theory Guide**.

Select the Length Scale Method. Three options are available in the drop-down list:

- Conservative** is the default length scale calculation method, for which you will enter the **Timescale Factor**. The **Timescale Factor** is a scaling factor used to scale the calculated time step. The default value is 1.0. You can increase or decrease it to increase or decrease the size of the time step, respectively.

- ii. **Aggressive** predicts a higher time step size than the **Conservative** method. You will also need to specify the **Timescale Factor**.
- iii. **User Specified** allows you to control the input for the **Length Scale**. This method is particularly useful in problems which has a specific length scale that is difficult to determine from the overall geometry of the problem. For example, in the case of flow over an airfoil, the appropriate length scale would be the length of the airfoil instead of the length scale calculated based on the geometry of the entire domain.
- iv. You can specify the **Verbosity**. This is an integer value of 0 or 1. The default value is 0. If you want to print the pseudo time step size, enter a value of 1 for the **Verbosity**.

Figure 29.22 The Run Calculation Task Page for the Automatic Pseudo Transient Option

2. Select the **Time Step Method** for the **Solid Zone**.

Note

Solid Zone will only appear in the interface when a solid zone is present in the domain. In solid zones, the same entry fields (e.g. **Timescale Factor**) as the fluid zones take on a different meaning.

- a. If you choose **User Specified**, you will enter the **Pseudo Time Step**, which is only used for the solid zone.
- b. If you choose **Automatic**, which is the default method for solid zones, the pseudo time step is calculated internally as described in [Automatic Pseudo Transient Time Step](#) in the [Theory Guide](#). Specify the **Timescale Factor** for the solid zone. You can control the time step in solid zones by adjusting the **Timescale Factor**.
3. Continue setting up your solution as you would a steady-state run, as described in [Performing Steady-State Calculations \(p. 1358\)](#).

29.14. Performing Time-Dependent Calculations

ANSYS FLUENT can solve the conservation equations in a time-dependent manner, to simulate a wide variety of time-dependent phenomena, such as

- vortex shedding and other time-periodic phenomena
- compressible filling and emptying problems
- transient heat conduction
- transient chemical mixing and reactions

[Figure 29.23 \(p. 1365\)](#) and [Figure 29.24 \(p. 1366\)](#) illustrate the time-dependent vortex shedding flow pattern in the wake of a cylinder.

Figure 29.23 Time-Dependent Calculation of Vortex Shedding (t=36.6 sec)

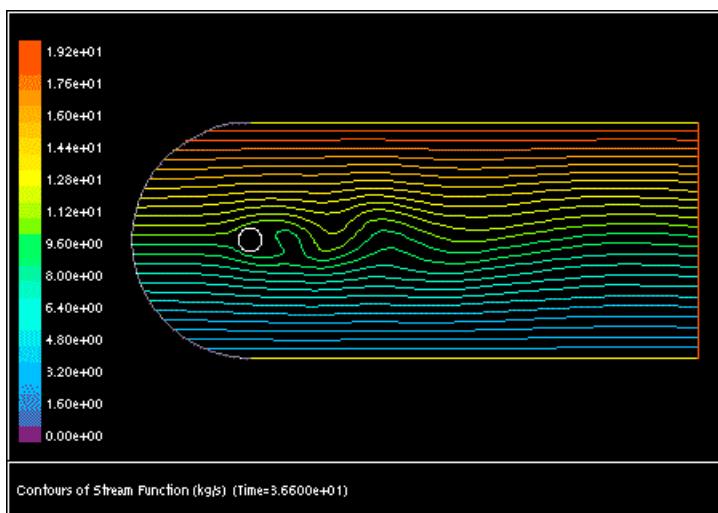

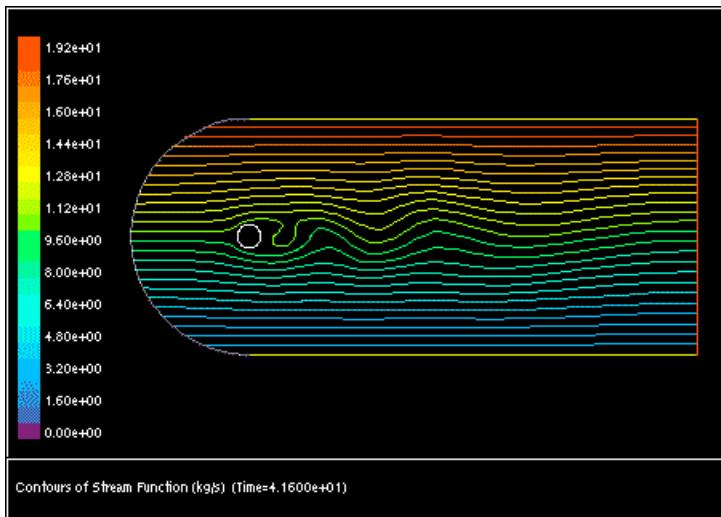

Figure 29.24 Time-Dependent Calculation of Vortex Shedding (t=41.6 sec)

Activating time dependence is sometimes useful when attempting to solve steady-state problems which tend toward instability (e.g., natural convection problems in which the Rayleigh number is close to the transition region). It is possible in many cases to reach a steady-state solution by integrating the time-dependent equations.

For details about temporal discretization, see [Temporal Discretization](#) in the [Theory Guide](#).

For additional information, please see the following sections:

[29.14.1. User Inputs for Time-Dependent Problems](#)

[29.14.2. Adaptive Time Stepping](#)

[29.14.3. Variable Time Stepping](#)

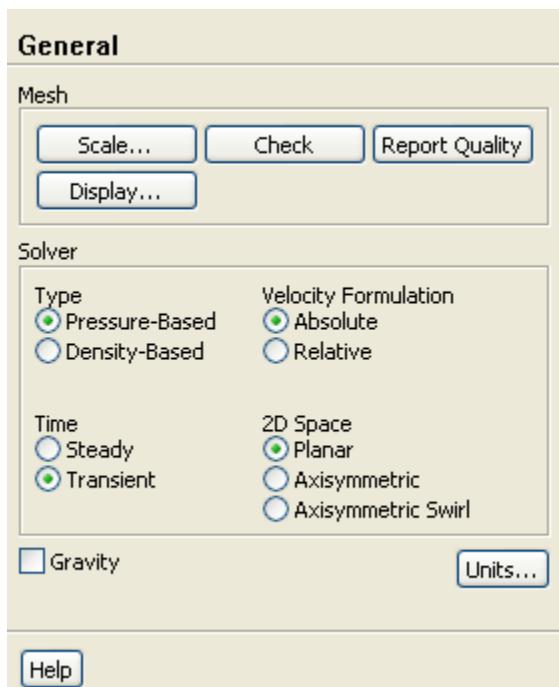

[29.14.4. Postprocessing for Time-Dependent Problems](#)

29.14.1. User Inputs for Time-Dependent Problems

To solve a transient problem, you will follow the procedure outlined below:

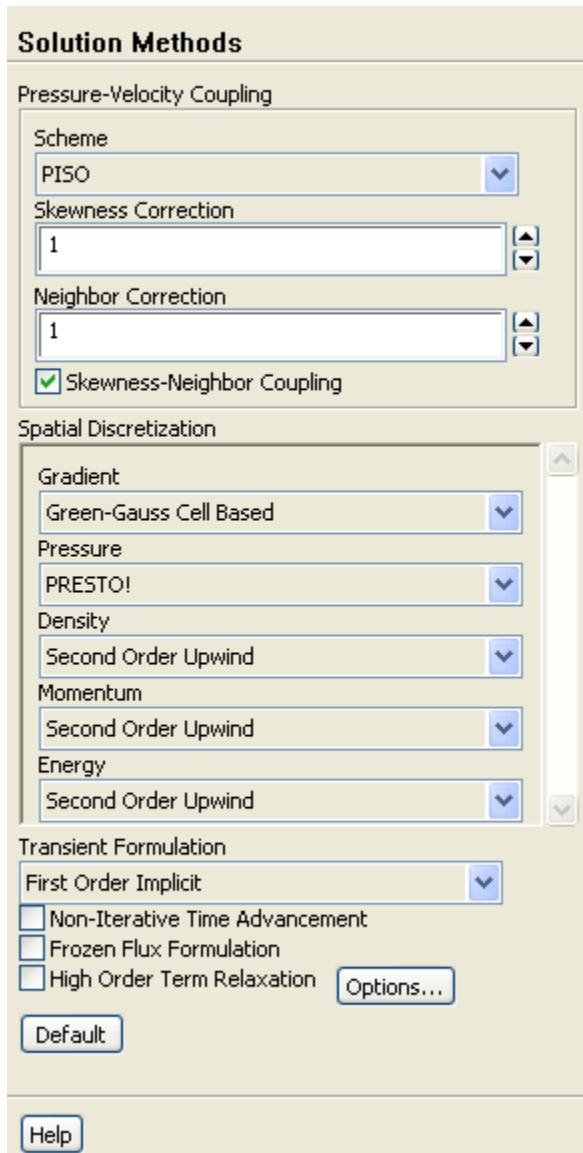

1. Enable the **Transient** option in the **General** task page ([Figure 29.25 \(p. 1367\)](#)).

Figure 29.25 The General Task Page for a Transient Calculation

2. Define all relevant models and boundary conditions. Note that any boundary conditions specified using user-defined functions can be made to vary in time. See the [UDF Manual](#) for details.
3. Specify the desired parameters in the **Solution Methods** task page (*Figure 29.26 (p. 1368)*).

◀ Solution Methods

Figure 29.26 The Solution Methods Task Page for a Transient Calculation

If you are using the pressure-based solver, select **PISO** from the **Scheme** drop-down list in the **Pressure-Velocity Coupling** group box. To increase the speed of the calculations, you may need to modify the parameters related to the PISO scheme from their default values. See [PISO \(p. 1322\)](#) for more information about the optimal use of the PISO algorithm.

Important

If you are using the LES turbulence model with small time steps, the PISO scheme may be too computationally expensive. It is therefore recommended that you select **SIMPLE** or **SIMPLEC** instead of **PISO**.

Important

It is best to select the **Coupled** pressure-velocity coupling scheme if you are using large time steps to solve your transient flow, or if you have a poor quality mesh.

Next, specify the desired **Transient Formulation**. The **First Order Implicit** formulation is sufficient for most problems. If you need improved accuracy, you can either use **Second Order Implicit** or **Bounded Second Order Implicit**. The **Bounded Second Order Implicit** formulation would provide better stability, since time discretization would always ensure the bounds for variables, if available.

Important

Note that while the **Bounded Second Order Implicit** formulation provides the same accuracy as the **Second Order Implicit** formulation, it actually provides better stability.

Important

The **Bounded Second Order Implicit** formulation is available only for the pressure-based solver, and not for the density-based solver.

The **Explicit** formulation (available only for the density-based solver) is used primarily to capture the transient behavior of moving waves, such as shocks. For details, see [Temporal Discretization in the Theory Guide](#).

When using the pressure-based solver, you have the additional options of selecting **Non-Iterative Time Advancement** and **Frozen Flux Formulation** for your time-dependent flow calculations (see [Time-Advancement Algorithm](#) and [Steady-State Iterative Algorithm](#) in the [Theory Guide](#), respectively). Note that the latter option is only available for single-phase transient problems that do not use a moving/deforming mesh model.

4. (optional) If you are using the explicit transient formulation or if you are using the adaptive time stepping method (described in a later step and in [Adaptive Time Stepping \(p. 1374\)](#)) it is recommended that you enable the printing of the current time (for the explicit transient formulation) or the current time step size (for the adaptive time stepping method) at each iteration, using the [Statistic Monitors Dialog Box \(p. 2068\)](#).

 **Monitors** →  **Statistic** → **Edit...**

Make sure that the desired item is selected from the **Statistics** selection list (**time** for the current time or **delta_time** for the current time step size) and enable the **Print** option. When ANSYS FLUENT prints the residuals to the console at each iteration, it will include a column with the current time or the current time step size.

5. (optional) Use the [Drag Monitor Dialog Box \(p. 2069\)](#), the [Lift Monitor Dialog Box \(p. 2070\)](#), the [Moment Monitor Dialog Box \(p. 2072\)](#), or the [Surface Monitor Dialog Box \(p. 2074\)](#) to monitor (and/or save to a file) time-varying force coefficient values or a report of a field variable or function on a surface as it changes with time. See [Monitoring Solution Convergence \(p. 1379\)](#) for details.
6. Set the initial conditions (at time $t = 0$) using the **Solution Initialization** task page.

 **Solution Initialization**

You can also read in a steady-state data file to set the initial conditions.

File → **Read** → **Data...**

7. Use the **Autosave** dialog box to specify the file name and frequency with which case and data files should be saved during the solution process. To open the **Autosave** dialog box, click the **Edit...** button next to **Autosave Every** in the **Calculation Activities** task page.

Calculation Activities (Autosave Case/Data) → Edit...

See [Automatic Saving of Case and Data Files \(p. 68\)](#) for details about automatic file saving.

The **Calculation Activities** task page also allows you to export solution and particle history data during the transient calculation. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for details.

If you want to create a graphical animation of the solution over time, you can use the [Solution Animation Dialog Box \(p. 2105\)](#) to set up the graphical displays that you want to use in the animation. See [Animating the Solution \(p. 1409\)](#) for details.

You may also want to request automatic execution of other commands using the [Execute Commands Dialog Box \(p. 2103\)](#). See [Executing Commands During the Calculation \(p. 1400\)](#) for details.

8. (optional) You can improve the convergence of the transient calculations by enabling the **Extrapolate Variables** option in the [Run Calculation Task Page \(p. 2107\)](#). This option instructs ANSYS FLUENT to predict the solution variable values for the next time step using a Taylor series expansion, and then inputs that predicted value as an initial guess for the inner iterations of the current time step. As a result, the absolute residual levels are lowered.

Note that the **Extrapolate Variables** option is not available if you are employing either the NITA scheme with the pressure-based solver or the explicit formulation with the density-based solver.

Important

If you use the **Extrapolate Variables** option when modeling an incompressible flow with the density-based solver, it is recommended that you disable the extrapolation of pressure values. After you have enabled the **Extrapolate Variables** option, type the following text command in the console:

```
> solve/set/extrapolate-eqn-vars/pressure
Extrapolate Pressure? [yes] no
```

9. (optional) If you want ANSYS FLUENT to gather data for time statistics (i.e., time-averaged and root-mean-square values for solution variables) during the calculation, follow these steps:

- Create a custom field function for each of the variables for which you want to postprocess unsteady statistics (e.g., $P^*|V|$), using the **Custom Field Function Calculator**. For detailed instructions, see [Creating a Custom Field Function \(p. 1709\)](#). Note that you do not need to take the extra step of creating custom field functions for the flow shear stresses, flow heat fluxes, or wall statistics, as there are options for selecting these variables directly in a later step.

Define → Custom Field Functions...

Important

The maximum number of custom field functions that can be calculated and post-processed for unsteady statistics is 50.

- b. Enable the **Data Sampling for Time Statistics** option in the *Run Calculation Task Page* (p. 2107).

◆ Run Calculation → ✓ Data Sampling for Time Statistics

Enabling this option will allow you to display and report both the mean and the root-mean-square (RMS) values, as described in *Postprocessing for Time-Dependent Problems* (p. 1378).

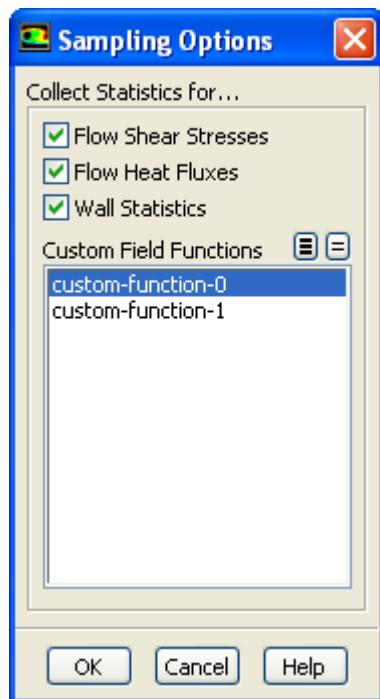

To specify the sampling interval, enter a value for **Sampling Interval**.

The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

To select the variables (which may be represented as custom field functions) for which you want to collect statistics, click the **Sampling Options...** button and make selections from the **Sampling Options** dialog box that opens (*Figure 29.27* (p. 1371)). Note that no custom field functions are selected by default.

◆ Run Calculation → Sampling Options...

Figure 29.27 The Sampling Options Dialog Box

Important

Note that gathering data for time statistics is not meaningful inside a moving cell zone (e.g., a sliding zone in a sliding mesh problem, a moving zone in a dynamic mesh problem).

- c. Initialize the flow statistics.

Solution Initialization → Reset Statistics

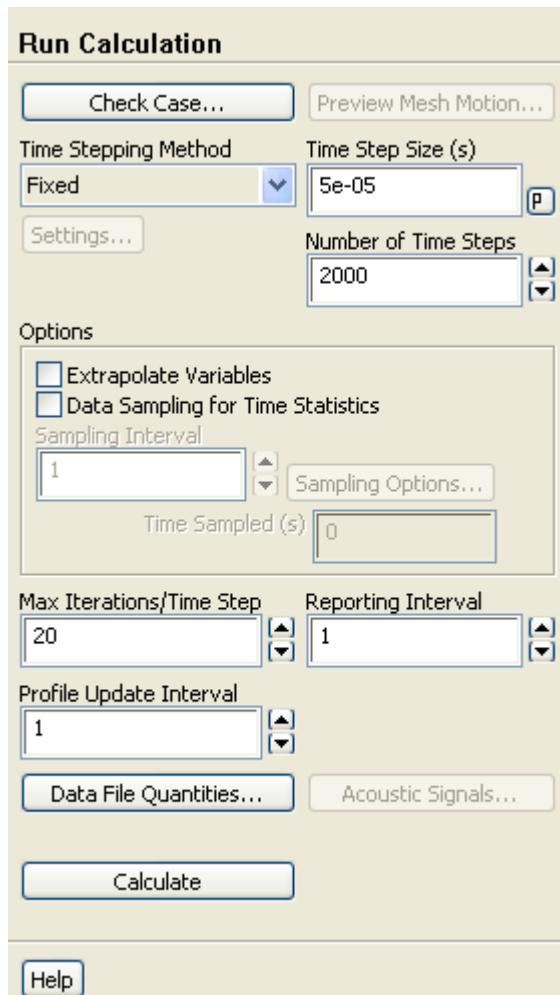

Note that you can also reset the flow statistics after you have gathered some data for time statistics. If you perform, say, 10 time steps with the **Data Sampling for Time Statistics** option enabled, check the results, and then continue the calculation for 10 more time steps, the time statistics will include the data gathered in the first 10 time steps unless you reinitialize the flow statistics.

10. Specify time-dependent solution parameters and start the calculation as described below for the implicit and explicit transient formulations:

- If you have chosen the **First Order Implicit**, **Second Order Implicit**, or **Bounded Second Order Implicit** formulation, the procedure is as follows:
 - Set the time-dependent solution parameters in the *Run Calculation Task Page* (p. 2107) (see *Figure 29.28* (p. 1372)).

Run Calculation

Figure 29.28 The Run Calculation Task Page for Implicit Transient Calculations

Solution parameters for the implicit transient formulations are as follows:

- **Max Iterations/Time Step:** When ANSYS FLUENT solves the time-dependent equations using the implicit formulation, multiple iterations may be necessary at each time step. This parameter sets a maximum for the number of iterations per time step. If the convergence criteria are met before this number of iterations is performed, the solution will advance to the next time step.
- **Time Step Size:** The time step size is the magnitude of Δt . Since the ANSYS FLUENT formulation is fully implicit, there is no stability criterion that needs to be met in determining Δt . However, to model transient phenomena properly, it is necessary to set Δt at least one order of magnitude smaller than the smallest time constant in the system being modeled. A good way to judge the choice of Δt is to observe the number of iterations ANSYS FLUENT needs to converge at each time step. The ideal number of iterations per time step is 5–10. If ANSYS FLUENT needs substantially more, the time step is too large. If ANSYS FLUENT needs only a few iterations per time step, Δt should be increased. Frequently a time-dependent problem has a very fast “startup” transient that decays rapidly. Therefore, it is often wise to choose a conservatively small Δt for the first 5–10 time steps. Δt may then be gradually increased as the calculation proceeds.

For time-periodic calculations, you should choose the time step based on the time scale of the periodicity. For a rotor/stator model, for example, you might want 20 time steps between each blade passing. For vortex shedding, you might want 20 steps per period.

To verify that your choice for Δt was proper after the calculation is complete, you can plot contours of the Courant number within the domain. To do so, select **Velocity...** and **Cell Courant Number** from the **Contours of** drop-down lists in the **Contours** dialog box. For a stable, efficient calculation, the Courant number should not exceed a value of 20–40 in most sensitive transient regions of the domain.

- **Time Stepping Method:** By default, the size of the time step is fixed (as indicated by the selection of **Fixed**).

To have ANSYS FLUENT modify the size of the time step as the calculation proceeds, select **Adaptive** and click the **Settings...** button to specify the parameters in the **Adaptive Time Step Settings** dialog box. See [Adaptive Time Stepping \(p. 1374\)](#) for details.

For transient volume of fluid (VOF) calculations that use the explicit scheme of VOF, you can select the **Variable** time stepping method. The parameters set through the **Parameters...** button are in many ways the same as for the adaptive time stepping method, with the exception of specifying a global Courant number (see [Variable Time Stepping \(p. 1377\)](#)).

Note that with the **Adaptive** or **Variable** time stepping method, the value you specify for the **Time Step Size** will be the initial size of the time step. As the calculation proceeds, the **Time Step Size** shown in the **Run Calculation** task page will be the size of the *current* time step.

- b. Specify the desired **Number of Time Steps** in the **Run Calculation** task page and click **Calculate**.

As it calculates a solution, ANSYS FLUENT will print the current time at the end of each time step.

- If you have chosen the **Explicit** transient formulation, you will follow a different procedure:
 - a. Use the default settings in the **Solution Controls** task page.

Solution Controls

If you have modified the parameters, you can click the **Default** button to retrieve the default settings.

- b. Specify the desired **Number of Iterations** and click **Calculate**.

Run Calculation

Remember that when the explicit transient formulation is used, each iteration is a time step. When ANSYS FLUENT prints the residuals to the console, it will include a column with the current time (if you requested this in step 4, above).

- You can access the information saved in a data file, which includes a standard set of quantities that were computed during the calculation, by clicking the **Data File Quantities...** button. More information about this feature is available in *Setting Data File Quantities* (p. 122).
11. Save the final data file (and case file, if you have modified it) so that you can continue the transient calculation later, if desired.

File → Write → Data...

29.14.1.1. Additional Inputs

The procedures for setting the reporting interval, updating UDF profiles, interrupting iterations, and resetting data are the same as those for steady-state calculations. See *Performing Steady-State Calculations* (p. 1358) for details.

Important

If you are using a user-defined function in your time-dependent calculation, note that, in addition to being updated after every n iterations (where n is the value of the **UDF Profile Update Interval**), the function will also be updated at the first iteration of each time step.

29.14.2. Adaptive Time Stepping

As mentioned in *User Inputs for Time-Dependent Problems* (p. 1366), it is possible to have the size of the time step change as the calculation proceeds, rather than specifying a fixed size for the entire calculation. This section provides a brief description of the algorithm that ANSYS FLUENT uses to compute the time step size, as well as an explanation of each of the parameters that you can set to control the adaptive time stepping.

Important

Adaptive time stepping is available only with the pressure-based and density-based implicit formulations; it cannot be used with the density-based explicit formulation. In addition, it cannot be used with the discrete phase model, second-order time integration, Euler-Euler multiphase models (*Approaches to Multiphase Modeling* in the *Theory Guide*), or user-defined scalars (*User-Defined Scalar (UDS) Transport Equations* (p. 505)).

29.14.2.1. The Adaptive Time Stepping Algorithm

The automatic determination of the time step size is based on the estimation of the truncation error associated with the time integration scheme. If the truncation error is smaller than a specified tolerance, the size of the time step is increased; if the truncation error is greater, the time step size is decreased.

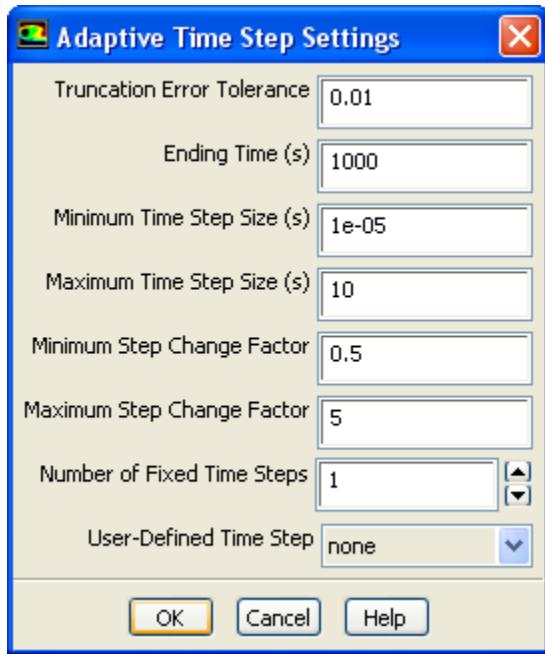

An estimation of the truncation error can be obtained by using a predictor-corrector type of algorithm [29] (p. 2368) in association with the time integration scheme. At each time step, a predicted solution can be obtained using a computationally inexpensive explicit method (forward Euler for the first-order unsteady formulation, Adams-Bashford for the second-order unsteady formulation). This predicted solution is used as an initial condition for the time step, and the correction is computed using the non-linear iterations associated with the implicit (pressure-based or density-based) formulation. The norm of the difference between the predicted and corrected solutions is used as a measure of the truncation error. By comparing the truncation error with the desired level of accuracy (i.e., the truncation error tolerance), ANSYS FLUENT is able to adjust the time step size by increasing it or decreasing it.

In cases where the truncation error remains above the specified tolerance, ANSYS FLUENT will try to meet the tolerance within 5 attempts. If this tolerance is met, then the iteration moves on to the next time step. An explicit scheme is used to predict the solution at each time step, then the explicit prediction is corrected with an implicit scheme. The truncation error, which is a function of the difference between the predicted and corrected solutions at a specific time is used to calculate the next time step. However, if the calculated truncation error is greater than the tolerance limit, we have the option of reverting from the currently performed iteration, which is moving from the n th step to $n+1$ th step, and performing the iteration with a smaller time step. Note that this option is not available for moving deforming meshes, sliding meshes, and the discrete phase model. Since the truncation error is proportional to the time step, decreasing the time step reduces the truncation error. This can be done until the truncation error goes below the tolerance limit.

29.14.2.2. Specifying Parameters for Adaptive Time Stepping

The parameters that control the adaptive time stepping appear in the **Adaptive Time Step Settings** dialog box, as described in [User Inputs for Time-Dependent Problems](#) (p. 1366).

Figure 29.29 The Adaptive Time Step Settings Dialog Box for Implicit Unsteady Calculations and Adaptive Time Stepping

These parameters are as follows:

Truncation Error Tolerance

specifies the threshold value to which the computed truncation error is compared. Increasing this value will lead to an increase in the size of the time step and a reduction in the accuracy of the solution. Decreasing it will lead to a reduction in the size of the time step and an increase in the solution accuracy, although the calculation will require more computational time. For most cases, the default value of 0.01 is acceptable.

Ending Time

specifies an ending time for the calculation. Since the ending time cannot be determined by multiplying the number of time steps by a fixed time step size, you need to specify it explicitly.

Minimum/Maximum Time Step Size

specify the upper and lower limits for the size of the time step. If the time step becomes very small, the computational expense may be too high; if the time step becomes very large, the solution accuracy may not be acceptable to you. You can set the limits that are appropriate for your simulation.

Minimum/Maximum Step Change Factor

limit the degree to which the time step size can change at each time step. Limiting the change results in a smoother calculation of the time step size, especially when high-frequency noise is present in the solution. If the time step change factor, f , is computed as the ratio between the specified truncation error tolerance and the computed truncation error, the size of time step Δt_n is computed as follows:

- If $1 < f < f_{max}$, Δt_n is increased to meet the desired tolerance.
- If $1 < f_{max} < f$, Δt_n is increased, but its maximum possible value is $f_{max} \Delta t_{n-1}$.
- If $f_{min} < f < 1$, Δt_n is unchanged.
- If $f < f_{min} < 1$, Δt_n is decreased.

Number of Fixed Time Steps

specifies the number of fixed-size time steps that should be performed before the size of the time step starts to change. The size of the fixed time step is the value specified for **Time Step Size** in the **Run Calculation** task page.

It is a good idea to perform a few fixed-size time steps before switching to the adaptive time stepping. Sometimes spurious discretization errors can be associated with an impulsive start in time. These errors are dissipated during the first few time steps, but they can adversely affect the adaptive time stepping and result in extremely small time steps at the beginning of the calculation.

Important

When the solution tends to exhibit incomplete convergence, rather than increasing the time step size or keeping the same time step size in the next step, ANSYS FLUENT reduces the time step size by at least half for the next time step (making sure that the time step size does not go below the specified minimum time step size).

29.14.2.3. Specifying a User-Defined Time Stepping Method

If you want to use your own adaptive time stepping method, instead of the method described above, you can create a user-defined function for your method and select it in the **User-Defined Time Step** drop-down list. The other inputs in the **Adaptive Time Step Settings** dialog box will not be used when you select a user-defined function.

See the [UDF Manual](#) for details about creating and using user-defined functions.

29.14.3. Variable Time Stepping

For VOF and Eulerian multiphase calculations (using the **Explicit** scheme), ANSYS FLUENT allows you to use variable time stepping in order to automatically change the time-step when an interface is moving through dense cells or if the interface velocity is high.

Variable time stepping is available for all the explicit schemes of VOF, which includes the donor-acceptor scheme as well. Variable time stepping is not available for the implicit scheme of VOF.

29.14.3.1. The Variable Time Stepping Algorithm

The global time-step Δt_{global} is changed in the following manner:

$$\Delta t_{global} = \frac{CFL_{global}}{\max \left(\sum \frac{\text{outgoing fluxes}}{\text{volume}} \right)} \quad (29-1)$$

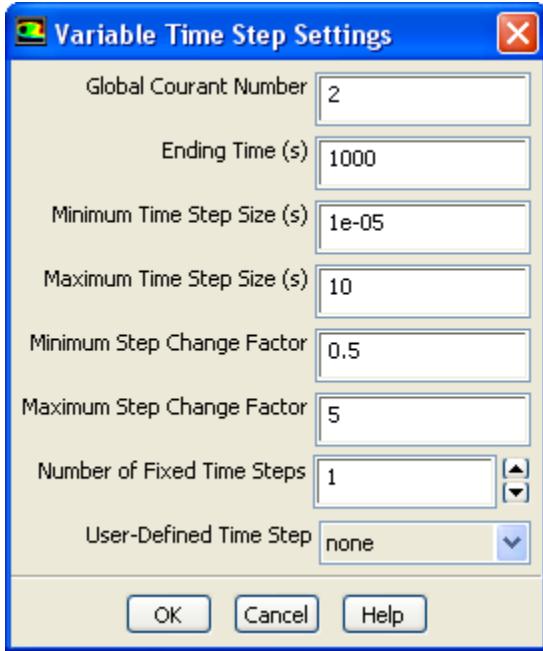

where the ratio $\sum \frac{\text{outgoing fluxes}}{\text{volume}}$ is calculated for each cell. ANSYS FLUENT takes the maximum of this ratio to calculate the global time step.

29.14.3.2. Specifying Parameters for Variable Time Stepping

For transient VOF calculations, when **Variable** is selected from the **Time Stepping Method** drop-down list, in the **Run Calculation** task page and the **Settings...** button is clicked, the **Variable Time Step**

Settings dialog box will open (*Figure 29.30* (p. 1378)). With the exception of the **Global Courant Number** field, all parameters are the same as for adaptive time stepping (see *Adaptive Time Stepping* (p. 1374)). The default value for the **Global Courant Number** is 2.

Figure 29.30 The Variable Time Step Settings Dialog Box for Implicit Unsteady Calculations and Variable Time Stepping

The variable time step is based on the maximum Courant number near the VOF interface. To calculate that Courant number, ANSYS FLUENT uses a flux-based definition where, in the region near the fluid interface, ANSYS FLUENT divides the volume of each cell by the sum of the outgoing fluxes. The resulting time represents the time it would take for the fluid to empty out of the cell. The smallest such time is used as the characteristic time of transit for a fluid element across a control volume.

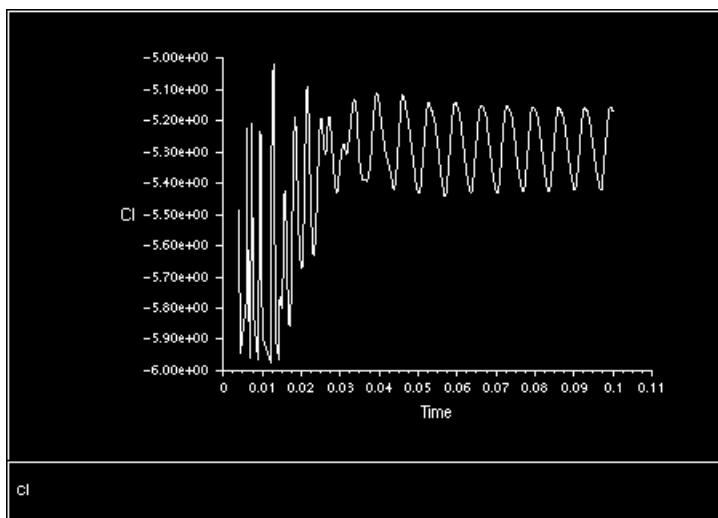

29.14.4. Postprocessing for Time-Dependent Problems

The postprocessing of time-dependent data is similar to that for steady-state data, with all graphical and alphanumeric commands available. You can read a data file that was saved at any point in the calculation (by you or with the autosave option) to restore the data at any of the time levels that were saved.

File → Read → Data...

ANSYS FLUENT will label any subsequent graphical or alphanumeric output with the time value of the current data set.

If you save data from the force or surface monitors to files (see step 5 in *User Inputs for Time-Dependent Problems* (p. 1366)), you can read these files back in and plot them to see a time history of the monitored quantity. *Figure 29.31* (p. 1379) shows a sample plot generated in this way.

Figure 29.31 Lift Coefficient Plot for a Time-Periodic Solution

If you enable the **Data Sampling for Time Statistics** option in the *Run Calculation Task Page* (p. 2107) (see *Performing Time-Dependent Calculations* (p. 1365) for details), ANSYS FLUENT will compute the time average (mean) of the instantaneous values and the root-mean-squares of those quantities and custom field functions that are enabled/selected in the **Sampling Options** dialog box.

The **Time Sampled** displays the time over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

The mean and root-mean-square (RMS) values for all solution variables will be available in the **Unsteady Statistics...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. For example, in the **Contours** dialog box, you could select **Unsteady Statistics...** and **RMS-uns-custom-function-0** for the **Contours of** drop-down lists in order to display the root-mean-squares of a custom field function named **uns-custom-function-0**.

29.15. Monitoring Solution Convergence

During the solution process you can monitor the convergence dynamically by checking residuals, statistics, force values, surface integrals, and volume integrals. You can print reports of or display plots of lift, drag, and moment coefficients, surface integrations, and residuals for the solution variables. For unsteady flows, you can also monitor elapsed time. Each of these monitoring features is described below.

For additional information, please see the following sections:

- 29.15.1. Monitoring Residuals
- 29.15.2. Monitoring Statistics
- 29.15.3. Monitoring Force and Moment Coefficients
- 29.15.4. Monitoring Surface Integrals
- 29.15.5. Monitoring Volume Integrals

29.15.1. Monitoring Residuals

At the end of each solver iteration, the residual sum for each of the conserved variables is computed and stored, thus recording the convergence history. This history is also saved in the data file. The residual sum is defined below.

On a computer with infinite precision, these residuals will go to zero as the solution converges. On an actual computer, the residuals decay to some small value ("round-off") and then stop changing ("level out"). For single-precision computations (the default for workstations and most computers), residuals can drop as many as six orders of magnitude before hitting round-off. Double-precision residuals can drop up to twelve orders of magnitude. Guidelines for judging convergence can be found in [Judging Convergence \(p. 1430\)](#).

29.15.1.1. Definition of Residuals for the Pressure-Based Solver

After discretization, the conservation equation for a general variable ϕ at a cell P can be written as

$$a_P \phi_P = \sum_{nb} a_{nb} \phi_{nb} + b \quad (29-2)$$

Here a_P is the center coefficient, a_{nb} are the influence coefficients for the neighboring cells, and b is the contribution of the constant part of the source term S_c in $S = S_c + S_p \phi$ and of the boundary conditions. In [Equation 29-2 \(p. 1380\)](#),

$$a_P = \sum_{nb} a_{nb} - S_p \quad (29-3)$$

The residual R^ϕ computed by ANSYS FLUENT's pressure-based solver is the imbalance in [Equation 29-2 \(p. 1380\)](#) summed over all the computational cells P . This is referred to as the "unscaled" residual. It may be written as

$$R^\phi = \sum_{cellsP} \left| \sum_{nb} a_{nb} \phi_{nb} + b - a_P \phi_P \right| \quad (29-4)$$

In general, it is difficult to judge convergence by examining the residuals defined by [Equation 29-4 \(p. 1380\)](#) since no scaling is employed. This is especially true in enclosed flows such as natural convection in a room where there is no inlet flow rate of ϕ with which to compare the residual.

ANSYS FLUENT scales the residual using two kinds of scaling factors, representative of the flow rate of ϕ through the domain. The factors are termed *global scaling* and *local scaling*. The type of scaling can be selected from the **Residual Monitors** dialog box. The "globally scaled" residual is defined as

$$R^\phi = \frac{\sum_{cellsP} \left| \sum_{nb} a_{nb} \phi_{nb} + b - a_P \phi_P \right|}{\sum_{cellsP} |a_P \phi_P|} \quad (29-5)$$

For the momentum equations the denominator term $a_P \phi_P$ is replaced by $a_P v_P$, where v_P is the magnitude of the velocity at cell P .

The "locally scaled" residual is defined as

$$R_\phi = \frac{\sqrt{\sum_{cells}^n \left(\frac{1}{n} \right) \left(\frac{\sum_{nb} a_{nb} \phi_{nb} + b - a_p \phi_p}{a_p} \right)^2}}{(\phi_{max} - \phi_{min})_{domain}} \quad (29-6)$$

As in global scaling, for the momentum, ϕ is replaced by v of the cell.

The scaled residual is a more appropriate indicator of convergence for most problems. The selection of scaling and convergence criteria for different types of scaling are discussed in [Judging Convergence \(p. 1430\)](#). The default residuals displayed by ANSYS FLUENT are global scaling.

For the continuity equation, the unscaled residual for the pressure-based solver is defined as

$$R_c^c = \sum_{cells P} |\text{rate of mass creation in cell } P| \quad (29-7)$$

The local scaling is the same for all equations. However, the global scaling treats continuity in a different way and it is defined as

$$\frac{R_c^c_{\text{iteration } N}}{R_c^c_{\text{iteration 5}}} \quad (29-8)$$

The denominator is the largest absolute value of the continuity residual in the first five iterations.

The scaled residuals described above are useful indicators of solution convergence. Guidelines for their use are given in [Judging Convergence \(p. 1430\)](#). It is sometimes useful to determine how much a residual has decreased during calculations as an additional measure of convergence. For this purpose, ANSYS FLUENT allows you to normalize the residual (either scaled or unscaled) by dividing by the maximum residual value after M iterations, where M is set by you in the [Residual Monitors Dialog Box \(p. 2065\)](#) in the **Iterations** field under **Residual Values**.

$$\bar{R}^\phi = \frac{R^\phi_{\text{iteration } N}}{R^\phi_{\text{iteration } M}} \quad (29-9)$$

Normalization in this manner ensures that the initial residuals for all equations are of $O(1)$ and is sometimes useful in judging overall convergence.

By default, $M = 5$. You can also specify the normalization factor (the denominator in [Equation 29-9 \(p. 1381\)](#)) manually in the [Residual Monitors Dialog Box \(p. 2065\)](#).

29.15.1.2. Definition of Residuals for the Density-Based Solver

A residual for the density-based solver is simply the time rate of change of the conserved variable (W). The RMS residual is the square root of the average of the squares of the residuals in each cell of the domain:

$$R(W) = \sqrt{\sum \left(\frac{\partial W}{\partial t} \right)^2} \quad (29-10)$$

Equation 29–10 (p. 1382) is the unscaled residual sum reported for all the coupled equations solved by ANSYS FLUENT's density-based solver.

Important

The residuals for the equations that are solved sequentially by the density-based solver (turbulence and other scalars, as discussed in [Density-Based Solver](#) in the [Theory Guide](#)) are the same as those described above for the pressure-based solver.

In general, it is difficult to judge convergence by examining the residuals defined by *Equation 29–10 (p. 1382)* since no scaling is employed. This is especially true in enclosed flows such as natural convection in a room where there is no inlet flow rate of ϕ with which to compare the residual. As with the pressure-based solver, ANSYS FLUENT uses two types of scaling for the density-based solver. The globally scaled residual is defined as

$$\frac{R(W)_{\text{iteration } N}}{R(W)_{\text{iteration 5}}} \quad (29-11)$$

The denominator is the largest absolute value of the residual in the first five iterations.

The locally scaled residual is calculated from the local flux imbalance in the cell. It is calculated using *Equation 29–12 (p. 1382)*:

$$R_\phi = \frac{\sqrt{\sum_n^{\text{cells}} \left(\frac{1}{n} \right) \left(\frac{\partial w}{\partial t} V \right)^2}}{(w_{\max} - w_{\min})_{\text{domain}}} \quad (29-12)$$

w is the conservative variable and V is the cell volume. The unscaled residual is always calculated from *Equation 29–10 (p. 1382)*.

The scaled residuals described above are useful indicators of solution convergence. Guidelines for their use are given in [Judging Convergence \(p. 1430\)](#). It is sometimes useful to determine how much a residual has decreased during calculations as an additional measure of convergence. For this purpose, ANSYS FLUENT allows you to normalize the residual (either scaled or unscaled) by dividing by the maximum residual value after M iterations, where M is set by you in the [Residual Monitors Dialog Box \(p. 2065\)](#) in the **Iterations** field under **Residual Values**.

Normalization of the residual sum is accomplished by dividing by the maximum residual value after M iterations, where M is set by you in the [Residual Monitors Dialog Box \(p. 2065\)](#) in the **Iterations** field under **Residual Values**:

$$\bar{R}(W) = \frac{R(W)_{\text{iteration } N}}{R(W)_{\text{iteration } M}} \quad (29-13)$$

Normalization in this manner ensures that the initial residuals for all equations are of $O(1)$ and is sometimes useful in judging overall convergence.

By default, $M = 5$, making the normalized residual equivalent to the scaled residual. You can also specify the normalization factor (the denominator in [Equation 29-13 \(p. 1383\)](#)) manually in the [Residual Monitors Dialog Box \(p. 2065\)](#).

29.15.1.3. Overview of Using the Residual Monitors Dialog Box

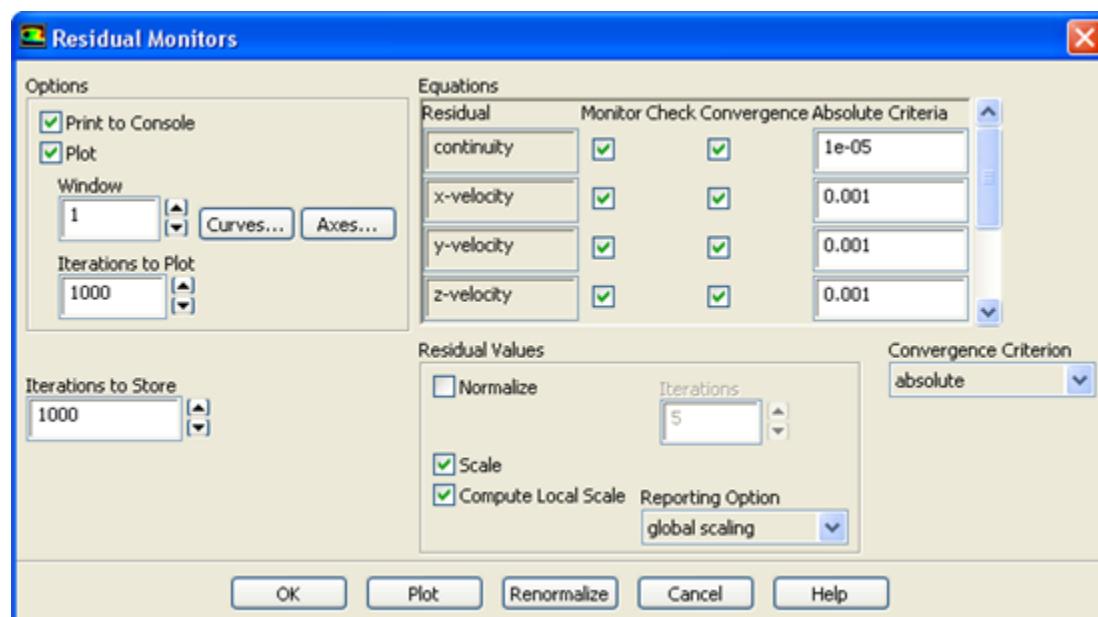

All inputs controlling the monitoring of residuals are entered using the [Residual Monitors Dialog Box \(p. 2065\)](#)([Figure 29.32 \(p. 1383\)](#)).

Monitors → Residuals → Edit...

or

Display → Residuals...

Figure 29.32 The Residual Monitors Dialog Box

In general, you will only need to enable residual plotting and modify the convergence criteria using this dialog box. Additional controls are available for disabling monitoring of particular residuals, and modifying normalization and plot parameters.

29.15.1.4. Printing and Plotting Residuals

By default, residual values for all relevant variables are printed in the console after each iteration. If you wish to disable this printout, turn off **Print to Console** under **Options**. To enable the plotting of residuals

after each iteration, turn on **Plot** under **Options**. Residuals will be plotted in the graphics window (with the window ID set in the **Window** field) during the calculation.

If you wish to display a plot of the current residual history, simply click the **Plot** push button.

29.15.1.5. Storing Residual History Points

Residual histories for each variable are automatically saved in the data file, regardless of whether they are being monitored. You can control the number of history points to be stored by changing the **Iterations to Store** entry. By default, up to 1000 points will be stored. If more than 1000 iterations are performed (i.e., the limit is reached), every other point will be discarded—leaving 500 history points—and the next 500 points will be stored. When the total hits 1000 again, every other point will again be discarded, etc. If you are performing a large number of iterations, you will lose a great deal of residual history information at the beginning of the calculation. In such cases, you should increase the **Iterations to Store** value to a more appropriate value. Of course, the larger this number is, the more memory you will need, the longer the plotting will take, and the more disk space you will need to store the data file.

29.15.1.6. Controlling Normalization and Scaling

By default, scaling of residuals (see [Equation 29–5 \(p. 1380\)](#) and [Equation 29–11 \(p. 1382\)](#)) is enabled and the default convergence criterion is 10^{-6} for energy and P-1 equations and 10^{-3} for all other equations. When the **Scale** option is enabled, global scaling will be applied by default. You can then activate the **Compute Local Scale** option and select the **Reporting Option** from the drop-down list. You have a choice to plot or print to the console the **local scaling** or the **global scaling** of residuals. By default, the **global scaling** of residuals will be plotted.

Note

When **Compute Local Scale** is enabled, ANSYS FLUENT computes and stores both the locally and globally scaled residuals from subsequent iterations, for the purpose of reporting. The scaled residuals are stored in the data file.

Important

Once the **Compute Local Scale** option is activated and you disable the **Scale** option, the **Compute Local Scale** option will not automatically be disabled. Instead, it will compute both the locally and globally scaled residuals, but only print or plot the unscaled residual.

Residual normalization (i.e., dividing the residuals by the largest value during the first few iterations) is also available but disabled by default.

Normalization can be used with both scaled and unscaled residuals. Note that if normalization is enabled, the convergence criterion may need to be adjusted appropriately. See [Judging Convergence \(p. 1430\)](#) for information about judging convergence based on the different types of residual reports. (Both the raw residuals and scaling factors are stored in the data file, so you can switch between scaled and unscaled residuals.)

To report unscaled residuals, simply disable the **Scale** option under **Residual Values**.

Important

If you switch from scaled to unscaled residuals (or vice versa) and you are normalizing the residuals (as described below), you must click the **Renormalize** button to recompute the normalization factors.

If you wish to normalize the residuals (see [Equation 29–9 \(p. 1381\)](#) or [Equation 29–13 \(p. 1383\)](#)), enable the **Normalize** option under **Residual Values**. The **Normalization Factor** column will be added to the dialog box at this time. ANSYS FLUENT will normalize the printed or plotted residual for each variable by the value indicated as the **Normalization Factor** for that variable. The default **Normalization Factor** is the maximum residual value after the first 5 iterations. To use the maximum residual value after a different number of iterations (i.e., specify a different value for M in [Equation 29–9 \(p. 1381\)](#) or [Equation 29–13 \(p. 1383\)](#)), you can modify the **Iterations** entry under **Residual Values**.

In some cases, the maximum residual may occur sometime after the iteration specified in the **Iterations** field. If this should occur, you can click the **Renormalize** button to set the normalization factors for all variables to the maximum values in the residual histories. Subsequent plots and printed reports will use the new normalization factor.

You can also specify the normalization factor (the denominator in [Equation 29–9 \(p. 1381\)](#) or [Equation 29–13 \(p. 1383\)](#)) explicitly. To modify the normalization factor for a particular variable, enter a new value in the corresponding **Normalization Factor** field in the [Residual Monitors Dialog Box \(p. 2065\)](#).

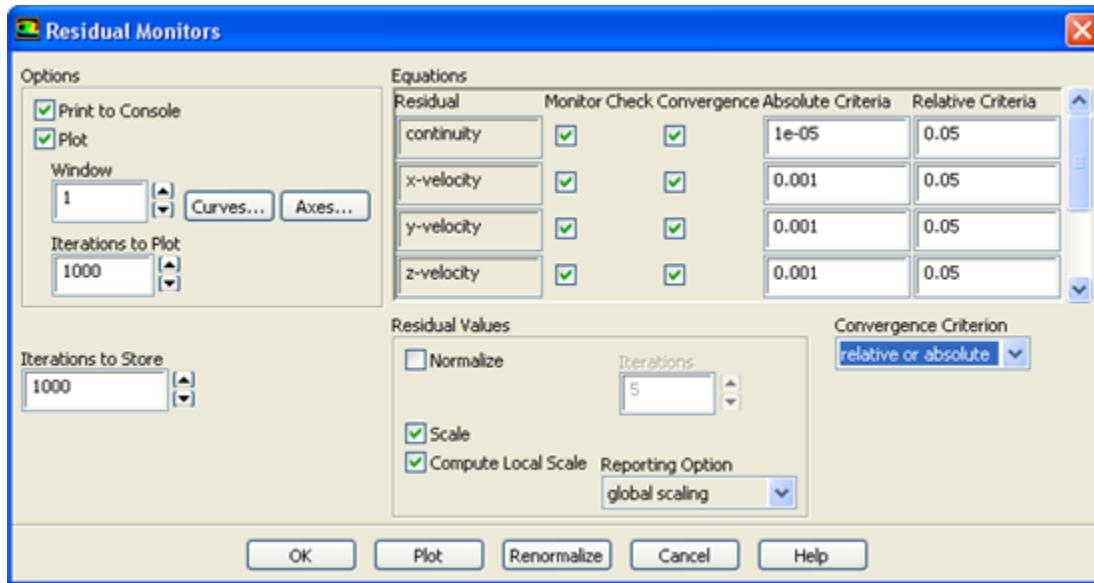

If you wish to report unnormalized, unscaled residuals ([Equation 29–4 \(p. 1380\)](#) or [Equation 29–10 \(p. 1382\)](#)), disable the **Normalize** and **Scale** options under **Residual Values** in the [Residual Monitors Dialog Box \(p. 2065\)](#). Note that unnormalized, unscaled residuals are stored in the data file regardless of whether the reported residuals are normalized or scaled.

29.15.1.7. Choosing a Convergence Criterion

The ability to choose certain convergence criteria provides you with alternative ways to check convergence when using the iterative transient solver. The various convergence criteria can be selected in the **Residual Monitors** dialog box from the **Convergence Criterion** drop-down list.

 **Monitors** →  **Residuals** → **Edit...**

Figure 29.33 The Residual Monitors Dialog Box Displaying Relative or Absolute Convergence

Four options are available for checking an equation for convergence:

absolute

This is the default. For steady-state cases, **absolute** and **none** are the only options available for selection. The residual (scaled and/or normalized) of an equation at an iteration is compared with a user-specified value. If the residual is less than the user-specified value, that equation is deemed to have converged for a timestep.

relative

The residual of an equation at an iteration of a timestep is compared with the residual at the start of the timestep. If the ratio of the two residuals is less than a user-specified value, that equation is deemed to have converged for a timestep.

relative or absolute

If either the **absolute** convergence criterion or the **relative** convergence criterion is met, the equation is considered converged.

The **Relative Criteria** can be set when **relative** or **relative or absolute** is selected.

none

Convergence checking is disabled.

In many situations, the **absolute** convergence criterion could be too stringent for transient flows causing a large number of iterations per timestep. For example, the scaling of the continuity equation is based on the value of the continuity residual in the first five iterations. The scaling factor could be low if the initial continuity residual is small and thus the scaled residual could fail to meet the **absolute** convergence criterion. With the **relative** convergence criterion, convergence is checked by comparing the residual at an iteration of a timestep with the residual at the beginning of the timestep and hence this problem is alleviated. The **relative or absolute** convergence criterion is useful in situations where the residuals of some of the equations are already very low at the start of a timestep (for example, when a particular variable has reached steady state), and the order of magnitude reduction in residuals is not possible. The **none** option allows you to disable convergence checking by selecting the option in the **Convergence Criterion** drop-down list.

Important

relative and **relative or absolute** convergence criteria are available only with the unsteady pressure-based solver and unsteady density-based solver.

The text command used to access the convergence criterion is

`solve → monitors → residual → criterion-type`

When `criterion-type` is entered, you will have the following choices:

Cri- terion	Type
0	absolute
1	relative
2	relative or abso- lute
3	none

For `criterion-type` 1 or 2, the text command `relative-conv-criteria` will appear under the residual text menu, where the various `relative-conv-criteria` can be set.

Important

If the NITA solver is enabled, no convergence criteria are available for selection.

29.15.1.8. Modifying Convergence Criteria

Depending on the **Convergence Criterion** you choose, ANSYS FLUENT will check for convergence. If convergence is being monitored, the solution will stop automatically when each variable meets its specified convergence criterion. Convergence checks can be performed only for variables for which you are monitoring residuals (i.e., variables for which the **Monitor** option is enabled).

You can choose whether or not you want to check the convergence for each variable by enabling or disabling the **Check Convergence** option for it in the [Residual Monitors Dialog Box \(p. 2065\)](#). To modify the convergence criterion for a particular variable, enter a new value in the corresponding convergence criterion field.

29.15.1.9. Disabling Monitoring

If your problem requires the solution of many equations (e.g., turbulence quantities and multiple species), a plot that includes all residuals may be difficult to read. In such cases, you may choose to monitor only a subset of the residuals, perhaps those that affect convergence the most. You can indicate whether or not you want to monitor residuals for each variable by enabling or disabling the relevant check box in the **Monitor** list of the [Residual Monitors Dialog Box \(p. 2065\)](#).

29.15.1.10. Plot Parameters

If you choose to plot the residual values (either interactively during the solution or using the **Plot** button after calculations are complete), there are several display parameters you can modify.

In the **Window** field under **Options**, you can specify the ID of the graphics window in which the plot will be drawn. When ANSYS FLUENT is iterating, the active graphics window is temporarily set to this window to update the residual plot, and then returned to its previous value. Thus, the residual plot can be maintained in a separate window that does not interfere with other graphical postprocessing.

You can modify the number of residual history points to be displayed in the plot by changing the **Iterations to Plot** entry under **Options**. If you specify n points, ANSYS FLUENT will display the last n history points. Since the y axis is scaled by the minimum and maximum values of all points in the plot, you can zoom in on the end of the residual history by setting **Iterations to Plot** to a value smaller than the number of iterations performed. If, for example, the residuals jumped early in the calculation when you turned on turbulence, that peak broadens the overall range in residual values, making the smaller fluctuations later on almost indistinguishable. By setting the value of **Iterations to Plot** so that the plot does not include that early peak, your y -axis range is better suited to the values that you are interested in seeing. For more information on residual history points, please refer to the discussion of storing residual history points, described earlier in this section.

You can also modify the attributes of the plot axes and the residual curves. Click the **Axes...** or **Curves...** button to open the *Axes Dialog Box* (p. 2179) or *Curves Dialog Box* (p. 2181). See *Axes Dialog Box* (p. 2179) and *Curves Dialog Box* (p. 2181) for details.

Important

Note that entering a value for **Iterations to Plot** does not necessarily mean *solved* iterations but rather *stored* (or sampled) data points. Note also that the frequency of the data storage will diminish towards the start of the solution as the number of solved iterations increases. Due to this, whenever the *stored* iterations is greater than the *solved* iterations, if you plot n iterations, you actually see a history that goes back further than n solved iterations.

29.15.1.11. Postprocessing Residual Values

If you are having solution convergence difficulties, it is often useful to plot the residual value fields (e.g., using contour plots) to determine where the high residual values are located. When you use one of the density-based solver, the residual values for all solution variables are available in the **Residuals...** category in the postprocessing dialog boxes. (If you read case and data files into ANSYS FLUENT, you will need to perform at least one iteration before the residual values are available for postprocessing.) For the pressure-based solver, however, only the mass imbalance in each cell is available by default.

If you want to plot residual value fields for a pressure-based solver calculation, you will need to do the following:

1. Read in the case and data files of interest (if they are not already in the current session).
2. Use the `expert` command in the solve/set/ text menu to enable the saving of residual values.

`solve → set → expert`

Among other questions, ANSYS FLUENT will ask if you want to save cell residuals for postprocessing. Enter `yes` or `y`, and keep the default settings for all of the other questions (by pressing the `<RETURN>` key).

3. Perform at least one iteration.

The solution variables for which residual values are available will appear in the **Residuals...** category in the postprocessing dialog boxes. Note that residual values are *not* available for the radiative transport equations solved by the discrete ordinates radiation model.

29.15.2. Monitoring Statistics

If you are solving a fully-developed periodic flow, you may want to monitor the pressure gradient or the bulk temperature ratio, as discussed in *Periodic Flows* (p. 514).

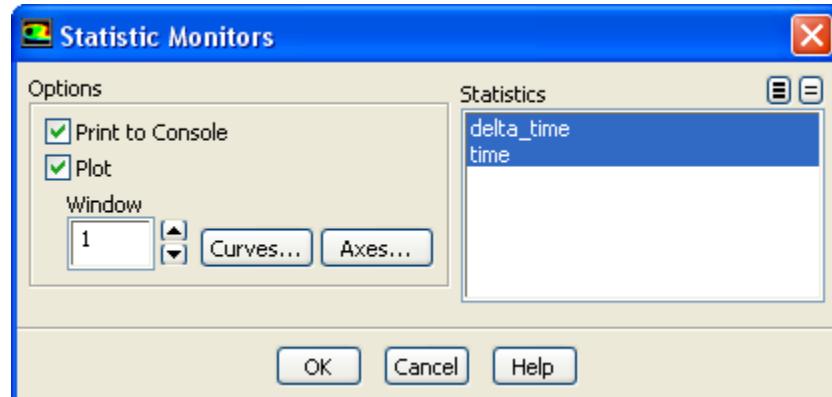

If you are solving an unsteady flow (especially if you are using the explicit time stepping option), you may want to monitor the “time” that has elapsed during the calculation. The physical time of the flow field starts at zero when you initialize the flow. (See *Performing Time-Dependent Calculations* (p. 1365) for details about modeling unsteady flows.)

If you are using the adaptive time stepping method described in *Adaptive Time Stepping* (p. 1374), you may want to monitor the size of the time step, Δt .

You can use the *Statistic Monitors Dialog Box* (p. 2068) (*Figure 29.34* (p. 1389)) to print or plot these quantities during the calculation.

Monitors → Statistic → Edit...

Figure 29.34 The Statistic Monitors Dialog Box

The procedure for setting up this monitor is listed below:

1. Indicate the type of report you want by enabling the **Print to Console** option for a printout and/or the **Plot** option for a plot.
2. Select the appropriate quantity in the **Statistics** list.
3. If you are plotting the quantities, you can set any of the plotting options discussed below.

29.15.2.1. Plot Parameters

If you choose to plot the statistics, there are several display parameters you can modify.

In the **Window** field, you can specify the ID of the graphics window in which the plot will be drawn (or in which the first plot will be drawn, if you are plotting more than one quantity.) When ANSYS FLUENT is iterating, the active graphics window is temporarily set to this window to update the plot, and then returned to its previous value. Thus, the statistics plot can be maintained in a separate window that

does not interfere with other graphical postprocessing. Note that additional quantities that you have selected in the **Statistics** list will be plotted in windows with incrementally higher IDs.

You can also modify the attributes of the plot axes and curves. Click the **Axes...** or **Curves...** button to open the *Axes Dialog Box* (p. 2179) or *Curves Dialog Box* (p. 2181). See *Axes Dialog Box* (p. 2179) and *Curves Dialog Box* (p. 2181) for details.

29.15.3. Monitoring Force and Moment Coefficients

You can set up your case file so that drag, lift, and moment coefficients are computed and stored at the end of every iteration (for steady-state solutions) or time step (for transient solutions), and thus create a convergence history. You can print and plot this convergence data, and also save it to an external file. The external file is written in the ANSYS FLUENT XY plot file format described in *XY Plot File Format* (p. 1599). Monitoring force coefficients can be useful when you are calculating external aerodynamics, for example, and are especially interested in the lift coefficient. By monitoring these values you may also be able to stop the calculation early and reduce the processing time, as sometimes the force and moment coefficients converge before the residuals have decreased three orders of magnitude. (In such an instance, you should be sure to check the mass flow rate and heat transfer rate as well, to ensure that the mass and energy are being suitably conserved. This is accomplished using the *Flux Reports Dialog Box* (p. 2184), as described in *Fluxes Through Boundaries* (p. 1635).)

Important

The force and moment coefficients are calculated using the reference values entered in the **Reference Values** task page. For information about how these coefficients are calculated, see *Computing Forces, Moments, and the Center of Pressure* in the Theory Guide.

29.15.3.1. Setting Up Force and Moment Coefficient Monitors

To begin setting up force or moment monitors, first enter appropriate values in the **Reference Values** task page, as described in *Reference Values* (p. 1648). The relevant values include the following:

- The force coefficients use the reference area, density, and velocity.
- The moment coefficients use the reference area, density, velocity and length.

Next, open the appropriate dialog box using the **Monitors** task page. Select either **Drag...**, **Lift...**, or **Moment...** from the **Create** drop-down button under the **Residuals, Statistic and Force Monitors** selection list to open the *Drag Monitor Dialog Box* (p. 2069), *Lift Monitor Dialog Box* (p. 2070), or *Moment Monitor Dialog Box* (p. 2072), respectively (*Figure 29.35* (p. 1391)—*Figure 29.37* (p. 1393)). Note that you can only access one of these monitor dialog boxes at a time, though multiple monitors of each of the three types can be used during the same simulation.

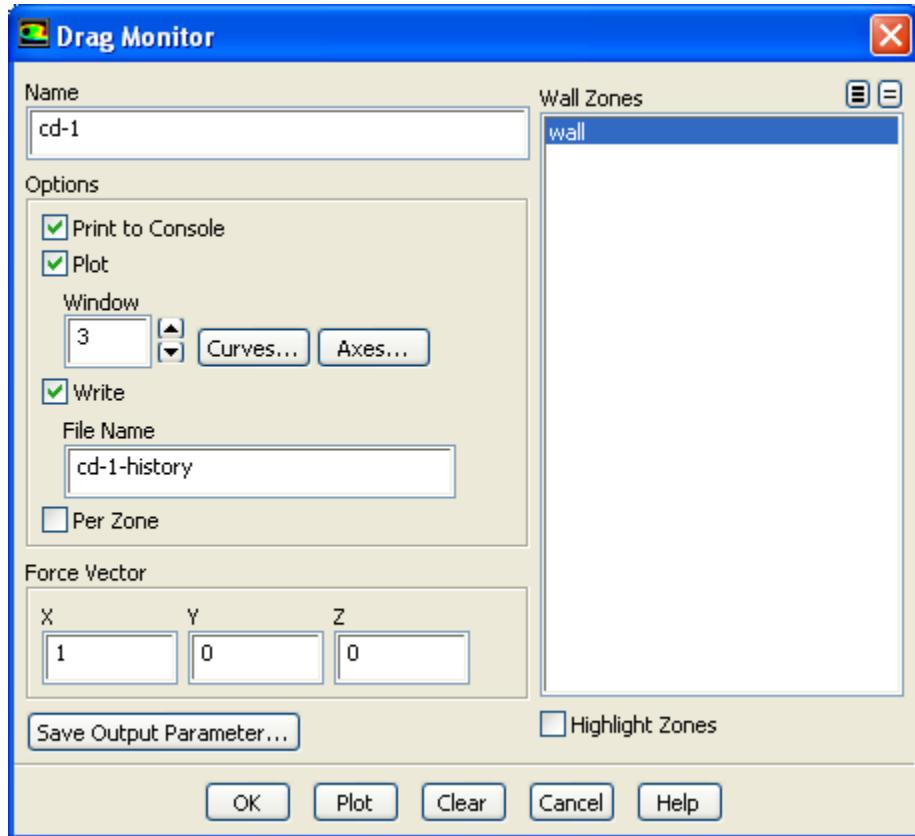

Figure 29.35 The Drag Monitor Dialog Box

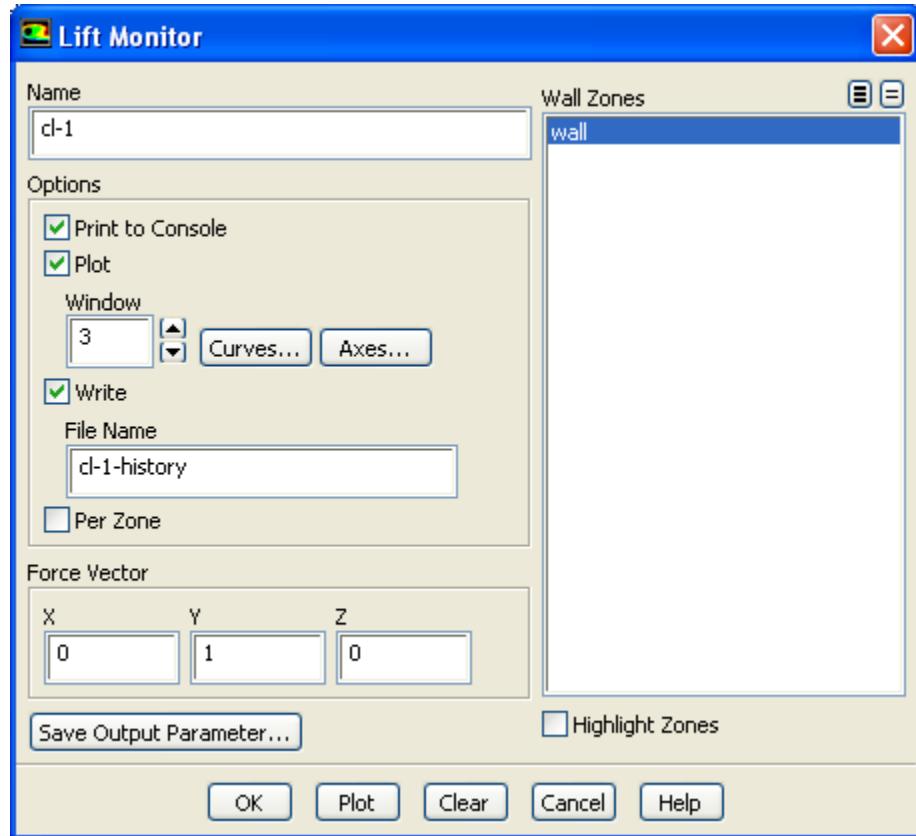

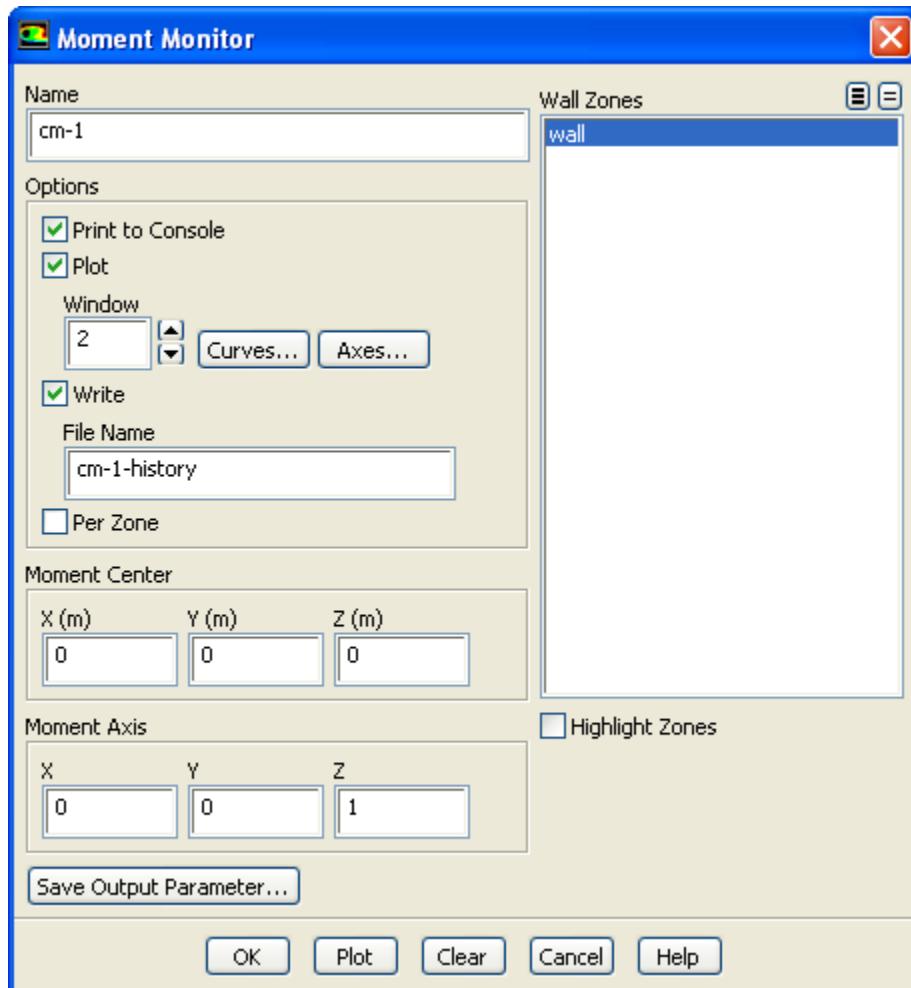

Figure 29.36 The Lift Monitor Dialog Box

Figure 29.37 The Moment Monitor Dialog Box

Complete the setup of the force and moment coefficient monitors by performing the following steps in the **Drag Monitor**, **Lift Monitor**, or **Moment Monitor** dialog box:

1. Enter the **Name** of the monitor, which will be displayed in the **Residuals, Statistic and Force Monitors** selection list of the **Monitors** task page.

Important

Note that the settings for the monitor will not be saved if you enter the same name as an existing monitor.

2. Indicate the method of reporting you want for the data (numerical display, plot, or file), as described in a section that follows.
3. If you want to monitor the force or moment coefficient data from individual wall zones rather than the net results from a group of wall zones, enable the **Per Zone** option. Further details are provided in a section that follows.
4. Depending on the coefficient that will be monitored, perform one of the following steps:

- In the **Drag Monitor** or **Lift Monitor** dialog box, enter the **X**, **Y**, and **Z** components of the **Force Vector** along which the forces will be computed. By default, the **Force Vector** for the drag coefficient is a unit vector in the *x* direction, whereas for the lift coefficient it is a unit vector in the *y* direction.
 - In the **Moment Monitor** dialog box, enter the Cartesian coordinates (**X**, **Y**, and **Z**) of the **Moment Center**, about which moments will be computed. The default **Moment Center** is **(0, 0, 0)**. You also need to enter the **X**, **Y**, and **Z** components for the **Moment Axis**, along which the moment coefficient will be calculated. By default, the **Moment Axis** is defined as a unit vector in the *z* direction.
5. Specify the wall zone(s) for which the coefficient(s) will be computed by making selections in the **Wall Zones** selection list.
 6. If you want to create an output parameter for either the drag, lift, or moment monitor for a selected wall zone, click the **Save Output Parameter...** button to open the *Save Output Parameter Dialog Box (p. 2201)*. In this dialog box, the **Per Zone** option (under **Options**) will not be considered for defining output parameters and ANSYS FLUENT will define a single output parameter.
 7. You have the option to highlight a selected boundary zone and have it displayed in the graphics window by enabling **Highlight Zone**.
 8. Click **OK** to save the monitor settings.
 9. If you need to revise the settings of a particular monitor after they have been saved, select the name of the monitor from the **Residuals, Statistic and Force Monitors** selection list of the **Monitors** task page, and click the **Edit...** button to reopen the force or moment coefficient monitor dialog box.

After you have set up all of the force and moment coefficient monitors, you can then run the calculation and view the data in the console, graphics window, or file.

Important

Only the processed force and moment coefficient data is saved. If you decide to change any of the parameters controlling the monitoring (e.g., the reference values, force vector, moment center, moment axis, wall zones) and run further calculations, you may see a discontinuity in the data, because the previous data is not updated to match the new settings. Usually, you will want to delete the previous force and moment coefficient data before continuing to iterate with revised monitor parameters.

29.15.3.1.1. Specifying the Reporting Methods

There are three methods available for reporting the force and moment coefficients. To display the coefficient value(s) in the console after every iteration or time step, enable the **Print to Console** option in the **Options** group box of the monitor dialog box. To plot the coefficient in the graphics window indicated in the **Window** text box, enable the **Plot** option. If you want to save the data to a file, enable the **Write** option and specify the **File Name**. You can enable any combination of these options simultaneously.

Important

If you choose *not* to save the force or moment coefficient data in a file, this information will be lost when you exit the current ANSYS FLUENT session.

You can display a plot of the coefficient monitor data generated during the last calculation even if the **Plot** option was not enabled during the calculation, as long as either **Print to Console** or **Write** was

enabled. Simply click the **Plot** button and the plot will be displayed in the active graphics window (if the **Plot** option is not enabled) or in the specified **Window** (if the **Plot** option is enabled).

29.15.3.1.1. Plot Parameters

If you choose to plot the force or moment coefficients (either by enabling the **Plot** option prior to running the solution or by clicking the **Plot** button after the calculation is complete), there are several display parameters you can modify:

- Under **Window**, you can specify the ID of the graphics window in which the plot for the force or moment coefficient will be displayed.
- You can modify the attributes of the coefficient curves and plot axes for each monitor. Click the **Curves...** or the **Axes...** button to open the *Curves Dialog Box* (p. 2181) or the *Axes Dialog Box* (p. 2179). See *Curves Dialog Box* (p. 2181) and *Axes Dialog Box* (p. 2179) for details.

29.15.3.1.2. Monitoring Individual Walls

By default, ANSYS FLUENT will compute and monitor the sum of the force or moment coefficients for all of the selected walls. If you have selected multiple walls and you want to monitor the force or moment coefficient on each wall separately, you can enable the **Per Zone** option in the **Options** group box in the monitor dialog box. The specified force vector or moment center and axis will apply to all of the selected walls.

If the monitor results are displayed in the console (using the **Print to Console** option), the force or moment coefficient for each wall zone will be printed in a separate column. If the results are plotted (using the **Plot** option or button), a separate curve for each wall zone will be drawn in the specified graphics window. If the results are written to a file (using the **Write** option), the file will be in a tab-separated column format based on the XY plot file format described in *XY Plot File Format* (p. 1599).

29.15.3.1.3. Discarding the Monitor Data

Should you decide that the data gathered by a force or moment monitor is not useful (e.g., if you are restarting the calculation with revised reference values), you can discard the data accumulated during the last calculation by clicking the **Clear** button. All of the data gathered as a result of the settings in that monitor dialog box will be deleted, including the associated file (with the name indicated in the **File Name** text box). When you use the **Clear** button, you will need to confirm the data discard in a *Question Dialog Box* (p. 33). Only the coefficient monitor data is discarded as a result of this operation; the solution data is not affected.

29.15.4. Monitoring Surface Integrals

At the end of each solver iteration or time step, the average, mass average, integral, flow rate, or other integral report of a field variable or function can be monitored on a surface. You can print and plot these convergence data, and also save them in an external file. The external file is written in the ANSYS FLUENT XY plot file format described in *XY Plot File Format* (p. 1599). The report types available are the same as those in the *Surface Integrals Dialog Box* (p. 2188), as described in *Surface Integration* (p. 1644).

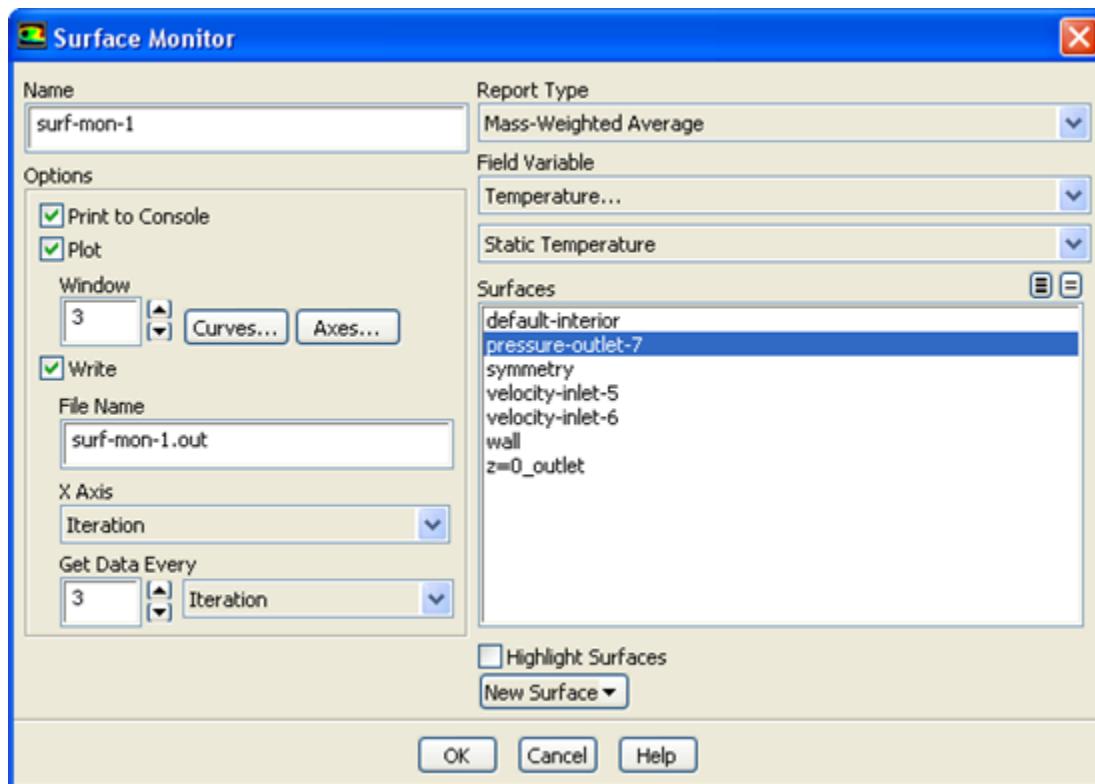

Monitoring surface integrals can be used to check for both iteration convergence and mesh independence. For example, you can monitor the average value of a certain variable on a surface. When this value stops changing, you can stop iterating. You can then adapt the mesh and reconverge the solution. The solution can be considered mesh-independent when the average value on the surface stops changing between adaptions.

29.15.4.1. Overview of Defining Surface Monitors

You can use the *Surface Monitor Dialog Box* (p. 2074) (Figure 29.38 (p. 1396)) to create surface monitors and indicate whether and when each one's history is to be printed, plotted, or saved. It also allows you to define what each monitor tracks (i.e., the average, integral, flow rate, mass average, uniformity index, or other integral report of a field variable or function on one or more surfaces).

Monitors (Surface Monitors) → Create...

Figure 29.38 The Surface Monitor Dialog Box

The procedure for defining surface monitors is as follows:

1. Enter a name for the monitor under the **Name** heading, and use the **Print to Console**, **Plot**, and **Write** check buttons to indicate the report(s) you want (plot, printout, or save to a file), as described below.
2. If you are plotting the data or writing them to a file, specify the parameter to be used as the *x*-axis value (the *y*-axis value corresponds to the monitored data). In the **X Axis** drop-down list, select **Iteration**, **Time Step**, or **Flow Time** as the *x*-axis function against which monitored data will be plotted or written. **Time Step** and **Flow Time** are valid choices only if you are calculating unsteady flow. If you choose **Time Step**, the *x* axis of the plot will indicate the time step, and if you choose **Flow Time**, it will indicate the elapsed time.
3. If you are plotting the monitored data, specify the ID of the graphics window in which the plot will be drawn in the **Window** field. When ANSYS FLUENT is iterating, the active graphics window is temporarily set to this window to update the plot, and then returned to its previous value. Thus, each surface-monitor plot can be maintained in a separate window that does not interfere with other graphical postprocessing.

In order to have multiple monitors display in a single graphics window, you can set the **Window** ID to correspond to the same ID for different monitors. This is useful when you have multiple monitor displays on the screen, you can set all monitors to the same display. For example, for three different monitors, you can set the **Window** ID to 1 for each of the different monitors in order to display all three monitors in a single window. The name of the monitors (`surf-mon-1.out`, etc.) will be different, but only the **Window** ID will remain the same. So that each monitor has data that is stored in a different file, but the data is displayed in the same window.

Important

Note that surface and volume monitors cannot be displayed in the same window.

Important

If multiple monitors are plotted in the same window, make sure you set an axes range that can be applied to all the monitors. This axes range will be the same for all the monitors in the shared plot window. Otherwise, the most recently defined monitor, sharing the same window as the other monitors, will determine the axes range. If the default option of **Auto Range** (in the **Axes** dialog box) is enabled for all the monitors sharing the same plot window, then the default value for **Minimum** will be the minimum value of all the monitors, and the default **Maximum** will be the maximum value of all the monitors.

Modifying plot attributes can be achieved by clicking the **Curves** and the **Axes** button. See [Modifying Axis Attributes \(p. 1601\)](#) [Modifying Curve Attributes \(p. 1603\)](#)

4. If you are writing the monitored data to a file, specify the **File Name**.
5. Indicate the frequency at which you want to plot, print, or write the surface monitor by entering a number under **Get Data Every**. A default value of 1 will allow you to monitor at every **Iteration** or **Time Step**. **Time Step** is a valid choice only if you are calculating unsteady flow. If you specify every **Iteration**, and the **Reporting Interval** in the [Run Calculation Task Page \(p. 2107\)](#) is greater than 1, the monitor will be updated at every reporting interval instead of at each iteration (e.g., for a reporting interval of 2, the monitor will be updated after every other iteration). If the reporting interval is 2 and monitor frequency is at **Get Data Every 3 Iterations**, then the monitoring will be done at multiples of six, which is the least common multiple of the two numbers). If you specify every **Time Step**, the reporting interval will have no effect; the monitor will always be updated after the specified number of time steps.
6. Choose the integration method for the surface monitor by selecting **Integral**, **Standard Deviation**, **Flow Rate**, **Mass Flow Rate**, **Volume Flow Rate**, **Area-Weighted Average**, **Mass-Weighted Average**, **Sum**, **Uniformity Index - Mass Weighted**, **Uniformity Index - Area Weighted**, **Facet Average**, **Facet Minimum**, **Facet Maximum**, **Vertex Average**, **Vertex Minimum**, or **Vertex Maximum** from the **Report Type** drop-down list. These methods are described in [Surface Integration \(p. 1644\)](#).
7. Unless you are reporting a mass flow rate or volume flow rate, specify the variable or function to be integrated in the **Field Variable** drop-down list. First select the desired category in the upper drop-down list. You can then select one of the related quantities in the lower list. (See [Field Function Definitions \(p. 1653\)](#) for an explanation of the variables in the list.)
8. In the **Surfaces** list, choose the surface or surfaces on which you wish to integrate.
9. Click **OK** in the **Surface Monitor** dialog box after you finish defining all surface monitors.

Note

If you want to set a monitor for an iso-surface, and the iso-surface is dependent on solver data (e.g., velocity, pressure, custom field function) make sure to set the monitor after initializing or reading the data file.

29.15.4.2. Printing, Plotting, and Saving Surface Integration Histories

There are three methods available for reporting the selected surface integration. To print the surface integration in the console after each iteration, enable the **Print to Console** option in the **Surface Monitor** dialog box. To plot the integrated values in the graphics window, enable the **Plot** option. If you want to save the values to a file, enable the **Write** option and specify the **File Name**. You can enable any combination of these options simultaneously.

Important

If you choose *not* to save the surface integration data to a file, this information will be lost when you exit the current ANSYS FLUENT session.

29.15.4.2.1. Plot Parameters

You can modify the attributes of the plot axes and curves used for each surface-monitor plot. Click the **Axes...** or **Curves...** button in the *Surface Monitor Dialog Box* (p. 2074) to open the *Axes Dialog Box* (p. 2179) or *Curves Dialog Box* (p. 2181) for that surface-monitor plot. See *Axes Dialog Box* (p. 2179) and *Curves Dialog Box* (p. 2181) for details.

29.15.5. Monitoring Volume Integrals

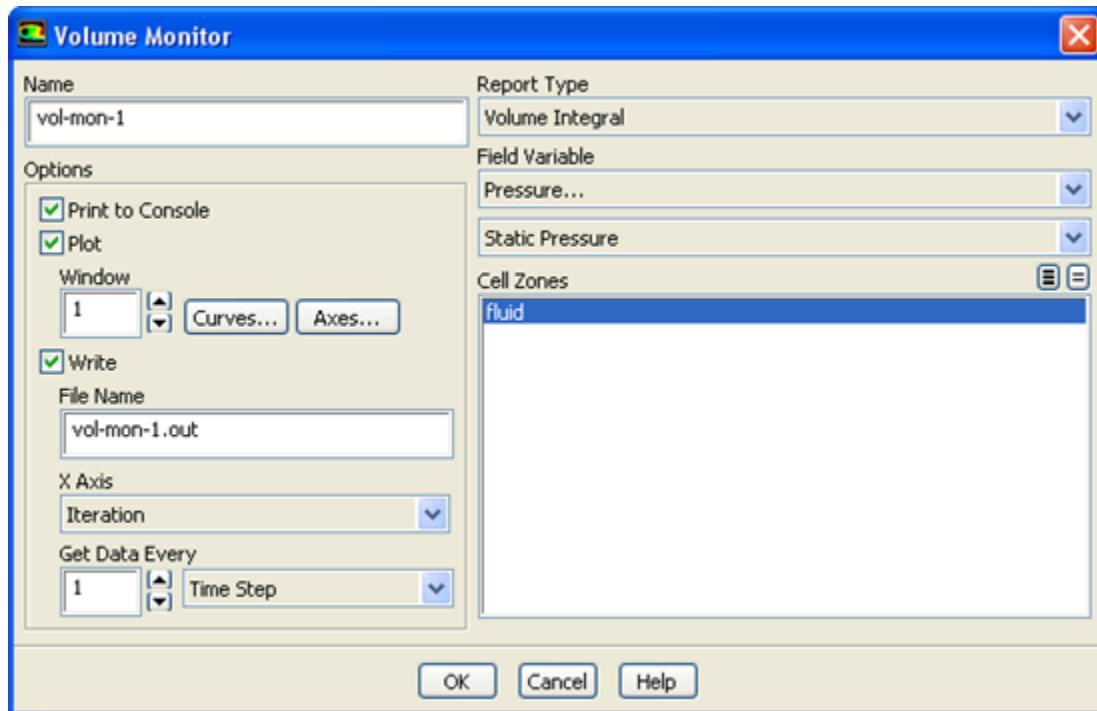

At the end of each solver iteration or time step, the volume or the sum, volume integral, volume average, mass integral, or mass average of a field variable or function can be monitored in one or more cell zones. You can print and plot these convergence data, and also save them in an external file. The external file is written in the ANSYS FLUENT XY plot file format described in *XY Plot File Format* (p. 1599). The report types available are the same as those in the *Volume Integrals Dialog Box* (p. 2192), as described in *Volume Integration* (p. 1646).

Monitoring volume integrals can be used to check for both iteration convergence and mesh independence. For example, you can monitor the average value of a certain variable in a particular cell zone. When this value stops changing, you can stop iterating. You can then adapt the mesh and reconverge the solution. The solution can be considered mesh-independent when the average value in the cell zone stops changing between adaptions.

29.15.5.1. Overview of Defining Volume Monitors

You can use the *Volume Integrals Dialog Box* (p. 2192) (*Figure 29.39* (p. 1399)) to create volume monitors and indicate whether and when each one's history is to be printed, plotted, or saved. You can also define what each monitor tracks (i.e., the volume or the sum, integral, or average of a field variable or function in one or more cell zones).

◀ **Monitors (Volume Monitors)** → **Create...**

Figure 29.39 The Volume Monitor Dialog Box

The procedure for defining volume monitors is as follows:

1. Enter a name for the monitor under the **Name** heading, and use the **Plot**, **Print to Console**, and **Write** check buttons to indicate the report(s) you want (plot, print out, or file), as described below.
2. If you are plotting the data or writing them to a file, specify the parameter to be used as the *x*-axis value (the *y*-axis value corresponds to the monitored data). In the **X Axis** drop-down list, select **Iteration**, **Time Step**, or **Flow Time** as the *x*-axis function against which monitored data will be plotted or written. **Time Step** and **Flow Time** are valid choices only if you are calculating unsteady flow. If you choose **Time Step**, the *x* axis of the plot will indicate the time step, and if you choose **Flow Time**, it will indicate the elapsed time.
3. If you are plotting the monitored data, specify the ID of the graphics window in which the plot will be drawn in the **Window** field. When ANSYS FLUENT is iterating, the active graphics window is temporarily set to this window to update the plot, and then returned to its previous value. Thus, each volume-monitor plot can be maintained in a separate window that does not interfere with other graphical postprocessing.
4. If you are writing the monitored data to a file, specify the **File Name**.
5. Indicate the frequency at which you want to plot, print, or write the volume monitor by entering a number under **Get Data Every**. A default value of 1 will allow you to monitor at every **Iteration** or **Time Step**.
6. Indicate whether you want to update the monitor every **Iteration** or every **Time Step** by selecting the appropriate item in the drop-down list. **Time Step** is a valid choice only if you are calculating unsteady flow. If you specify every **Iteration**, and the **Reporting Interval** in the *Run Calculation Task Page* (p. 2107) is greater than 1, the monitor will be updated at every reporting interval instead of at each iteration (e.g., for a reporting interval of 2, the monitor will be updated after every other iteration. If the reporting interval is 2 and monitor frequency is at **Get Data Every 3 Iterations**, then the monitoring will be done at multiples of six, which is the least common multiple of the two numbers). If you specify

every **Time Step**, the reporting interval will have no effect; the monitor will always be updated after the specified number of time steps.

7. Choose the integration method for the volume monitor by selecting **Volume**, **Sum**, **Max**, **Min**, **Volume Integral**, **Volume-Average**, **Mass Integral**, or **Mass-Average** in the **Report Type** drop-down list. These methods are described in [Volume Integration \(p. 1646\)](#).
8. Specify the variable or function to be integrated in the **Field Variable** drop-down list. First select the desired category in the upper drop-down list. You can then select one of the related quantities in the lower list. (See [Field Function Definitions \(p. 1653\)](#) for an explanation of the variables in the list.)
9. In the **Cell Zones** list, choose the cell zone(s) on which you wish to integrate.
10. Remember to click **OK** in the **Volume Monitor** dialog box after you finish defining all volume monitors.

29.15.5.2. Printing, Plotting, and Saving Volume Integration Histories

There are three methods available for reporting the selected volume integration. To print the volume integration in the console after each iteration, Enable the **Print to Console** option in the **Volume Monitor** dialog box. To plot the integrated values in the graphics window indicated in **Window**, enable the **Plot** option. If you want to save the values to a file, enable the **Write** option and specify the **File Name**. You can enable any combination of these options simultaneously.

Important

If you choose *not* to save the volume integration data to a file, this information will be lost when you exit the current ANSYS FLUENT session.

29.15.5.2.1. Plot Parameters

You can modify the attributes of the plot axes and curves used for each volume-monitor plot. Click the **Axes...** or **Curves...** button in the [Volume Integrals Dialog Box \(p. 2192\)](#) for the appropriate monitor to open the [Axes Dialog Box \(p. 2179\)](#) or [Curves Dialog Box \(p. 2181\)](#) for that volume-monitor plot. See [Axes Dialog Box \(p. 2179\)](#) and [Curves Dialog Box \(p. 2181\)](#) for details.

29.16. Executing Commands During the Calculation

As described in [Monitoring Solution Convergence \(p. 1379\)](#) and [Animating the Solution \(p. 1409\)](#), respectively, you can report and monitor various quantities (e.g., residuals, force coefficients) and create animations of the solution while the solver is performing calculations. ANSYS FLUENT also includes a feature that allows you to define your own command(s) to be executed during the calculation at specified intervals. For example, you can ask ANSYS FLUENT to perform gradient adaption after a set number of iterations. You will specify a series of text commands or use the GUI to define the steps to be performed.

Important

Note that the **Calculation Activities** task page provides options to perform the following during the calculation:

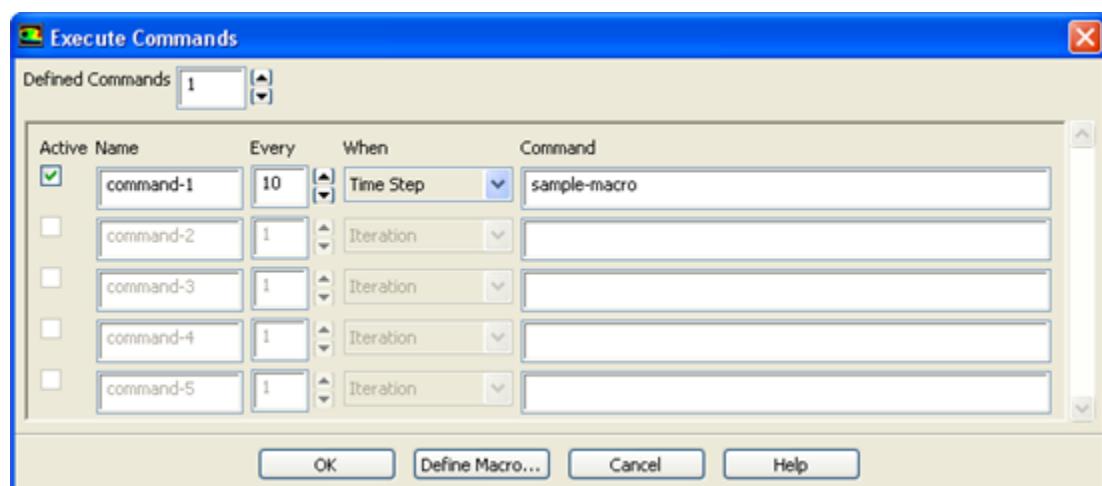

- save case and data files
- export transient solution files
- export transient particle history data files

Each of these options has their own dialog box, which should be used rather than executing a command to perform them. See *Automatic Saving of Case and Data Files* (p. 68) and *Exporting Data During a Transient Calculation* (p. 102) for details.

You will indicate the command(s) that you want the solver to execute at specified intervals during the calculation using the *Execute Commands Dialog Box* (p. 2103) (*Figure 29.40* (p. 1401)).

◆ Calculation Activities (Execute Commands) → Create/Edit...

Figure 29.40 The Execute Commands Dialog Box

The procedure is as follows:

1. Increase the **Defined Commands** value to the number of commands you wish to specify. As this value is increased, additional command entries will become editable. For each command, you will perform the following steps.
2. Enable the **Active** check button next to the command if you want it to be executed during the calculation. You may define multiple commands and choose to use only a subset of them by turning off the check button for those that you do not wish to use.
3. Enter a name for the command under the **Name** heading.
4. Indicate how often you want the command to be executed by setting the interval under **Every** and selecting **Iteration** or **Time Step** in the drop-down list below **When**. (**Time Step** is a valid choice only if you are calculating unsteady flow.) For example, to execute the command every 10 iterations, you would enter 10 under **Every** and select **Iteration** under **When**.

Important

If you specify an interval in iterations, be sure to keep the **Reporting Interval** in the [Run Calculation Task Page \(p. 2107\)](#) at its default value of 1.

5. Define the command by entering a series of text commands in the **Command** field, or by entering the name of a command macro you have defined (or will define) as described in [Defining Macros \(p. 1402\)](#).

Note

Make sure that the text commands you have entered in the **Command** field of the **Execute Commands** dialog box does not exceed 127 characters.

Important

If the command to be executed involves saving a file, see [Saving Files During the Calculation \(p. 1404\)](#) for important information.

For additional information, please see the following sections:

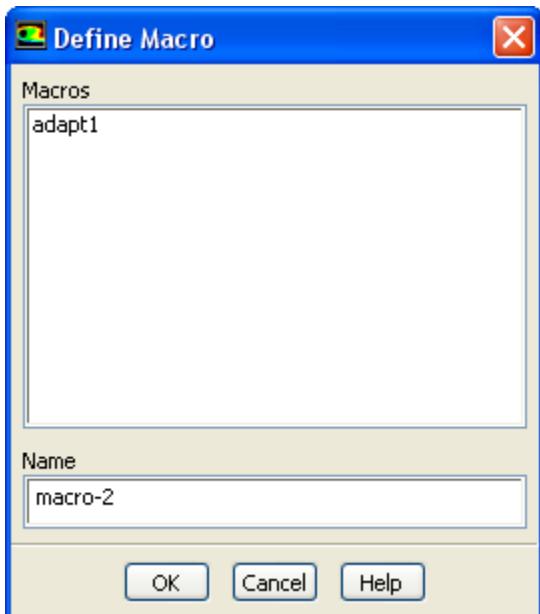

- 29.16.1. Defining Macros
- 29.16.2. Saving Files During the Calculation

29.16.1. Defining Macros

Macros that you define for automatic execution during the calculation can also be used interactively by you during the problem setup or postprocessing. For example, if you define a macro that performs a certain type of adaption after each iteration, you can also use the macro to perform this adaption interactively.

Definition of a macro is accomplished as follows:

1. In the [Execute Commands Dialog Box \(p. 2103\)](#), click the **Define Macro...** button to open the [Define Macro Dialog Box \(p. 2103\)](#) ([Figure 29.41 \(p. 1403\)](#)). Since this is a “modal” dialog box, the solver will not allow you to do anything else until you perform step 2, below.

Figure 29.41 The Define Macro Dialog Box

2. In the **Define Macro** dialog box, specify a **Name** for the macro (e.g., adapt1) and click **OK**. (The **Define Macro...** button in the **Execute Commands** dialog box will become the **End Macro** button.)
3. Perform the steps that you want the macro to perform. For example, if you want the macro to perform gradient adaption, open the **Gradient Adaption** dialog box, specify the appropriate adaption function and parameters, and click **Adapt** to perform the adaption.

Important

If the command to be executed involves saving a file, see *Saving Files During the Calculation* (p. 1404) for important information.

4. When you have completed the steps you wish the macro to perform, click the **End Macro** button in the **Execute Commands** dialog box.

As noted above, once you have defined a macro for execution during the calculation, you can use it at any time. If you defined the macro called adapt1 to adapt based on pressure gradient, you can simply type adapt1 in the console to perform this adaption. This macro is independent of any text menus, so you need not move to a different text menu to use it. Macros can be saved to and read from files. To save all macros that are currently defined, use the `file/write-macros` text command. To read all the macros in a macro file, use the `file/read-macros` text command.

Important

A macro, like a journal file, is a simple record/playback function. It will therefore know nothing about the state in which it was recorded or the state in which it is being played back. You must be careful not to change directories while defining a macro. Also, you must be careful that all surfaces, variables, etc. that are used by the macro have been properly defined when you (or ANSYS FLUENT) invoke the macro.

29.16.2. Saving Files During the Calculation

If the command to be executed during the calculation involves saving a file, you should include a special character in the file name when you enter it in [The Select File Dialog Box \(p. 33\)](#) so that the solver will know to assign a new name to each file it saves. See [Automatic Numbering of Files \(p. 63\)](#) for details about these special characters for filenames.

Important

Note that the **Calculation Activities** task page provides options to perform the following during the calculation:

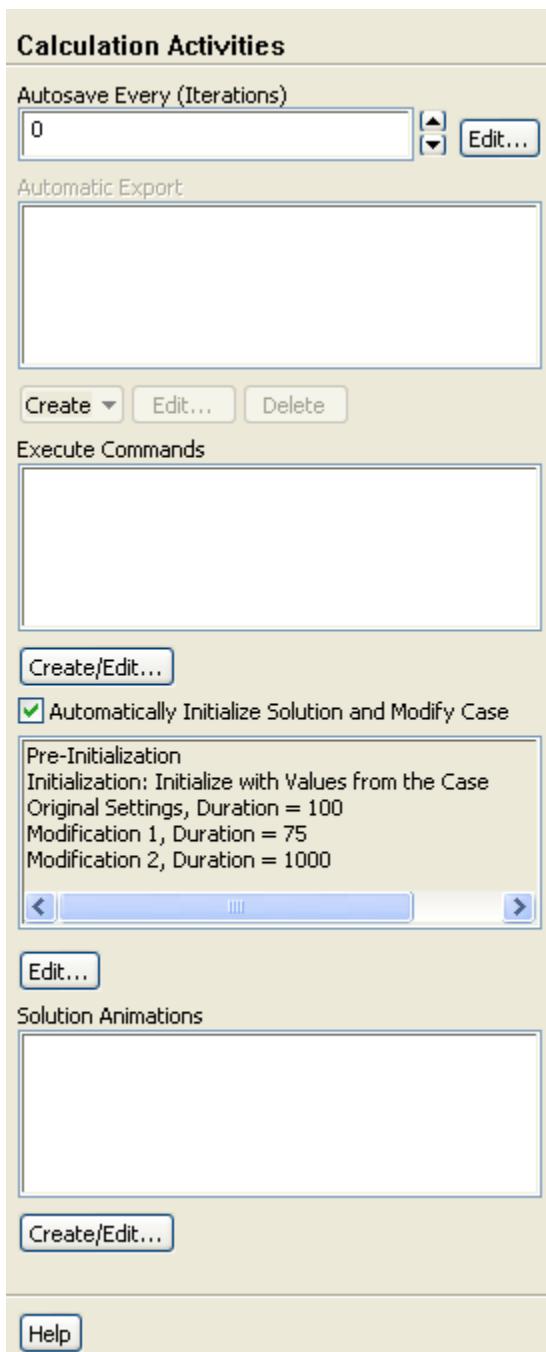

- save case and data files
- export transient solution files
- export transient particle history data files

Each of these options has their own dialog box, which should be used rather than the **Execute Commands** dialog box. See [Automatic Saving of Case and Data Files \(p. 68\)](#) and [Exporting Data During a Transient Calculation \(p. 102\)](#) for details.

29.17. Automatic Initialization of the Solution and Case Modification

While running a case manually, you can perform certain activities which may facilitate convergence. These actions may take place before initialization, after initialization and/or at other points during the calculation. The process described in this section allows you to enter text commands at each of these times when a case is run from the **Run Calculation** task page, Workbench, or in batch. In the **Calculation Activities** task page, enable **Automatically Initialize Solution and Modify Case** to automatically modify the case.

↳ **Calculation Activities** → **Automatically Initialize Solution and Modify Case** → **Edit...**

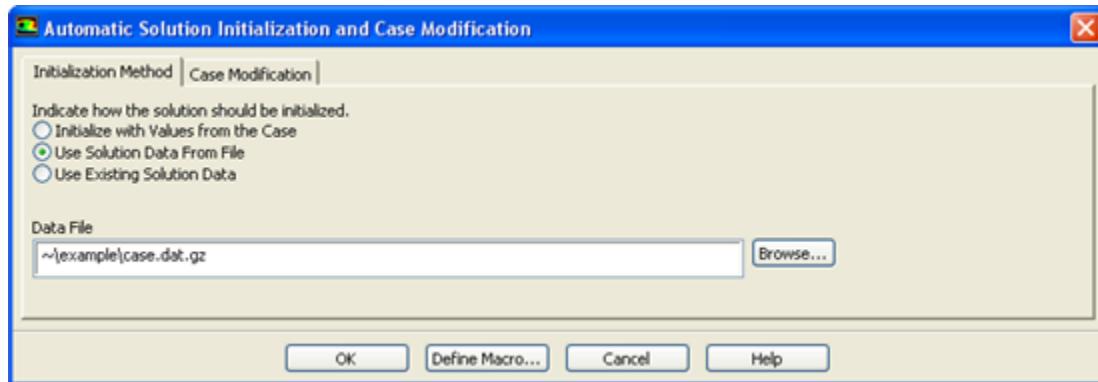

Figure 29.42 The Automatically Initialize Solution and Modify Case Option

When using this option, you can edit the calculation settings. Note that the original settings always exist and cannot be deleted. The duration of the calculation is defined, so immediately after enabling **Automatically Initialize Solution and Modify Case**, you will notice that the **Calculation Activities** task page reports that the case will be run with the original settings for a single iteration.

You can now control the number of iterations or time steps for the calculation. When **Automatically Initialize Solution and Modify Case** option is disabled, you will have to specify the iterations or time steps using the **Run Calculation** task page.

For an uninitialized case, clicking the **Edit...** button will display the **Automatic Solution Initialization and Case Modification** dialog box, which allows you to specify the initialization method and to modify the case.

Figure 29.43 The Automatic Solution Initialization and Case Modification Dialog Box

In the **Initialization Method** tab, you can specify four different initialization methods:

Initialize with Values from the Case

uses the values set in the **Solution Initialization** task page.

Use Solution Data from File

requires you to read in a data file containing the desired initialization for this case, as shown in *Figure 29.43 (p. 1406)*.

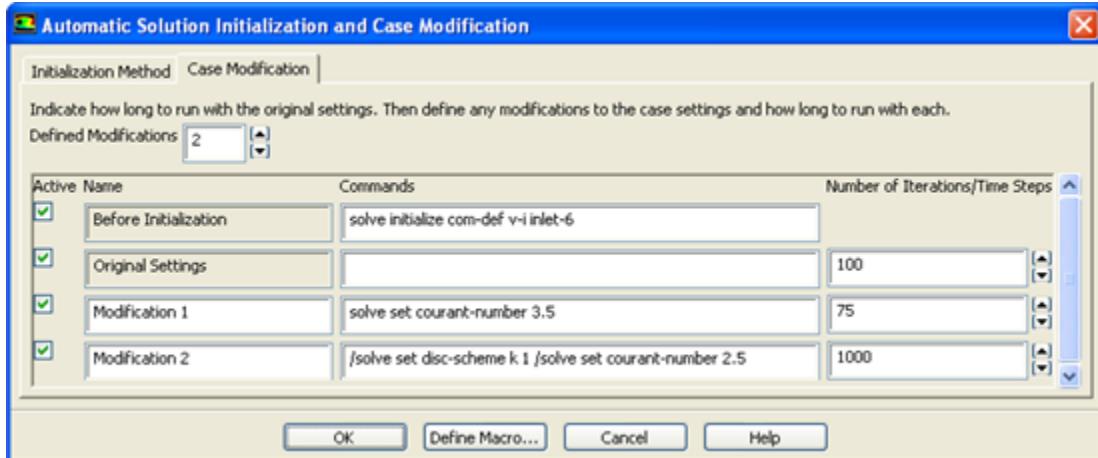

Use Existing Solution Data

is analogous to changing the values in a case and continuing the calculation. However, the iteration counter will be reset to 0 so that the modifications can be applied. Use this method when no solution data exists, similar to the first run.

Important

Whenever the case is initialized, the iteration count is set to 0.

In the **Case Modification** tab, you can indicate how long you would like to run with the original settings, then make any modifications to the case settings.

Figure 29.44 The Case Modification Tab

If you decide to make no modifications, then the counter in the **Defined Modifications** box will be set to 0. However, you still have the option to specify settings that you would like to apply before initialization, or you can change your original settings. If **Before Initialization** is enabled, then you can type the text commands in the **Commands** field. If **Original Settings** is enabled, you can type text commands in the **Commands** field, and/or specify the **Number of Iterations/Time Steps**. When entering more than one text command in a single **Commands** field, begin each text command with a /, as shown in *Figure 29.44 (p. 1407)*.

Note

Make sure that the text commands you have entered in the **Commands** field does not exceed 127 characters.

Important

Note that some text commands require arguments (e.g., numbers, file names, yes/no responses), which are requested through follow-up prompts in the console. When entering such text commands in the **Commands** field of the **Case Modification** tab, be sure to include your responses to the prompts. If you do not include these responses, the associated command will not be executed (unless it is a yes/no question, in which case ANSYS FLUENT will use yes by default).

If you decide to run the calculation further with modifications to your case, increase the number of **Defined Modifications** and specify additional commands. The settings shown in *Figure 29.44 (p. 1407)* result in the following actions:

1. The default initial values for initialization are computed from the velocity-inlet zone **inlet-6**.
2. The iteration count is set to 0 (in all situations) and the solution is initialized.
3. The calculation is run for 100 iterations or until convergence.
4. The Courant number is set to 3.5.
5. The calculation continues for 75 iterations or until convergence.
6. The discretization scheme for turbulent kinetic energy is set to second order upwind, and the Courant number is set to 2.5.

- The calculation continues for 1000 iterations or until convergence.

You can make the above changes sequentially and run your case, or you can specify them all at once. When you have completed making the modifications, click **OK**. A **Question** dialog box may appear, prompting you to take specific actions. For example, if the **Original Settings** field is empty, then you may be notified that the original settings will be lost if the case is saved after the modifications are applied. It will prompt you for a response when asked if you would like to add commands that specify the original settings.

Important

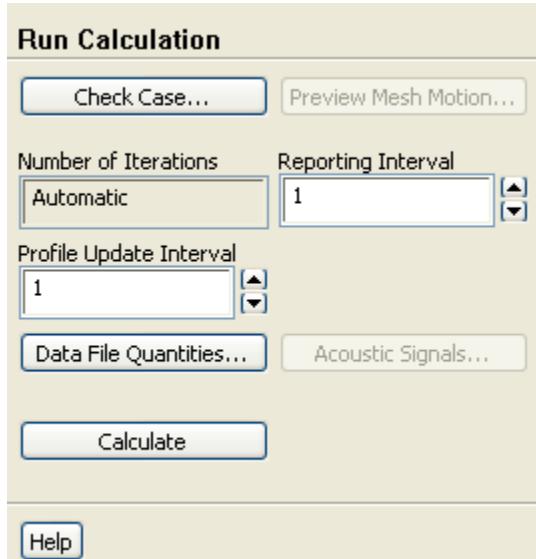

If you specify commands for the **Original Settings**, they will be applied to the case before the first iteration/time step.

Your actions will be summarized in the **Calculation Activities** task page, as shown in [Figure 29.42 \(p. 1405\)](#).

If you disable **Automatically Initialize Solution and Modify Case**, the settings will be disabled and retained, but will not be applied to the case.

When **Automatically Initialize the Solution and Modify the Case** is enabled, settings defined in the **Run Calculation** task page will be ignored. Instead, the **Number of Iterations** will be defined as **Automatic**, as shown in [Figure 29.45 \(p. 1408\)](#).

Figure 29.45 The Run Calculation Task Page

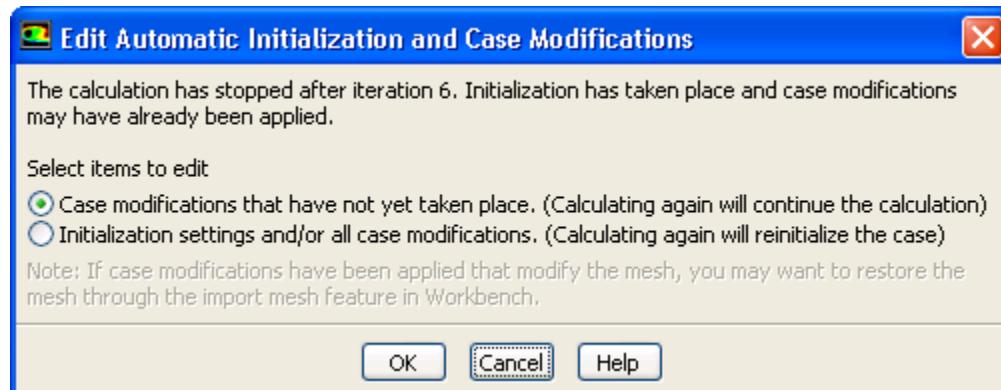

For additional information, please see the following sections:

[29.17.1. Altering the Solution Initialization and Case Modification after Calculating](#)

29.17.1. Altering the Solution Initialization and Case Modification after Calculating

If you decide to edit the solution initialization and case modification settings and one or more iterations have been calculated, then clicking the **Edit...** button for the **Automatically Initialize Solution and Modify Case** option will open the **Edit Automatic Initialization and Case Modifications** dialog box, as shown in [Figure 29.46 \(p. 1409\)](#).

Figure 29.46 The Edit Automatic Initialization and Case Modifications Dialog Box

If you select the first option, the initialization controls and modifications that have already taken place are disabled, therefore you can edit the case modifications that have yet to take place.

If you select the second option, all controls in the **Automatic Solution Initialization and Case Modification** dialog box are enabled and therefore, you can modify any of the settings.

29.18. Animating the Solution

During the calculation, you can have ANSYS FLUENT create an animation of contours, vectors, XY plots, monitor plots (residual, statistic, force, surface, or volume), or the mesh (useful primarily for moving mesh simulations). Before you begin the calculation, you will specify and display the variables and types of plots you want to animate, and how often you want plots to be saved. At the specified intervals, ANSYS FLUENT will display the requested plots, and store each one. When the calculation is complete, you can play back the animation sequence, modify the view (for mesh, contour, and vector plots), if desired, and save the animation to a series of picture files or an MPEG file.

Instructions for defining a solution animation sequence are provided in [Defining an Animation Sequence \(p. 1409\)](#). [Playing an Animation Sequence \(p. 1413\)](#) describes how to play back and save the animation sequences you have created, and how to read a previously-saved animation sequence into ANSYS FLUENT.

For additional information, please see the following sections:

- [29.18.1. Defining an Animation Sequence](#)
- [29.18.2. Playing an Animation Sequence](#)
- [29.18.3. Saving an Animation Sequence](#)
- [29.18.4. Reading an Animation Sequence](#)

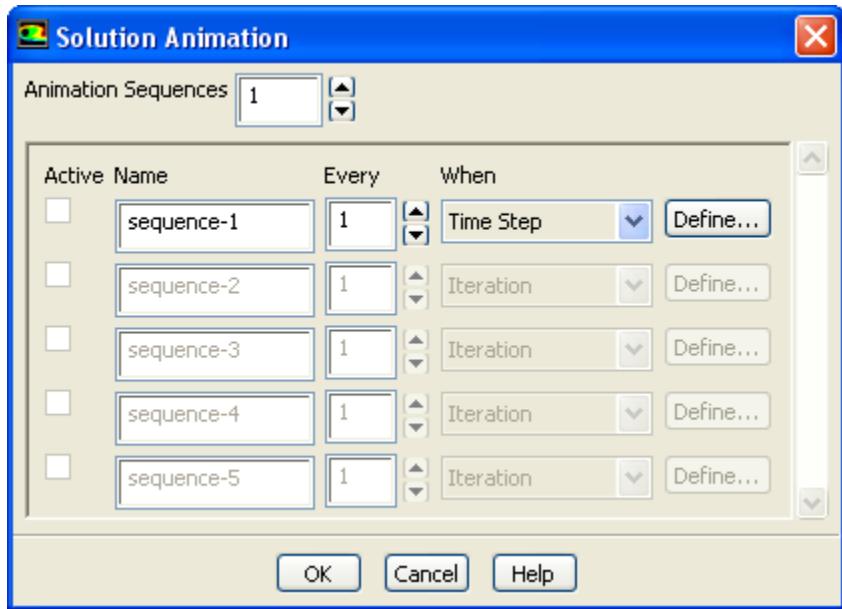

29.18.1. Defining an Animation Sequence

You can use the [Solution Animation Dialog Box \(p. 2105\)](#) ([Figure 29.47 \(p. 1410\)](#)) to create an animation sequence and indicate how often each frame of the sequence should be created. The [Animation Sequence Dialog Box \(p. 2106\)](#) ([Figure 29.48 \(p. 1411\)](#)), opened from the **Solution Animation** dialog box, allows you to define what each sequence displays (e.g., contours or vectors of a particular variable), where it is displayed, and how each frame is stored.

You will begin the animation sequence definition in the [Solution Animation Dialog Box \(p. 2105\)](#) ([Figure 29.47 \(p. 1410\)](#)).

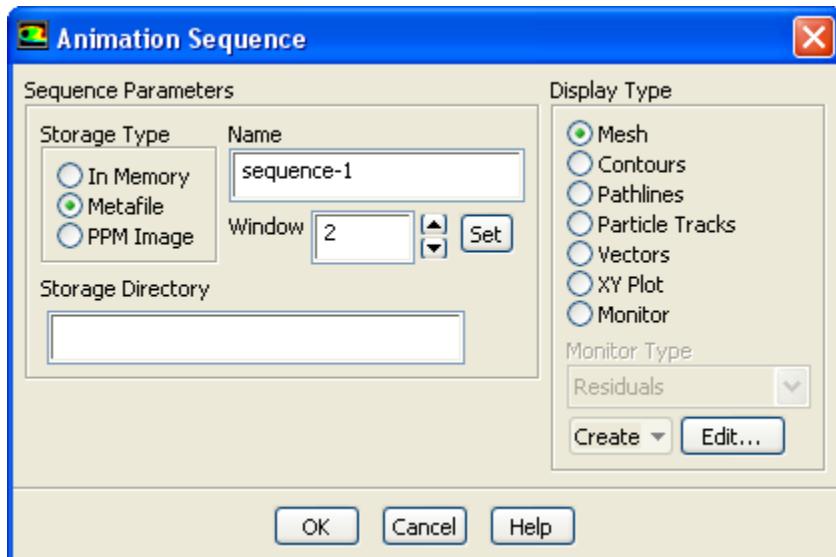

Calculation Activities (Solution Animations) → Create/Edit...

Figure 29.47 The Solution Animation Dialog Box

The procedure is as follows:

1. Increase the **Animation Sequences** value to the number of animation sequences you wish to specify. As this value is increased, additional sequence entries in the dialog box will become editable. For each sequence, you will perform the following steps.
2. Enter a name for the sequence under the **Name** heading. This name will be used to identify the sequence in the **Playback** dialog box, where you can play back the animation sequences that you have defined or read in. This name will also be used as the prefix for the file names if you save the sequence frames to disk.
3. Indicate how often you want to create a new frame in the sequence by setting the interval under **Every** and selecting **Iteration** or **Time Step** in the drop-down list below **When**. (**Time Step** is a valid choice only if you are calculating unsteady flow.) For example, to create a frame every 10 time steps, you would enter 10 under **Every** and select **Time Step** under **When**.
4. Click the **Define...** button to open the *Animation Sequence Dialog Box* (p. 2106) (Figure 29.48 (p. 1411)).

Figure 29.48 The Animation Sequence Dialog Box

5. Define the **Sequence Parameters** in the **Animation Sequence** dialog box.
 - a. Specify whether you want ANSYS FLUENT to save the animation sequence frames in memory or on your computer's hard drive. To save the animation sequence in memory, select **In Memory** under **Storage Type**. To save the animation sequence to your computer's hard drive as a graphics metafile, select **Metafile** under **Storage Type**. To save the animation sequence to your computer's hard drive as a pixmap image, select **PPM Image** under **Storage Type**.

Important

Note that the ANSYS FLUENT metafiles created for each frame in the animation sequence contain information about the entire scene, not just the view that is displayed in the plot. As a result, they can be quite large. By default, the files will be stored to disk. If you do not want to use up disk space to store them, you can instead choose to store them in memory. Storing them in memory will, however, reduce the amount of memory available to the solver. Note that the playback of a sequence stored in memory will be faster than one stored to disk.

Important

An advantage to saving the animation sequence using the **PPM Image** option is that you can use the separate pixmap image files for the creation of a single GIF file. GIF file creation can be done quickly with graphics tools provided by other third-party graphics packages such as ImageMagick, i.e., animate or convert. For example, if you save the PPM files starting with the string sequence-2, and you are using the ImageMagick software, you can use the convert command with the -adjoin option to create a single GIF file out of the sequence using the following command.

```
convert -adjoin sequence-2_00*.ppm sequence2.gif
```

- b. If you selected **Metafile** or **PPM Image** under **Storage Type**, specify the directory where you want to store the files in the **Storage Directory** field. (This can be a relative or absolute path.)

- c. Specify the ID of the graphics window where you want the plot to be displayed in the **Window** field, and click **Set**. (The specified window will open, if it is not already open.)

When ANSYS FLUENT is iterating, the active graphics window is set to this window to update the plot. If you want to maintain each animation in a separate window, specify a different **Window** ID for each.

6. Define the display properties for the sequence.

- a. Under **Display Type** in the **Animation Sequence** dialog box, choose the type of display you want to animate by selecting **Mesh**, **Contours**, **Pathlines**, **Particle Tracks**, **Vectors**, **XY Plot**, or **Monitor**. If you choose **Monitor**, you can select any of the available monitor plots in the **Monitor Type** drop-down list (e.g., **Residuals**, **Statistics**). Furthermore, you can create new monitors: open the **Surface Monitor**, **Volume Monitor**, **Drag Monitor**, **Lift Monitor**, and **Moment Monitor** dialog boxes by selecting the appropriate item from the list available through the **Create** drop-down button. The names of these new monitors will then be available for selection in the **Monitor Type** drop-down list.

The first time that you select **Contours**, **Vectors**, or **XY Plot**, or one of the monitor types if you select **Monitor**, ANSYS FLUENT will open the corresponding dialog box (e.g., the [Contours Dialog Box \(p. 2120\)](#) or the [Vectors Dialog Box \(p. 2123\)](#)) so you can modify the settings and generate the display. To make subsequent modifications to the display settings for any of the display types, click the **Edit...** button to open the dialog box for the selected **Display Type**.

- b. Define the display in the dialog box for the selected **Display Type** (e.g., the **Contours** or **Solution XY Plot** dialog box), and click **Display** or **Plot**.

Important

You must click **Display** or **Plot** to initialize the scene to be repeated during the calculation.

See below for guidelines on defining display properties for mesh, contour, and vector displays.

7. Remember to click **OK** in the **Solution Animation** dialog box after you finish defining all animation sequences.

Note that, when you click **OK** in the **Animation Sequence** dialog box for a sequence, the **Active** button for that sequence in the **Solution Animation** dialog box will be turned on automatically. You can choose to use a subset of the sequences you have defined by turning off the **Active** button for those that you currently do not wish to use.

29.18.1.1. Guidelines for Defining an Animation Sequence

If you are defining an animation sequence containing mesh, contour, or vector displays, note the following when you are defining the display:

- If you want to include lighting effects in the animation frames, be sure to define the lights before you begin the calculation. See [Adding Lights \(p. 1544\)](#) for information about adding lights to the display.
- If you want to maintain a constant range of colors in a contour or vector display, you can specify a range explicitly by turning off the **Auto Range** option in the **Contours** or **Vectors** dialog box. See [Specifying the Range of Magnitudes Displayed \(p. 1510\)](#) or [Specifying the Range of Magnitudes Displayed \(p. 1517\)](#) for details.

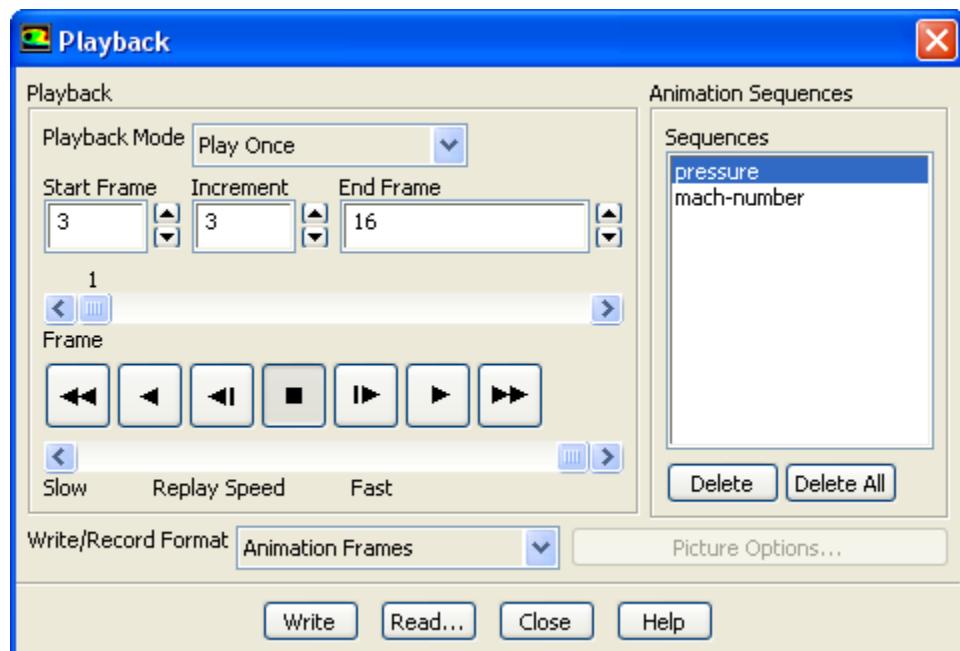

- Scene manipulations that are specified using the **Scene Description** dialog box will *not* be included in the animation sequence frames. View modifications such as mirroring across a symmetry plan *will* be included.

29.18.2. Playing an Animation Sequence

Once you have defined a sequence (as described in [Defining an Animation Sequence \(p. 1409\)](#)) and performed a calculation, or read in a previously created animation sequence (as described in [Reading an Animation Sequence \(p. 1416\)](#)), you can play back the sequence using the **Playback Dialog Box** (p. 2147) ([Figure 29.49 \(p. 1413\)](#)).

◆ **Graphics and Animation** → **Solution Animation Playback** → **Set Up...**

Figure 29.49 The Playback Dialog Box

Under **Animation Sequences** in the **Playback** dialog box, select the sequence you want to play in the **Sequences** list. To play the animation once through from start to finish, click the “play” button under the **Playback** heading. (The buttons function in a way similar to those on a standard video cassette player. “Play” is the second button from the right—a single triangle pointing to the right.) To play the animation backwards once, click the “play reverse” button (the second from the left—a single triangle point to the left). As the animation plays, the **Frame** scale shows the number of the frame that is currently displayed, as well as its relative position in the entire animation. If, instead of playing the complete animation sequence, you want to jump to a particular frame, move the **Frame** slider bar to the desired frame number, and the frame corresponding to the new frame number will be displayed in the graphics window.

Important

For smoother animations, enable the **Double Buffering** option in the [Display Options Dialog Box \(p. 2148\)](#) (see [Modifying the Rendering Options \(p. 1546\)](#)). This will reduce screen flicker during graphics updates.

Additional options for playing back animations are described below.

29.18.2.1. Modifying the View

If you want to replay the animation sequence with a different view of the scene, you can use your mouse to modify (e.g., translate, rotate, zoom) it in the graphics window where the animation is displayed. Note that any changes you make to the view for an animation sequence will be lost when you select a new sequence (or reselect the current sequence) in the **Sequences** list.

29.18.2.2. Modifying the Playback Speed

Different computers will play the animation sequence at different speeds, depending on the complexity of the scene and the type of hardware used for graphics. You may want to slow down the playback speed for optimal viewing. Move the **Replay Speed** slider bar to the left to reduce the playback speed (and to the right to increase it).

29.18.2.3. Playing Back an Excerpt

You may sometimes want to play only one portion of a long animation sequence. To do this, you can modify the **Start Frame** and the **End Frame** under the **Playback** heading. For example, if your animation contains 50 frames, but you want to play only frames 20 to 35, you can set **Start Frame** to 20 and **End Frame** to 35. When you play the animation, it will start at frame 20 and finish at frame 35.

29.18.2.4. “Fast-Forwarding” the Animation

You can “fast-forward” or “fast-reverse” the animation by skipping some of the frames during playback. To fast-forward the animation, you will need to set the **Increment** and click the fast-forward button (the last button on the right—two triangles pointing to the right). If, for example, your **Start Frame** is 1, your **End Frame** is 15, and your **Increment** is 2, when you click the fast-forward button, the animation will show frames 1, 3, 5, 7, 9, 11, 13 and 15. Clicking on the fast-reverse button (the first button on the left—two triangles pointing to the left) will show frames 15, 13, 11,...1.

29.18.2.5. Continuous Animation

If you want the playback of the animation to repeat continuously, there are two options available. To continuously play the animation from beginning to end (or from end to beginning, if you use one of the reverse play buttons), select **Auto Repeat** in the **Playback Mode** drop-down list. To play the animation back and forth continuously, reversing the playback direction each time, select **Auto Reverse** in the **Playback Mode** drop-down list.

To turn off the continuous playback, select **Play Once** in the **Playback Mode** list. This is the default setting.

29.18.2.6. Stopping the Animation

To stop the animation during playback, click the “stop” button (the square in the middle of the playback control buttons). If your animation contains very complicated scenes, there may be a slight delay before the animation stops.

29.18.2.7. Advancing the Animation Frame by Frame

To advance the animation manually frame by frame, use the third button from the right (a vertical bar with a triangle pointing to the right). Each time you click this button, the next frame will be displayed

in the graphics window. To reverse the animation frame by frame, use the third button from the left (a left-pointing triangle with a vertical bar). Frame-by-frame playback allows you to freeze the animation at points that are of particular interest.

29.18.2.8. Deleting an Animation Sequence

If you want to remove one of the sequences that you have created or read in, select it in the **Sequences** list and click the **Delete** button. If you want to delete all sequences, click the **Delete All** button.

Important

Note that if you delete a sequence that has not yet been saved to disk (i.e., if you selected **In Memory** under **Storage Type** in the **Animation Sequence** dialog box), it will be removed from memory permanently. If you want to keep any animation sequences that are stored only in memory, you should be sure to save them (as described in *Saving an Animation Sequence (p. 1415)*) before you delete them from the **Sequences** list or exit ANSYS FLUENT.

29.18.3. Saving an Animation Sequence

Once you have created an animation sequence, you can save it in any of the following formats:

- Solution animation file containing the ANSYS FLUENT metafiles
- Picture files, each containing a frame of the animation sequence
- MPEG file containing each frame of the animation sequence

Note that, if you are saving picture files or an MPEG file, you can modify the view (e.g., translate, rotate, zoom) in the graphics window where the animation is displayed, and save the modified view instead of the original view.

29.18.3.1. Solution Animation File

If you selected **Metafile** or **PPM Image** under **Storage Type** in the *Animation Sequence Dialog Box (p. 2106)*, then ANSYS FLUENT will save the solution animation file for you automatically. It will be saved in the specified **Storage Directory**, and its name will be the **Name** you specified for the sequence, with a **.cxa** extension (e.g., **pressure-contour.cxa**). In addition to the **.cxa** file, ANSYS FLUENT will also save a metafile with a **.hmf** extension for each frame (e.g., **pressure-contour_0002.hmf**). The **.cxa** file contains a list of the associated **.hmf** files, and tells ANSYS FLUENT the order in which to display them.

If you selected **In Memory** under **Storage Type**, then the solution animation file (**.cxa**) and the associated metafiles (**.hmf**) will be lost when you exit from ANSYS FLUENT, unless you save them as described below.

You can save the animation sequence to a file that can be read back into ANSYS FLUENT (see *Reading an Animation Sequence (p. 1416)*) when you want to replay the animation. As noted in *Reading an Animation Sequence (p. 1416)*, the solution animation file can be used for playback in ANSYS FLUENT independent of the case and data files that were used to generate it.

To save a solution animation file (and the associated metafiles), select **Animation Frames** in the **Write/Record Format** drop-down list in the **Playback** dialog box, and click the **Write** button. ANSYS FLUENT will save a **.cxa** file, as well as a **.hmf** file for each frame of the animation sequence. The file-name for the **.cxa** file will be the specified sequence **Name** (e.g., **pressure-contour.cxa**), and

the file names for the metafiles will consist of the specified sequence **Name** followed by a frame number (e.g., pressure-contour_0002.hmf). All of the files (.cxa and .hmf) will be saved in the current working directory.

29.18.3.2. Picture File

You can also generate a picture file for each frame in the animation sequence. This feature allows you to save your sequence frames to picture files used by an external animation program such as ImageMagick. As noted above, you can modify the view in the graphics window before you save the picture files.

To save the animation as a series of picture files, follow these steps:

1. Select **Picture Files** in the **Write/Record Format** drop-down list in the **Playback** dialog box.
2. If necessary, click the **Picture Options...** button to open the *Save Picture Dialog Box* (p. 2144) and set the appropriate parameters for saving the picture files. (If you are saving picture files for use with ImageMagick, for example, you may want to select the window dump format. See *Window Dumps (Linux Systems Only)* (p. 122) **Apply** in the **Save Picture** dialog box to save your modified settings.)

Important

Do not click the **Save...** button in the **Save Picture** dialog box. You will save the picture files from the **Playback** dialog box in the next step.

3. In the **Playback** dialog box, click the **Write** button. ANSYS FLUENT will replay the animation, saving each frame to a separate file. The filenames will consist of the specified sequence **Name** followed by an animation sequence and a frame number (e.g., pressure-contour_1_0002.ps), and they will all be saved in the current working directory.

29.18.3.3. MPEG File

It is also possible to save all of the frames of the animation sequence in an MPEG file, which can be viewed using an MPEG decoder such as **mpeg_play**. Saving the entire animation to an MPEG file will require less disk space than storing individual window dump files (using the picture method), but the MPEG file will yield lower-quality images.

As noted above, you can modify the view in the graphics window before you save the MPEG file.

To save the animation to an MPEG file, follow these steps:

1. Select **MPEG** in the **Write/Record Format** drop-down list in the **Playback** dialog box.
2. Click the **Write** button.

ANSYS FLUENT will replay the animation and save each frame to a separate scratch file, and then it will combine all the files into a single MPEG file. The name of the MPEG file will be the specified sequence **Name** with an .mpg extension (e.g., pressure-contour.mpg), and it will be saved in the current working directory.

29.18.4. Reading an Animation Sequence

If you have saved an animation sequence to a solution animation file (as described in *Saving an Animation Sequence* (p. 1415)), you can read that file back in at a later time (or in a different session) and play the

animation. Note that you can read a solution animation file into any ANSYS FLUENT session; you do not need to read in the corresponding case and data files. In fact, you do not need to read in any case and data files at all before you read a solution animation file into ANSYS FLUENT.

To read a solution animation file, click the **Read...** button in the *Playback Dialog Box* (p. 2147). In *The Select File Dialog Box* (p. 33), specify the name of the file to be read.

29.19. Checking Your Case Setup

After you have set up your case, and prior to solving it, you can check your case setup using the *Case Check Dialog Box* (p. 2112) (*Figure 29.50* (p. 1417)). This function provides you with guidance and best practices when choosing case parameters and models. Your case will be checked for compliance in the mesh, models, boundary and cell zone conditions, material properties, and solver categories. Established rules will be available for each category, with recommended changes to your current settings. At your discretion, you may elect to apply the recommendations, or keep your current settings.

To access the *Case Check Dialog Box* (p. 2112) (*Figure 29.50* (p. 1417)), go to

◆ **Run Calculation** → **Check Case...**

If there are no problems with your case setup, then an information dialog box (*Figure 29.51* (p. 1418)) will appear stating that no recommendations need to be made at this time, otherwise, the *Case Check Dialog Box* (p. 2112) will open.

Figure 29.50 The Case Check Dialog Box

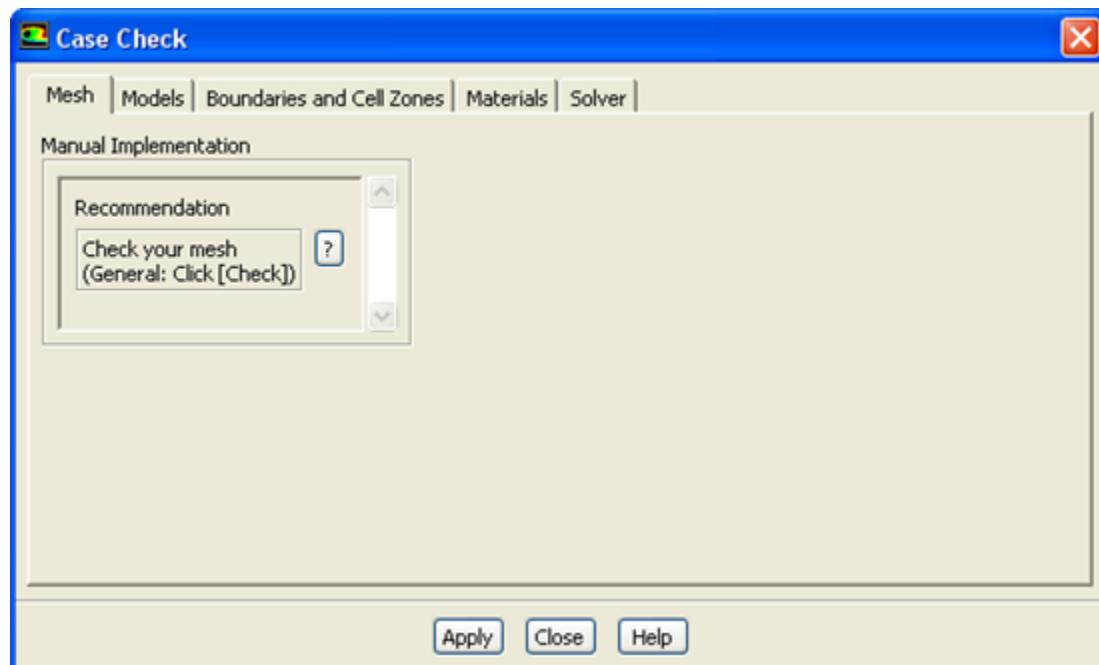

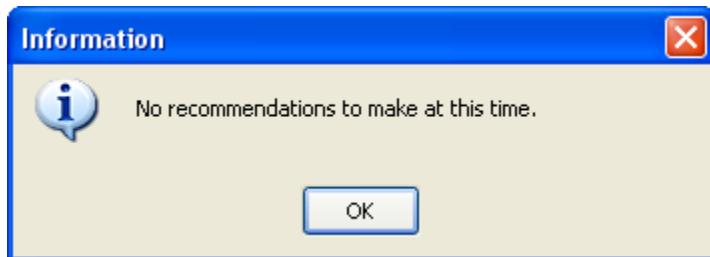

Figure 29.51 The Information Dialog Box

In the **Case Check** dialog box, each of the tabs **Mesh, Models, Boundaries and Cell Zones, Materials**, and **Solver** may contain recommendations. For each of the tabs that are enabled, best practices will be listed.

In some cases, the dialog box will be split based on the method that the recommendation is applied. There are two ways you can apply the listed recommendations:

Automatic Implementation

ANSYS FLUENT applies the change for you.

Manual Implementation

You will manually change your case settings.

For additional information, please see the following sections:

[29.19.1. Automatic Implementation](#)

[29.19.2. Manual Implementation](#)

29.19.1. Automatic Implementation

To the left of each of the recommendations listed under **Automatic Implementation** (e.g., *Figure 29.53 (p. 1421)*), there is an enabled **Apply** check box. An enabled check box will result in ANSYS FLUENT applying the change to your case automatically. If there are some recommendations that you do not want ANSYS FLUENT to implement automatically, then click the **Apply** check box to toggle off and disable the implementation of a particular recommendation. After going through all the tabs and determining which rules you want applied automatically, click the **Apply** button at the bottom of the dialog box. Changes to your settings will be applied to all recommendations throughout the dialog box with an enabled **Apply** check box. ANSYS FLUENT will print a message in the console notifying you that the applied recommendation has been implemented.

ANSYS FLUENT will ask you if you want to save the case before proceeding to the next step. If you choose **Yes**, *The Select File Dialog Box (p. 33)* will open allowing you to save your case with the new settings. If you select **No**, all the changes made to the case file will be lost once you exit ANSYS FLUENT.

29.19.2. Manual Implementation

For recommendations that are listed under **Manual Implementation**, ANSYS FLUENT cannot apply the changes for you. Therefore, if you opt to make a change to your current settings, based on the listed recommendations, then you will need to manually make the changes by opening the affected dialog boxes or task pages and applying what was recommended.

To the right of the recommendations is a **?**, which essentially acts as a help button, leading you to related documentation on the specific topic.

At the bottom of each recommendation, there is a path which will guide you to the dialog box or task page where you can make the changes. For example, in the **Mesh** tab, you will see the following recommendation:

Check your mesh.
(General: Click [Check])

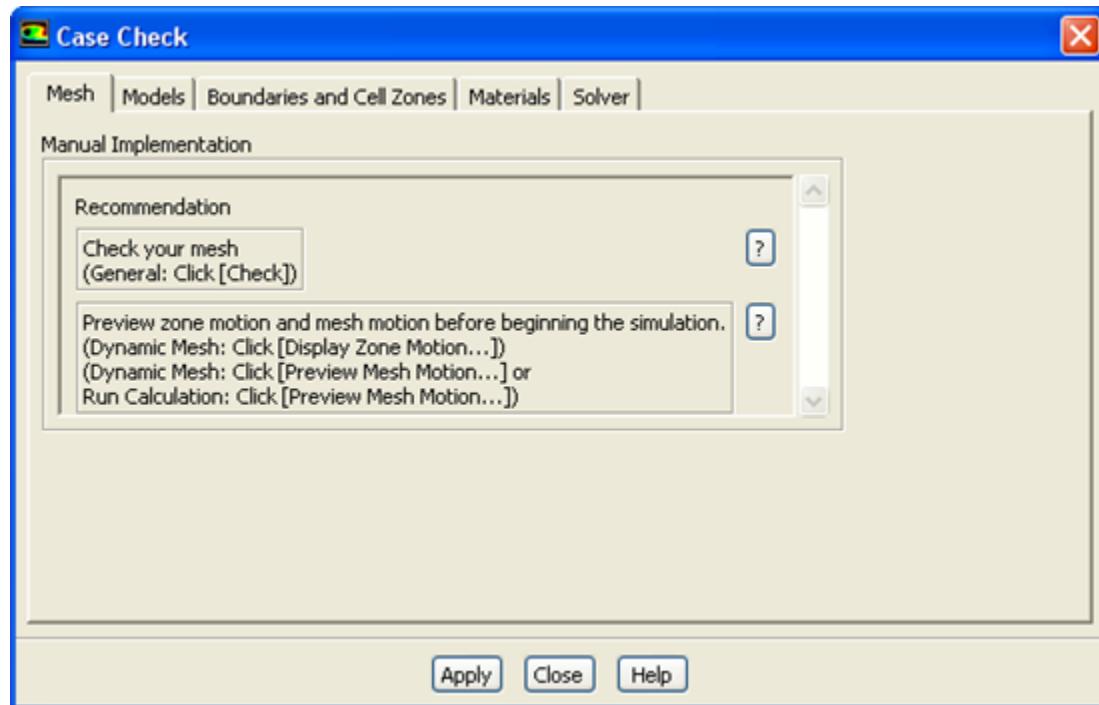

To perform the action, highlight **General** in the navigation pane, then click the **Check** button in the **Mesh** group box. You will see a path for each recommendation, in each of the tabs.

Each of the case check rules are described in the following sections:

- [29.19.2.1. Checking the Mesh](#)
- [29.19.2.2. Checking Model Selections](#)
- [29.19.2.3. Checking Boundary and Cell Zone Conditions](#)
- [29.19.2.4. Checking Material Properties](#)
- [29.19.2.5. Checking the Solver Settings](#)

29.19.2.1. Checking the Mesh

Figure 29.52 The Mesh Tab in the Case Check Dialog Box

The following recommendations appear under the **Mesh** tab ([Figure 29.52 \(p. 1419\)](#)):

- **Check your mesh.**

If you have not already checked your mesh, it is best practice that you do so immediately after reading in your mesh, or after any mesh modification. To check your mesh go to

Checking the mesh will help you detect any mesh trouble before you get started with your problem setup. You can learn more about the information obtained when checking your mesh, by going to [Checking the Mesh \(p. 173\)](#).

- **Improve the mesh quality before proceeding with your simulation. The maximum cell skewness is greater than 0.98.**

Check the quality of your mesh immediately after reading in your mesh, or after any mesh modification. The quality of the mesh plays a significant role in the accuracy and stability of the numerical computation. You can learn more about the quality of your mesh by going to [Mesh Quality \(p. 145\)](#).

General → Report Quality

- **Preview zone motion and mesh motion before beginning the simulation.**

After setting up your case using the **Dynamic Mesh** model, it is worth while to preview your mesh prior to running your simulation. You can preview **Zone Motion** by going to

Dynamic Mesh → Dynamic Mesh → Display Zone Motion...

To preview the **Mesh Motion**, go to

Dynamic Mesh → Dynamic Mesh → Preview Mesh Motion...

Run Calculation → Preview Mesh Motion...

It is important that you preview zone motion first and then mesh motion. Zone motion shows the motion of all dynamic zones with the prescribed rigid body motion, using the graphics library. It is a very fast process and does not alter the mesh. Previewing the zone motion will show you if the motion is setup properly (e.g. zones moving in the wrong direction or rotating about the wrong center). It is much more difficult to detect these problems with mesh motion because small time steps are performed and no continuous animation is shown.

Mesh motion should always be done for dynamic mesh cases with prescribed motion. Mesh motion will only show the validity of the mesh during the simulation. Mesh deformation and dynamic zones without rigid body motion will be considered during a mesh motion preview.

Both the **Mesh Motion** and **Zone Motion** dialog boxes will have a **Preview** button which will allow you to view the mesh or zone motion prior to running your case. You can obtain more information on mesh motion and zone motion by going to [Previewing the Dynamic Mesh \(p. 661\)](#).

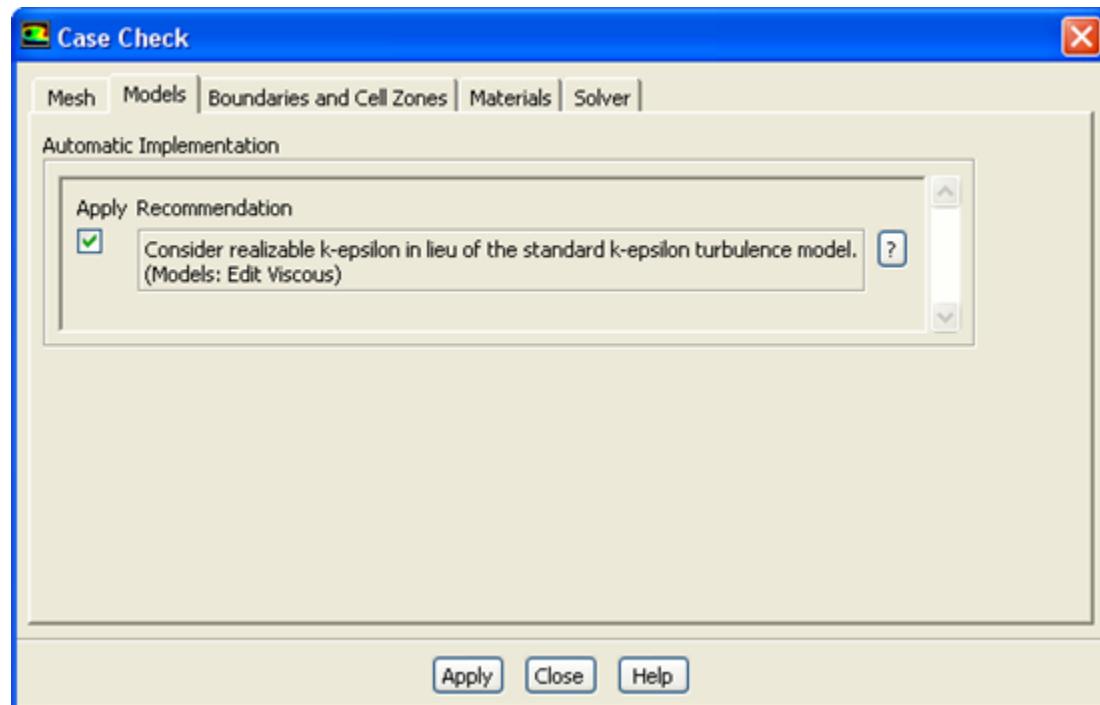

- **Translate the mesh for axisymmetric geometry containing nodes below the x-axis.**

If either **Axisymmetric** or **Axisymmetric Swirl** is specified in the **General** task page and there are mesh nodes that fall below the X-axis, then it is recommended that you translate the mesh. Nodes below the x axis are forbidden for axisymmetric cases, since the axisymmetric cell volumes are created by rotating the 2D cell volume about the x axis; thus nodes below the x axis would create negative volumes. To find out if there are any nodes that lie below the x-axis, perform a mesh check ([Checking the Mesh \(p. 173\)](#)). For information on translating the mesh, see [Translating the Mesh \(p. 207\)](#). To access the **Mesh Translate** dialog box, go to

Mesh → Translate...

29.19.2.2. Checking Model Selections

Figure 29.53 The Models Tab in the Case Check Dialog Box

The following recommendations appear under the **Models** tab (Figure 29.53 (p. 1421)):

- **Consider realizable k-epsilon in lieu of the standard k-epsilon turbulence model.**

The realizable k - ε model is a more recent development of the standard k - ε model and differs from it in that the realizable k - ε model contains a new formulation for the turbulent viscosity, as well as a new transport equation for the dissipation rate, ε , derived from an exact equation for the transport of the mean-square vorticity fluctuation.

realizable k - ε model means that the model satisfies certain mathematical constraints on the Reynolds stresses, consistent with the physics of turbulent flows. For more information on the standard k - ε model and the realizable k - ε model, visit [Standard \$k\$ - \$\varepsilon\$ Model](#) and [Realizable \$k\$ - \$\varepsilon\$ Model](#) (in the [Theory Guide](#)), respectively.

↳ **Models** → **Viscous** → **Edit...**

For information on all k - ε model options, go to [Standard, RNG, and Realizable \$k\$ - \$\varepsilon\$ Models](#) in the [Theory Guide](#).

- **Disable DO/Energy coupling if the optical thickness is less than 10.**

DO/Energy coupling should only be used when the optical thickness is greater than 10. Refer to [Energy Coupling and the DO Model](#) in the [Theory Guide](#) for more information.

↳ **Models** → **Radiation** → **Edit...**

- **Verify that the temperature specified for boundary zones that do not participate in the view factor calculation is appropriate.**

When using the S2S radiation model, make sure that you set the temperature for boundaries that do not participate in the view factor calculation to an appropriate value. In most cases the appropriate value is the ambient temperature, which by default is assumed to be 300 K. See *Specifying Boundary Zone Participation* (p. 763) for more information.

 **Models** →  **Radiation** → **Edit...**

- **Change the under-relaxation factor for the mixing plane model to 1.0.**

If you have created a mixing plane, set the **Under-Relaxation** in the **Mixing Plane** dialog box to 1. Look under Global Parameters in *Setting Up the Mixing Plane Model* (p. 551) for information about the mixing plane under-relaxation.

Define → **Mixing Planes...**

- **Enable the smoothing option for dynamic mesh simulations when remeshing.**

When your case involves the use of dynamic meshes and remeshing is enabled, then it is recommended that you also perform smoothing on the mesh. For a complete discussion of smoothing and remeshing, see *Setting Dynamic Mesh Modeling Parameters* (p. 574).

 **Dynamic Mesh** →  **Dynamic Mesh**

- **Disable species inlet diffusion for laminar flow with species transport.**

By default, ANSYS FLUENT includes the diffusion flux of species at inlets. In some cases involving species transport and laminar flow, it is recommended that the **Inlet Diffusion** option in the **Species Model** dialog box is disabled. For example,

- If you wish to include only the convective transport of species through the inlets of your domain.
- If at one of the inlets, the convective flux is very small, resulting in mass loss by diffusion through the inlet.

 **Models** →  **Species** → **Edit...**

For more information about diffusion at inlets, go to *Defining Cell Zone and Boundary Conditions for Species* (p. 878).

- **Include turbulence interaction for the NOx model.**

When running thermal NOx simulations and your flow is turbulent, then be sure to set the NOx **Turbulence Interaction Mode**.

 **Models** →  **NOx** → **Edit...**

In turbulent combustion calculations, ANSYS FLUENT solves the density-weighted time-averaged Navier-Stokes equations for temperature, velocity, and species concentrations or mean mixture fraction and variance. Methods of modeling the mean turbulent reaction rate can be based on either moment methods or probability density function (PDF) techniques. ANSYS FLUENT uses the PDF approach.

To learn about how this feature is set up, go to *Setting Turbulence Parameters* (p. 1022).

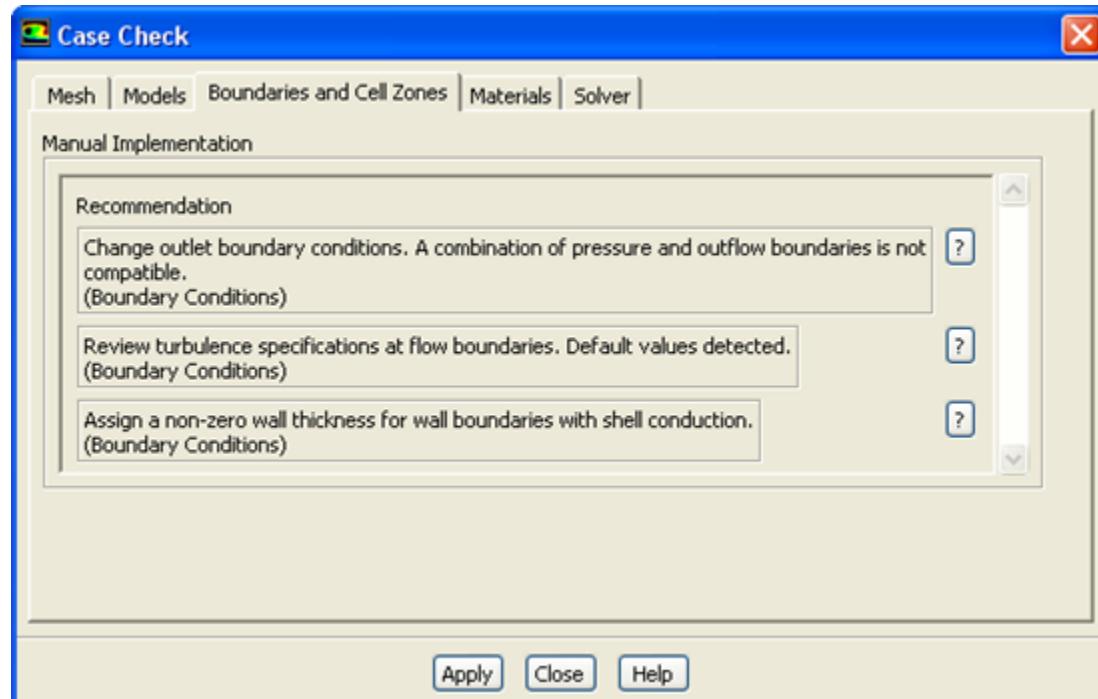

- **Consider using the default Schnerr-Sauer or the Zwart-Gerber-Belamri cavitation model.**

When using the mixture multiphase model with the Singhal et. al cavitation model enabled, consider changing it to either the Schnerr-Sauer or the Zwart-Gerber-Belamri cavitation model. Refer to [Cavitation Models](#) in the Theory Guide for more information.

29.19.2.3. Checking Boundary and Cell Zone Conditions

Figure 29.54 The Boundaries and Cell Zones Tab in the Case Check Dialog Box

The following recommendations appear under the **Boundaries and Cell Zones** tab ([Figure 29.54 \(p. 1423\)](#)):

- **Apply an axis boundary on the centerline (x-axis).**

For geometry that is axisymmetric or axisymmetric swirl (as set in the **General** task page), the centerline (x-axis) boundary type should be set to **axis**. See [Axis Boundary Conditions \(p. 338\)](#).

- **Change inlet boundary conditions. Velocity inlet boundary conditions are not compatible with compressible flow.**

This boundary condition is intended for incompressible flows, and its use in compressible flows will lead to a nonphysical result because it allows stagnation conditions to float to any level (see [Velocity Inlet Boundary Conditions \(p. 276\)](#)). If you decide to select a different boundary type, go to the **Boundary Conditions** task page.

- **Change outlet boundary conditions. A combination of pressure and outflow boundaries is not compatible.**

Outflow boundary conditions in ANSYS FLUENT are used to model flow exits where the details of the flow velocity and pressure are not known prior to solution of the flow problem. One of the limitations when using outflow boundary conditions is that outflow boundary conditions are not compatible with pressure inlets. Therefore, it is recommended that you use velocity or mass flow inlets instead of pressure inlets when used in combination with outflow boundaries. See [Outflow Boundary Conditions \(p. 306\)](#) for a list of limitations that exist with outflow boundaries.

Boundary Conditions

- **Change outlet boundary conditions. Outflow boundary conditions are not compatible with the ideal gas law for density.**

Outflow boundaries cannot be used if you are modeling unsteady flows with varying density, even if the flow is incompressible. See [Outflow Boundary Conditions \(p. 306\)](#) for more limitations that exist with outflow boundaries.

Boundary Conditions

- **Non-zero operating pressure set. This will be added to gauge pressure inputs.**

For cases that have density specified as the ideal gas law, and the operating pressure is greater than zero, the operating pressure will be added to the gauge pressure to yield the absolute pressure. For more information, see [Density Inputs for the Ideal Gas Law for Compressible Flows \(p. 424\)](#) and [Operating Pressure, Gauge Pressure, and Absolute Pressure \(p. 469\)](#).

Boundary Conditions → Operating Conditions...

- **Apply positive non-zero pressure boundary conditions when using the ideal gas law for density.**

In compressible flows, isentropic relations for an ideal gas are applied to relate total pressure, static pressure, and velocity at a pressure inlet boundary. Your input of total pressure, p'_0 at the inlet and the static pressure, $p'_{s'}$ in the adjacent fluid cell are related, as described in [Equation 7-64 \(p. 276\)](#) [Equation 7-65 \(p. 276\)](#) of [Calculation Procedure at Pressure Inlet Boundaries \(p. 275\)](#). It is recommended that pressure boundary conditions are not set to zero for compressible flows that use the ideal gas law.

Boundary Conditions

- **Review turbulence specifications at flow boundaries. Default values detected.**

If your case setup has any of the turbulence models enabled, be sure to review the default parameters for the **K and Epsilon Turbulence Specification Method** in the outlet and inlet boundary conditions. ANSYS FLUENT's default parameters for the **Backflow Turbulent Kinetic Energy** and **Backflow Turbulent Dissipation Rate** are 1. You can either adjust the values, or select a different **Turbulence Specification Method**. For general information turbulence parameters, see [Determining Turbulence Parameters \(p. 262\)](#).

Boundary Conditions

- **Assign a non-zero wall thickness for wall boundaries with shell conduction.**

When the **Shell Conduction** option is enabled in the **Wall** boundary condition dialog box, ANSYS FLUENT will compute heat conduction within the wall, in addition to conduction across the wall.

therefore, you must specify a non-zero **Wall Thickness** in the **Wall** dialog box, because the shell conduction model is relevant only for walls with non-zero thickness. See *Shell Conduction in Thin-Walls* (p. 327) for information on shell conduction in thin walls.

Boundary Conditions

- **Assign a value of 0 or 1 for VOF at the inlet or outlet boundary conditions.**

When enabling the VOF model, the **Volume Fraction** in the inlet and outlet boundary conditions for each phase should be set either to 0 or 1. No intermediate values are permitted. For general information on boundary condition setup, see *Defining Multiphase Cell Zone and Boundary Conditions* (p. 1189).

Boundary Conditions

- **Change the outlet boundary condition. Outflow boundary condition is not compatible with current multiphase settings.**

You cannot assign an outflow boundary condition when using the mixture and Eulerian multiphase models. Note the limitations of this boundary condition in *Outflow Boundary Conditions* (p. 306). ANSYS FLUENT can model the effects of open channel flow using the VOF formulation. In such a case, outflow boundary conditions can be used at the outlet of open channel flows, to model flow exits where the details of the flow velocity and pressure are not known prior to solving the flow problem. See *Open Channel Flow* in the **Theory Guide**, under the heading **Outflow Boundary**, for more information.

Boundary Conditions

- **Review wall motion. Stationary wall motion relative to adjacent cell zone detected.**

In cases where the fluid zone motion type is specified as **Moving Mesh** or **Moving Reference Frame**, all wall zones should be set to **Moving Wall** in the **Momentum** tab in the **Wallboundary** conditions dialog box. The wall motion should be defined **Relative to Adjacent Cell Zone**. The exception to this is if the walls are stationary in the absolute frame. To define wall motion, see *Inputs at Wall Boundaries* (p. 313).

Boundary Conditions

- **Assign non-zero velocities when specifying a moving fluid zone.**

If selecting either **Moving Mesh** or **Moving Reference Frame** in the **Fluid** dialog box, be sure to set non-zero values for the rotational and translational velocities. Refer to *Defining Zone Motion* (p. 224) for user inputs.

Cell Zone Conditions

- **Review flow specifications at inlet boundaries. Default values detected.**

For **mass-flow-inlet** and **velocity-inlet** boundary conditions, the default values in ANSYS FLUENT are 1kg/s and 0m/s, respectively. Review the settings and adjust accordingly. See *Default Settings at Velocity Inlet Boundaries* (p. 281) and *Default Settings at Mass Flow Inlet Boundaries* (p. 288) for default parameters of velocity inlets and mass flow inlets, respectively.

Boundary Conditions

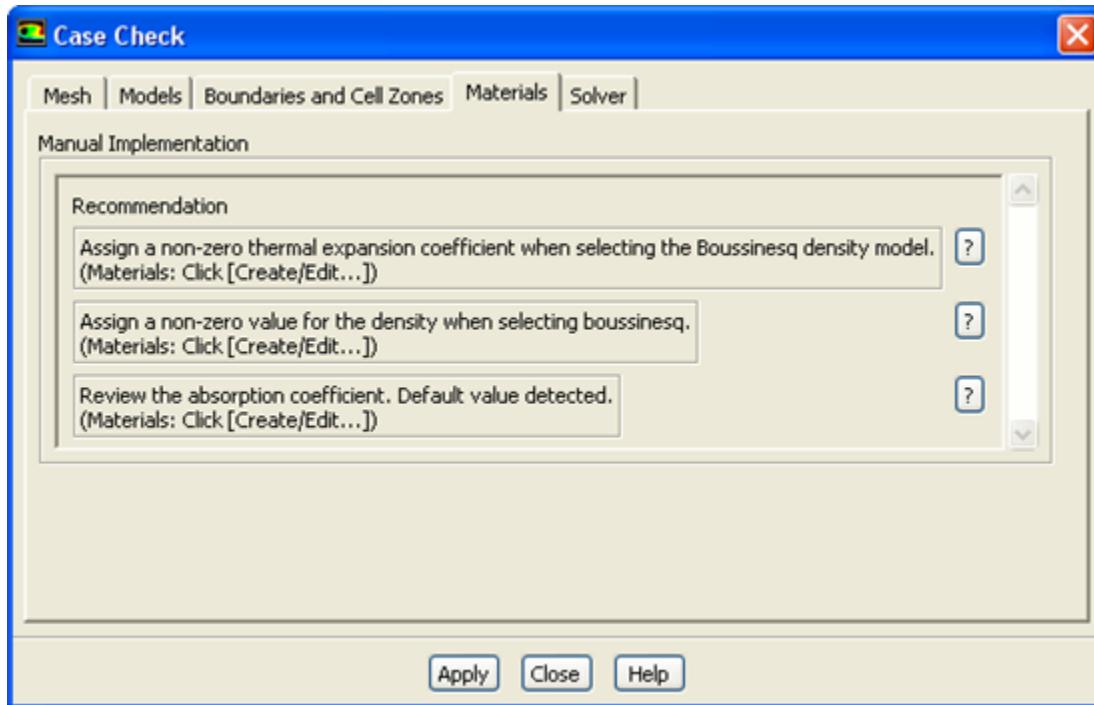

- **Define the porous zone when using the heat exchanger model.**

Heat exchanger models always require the definition of the porous media zone on the primary side for the macro model and for both primary and auxiliary sides for the dual cell model. See [Streamwise Pressure Drop](#) in the [Theory Guide](#) for more information.

Cell Zone Conditions

29.19.2.4. Checking Material Properties

Figure 29.55 The Materials Tab in the Case Check Dialog Box

The following recommendations appear under the **Materials** tab ([Figure 29.55](#) (p. 1426)):

- **Assign individual fluid Cps to polynomial functions of temperature.**

For cases with species transport and volumetric reactions, it is best practice to specify the specific heat capacity C_p as a polynomial that is a function of temperature. See [Defining Properties for the Mixture and Its Constituent Species](#) (p. 861) and [Specific Heat Capacity as a Function of Temperature](#) (p. 453) for information on defining material properties for the species in the mixture.

Materials

- **Assign a non-zero value for the density when selecting boussinesq.**

The Boussinesq model is used for natural convection problems involving small changes in temperature. To enable the Boussinesq approximation for density, choose **boussinesq** from the **Density** drop-down list in the **Create/Edit Materials** dialog box and specify a constant value for **Density**. See [Inputs for the Boussinesq Approximation](#) (p. 422).

Materials

- Review the absorption coefficient. Default value detected.**

If any of the radiation models are enabled. Enter an absorption coefficient for the material listed (*Radiation Properties* (p. 454)).

Materials

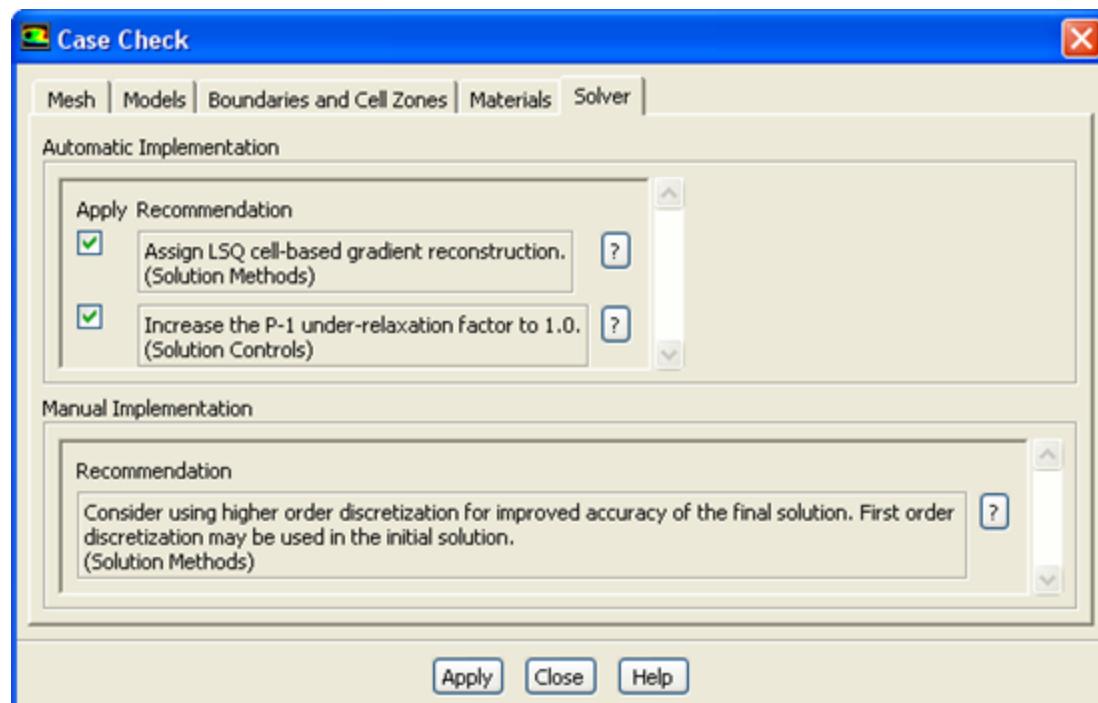

- Assign a non-zero thermal expansion coefficient when selecting the Boussinesq density model.**

When selecting **boussinesq** to describe the density of your material, be sure to enter a valid thermal expansion coefficient for your material. For detailed information on the Boussinesq model, see *The Boussinesq Model* (p. 744).

Materials

29.19.2.5. Checking the Solver Settings

Figure 29.56 The Solver Tab in the Case Check Dialog Box

The following recommendations appear under the **Solver** tab (Figure 29.56 (p. 1427)):

- Enable the unsteady solver option when selecting moving mesh for the fluid boundary.**

If the motion type of the fluid boundary condition is specified as **Moving Mesh**, then your case should be specified as **Transient** in the **General** task page. Visit *Setting Up the Sliding Mesh Problem* (p. 566) for steps on setting up moving mesh problem.

General

- Assign LSQ cell-based gradient reconstruction.**

The least squares cell-based averaging scheme is known to be as accurate as the node-based gradient for irregular unstructured meshes, but less expensive to compute than the node-based gradient. Therefore, it is recommended that least squares cell-based gradient reconstruction is used. See [Evaluation of Gradients and Derivatives](#) in the [Theory Guide](#) for more information on gradient options.

Solution Methods

- **Change the under-relaxation factor for the energy equation to at least 0.90.**

It is recommended to set the energy under-relaxation factor between 0.90 and 1.0. If you decide to apply this recommendation, then ANSYS FLUENT will automatically set the energy under-relaxation factor to 0.90. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See [Solution Strategies for Heat Transfer Modeling](#) (p. 739) for the underrelaxation of the energy equation.

Solution Controls

- **Increase the NOx under-relaxation factor to at least 0.90.**

If the NOx model is enabled, set the NOx under-relaxation factor to a value of at least 0.90 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS FLUENT will automatically set the NOx under-relaxation factor to 0.90. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See [Using the NOx Model](#) (p. 1009).

Solution Controls

- **Increase the Discrete Ordinates under-relaxation factor to at least 0.90.**

If the Discrete Ordinates (DO) radiation model is enabled, set the radiation under-relaxation factor to a value of at least 0.90 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS FLUENT will automatically set the radiation under-relaxation factor to 0.90. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See [DO Solution Parameters](#) (p. 784).

Solution Controls

- **Increase the P1 under-relaxation factor to 1.0.**

If the P1 radiation model is enabled, set the radiation under-relaxation factor to 1.0 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS FLUENT will automatically set the radiation under-relaxation factor to 1.0. See [P-1 Model Solution Parameters](#) (p. 782).

Solution Controls

- **Increase the species and energy under-relaxation factors to at least 0.90.**

For a case with species transport and energy defined, set the species and energy under-relaxation factors to a value of at least 0.90. If you decide to apply this recommendation, then ANSYS FLU-

ENT will automatically set the species and energy under-relaxation factors to 0.90. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See *Solution Procedures for Chemical Mixing and Finite-Rate Chemistry* (p. 879).

Solution Controls

- **Assign a value of 1 for the under-relaxation factor for unsteady DPM with 1 DPM update per time step.**

It is recommended that the DPM under-relaxation factor be set to 1 for unsteady DPM with 1 DPM update per time step.

Solution Controls

- **Increase the mean mixture fraction under-relaxation factor to at least 0.90.**

If the non-premixed or partially premixed combustion models are enabled, then it is best to set the mean mixture under-relaxation factor to a value of at least 0.90 to ensure full convergence. If you decide to apply this recommendation, then ANSYS FLUENT will automatically set the mean mixture under-relaxation factor to 0.90. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See *Solving the Flow Problem* (p. 950).

Solution Controls

- **Consider using higher order discretization for improved accuracy of the final solution. First-order discretization may be used in the initial solution.**

It is generally advisable to obtain an initial solution using first-order accurate discretization; however, second order discretization is recommended for improved accuracy of the final solution. See *Choosing the Spatial Discretization Scheme* (p. 1314) for more information on discretization schemes.

Solution Methods

- **Select the absolute reference frame for initializing cases when using the MRF model.**

When using the MRF model, always use the absolute reference frame while initializing the solution. Select **Absolute** under **Reference Frame** in the **Solution Initialization** task page. If the **Relative to Cell Zone** option is selected, which is the default option, the initial flow field can contain discontinuities, which can cause convergence problems in the first few iterations. Refer to *Initializing the Entire Flow Field Using Standard Initialization* (p. 1349) for more information.

Solution Initialization → Initialize

- **Choose PRESTO! for the pressure discretization scheme.**

When using the VOF model, it is recommended that you use **PRESTO!** as the pressure discretization scheme. This scheme is recommended for flows with high swirl numbers, a high-Rayleigh-number natural convection, high-speed rotating flows, flows involving porous media, and flows in strongly curved domains. See *Choosing the Pressure Interpolation Scheme* (p. 1316) for more information.

Solution Methods

29.20. Convergence and Stability

Convergence can be hindered by a number of factors. Large numbers of computational cells, overly conservative under-relaxation factors, and complex flow physics are often the main causes. Sometimes it is difficult to know whether you have a converged solution. In the following sections, some of the numerical controls and modeling techniques that can be exercised to enhance convergence and maintain stability are examined.

29.20.1. Judging Convergence

29.20.2. Step-by-Step Solution Processes

29.20.3. Modifying Algebraic Multigrid Parameters

29.20.4. Modifying the Multi-Stage Parameters

29.20.5. Robustness on Meshes of Poor Quality

You should also refer to [Choosing the Spatial Discretization Scheme \(p. 1314\)](#) and [Choosing the Pressure-Velocity Coupling Method \(p. 1321\)](#) for information about how the choice of discretization scheme or (for the pressure-based solver) pressure-velocity coupling scheme can affect convergence. Manipulation of under-relaxation parameters and multigrid settings to enhance convergence is discussed in [Setting Under-Relaxation Factors \(p. 1323\)](#) and [Modifying Algebraic Multigrid Parameters \(p. 1432\)](#).

29.20.1. Judging Convergence

There are no universal metrics for judging convergence. Residual definitions that are useful for one class of problem are sometimes misleading for other classes of problems. Therefore it is a good idea to judge convergence not only by examining residual levels, but also by monitoring relevant integrated quantities such as drag or heat transfer coefficient.

For most problems, the default convergence criterion in ANSYS FLUENT is sufficient. This criterion requires that the globally scaled residuals, defined by [Equation 29–5 \(p. 1380\)](#) or [Equation 29–11 \(p. 1382\)](#) decrease to 10^{-3} for all equations except the energy and P-1 equations, for which the criterion is 10^{-6} . Locally scaled residuals defined by [Equation 29–6 \(p. 1381\)](#) or [Equation 29–12 \(p. 1382\)](#) decrease to 10^{-5} for all equations.

Sometimes, however, this criterion may not be appropriate. Typical situations are listed below.

- If you make a good initial guess of the flow field, the initial continuity residual may be very small leading to a large scaled residual for the continuity equation. In such a situation it is useful to examine the unscaled residual and compare it with an appropriate scale, such as the mass flow rate at the inlet.
- For some equations, such as for turbulence quantities, a poor initial guess may result in high scale factors. In such cases, scaled residuals will start low, increase as non-linear sources build up, and eventually decrease. It is therefore good practice to judge convergence not just from the value of the residual itself, but from its behavior. You should ensure that the residual continues to decrease (or remain low) for several iterations (say 50 or more) before concluding that the solution has converged.

Another popular approach to judging convergence is to require that the unscaled residuals drop by three orders of magnitude. ANSYS FLUENT provides residual normalization for this purpose, as discussed in [Definition of Residuals for the Pressure-Based Solver \(p. 1380\)](#), where residuals are defined for both the pressure-based solver and the density-based solver. In this approach the convergence criterion is that the normalized unscaled residuals should drop to 10^{-3} . However, this requirement may not be appropriate in many cases:

- If you have provided a very good initial guess, the residuals may not drop three orders of magnitude. In a nearly-isothermal flow, for example, energy residuals may not drop three orders if the initial guess of temperature is very close to the final solution.
- If the governing equation contains non-linear source terms which are zero at the beginning of the calculation and build up slowly during computation, the residuals may not drop three orders of magnitude. In the case of natural convection in an enclosure, for example, initial momentum residuals may be very close to zero because the initial uniform temperature guess does not generate buoyancy. In such a case, the initial nearly-zero residual is not a good scale for the residual.
- If the variable of interest is nearly zero everywhere, the residuals may not drop three orders of magnitude. In fully-developed flow in a pipe, for example, the cross-sectional velocities are zero. If these velocities have been initialized to zero, initial (and final) residuals are both close to zero, and a three-order drop cannot be expected.

In such cases, it is wise to monitor integrated quantities, such as drag or overall heat transfer coefficient, before concluding that the solution has converged. It may also be useful to examine the un-normalized unscaled residual, and determine if the residual is small compared to some appropriate scale. Alternatively, the scaled residual defined by [Equation 29–5 \(p. 1380\)](#) or [Equation 29–11 \(p. 1382\)](#) (the default) may be considered.

Conversely, it is possible that if the initial guess is very bad, the initial residuals are so large that a three-order drop in residual does not guarantee convergence. This is specially true for k and ε equations where good initial guesses are difficult. Here again it is useful to examine overall integrated quantities that you are particularly interested in. If the solution is unconverged, you may drop the convergence tolerance, as described in [Modifying Convergence Criteria \(p. 1387\)](#).

29.20.2. Step-by-Step Solution Processes

One important technique for speeding convergence for complex problems is to tackle the problem one step at a time. When modeling a problem with heat transfer, you can begin with the calculation of the isothermal flow. To solve turbulent flow, you might start with the calculation of laminar flow. When modeling a reacting flow, you can begin by computing a partially converged solution to the non-reacting flow, possibly including the species mixing. When modeling a discrete phase, such as fuel evaporating from droplets, it is a good idea to solve the gas-phase flow field first. Such solutions generally serve as a good starting point for the calculation of the more complex problems. These step-by-step techniques involve using the [Solution Controls Task Page \(p. 2052\)](#) to turn equations on and off in the **Equations** dialog box.

29.20.2.1. Selecting a Subset of the Solution Equations

ANSYS FLUENT automatically solves each equation that is turned on using the **Models** family of dialog boxes. If you specify in the [Viscous Model Dialog Box \(p. 1778\)](#) that the flow is turbulent, equations for conservation of turbulence quantities are turned on. If you specify in the [Energy Dialog Box \(p. 1778\)](#) that ANSYS FLUENT should enable energy, the energy equation is activated. Convergence can be sped up by focusing the computational effort on the equations of primary importance. The **Equations** list in the [Equations Dialog Box \(p. 2054\)](#) allows you to turn individual equations on or off temporarily.

Solution Controls → **Equations...**

A typical example is the computation of a flow with heat transfer. Initially, you will define the full problem scope, including the thermal boundary conditions and temperature-dependent flow properties. Following the problem setup, you will use the **Equations** dialog box to temporarily turn off the energy

equation. You can then compute an isothermal flow field, remembering to set a reasonable initial value for the temperature of the fluid.

Important

This is possible only for the pressure-based solver; the density-based solver solves the energy equation together with the flow equations in a coupled manner, so you cannot turn off the energy equation as described above.

When the isothermal flow is reasonably well converged, you can turn the energy equation back on. You can actually turn off the momentum and continuity equations while the initial energy field is being computed. When the energy field begins to converge well, you can turn the momentum and continuity equations back on so that the flow pattern can adjust to the new temperature field. The temperature will couple back into the flow solution by its impact on fluid properties such as density and viscosity. The temperature field will have no effect on the flow field if the fluid properties (e.g., density, viscosity) do not vary with temperature. In such cases, you can compute the energy field without turning the flow equations back on again.

Important

If you have specified temperature-dependent flow properties, you should be sure that a realistic value has been set for temperature throughout the domain before disabling calculation of the energy equation. If an unrealistic temperature value is used, the flow properties dependent on temperature will also be unrealistic, and the flow field will be adversely affected. Instructions for initializing the temperature field or patching a temperature field onto an existing solution are provided in *Initializing the Solution* (p. 1348).

29.20.2.2. Turning Reactions On and Off

To solve a species mixing problem prior to solving a reacting flow, you should set up the problem including all of the reaction information, and save the complete case file. To turn off the reaction so that only the species mixing problem can be solved, you can use the *Species Model Dialog Box* (p. 1814) to turn off the **Volumetric** option under **Reactions**.

Models → **Species** → **Edit...**

Once the species mixing problem has partially converged, you can return to the **Species Model** dialog box and turn the **Volumetric Reactions** option on again. You can then resume the calculation starting from the partially converged data.

For combustion problems you may want to patch a hot temperature in the vicinity of the anticipated reactions before you restart the calculation. See *Patching Values in Selected Cells* (p. 1351) for information about patching an initial value for a flow variable.

29.20.3. Modifying Algebraic Multigrid Parameters

The default algebraic multigrid settings are appropriate for nearly all problems, but in rare cases you may need to make minor adjustments. *Setting Algebraic Multigrid Parameters* (p. 1336) describes how to analyze the multigrid solver's performance to determine which parameters.

29.20.4. Modifying the Multi-Stage Parameters

It is possible to make several changes to the multi-stage time-stepping scheme itself. See [Changing the Multi-Stage Scheme \(p. 1346\)](#) for detailed information.

29.20.5. Robustness on Meshes of Poor Quality

Poor quality meshes are meshes containing highly skewed cells, highly non-orthogonal cells, non-convex cells, or cells with left-handed faces. Such mesh elements tend to decrease the numerical stability of traditional CFD discretization algorithms. These mesh elements require special treatment, namely, a numerical correction of the transport equation discretization, which is intended to improve the numerical properties of the solution algorithms at mesh cells of poor quality.

In order to facilitate solution convergence on meshes of poor quality, the ANSYS FLUENT solver can apply a local solution correction, limited spatially to distorted cells of the mesh. The corrected solution can be of 0th, 1st, or 2nd order:

- The 0th order scheme applies an algorithm that computes the solution variable for the transport equation in the bad cells by assembling the solution directly from the surrounding solution in the better quality cells.
- The 1st order scheme applies locally low order discretization methods and neglects some non-orthogonal contributions to the gradients when computing the diffusive fluxes.
- The 2nd order scheme only modifies the numerics in the bad cells by assembling the gradient vector for the given solution variable from the gradients in the surrounding better quality cells.

In other words, the discretization error will be independent of the mesh size in this region if 0th order is used. It will decrease linearly with subsequent grid refinement when 1st order is used, and quadratically when the 2nd order option is selected. By default, highly skewed cells and highly non-orthogonal cells do not have this special treatment applied to them, but this can be enabled through the TUI.

If you read in a poor quality mesh containing cells and faces with corrupt metrics, you will see a warning in the TUI of the form:

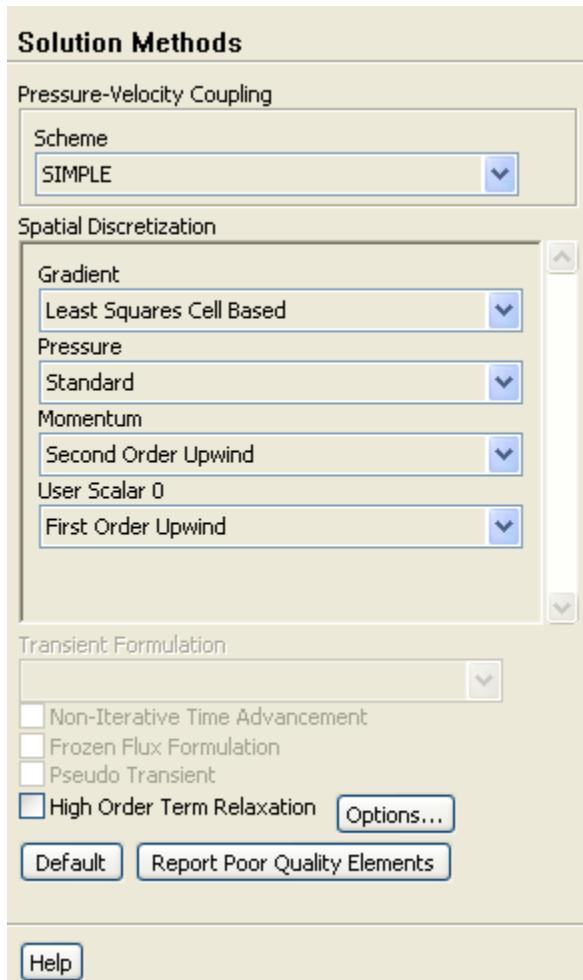

Info: The mesh contains elements that are invalid or of poor quality.

A different numerical scheme will be applied to these elements, which may affect the quality of the solution. It is recommended that you consider removing the invalid and poor quality elements in the mesh.

For more information on the invalid and poor quality elements, please use the following TUI commands:

```
/mesh/check  
/mesh/repair-improve/report-poor-elements.
```

Additionally, in the **Solution Methods** task page, the **Report Poor Quality Elements** button will appear, which can be used to report more statistics on the number and type of cells which ANSYS FLUENT has identified as having poor quality (see [Figure 29.57 \(p. 1434\)](#)).

Figure 29.57 Reporting Poor Quality Elements

In general, it is recommended that you use the 1st order solution correction, which provides a reasonable compromise between accuracy trade-off and stability gain. For meshes of better (and yet low) quality it is advisable to try the 2nd order option, which will preserve the mesh convergence behavior provided by the convection term discretization schemes. In case no convergence is obtained with any of the aforementioned schemes, you should use the 0th order option, which will provide the highest stability and at the same time the lowest accuracy. In regions with highly nonlinear flow physics this scheme can yield highly nonphysical results.

You can enable/disable this option and specify the order of mesh convergence of the corrected numerical solution using the following text command:

```
solve/set/poor-mesh-numerics
```

After enabling this option, enter the corrected solution order. You will enter 0, 1, or 2, which correspond to the 0th order scheme, 1st order scheme, and 2nd order scheme, respectively, as described above.

The computational time (or cost or runtime requirements) for all three schemes will increase linearly as the number of cells identified as poor quality cells increases. Provided that there is reasonable convergence behavior with all three schemes, the 1st order option will be the fastest; 0th and 2nd order will have similar runtimes.

The local solution correction can also be applied to highly skewed cells and highly non-orthogonal cells. This can be enabled using the following text command:

```
solve/set/poor-mesh-numerics-quality-based
```

Note

The local solution correction is available for both the pressure-based and the density-based solvers. It is applied to all transport equations solved by ANSYS FLUENT.

29.21. Solution Steering

For additional information, please see the following sections:

- [29.21.1. Overview of Solution Steering](#)
- [29.21.2. Solution Steering Strategy](#)
- [29.21.3. Using Solution Steering](#)

29.21.1. Overview of Solution Steering

Solution steering in the density-based implicit solver provides you with an expert system that will help navigate the flow solution from a starting initial guess to a converged solution with minimum user interaction. When you apply solution steering, you will be required to select the type of flow that best characterizes the solution domain and the maximum desired accuracy, and then allow the solver to take the solution to convergence. As the solver proceeds with the solution iteration, certain solver parameters will be adjusted behind the scenes to insure that a converged solution to steady state is possible.

Important

Solution steering is available only for steady-state flows in the density-based implicit solver.

29.21.2. Solution Steering Strategy

The convergence to steady-state solution is achieved in two stages. The parameters that are used in these stages are determined and set based on user input for the type of flow that can best characterize the solution domain. The type of flows available for selection are classified based on flow compressibility as well as the dominant flow Mach number in the solution domain.

The following flow types are available:

- Incompressible (if the flow is incompressible, i.e. density is constant)
- Subsonic (if the flow is compressible and $M < 0.75$)
- Transonic (if the flow is compressible and $0.65 < M < 1.2$)
- Supersonic (if the flow is compressible and $1.10 < M < 2.5$)
- Hypersonic (if the flow is compressible and $2.0 < M$)

Important

There is no exact Mach number cut-off for these regions, therefore, the above Mach number ranges are just a simple guideline to help you select a flow type.

Solution steering will typically perform full multigrid (FMG) initialization followed by two iterative stages. The purpose of each stage is described below.

29.21.2.1. Initialization

Immediately before the start of the iteration, solution steering will perform full multigrid initialization to obtain the best possible initial starting solution.

Stage 1:

The purpose of Stage 1 is to navigate the solution from the difficult initial phase of the solution toward convergence by insuring maximum stability. During this stage, the solution is advanced gradually from 1st-order accuracy to maximum accuracy (user specified and typically 2nd-order) at a constant low CFL value.

Stage 2:

In this stage the solution is driven hard towards convergence by regular adjustments of the CFL value to insure fast convergence as well as to prevent possible divergence.

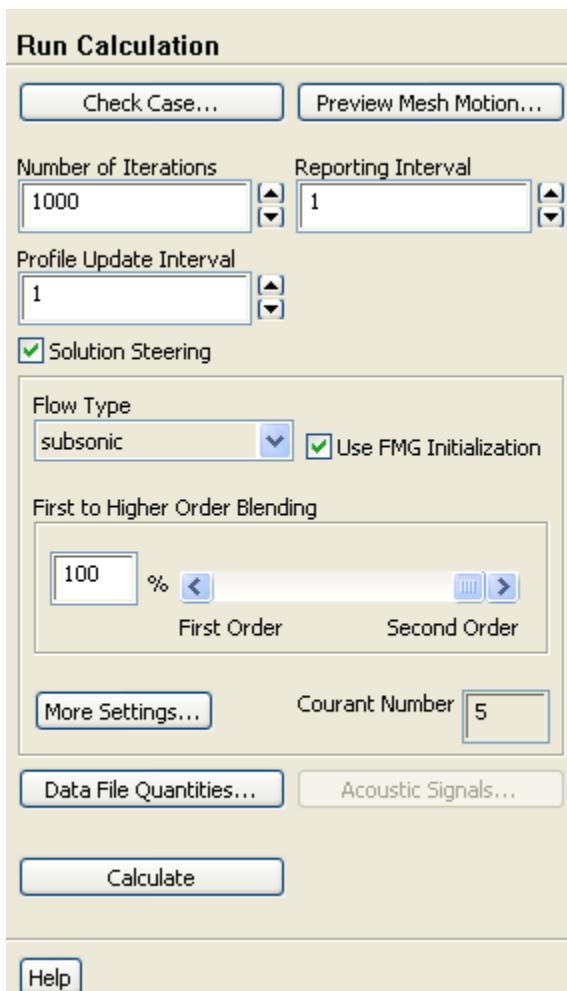

In stage 2, the residual history is monitored and analyzed through regular intervals to determine if an increase or decrease in CFL value is needed to obtain fast convergence or to prevent divergence.

29.21.3. Using Solution Steering

Solution steering is disabled by default. However, when the following criteria are met, the solution steering feature will become available for selection:

Feature	Setting
Solver Type	Density Based
Solver Formulation	Implicit
Time Formulation	Steady
Data is valid (either data file has been read or flow has been initialized)	

To activate solution steering, click the **Solution Steering** check box as shown in [Figure 29.58 \(p. 1437\)](#).

Figure 29.58 The Run Calculation Task Page with Solution Steering Enabled

The **Run Calculation** task page will then expand to display the solution steering main controls (see [Figure 29.58 \(p. 1437\)](#)). To obtain a flow solution using solution steering, you will need to perform the following:

1. Select the type of flow.
2. Select the maximum accuracy desired (first to second order blending).
3. Click **Calculate**.

The user can also adjust the number of iterations, or customize the parameters of the solution steering if the default setting is not sufficient for the type of flow problem being solved.

Before using solution steering, you will need to prepare and set up the case as usual as described in the Getting Started Manual.

Once **Solution Steering** is activated, specify the following:

Flow Type

allows you to select the flow type that best describes the flow in the solution domain. Five choices are available: **incompressible**, **subsonic**, **transonic**, **supersonic**, and **hypersonic**.

FMG Initialization

when enabled allows for full multigrid initialization before starting stages 1 and 2. FMG initialization is enabled by default.

First to Higher Order Blending

allows you to reduce the desired solution accuracy by selecting a blending factor less than 100%. The default setting is 100%. See [First-to-Higher Order Blending](#) in the Theory Guide for more information.

The blending factor will be grayed out if **Second Order Upwind** discretization for the **Flow** equations is not selected in the **Solution Methods** task page. The solution accuracy may be reduced (typical values are 75% or 50%) if it is not possible to obtain a converged solution with the maximum second-order accuracy (i.e. blending = 100%)

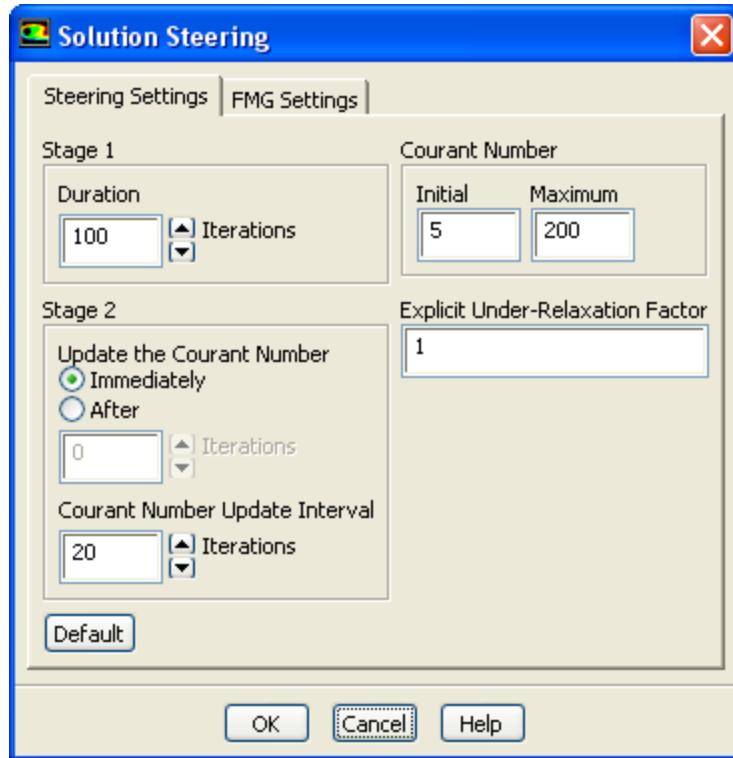

Courant Number

in the **Run Calculation** task page is a non-adjustable field displaying the current CFL number, which allows you to view it during the calculation.

More Settings...

opens the **Solution Steering** dialog box, providing a host of settings that control the solution steering strategy, as shown in [Figure 29.59 \(p. 1438\)](#).

Figure 29.59 The Solution Steering Dialog Box

The **Solution Steering** dialog box, shown in [Figure 29.59 \(p. 1438\)](#), contains two tabs. The **Steering Settings** tab sets the solution steering parameters and the **FMG Settings** sets the full multigrid initialization parameters.

In the **Steering Setting** tab, you can modify the parameters used in Stages 1 and 2.

Stage 1

Duration is the number of iterations in stage 1. The CFL number used during these iterations is set in the **Initial** field, in the **Courant Number** group box.

Stage 2

The Courant number update in stage 2 can start immediately after the end of stage 1, or after a certain designated number of iterations. If the Courant number update is to start immediately after stage 1 then **Immediately** should be selected (this is the default option). If the Courant number update is desired after some lagged period of iterations, then **After** should be selected and the lag in the number of iterations should be entered in the field below it. The frequency at which the Courant number is updated is defined in **Courant Number Update Interval** field.

Courant Number

Initial is the starting Courant number and **Maximum** is the maximum allowed Courant number. The solution steering algorithm will not allow the solver to exceed the maximum Courant number, but will allow the solver to use a Courant number less than the initial Courant number if divergence in the solution has occurred.

Explicit Under-Relaxation Factor

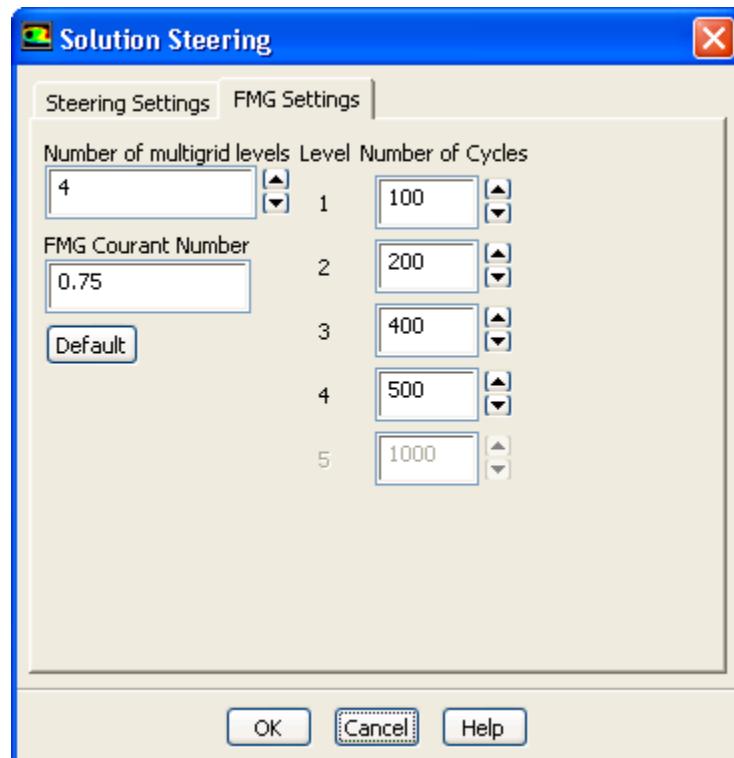

allows the solution to be under-relaxed to improve convergence. The under-relaxation value is determined by the **Flow Type** that you selected in the **Run Calculation** task page, when **Solution Steering** was enabled. In general, you do not need to alter the default value set in this field. Refer to [Under-Relaxation of Variables](#) in the [Theory Guide](#) for more information about explicit relaxation.

Default

is available in the **Steering Settings** tab to reset any changes made to the parameters to their original default values.

In the **FMG Settings** tab ([Figure 29.60 \(p. 1439\)](#)), the **Number of multigrid levels** and **Number of Cycles** in each **Level**, as well as the **FMG Courant Number** used in the FMG initialization can be adjusted. The default values used in the multigrid settings are determined from the type of flow that you selected, the size of the mesh, and the flow dimensionality. The **Default** button is used to reset any changes to the original default values. For more information about FMG initialization, refer to [Full Multigrid \(FMG\) Initialization \(p. 1353\)](#).

Figure 29.60 The FMG Settings Tab in the Solution Steering Dialog Box

Chapter 30: Adapting the Mesh

The solution-adaptive mesh refinement feature of ANSYS FLUENT allows you to refine and/or coarsen your mesh based on geometric and numerical solution data. In addition, ANSYS FLUENT provides tools for creating and viewing adaption fields customized to particular applications. For information about the theory behind mesh adaption in ANSYS FLUENT, see "[Adapting the Mesh](#)" in the [Theory Guide](#). Information about using the adaption process in ANSYS FLUENT is described in detail in the following sections.

- [30.1. Using Adaption](#)
- [30.2. Boundary Adaption](#)
- [30.3. Gradient Adaption](#)
- [30.4. Dynamic Gradient Adaption](#)
- [30.5. Isovalue Adaption](#)
- [30.6. Region Adaption](#)
- [30.7. Volume Adaption](#)
- [30.8. Yplus/Ystar Adaption](#)
- [30.9. Anisotropic Adaption](#)
- [30.10. Geometry-Based Adaption](#)
- [30.11. Registers](#)
- [30.12. Mesh Adaption Controls](#)
- [30.13. Improving the Mesh by Smoothing and Swapping](#)

30.1. Using Adaption

Two significant advantages of the unstructured mesh capability in ANSYS FLUENT are:

- reduced setup time compared to structured meshes
- the ability to incorporate solution-adaptive refinement of the mesh

By using solution-adaptive refinement, you can add cells where they are needed in the mesh, thus enabling the features of the flow field to be better resolved. When adaption is used properly, the resulting mesh is optimal for the flow solution because the solution is used to determine where more cells need to be added. Thus, computational resources are not wasted by the inclusion of unnecessary cells, as occurs in the structured mesh approach. Also, the effect of mesh refinement on the solution can be studied without completely regenerating the mesh.

Note

When you perform mesh adaption in a parallel computation, a load balancing step will be performed by ANSYS FLUENT by default.

The automatic load balancing will not occur in conjunction with dynamic adaption. See [Dynamic Gradient Adaption \(p. 1449\)](#) for information on dynamic adaption, and [Load Balancing \(p. 1745\)](#) for information on load balancing in parallel ANSYS FLUENT. For information about the static adaption process, see [Static Adaption Process](#) in the [Theory Guide](#).

For additional information, please see the following sections:

[30.1.1. Adaption Example](#)

[30.1.2. Adaption Guidelines](#)

30.1.1. Adaption Example

An example of the effective use of adaption is in the solution of the compressible, turbulent flow through a 2D turbine cascade. The initial mesh around the blade is fine, as shown in [Figure 30.1 \(p. 1442\)](#). The surface node distribution thus provides adequate definition of the blade geometry, and enables the turbulent boundary layer to be properly resolved without further adaption. On the other hand, the mesh on the inlet, outlet, and periodic boundaries is comparatively coarse. To ensure that the flow in the blade passage is appropriately resolved, solution-adaptive refinement was used to create the mesh shown in [Figure 30.2 \(p. 1443\)](#).

Figure 30.1 Turbine Cascade Mesh Before Adaption

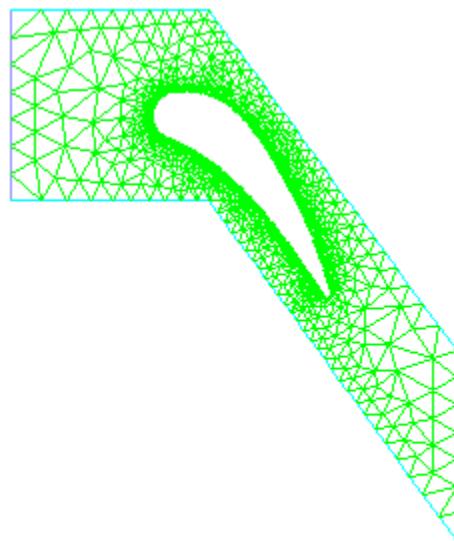

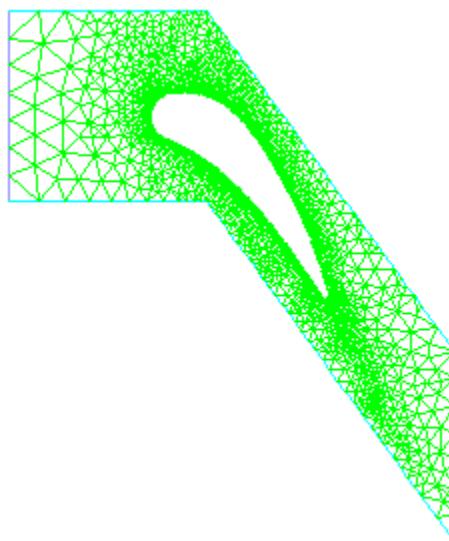

Figure 30.2 Turbine Cascade Mesh after Adaption

While the procedure for solution adaption will vary according to the flow being solved, it is instructive to examine the adaption process used for the turbine cascade shown in the previous figure. Though this example involves compressible flow, the general procedure is applicable for incompressible flows as well.

1. Display contours of pressure adaption function to determine a suitable refinement threshold (see [Gradient Adaption \(p. 1447\)](#)).
2. “Mark the cells within the refinement threshold, creating a refinement register (see [Adaption Registers](#) in the [Theory Guide](#) and [Gradient Adaption \(p. 1447\)](#)).
3. Repeat the process described in steps 1 and 2, using gradients of Mach number as a refinement criterion.
4. To refine in the wake region, use isovalue of total pressure as a criterion (see [Isovalue Adaption \(p. 1451\)](#)). This causes cells within the boundary layer and the wake to be marked, since these are both regions of high total-pressure loss.
5. Use the [Manage Adaption Registers Dialog Box \(p. 2287\)](#) to combine the three refinement registers into a single register (see [Manipulating Adaption Registers \(p. 1459\)](#)).
6. Limit the minimum cell volume for adaption to prevent the addition of cells within the boundary layer, where the mesh was judged to be fine enough already (see [Adapt/Controls... \(p. 2288\)](#)).
7. Refine the cells contained in the resulting adaption register (see [Manipulating Adaption Registers \(p. 1459\)](#)).
8. Perform successive smoothing and swapping iterations using the [Smooth/Swap Mesh Dialog Box \(p. 2293\)](#) (see [Face Swapping \(p. 1470\)](#)).

The effect of refining on gradients is evident in the finer mesh ahead of the leading edge of the blade and within the blade passage ([Figure 30.2 \(p. 1443\)](#)). The finer mesh in the wake region is due to the adaption using isovalue of total pressure.

30.1.2. Adaption Guidelines

The advantages of solution-adaptive refinement, when used properly (as in the turbine cascade example in [Adaption Example \(p. 1442\)](#)), are significant. However, this capability must be used carefully to avoid certain pitfalls. Some guidelines for proper usage of solution-adaptive refinement are as follows:

- The surface mesh must be fine enough to adequately represent the important features of the geometry.

For example, it would be bad practice to place too few nodes on the surface of a highly-curved airfoil, and then use solution refinement to add nodes on the surface. The surface will always contain the facets contained in the initial mesh, regardless of the additional nodes introduced by refinement.

- The initial mesh should contain sufficient cells to capture the essential features of the flow field.

Consider the following example, in which you want to predict the shock forming around a bluff body in supersonic flow. To obtain a reasonable first solution, the initial mesh should contain enough cells and also have sufficient resolution to represent the shape of the body. Subsequent gradient adaption can be used to sharpen the shock and to establish a mesh-independent solution.

- Polyhedral cells are not eligible for adaption. The presence of polyhedral cells in a mesh may or may not limit the eligibility of other cells for adaption, depending on the manner in which the polyhedral cells were created:
 - If the domain was converted to polyhedra (see [Converting the Domain to a Polyhedra \(p. 180\)](#)), then no part of the mesh can be adapted (even if hexahedral cells are present in the mesh after conversion).
 - If the polyhedra are a result of converting skewed tetrahedral cells (see [Converting Skewed Cells to Polyhedra \(p. 184\)](#)) or converting the transitional cells of a hexcore mesh, then the nonpolyhedral cells may be adapted. The polyhedral cells, however, will be automatically unmarked from the register when adaption is initiated and will remain unchanged.
- Obtain a reasonably well-converged solution before performing an adaption. If you adapt to an incorrect solution, cells will be added in the wrong region of the flow.

Use careful judgment in deciding how well to converge the solution before adapting, because there is a trade-off between adapting too early to an unconverged solution and wasting time by continuing to iterate when the solution is not changing significantly. This does not directly apply to dynamic adaption, because here the solution is adapted either at every iteration or at every time step, depending on which solver is being used.

- Write a case and data file before starting the adaption process. If you generate an undesirable mesh, you can restart the process with the saved files. This does not directly apply to dynamic adaption, because here the solution is adapted either at every iteration or at every time step, depending on which solver is being used.
- Select suitable variables when performing gradient adaption. For some flows, the choice is clear. For instance, adapting on gradients of pressure is a good criterion for refining in the region of shock waves. In most incompressible flows, however, it makes little sense to refine on pressure gradients. A more suitable parameter in an incompressible flow might be mean velocity gradients. If the flow feature of interest is a turbulent shear flow, it will be important to resolve the gradients of turbulent kinetic energy and turbulent energy dissipation, so these might be appropriate refinement variables. In reacting flows, temperature or concentration (or mole or mass fraction) of reacting species might be appropriate.
- Do not over-refine a particular region of the solution domain. It causes very large gradients in cell volume. Such poor adaption practice can adversely affect the accuracy of the solution.

30.2. Boundary Adaption

This section describes how to perform boundary adaption. For more information, see [Boundary Adaption](#) in the [Theory Guide](#).

For additional information, please see the following section:

30.2.1. Performing Boundary Adaption

You can perform the boundary adaption in three different ways based on:

- number of cells

In this case, the distance of a cell from the boundary is measured in number of cells.

- normal distance

In this case, the cell refinement is based on the normal distance of a cell from the boundary.

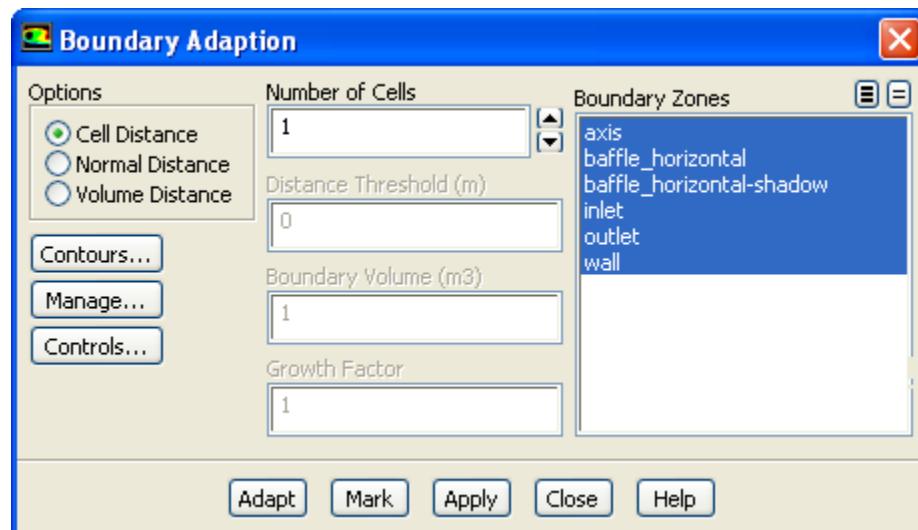

- target boundary volume

In this case, the cell refinement is based on a target boundary volume and growth factor.

You can use any of these methods in the [Boundary Adaption Dialog Box](#) (p. 2276) ([Figure 30.3](#) (p. 1445)).

Adapt → Boundary...

Figure 30.3 The Boundary Adaption Dialog Box

30.2.1.1. Boundary Adaption Based on Number of Cells

The procedure for performing adaption based on the distance of a cell from the boundary in terms of the number of cells is as follows:

1. In the [Boundary Adaption Dialog Box](#) (p. 2276) ([Figure 30.3](#) (p. 1445)), select **Cell Distance** under **Options**, choose the boundary zones near which you want to refine cells in the **Boundary Zones** list, and click **Apply**.

This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Click the **Contours...** button to open the *Contours Dialog Box* (p. 2120).
 - a. Enable **Filled** contours, disable **Node Values**.
 - b. Select **Adaption...** and **Boundary Cell Distance** in the **Contours of** drop-down list.
 - c. Select the appropriate surfaces (3D only).
 - d. Click **Display** to see the location of cells with each value of boundary cell distance.

By displaying different ranges of values (as described in *Specifying the Range of Magnitudes Displayed* (p. 1510)), you can determine the cell distance of the cells you wish to adapt.

3. Set the **Number of Cells** to the desired value.
 - If you retain the default value of 1, only those cells that have edges (2D) or faces (3D) on the specified boundary zone(s) (i.e., those cells with a boundary cell distance of 1) will be marked or adapted.
 - If you increase the value to 2, cells with a boundary cell distance of 2 will also be marked/adapted, and so on.
4. (optional) If you want to set any adaption options (described in *Adapt/Controls...* (p. 2288)), click on the **Controls...** button to open the *Mesh Adaption Controls Dialog Box* (p. 2288).
5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in *Manipulating Adaption Registers* (p. 1459)), or click **Adapt** to perform the refinement immediately.

30.2.1.2. Boundary Adaption Based on Normal Distance

The procedure for performing refinement based on a cell's normal distance from the boundary (i.e., the distance between the centroid of a cell and the boundary) is as follows:

1. In the *Boundary Adaption Dialog Box* (p. 2276), select **Normal Distance** under **Options**, choose the boundary zones near which you want to refine cells in the **Boundary Zones** list, and click **Apply**.

This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Open the *Contours Dialog Box* (p. 2120) by clicking on the **Contours...** button.
 - a. Enable **Filled** contours, disable **Node Values**.
 - b. Choose **Adaption...** and **Boundary Normal Distance** in the **Contours of** drop-down list.
 - c. Select the appropriate surfaces (3D only).
 - d. Click **Display** to see the location of cells with each value of normal distance.

By displaying different ranges of values (as described in *Specifying the Range of Magnitudes Displayed* (p. 1510)), you can determine the normal distance of the cells you wish to adapt.

3. Set the **Distance Threshold** to the desired value. Cells with a normal distance to the selected boundary zone(s) less than or equal to this value will be marked or adapted.
4. (optional) If you want to set any adaption options (described in *Adapt/Controls...* (p. 2288)), click on the **Controls...** button to open the *Mesh Adaption Controls Dialog Box* (p. 2288).
5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in *Manipulating Adaption Registers* (p. 1459)), or click **Adapt** to perform the refinement immediately.

30.2.1.3. Boundary Adaption Based on Target Boundary Volume

This boundary adaption allows you to produce exponentially larger (or smaller) cells as you get further from the boundaries. The cells are marked for refinement based on the following equation:

$$V_n > V_{\text{boundary}} e^{\alpha d} \quad (30-1)$$

where V_n is the cell volume, V_{boundary} is the specified boundary volume (**Boundary Volume**), α is the exponential growth factor (**Growth Factor**), and d is the normal distance of the cell centroid from the selected boundaries. $V_{\text{boundary}} e^{\alpha d}$ is the target volume for a cell.

The procedure for this type of boundary refinement is as follows:

1. In the [Boundary Adaption Dialog Box \(p. 2276\)](#), select **Volume Distance** under **Options**, set the **Boundary Volume** and **Growth Factor** to the desired values, select the boundary zones in the **Boundary Zones** list where you want the **Boundary Volume** to be applied, and click **Apply**.

This operation is performed to fill the cell distance variable for each cell to be visualized in Step 2.

2. (optional) Open the [Contours Dialog Box \(p. 2120\)](#) by clicking the **Contours...** button.
 - a. Enable **Filled** contours, disable **Node Values**.
 - b. Choose **Adaption...** and **Boundary Normal Distance** in the **Contours of** drop-down list.
 - c. Select the appropriate surfaces (3D only).
 - d. Click **Display** to see the contours of the target volume.

By displaying different ranges of values (as described in [Specifying the Range of Magnitudes Displayed \(p. 1510\)](#)), you can determine the normal distance of the cells you wish to adapt.

You can modify the values of the inputs (**Boundary Volume**, **Growth Factor**, and/or **Boundary Zones**), click **Apply** in the **Boundary Adaption** dialog box, and then redisplay the contour plot to visualize the modified target volume distribution.

3. (optional) If you want to set any adaption options (described in [Adapt/Controls... \(p. 2288\)](#)), click on the **Controls...** button to open the [Mesh Adaption Controls Dialog Box \(p. 2288\)](#).
4. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in [Manipulating Adaption Registers \(p. 1459\)](#)), or click **Adapt** to perform the refinement immediately.

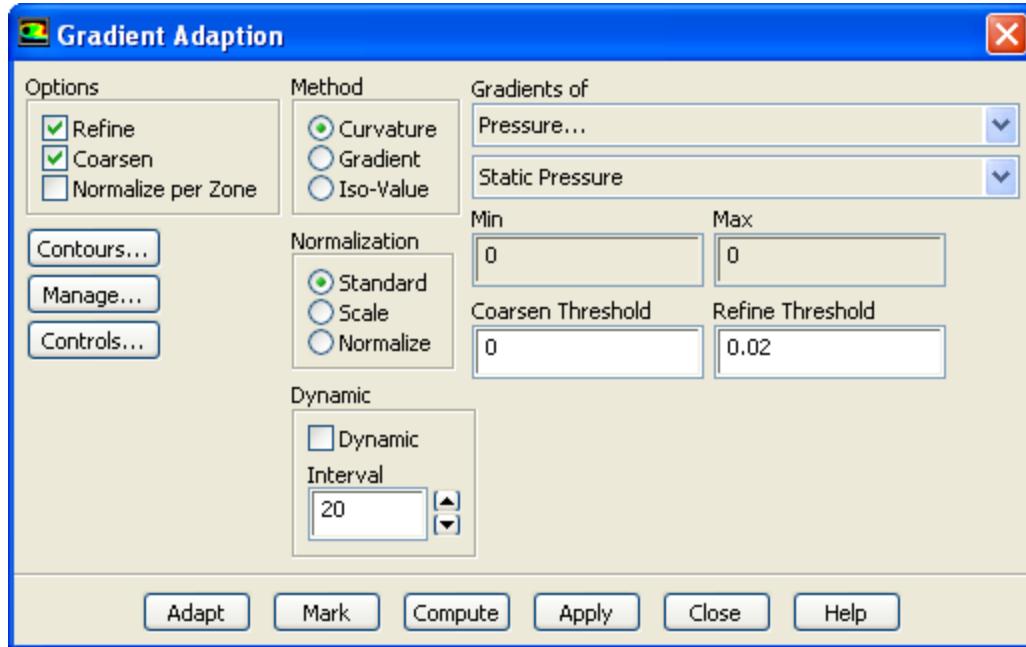

30.3. Gradient Adaption

This section describes how to perform gradient adaption. For more information, see [Gradient Adaption](#) in the [Theory Guide](#).

For additional information, please see the following section:

30.3.1. Performing Gradient Adaption

The [Gradient Adaption Dialog Box \(p. 2277\)](#) ([Figure 30.4 \(p. 1448\)](#)) allows you to perform gradient adaption.

Adapt → Gradient...**Figure 30.4 The Gradient Adaption Dialog Box**

The procedure for performing gradient adaption is as follows:

1. Select the appropriate adaption method.
 - **Curvature** is the default method, and is recommended for problems with smooth solutions.
 - **Gradient** is recommended for problems with strong shocks (e.g., supersonic inviscid flows).
 - **Iso-Value** is recommended for problems where derivatives are not helpful, or when you want to customize the adaption criterion (using custom field functions, user-defined scalars, etc.).
2. Select a **Normalization** method:
 - **Standard**, if normalization of the gradient or curvature is not to be performed.
 - **Scale**, if the gradient or curvature is to be scaled by the average value in the domain.
 - **Normalize**, if the gradient or curvature is to be scaled by the maximum value of the variable in the domain (i.e., the gradient or curvature is bounded by [0, 1]).

Using either scaling or normalization makes the setting of the refine and coarsen thresholds much simpler, and almost independent of the current solution and specific problem.

This is especially important when using the automated dynamic adaption process.

3. Select the required solution variable in the **Gradients of** drop-down list.
4. Click **Compute**.
5. Click **Contours...** to open the *Contours Dialog Box* (p. 2120).
 - a. Enable **Filled** contours, disable **Node Values**, and select **Adaption...** and **Existing Value** in the **Contours of** drop-down lists.
 - b. Select the appropriate surfaces (3D only).
 - c. Click **Display** to see the location of cells with each curvature value.

By displaying different ranges of values (as described in [Specifying the Range of Magnitudes Displayed \(p. 1510\)](#)), you can determine the range of curvatures for which you want to adapt cells.

If you are using normalization, the range for the curvatures of any variable will always be [0, 1].

6. Set the values for **Refine Threshold**.

Cells with gradient values above this value will be either marked or refined.

7. Select the **Normalize per Zone** option for cases where different flow conditions exist for different zones.

This approach of *zonal normalization* normalizes (i.e., scales) each zone of the domain, in contrast to normalization on the whole domain. This approach is useful for dynamic adaption (see [Dynamic Gradient Adaption \(p. 1449\)](#) for details), where you want to solve the flow problem involving different flow intensities in the different cell zones.

If you use gradient adaption for the whole domain, the small gradients may be neglected in comparison to large gradients depending on the adaption threshold. Activating **Normalize per Zone** in the [Gradient Adaption Dialog Box \(p. 2277\)](#) will scale or normalize each zone independently, which means the strongest gradient for each zone is considered separately for adaption of that zone.

Note

If you expect gradients of different intensities throughout the domain and you want to resolve them, separate the domain into different zones for precise zonal normalization. This approach is referred as zonal adaption.

8. If you want to coarsen the mesh, set the **Coarsen Threshold** to a non-zero value. Cells with gradient values below the specified value will be either marked or coarsened.
9. To set adaption options (described in [Adapt/Controls... \(p. 2288\)](#)), click **Controls...** to open the [Mesh Adaption Controls Dialog Box \(p. 2288\)](#).
10. To mark the cells for adaption (refinement/coarsening), click **Mark**. You can then place the cells in an adaption register, which can be manipulated (as described in [Manipulating Adaption Registers \(p. 1459\)](#)). To perform the adaption immediately, click **Adapt**.

Note

To disable refinement, coarsening, or marking for refinement/coarsening, disable the **Refine** or **Coarsen** option before marking or adapting.

30.4. Dynamic Gradient Adaption

This section describes how to perform dynamic gradient adaption. For more information, see [Dynamic Gradient Adaption](#) in the [Theory Guide](#).

For additional information, please see the following section:

[30.4.1. Dynamic Gradient Adaption Approach](#)

30.4.1. Dynamic Gradient Adaption Approach

The dynamic gradient adaption executes the gradient adaption automatically. Though all options of gradient adaption are valid for the dynamic gradient adaption, some specific settings are recommended:

In the **Gradient Adaption** dialog box:

- Enable the **Refine** and **Coarsen** options.
- The **Normalize per Zone** enables zonal normalization for the dynamic adaption. See [Performing Gradient Adaption \(p. 1447\)](#) (step 7 (p. 1449)) for details.
- For **Normalization**, use either the **Scale** or the **Normalize** option.

*The non-normalized values of the gradient or the curvature of a variable (obtained by selecting **Standard** for the **Normalization**) are generally strongly solution dependent, and therefore would require re-adjustment of the **Coarsen Threshold** and **Refine Threshold** as the solution proceeds.*

- For dynamic adaption, scaling is preferred if you wish to resolve regions of small values of the gradient (or curvature/isovalues) accurately, in addition to the region of highest gradient (or curvature/isovalues).

Scaling does not take very high values of the gradient or curvature into account to the degree that normalization does.

- The starting values for **Refine Threshold** and **Coarsen Threshold** are 1e10 and 0 respectively.

The more refinement you want, the smaller these values should be.

- Specify the **Interval** between two consecutive automatic mesh adaptions. Depending on whether you are performing a steady-state or a time-dependent solution, specify **Interval** in iterations or time steps, respectively.

This value depends on the type of problem solved and the time step used (where applicable). For steady-state problems, values of 100 or higher are reasonable. For time-dependent problems, values of 10 or lower are often required.

If you are using the density-based explicit solver with explicit transient formulation, your input will be in number of iterations.

In the **Mesh Adaption Controls** dialog box:

- Set values for **Min # of Cells**, **Max # of Cells**, **Max Level of Refine**, or **Min Cell Volume**.

The limits for the **Min # of Cells** and **Max # of Cells** can affect the **Coarsen Threshold** and **Refine Threshold** values. If either the **Min # of Cells** or the **Max # of Cells** are violated, the **Coarsen Threshold** or the **Refine Threshold** are adjusted to fulfill the limits for the **Min # of Cells** or the **Max # of Cells**.

- The default value for **Max Level of Refine** is 2, which is a good start for most problems. If required, you can increase this value.

Important

Even in a 2D problem, the default value of 2 can increase the number of cells by a factor of 16 in the adapted regions. A value of zero leaves this parameter unbounded: in this case, you should use a suitable limit for **Min Cell Volume**.

30.4.1.1. Examples of Dynamic Gradient Adaption

Example 1: Steady-state problem

Consider a supersonic flow over a blunt body. To determine the wave drag for such problem, first resolve the shock wave. Start with a coarse mesh and set up dynamic adaption. As you start iterating the solution, the solver will produce a blurred shock, probably in an incorrect location. After the adaptions, the shock will become sharper and move into the correct location.

Example 2: Time-dependent problem

Consider a traveling shock wave. To determine the precise pressure amplitudes and arrival times at a number of locations, you need to resolve the shock wave over the time, so that you can maintain the correct shock strength and its location. Dynamic adaption is efficient in this case, as it refines the mesh near the shock, and at the same time, it coarsens the mesh wherever needed.

30.5. Isovalue Adaption

This section describes how to perform isovalue adaption. For more information, see [Isovalue Adaption](#) in the [Theory Guide](#).

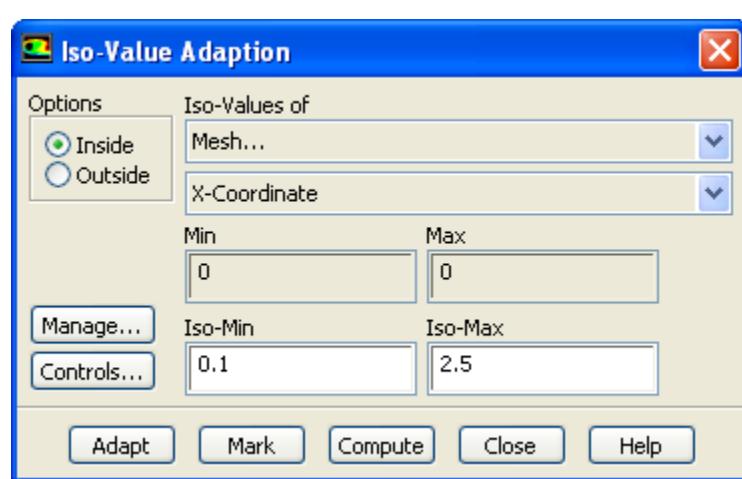

For additional information, please see the following section:

30.5.1. Performing Isovalue Adaption

You can perform isovalue adaption in the [Iso-Value Adaption Dialog Box](#) (p. 2280) (*Figure 30.5 (p. 1451)*).

Adapt → Iso-Value...

Figure 30.5 The Iso-Value Adaption Dialog Box

The general procedure for performing isovalue adaption is as follows:

1. Select the desired solution variable in the **Iso-Values of** drop-down lists and click **Compute** to update the **Min** and **Max** fields.
2. Choose the **Inside** or **Outside** option and set the **Iso-Min** and **Iso-Max** values.
 - If you choose **Inside**, cells with isovalue between **Iso-Min** and **Iso-Max** will be marked or refined.

- If you choose **Outside**, cells with isovalues less than **Iso-Min** or greater than **Iso-Max** will be marked or refined.
3. (optional) If you want to set any adaption options (described in [Adapt/Controls... \(p. 2288\)](#)), click the **Controls...** button to open the *Mesh Adaption Controls Dialog Box* (p. 2288).
 4. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in [Manipulating Adaption Registers \(p. 1459\)](#)), or click **Adapt** to perform the refinement immediately.

30.6. Region Adaption

This section describes how to perform region adaption. For more information, see [Region Adaption](#) in the [Theory Guide](#).

For additional information, please see the following section:

30.6.1. Performing Region Adaption

You will perform region adaption in the *Region Adaption Dialog Box* (p. 2281) ([Figure 30.6 \(p. 1452\)](#)).

Adapt → **Region...**

Figure 30.6 The Region Adaption Dialog Box

The procedure for performing isovalue adaption is as follows:

1. In the *Region Adaption Dialog Box* (p. 2281), select the **Inside** or **Outside** option.
 - If you choose **Inside**, cells with centroids within the specified region will be marked or refined.
 - If you choose **Outside**, cells with centroids outside the specified region will be marked or refined.
2. Specify the shape of the region.

In 2D, you may specify a **Quad** (i.e., a quadrilateral), **Circle**, or **Cylinder** by making a selection from the **Shape** group box. In 3D, your options include **Hex** (i.e., a hexahedron), **Sphere**, or **Cylinder**.

3. Define the region by entering values into the dialog box or by using the mouse.

In the dialog box, the inputs are as follows:

- To define a hexahedron or quadrilateral, enter the coordinates of two points defining the diagonal of the box.
For a hexahedron, define **X Min**, **Y Min**, and **Z Min**, as well as **X Max**, **Y Max**, and **Z Max**. For a quadrilateral, define **X Min** and **Y Min**, as well as **X Max** and **Y Max**.
- To define a sphere or circle, enter the values for the **Radius** and the coordinates of its center: **X Center**, **Y Center**, and **Z Center** for a sphere, or **X Center** and **Y Center** for a circle.
- To define a cylinder, enter the value for the **Radius** and the minimum and maximum coordinates defining the cylinder axis: **X-Axis Min**, **Y-Axis Min**, and **Z-Axis Min**, as well as **X-Axis Max**, **Y-Axis Max**, and **Z-Axis Max** for 3D, or **X-Axis Min** and **Y-Axis Min**, as well as **X-Axis Max** and **Y-Axis Max** for 2D. In 2D, this will be the width of the resulting rectangle.

4. To define the region using the mouse, click on the **Select Points with Mouse** button. Using the right mouse button, select the input coordinates from a display of the mesh or solution field. After selecting the points, the values will be loaded automatically into the appropriate fields in the dialog box. See [Controlling the Mouse Button Functions \(p. 1548\)](#) for details about mouse button functions.

You have the option of editing these values before marking or adapting.

- To define a hexahedron or quadrilateral, select the two points of the diagonal in any order.
 - To define a sphere or circle, first select the location of the centroid and then select a point that lies on the sphere/circle (i.e., a point that is one radius away from the centroid).
 - To define a cylinder, first select the two points that define the cylinder axis and then select a point that is one radius away from the axis.
5. (optional) If you want to set any adaption options (described in [Adapt/Controls... \(p. 2288\)](#)), click the **Controls...** button to open the [Mesh Adaption Controls Dialog Box \(p. 2288\)](#).
 6. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated as described in [Manipulating Adaption Registers \(p. 1459\)](#)), or click **Adapt** to perform the refinement immediately.

30.7. Volume Adaption

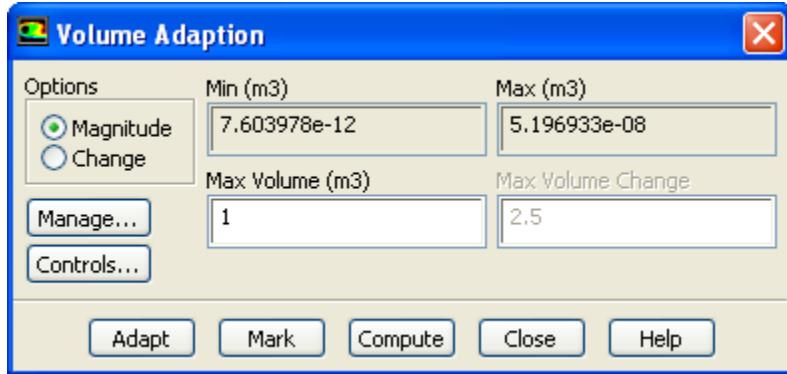

This section describes how to perform volume adaption. For more information, see [Volume Adaption](#) in the [Theory Guide](#).

For additional information, please see the following section:

30.7.1. Performing Volume Adaption

You will perform volume adaption in the [Volume Adaption Dialog Box \(p. 2283\)](#) ([Figure 30.7 \(p. 1454\)](#)).

Adapt → Volume...

Figure 30.7 The Volume Adaption Dialog Box

The procedure for performing volume adaption is as follows:

1. In the *Volume Adaption Dialog Box* (p. 2283), specify whether you want to adapt based on volume magnitude or volume change by selecting the **Magnitude** or **Change** option.
2. Click **Compute** to update the **Min** and **Max** fields. These fields will show the range of cell volumes or cell volume changes (defined in *Volume Adaption Approach* in the Theory Guide), depending on your selection in step 1.
3. Set the **Max Volume** or **Max Volume Change** value.
 - a. If you have chosen to adapt based on volume **Magnitude**, cells that have volumes greater than **Max Volume** will be marked or refined.
 - b. If you are adapting based on volume **Change**, cells with volume changes greater than **Max Volume Change** will be marked or refined.
4. (optional) If you want to set any adaption options (described in *Adapt/Controls...* (p. 2288)), click the **Controls...** button to open the *Mesh Adaption Controls Dialog Box* (p. 2288).
5. Click **Mark** to mark the cells for refinement by placing them in an adaption register (which can be manipulated, as described in *Manipulating Adaption Registers* (p. 1459)), or click **Adapt** to perform the refinement immediately.

30.8. Yplus/Ystar Adaption

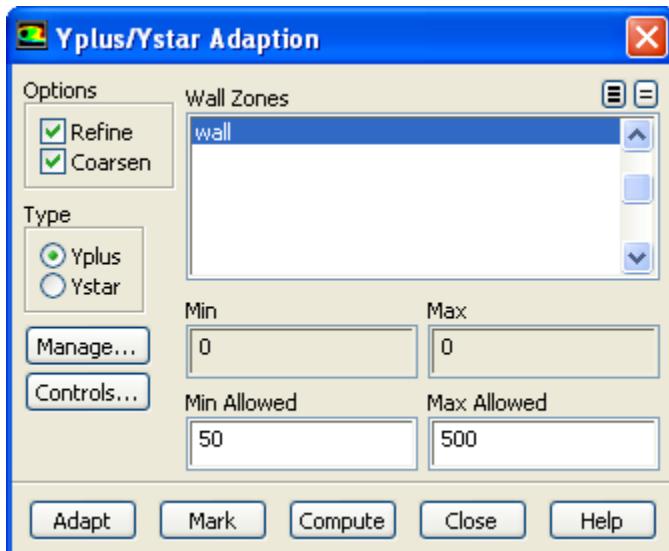

This section describes how to perform Yplus/Ystar adaption. For more information, see *Yplus/Ystar Adaption* in the *Theory Guide*.

For additional information, please see the following section:

30.8.1. Performing Yplus or Ystar Adaption

You will perform Yplus or Ystar adaption in the *Yplus/Ystar Adaption Dialog Box* (p. 2284) (*Figure 30.8* (p. 1455)).

Adapt → Yplus/Ystar...

Figure 30.8 The Yplus/Ystar Adaption Dialog Box

The procedure for performing y^+ or y^* adaption is as follows:

1. In the *Yplus/Ystar Adaption Dialog Box* (p. 2284), select **Yplus** or **Ystar** as the adaption **Type**.
 - Select **Yplus** if you are using the enhanced wall treatment.
 - If you are using wall functions, you can select either type.
2. Select the wall zones for which you want boundary cells to be marked or adapted in the **Wall Zones** list, and click **Compute** to update the **Min** and **Max** fields. The values displayed are the minimum and maximum values for all wall zones, not just of those selected.
3. Set the **Min Allowed** and **Max Allowed**. Cells with y^+ or y^* values below **Min Allowed** will be coarsened or marked for coarsening, and cells with y^+ or y^* values above **Max Allowed** will be refined or marked for refinement.
4. (optional) If you want to set any adaption options (described in *Adapt/Controls...* (p. 2288)), click the **Controls...** button to open the *Mesh Adaption Controls Dialog Box* (p. 2288).
5. Click **Mark** to mark the cells for adaption (refinement/coarsening) by placing them in an adaption register (which can be manipulated as described in *Manipulating Adaption Registers* (p. 1459)), or click **Adapt** to perform the adaption immediately.

To disable refinement or coarsening, or marking for refinement or coarsening, turn off the **Refine** or **Coarsen** option before marking or adapting.

30.9. Anisotropic Adaption

This section describes how to perform anisotropic adaption. For more information, see *Anisotropic Adaption* in the *Theory Guide*.

For additional information, please see the following sections:

- [30.9.1. Limitations of Anisotropic Adaption](#)
- [30.9.2. Performing Anisotropic Adaption](#)

30.9.1. Limitations of Anisotropic Adaption

Since anisotropic adaption is available only for specific cell types, the following limitations exist:

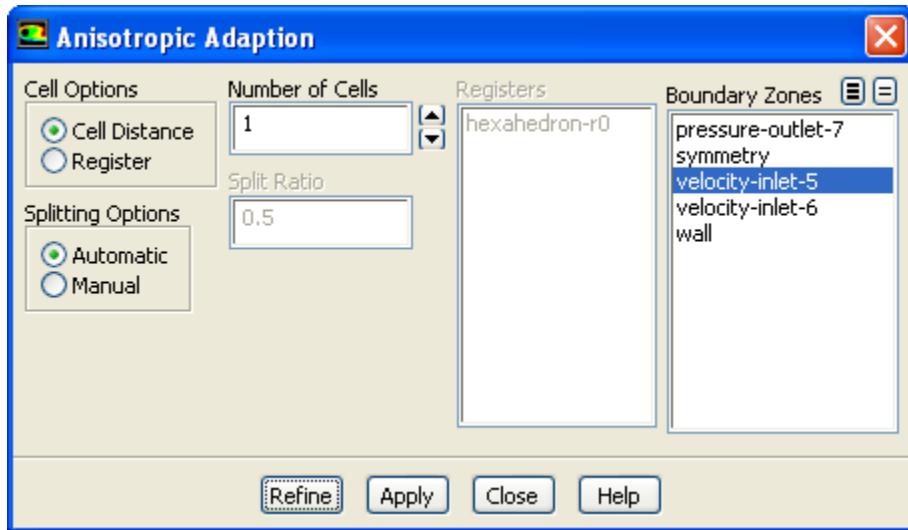

- It is only available in 3D.
- It only works for hexahedral cells or prism cells.
- Each cell can only be split into two, with a given splitting ratio in the normal direction of the boundary face. Multiple layers can be achieved by multiple refinement.
- Each cell to be split can only be reached once from any of the boundary faces; otherwise, the refinement will not be processed.
- Unlike other adaption functionalities, the subdivided cells cannot be coarsened again, because all the cells that are adjacent to the refined cells are converted into polyhedral cells.

30.9.2. Performing Anisotropic Adaption

You will perform anisotropic adaption in the *Anisotropic Adaption Dialog Box* (p. 2286) (*Figure 30.9* (p. 1456)).

Adapt → **Anisotropic...**

Figure 30.9 The Anisotropic Adaption Dialog Box

The procedure for performing anisotropic adaption is as follows:

1. In the *Anisotropic Adaption Dialog Box* (p. 2286), select **Cell Distance** or **Register** from the **Cell Options** group box. This allows you to control the marking of boundary layer cells. Select **Cell Distance** and enter the **Number of Cells** to be adapted and marked using the distance from the boundary zone. Select **Register** to adapt and mark cells using an existing **Register**.
2. The **Splitting Options** control how the splitting ratio is computed. It is defined as follows:

$$\text{splitting ratio} = \frac{\text{height of the splitting point to the base face}}{\text{original height of the cell}}$$

By default, **Automatic** is selected, resulting in the ratio being computed automatically from the mesh. If you selected **Manual**, enter the desired **Split Ratio**. If you choose to compute the split ratio automatically, the split ratio of the first layer is computed, and it may be 0.5 if the original

cells are uniformly distributed, resulting in the height of the first layer being the same as the height of the second layer.

Important

Note that the **Split Ratio** that you enter is only applicable to the first layer, and all the other layers are split with a ratio of 0.5.

3. For the **Cell Distance** option, one or more boundary face zones must be selected before marking the cells for refinement.
4. For the **Register** option, select a register in the list. Note that one or more boundary face zones must be selected before doing the refinement.
5. Click **Refine** to refine the marked cells.

30.10. Geometry-Based Adaption

This section describes how to perform geometry-based adaption. For more information, see [Geometry-Based Adaption](#) in the Theory Guide.

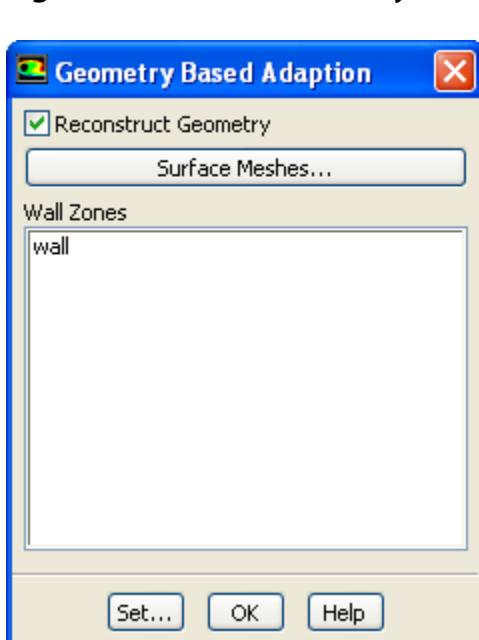

For additional information, please see the following section:

[30.10.1. Performing Geometry-Based Adaption](#)

The [Geometry Based Adaption Dialog Box \(p. 2290\)](#) (*Figure 30.10 (p. 1457)*) allows you to reconstruct the geometry while performing boundary adaption.

Adapt → Geometry...

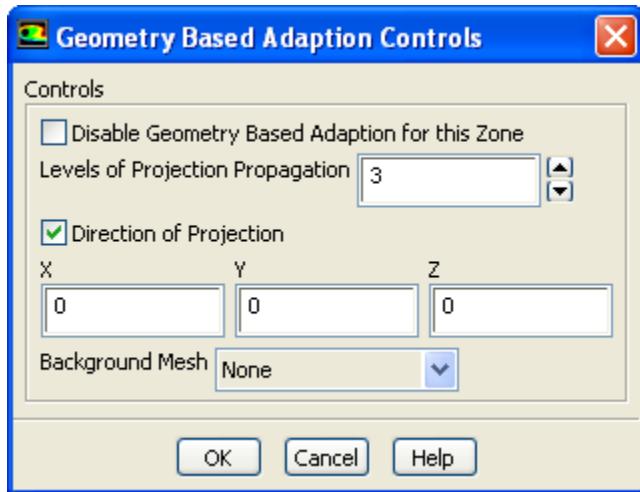

Figure 30.10 The Geometry Based Adaption Dialog Box

The procedure for performing geometry-based adaption is as follows:

1. Enable the **Reconstruct Geometry** option.
2. Under **Wall Zones**, select the zone you want to adapt and click **Set....** The [Geometry Based Adaption Controls Dialog Box \(p. 2291\)](#) will open.

Figure 30.11 The Geometry Based Adaption Controls Dialog Box

In the [Geometry Based Adaption Controls Dialog Box \(p. 2291\)](#), set the following parameters:

- Specify **Levels of Projection Propagation** to indicate the number of layers of the nodes you want to project.
- Enable **Direction of Projection** and specify the directions in which you want to project the nodes.

This will activate the parameters X, Y, and Z. If you want node projection in the X direction, specify X=1. If you do not activate this option, the node projection will take place at the nearest point.

- (optional) If you have a fine surface mesh for the geometry, you can use the **Background Mesh** option to load the surface mesh as a background mesh. This will project the nodes based on the background mesh and reconstruct the geometry more accurately.
- To disable the geometry reconstruction for any zone in the domain, activate **Disable Geometry Based Adaption for this Zone**.

3. To disable geometry-based adaption for the whole domain, disable **Reconstruct Geometry**.

After setting the parameters for geometry-based adaption, proceed to perform mesh adaption.

30.11. Registers

This section describes how to use registers for adaption. For more information, see [Registers](#) in the [Theory Guide](#).

For additional information, please see the following sections:

- 30.11.1. Manipulating Adaption Registers
- 30.11.2. Modifying Adaption Marks
- 30.11.3. Displaying Registers
- 30.11.4. Adapting to Registers

30.11.1. Manipulating Adaption Registers

You can manipulate, delete, and display adaption registers by marking cells for adaption. Since these registers are used to adapt the mesh, the ability to manipulate them provides additional control over the adaption process.

Management of adaption registers is performed in the [Manage Adaption Registers Dialog Box \(p. 2287\)](#) ([Figure 30.12 \(p. 1459\)](#)). You can also open this dialog box by clicking on the **Manage...** button in any of the adaption dialog boxes.

Adapt → Manage...

Figure 30.12 The Manage Adaption Registers Dialog Box

You can modify and manipulate adaption registers by:

- changing the register types
- combining the registers
- deleting the registers

30.11.1.1. Changing Register Types

If the adaption register is converted to a mask, the cells marked for refinement are ACTIVE, and all other cells are INACTIVE (i.e., the cells marked for coarsening are ignored). Generally, the adaption registers converted to masks are those that are generated by adaption functions that mark cells exclusively for refinement, such as region or isovalue adaption functions. The other major difference between adaption and mask registers is the manner in which they are combined.

To change the type of one or more registers from adaption to mask, or vice versa, do the following:

1. Choose the register(s) in the **Registers** list.
2. Click the **Change Type** button under **Register Actions**.

The new type of the register (if multiple registers are selected, the most recently selected or deselected register) will be shown as the **Type** under **Register Info**. Select each register individually to see what its current type is.

30.11.1.2. Combining Registers

After the individual adaption registers have been created and appropriately modified, they are combined to create hybrid adaption functions.

1. Any number of registers can be combined in the following manner:
 - All adaption registers are combined into a new adaption register.
 - All mask registers are combined into a new mask register.
 - The new adaption and mask registers are combined.
2. Any number of adaption registers can be combined in the following manner:
 - If the cell is marked for refinement in any of the registers, mark the cell for refinement in the new register (bitwise OR).
 - If the cell is marked for coarsening in all of the registers, mark the cell for coarsening in the new register (bitwise AND).
3. The mask registers are combined in a manner similar to the refinement marks. If any cell is marked ACTIVE, the cell in the new register is marked ACTIVE (bitwise OR).
4. Finally, in the combination of an adaption and mask register, only cells that are marked in the mask register can have an adaption mark in the combined register (bitwise AND).

For example, creating an adaption function based on pressure gradient may generate cells marked for refinement and coarsening throughout the entire solution domain. If this register is then combined with a mask register created from cells marked inside a sphere, only the cells inside the sphere will be marked for refinement or coarsening in the new register.

Note

The effect of masks depends on the order in which they are applied.

For example, consider two adjacent, circular masks. Applying one mask to the adaption register and then applying the other mask to the result of the first combination would give a much different result than applying the combination of the two masks to the initial adaption register. The second combination results in a greater possible number of marked cells.

To combine two or more registers, do the following:

1. Choose the registers in the **Registers** list.
2. Click the **Combine** button under **Register Actions**.

The selected registers will remain intact, and the register(s) resulting from the combination will be added to the **Registers** list. In some instances, three new registers may be created:

- a combination of the adaption registers
- a combination of the mask registers
- a combination of the two combined registers

For more information about combining registers, see [Adaption Registers](#) in the [Theory Guide](#).

30.11.1.3. Deleting Registers

The primary reason for deleting registers is to discard unwanted adaption registers. This will reduce confusion and the possibility of generating undesired results by selecting these discarded registers. In addition, only 32 adaption registers can exist at one time. Therefore, you should discard unwanted registers to make room for new ones. You can delete any number of adaption registers.

To permanently remove one or more registers, do the following:

1. Choose the register(s) in the **Registers** list.
2. Click the **Delete** button under **Register Actions**.

30.11.2. Modifying Adaption Marks

The adaption marks are the identifiers that designate whether a cell should be refined, coarsened, or neutral. The operations used for modifying the adaption marks are:

- **Exchange:** This changes the cells marked for refinement into cells marked for coarsening, and all cells originally marked for coarsening into cells marked for refinement. This operation is applied to adaption registers that have only refinement marks.

For example, the exchange operation can be used to coarsen a rectangular region. First, create an adaption register that marks a rectangular region of cells for refinement. Then use the **Exchange** operation to modify the cell marks, creating a rectangular region with cells marked for coarsening.

- **Invert:** This operation can only be used with mask registers. It toggles the mask markings, i.e., all cells marked ACTIVE are switched to INACTIVE, and all cells marked INACTIVE are switched to ACTIVE.

For example, if you generate a mask that defines a circular region, you can quickly modify the mask to define the region outside of the circle using the **Invert** operation.

- **Limit:** This operation applies the present adaption volume limit to the selected adaption register. For information on adaption limits, see [Mesh Adaption Controls](#) (p. 1463). You generally use this operation to determine the effect of the present limits on the adaption process. You can use the volume limit to create a uniform mesh by setting the limit to refine only the large cells. After all the cells have reached a uniform size, you can continue the refinement process to the desired resolution.
- **Fill:** This operation marks the cells in the adaption register that are not marked for refinement. You can use the **Fill** operation to combine multiple registers to make a new register.

Note the following:

- When you combine registers, a cell will be marked for coarsening only if it is marked for coarsening in all of the registers.
- If you create an adaption register with an operation that only marks cells for refinement, but you do not want to prohibit coarsening, use the **Fill** operation before combining the register with any other registers.

The process for modifying adaption marks is as follows:

1. Choose the register(s) in the **Registers** list.
2. Click the **Exchange, Invert, Limit, or Fill** button under **Mark Actions**.

30.11.3. Displaying Registers

Viewing the cell markings is often helpful in the process of creating hybrid adaption functions. You can plot a marker at the cell centroid and/or a wireframe of the cell to view the state of the cell. By default, the cells marked for refinement are colored in red, and the cells marked for coarsening are marked in cyan. In addition, cells marked ACTIVE in a mask register are also colored red. These are the cells that are marked for adaption, but the final number of cells added or subtracted from the mesh depends on the adaption limits and the mesh characteristics.

To display a register, do the following:

1. Choose the register in the **Registers** list.
2. Set the display options by clicking on the **Options...** button.
3. Click the **Display** button.

30.11.3.1. Adaption Display Options

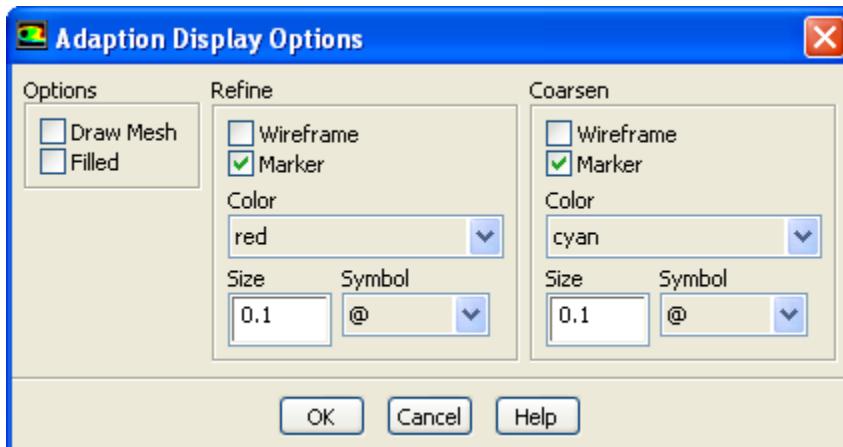

Various aspects of the adaption register display can be modified, such as the wireframe visibility and shading, marker visibility, color, size, and symbol. Also, you can select either surface or zone meshes for the display.

The adaption register display capability allows you to view the cells that are flagged for adaption.

- Depending on the dimension of the problem and the number of flagged cells, you can customize the adaption display options. The most common method for viewing flagged cells in 2D is to draw the mesh and filled wireframes, but this is impractical in 3D. In three dimensions, you can plot the centroid markers of the cells with the mesh of selected boundary zones.
- You can use markers and/or wireframes to display the flagged cells in an adaption or mask register. The marker is a symbol placed at the centroid of the cell. There is a refine marker and a coarsen marker. You can change the symbol, color, and size of these markers. A wireframe is composed of the edges of the triangle or tetrahedron. Its color is the same as the respective marker color, and can be filled, if required.
- Portions of the mesh can be drawn with the marker symbols or wireframes to aid in evaluating the location of marked cells.

All of these options are set in the [Adaption Display Options Dialog Box \(p. 2292\)](#) ([Figure 30.13 \(p. 1463\)](#)). You can also open this dialog box by clicking on the **Options...** button in the [Manage Adaption Registers Dialog Box \(p. 2287\)](#).

Adapt → Display Options...

Figure 30.13 The Adaption Display Options Dialog Box

- To enable or disable the display of wireframes for cells marked for refinement/coarsening, turn the **Wireframe** option on or off under **Refine** and/or **Coarsen**. To draw filled wireframes (i.e., using a solid color, instead of the outline) turn on the **Filled** option.
- To enable or disable the display of markers for cells marked for refinement/coarsening, turn the **Marker** option on or off under **Refine** and/or **Coarsen**. Use markers to specify their size in the **Size** field, and their symbol in the **Symbol** drop-down list.
- To change the color of the refine or coarsen markers/wireframes, select a new color in the **Color** drop-down list under **Refine** or **Coarsen**. By default, refine markers/wireframes are red and coarsen markers/wireframes are cyan.
- To include portions of the mesh in the register display, enable the **Draw Mesh** option. The [Mesh Display Dialog Box \(p. 1767\)](#) will open automatically, where you can set the mesh display parameters. When you click **Display** in the [Manage Adaption Registers Dialog Box \(p. 2287\)](#), the mesh display, as defined in the [Mesh Display Dialog Box \(p. 1767\)](#), will be included in the register display.

30.11.4. Adapting to Registers

These register tools provide you with the ability to create hybrid adaption functions customized to your flow-field application. The customized adaption function is used to direct the refinement and coarsening of the mesh.

To perform the adaption, follow these steps:

1. Choose the register in the **Registers** list.
2. Click the **Adapt** button.

30.12. Mesh Adaption Controls

ANSYS FLUENT allows you to:

- Place restrictions on the cell zones.
- Limit adaption by cell volume or volume weight.
- Limit the total number of cells that can be produced from the adaption process.
- Modify the intensity of the volume weighting in the gradient function.

- Restrict the adaption process to refinement and/or coarsening, and control which nodes are eligible for possible elimination from the mesh during coarsening.

The parameters controlling the aspects of adaption are set in the *Mesh Adaption Controls Dialog Box* (p. 2288) (*Figure 30.14* (p. 1464)).

You can open this dialog box by using the **Adapt/Controls...** menu item or by clicking the **Controls...** button in any of the adaption dialog boxes.

Adapt → Controls...

Figure 30.14 The Mesh Adaption Controls Dialog Box

Note

Write a case and data file before starting the adaption process. Then, if you generate an undesirable mesh, you can restart the process with the saved files.

For additional information, please see the following sections:

- 30.12.1. Limiting Adaption by Zone
- 30.12.2. Limiting Adaption by Cell Volume or Volume Weight
- 30.12.3. Limiting the Total Number of Cells
- 30.12.4. Controlling the Levels of Refinement During Hanging Node Adaption

30.12.1. Limiting Adaption by Zone

You can limit the adaption process to specified cell zones. The cells composing the fluid and solid regions of the analysis generally have very different resolution requirements and error indicators. Limiting the adaption to a specific cell zone and use different adaption functions to create the optimal mesh.

To limit the adaption to a particular cell zone (or to particular cell zones), select the cell zones in which you want to perform adaption in the **Zones** list. By default, adaption will be performed in all cell zones.

30.12.2. Limiting Adaption by Cell Volume or Volume Weight

The minimum cell volume limit restricts the refinement process to cells with volumes greater than the limit. Use this to initiate the refinement process on larger cells, gradually reducing the limit to create a uniform cell size distribution. Set this limit in the **Min Cell Volume** field. The input that you will give in this field for a 2D axisymmetric problem will be interpreted as the minimum cell area.

In addition, the gradient volume weight can be modified. A value of zero eliminates volume weighting, a value of unity uses the entire volume, and values between 0 and 1 scale the volume weighting. Set this value in the **Volume Weight** field. For more information, see [Gradient Adaption Approach](#) in the Theory Guide.

30.12.3. Limiting the Total Number of Cells

The maximum number of cells is a restriction that prevents ANSYS FLUENT from creating more cells than required for the present analysis. In addition, it saves the time you would spend waiting for the mesh adaption process to complete the creation of these cells. However, this premature termination of the refinement process can produce undesirable mesh quality depending on the order in which the cells were visited, which is based on the cell arrangement in memory (random).

During the dynamic gradient adaption, the resulting number of cells after adaption is estimated. If this number exceeds the maximum number of cells, both the **Coarsen Threshold** and the **Refine Threshold** are updated. This is done to ensure the best possible mesh resolution with the specified number of cells. You can also specify the minimum number of cells. This is helpful if strong structures of the flow that were resolved with the adaption vanished (e.g., left the domain) and you want to resolve the remaining weaker ones. This would otherwise require modifying the **Coarsen Threshold** and the **Refine Threshold**.

You can set the total number of cells allowed in the mesh in the **Max # of Cells** field. The minimum number of cells in the mesh can be set in the **Min # of Cells** field. The default values of zero places no limits on the number of cells.

30.12.4. Controlling the Levels of Refinement During Hanging Node Adaption

You can control the number of levels of refinement used to split cells during nonconformal adaption by setting the **Max Level of Refine**. The default value of 2 is a good start for most problems. If this is not sufficient, you can increase this value.

Note

Even in a 2D problem, the default value of 2 can increase the number of cells by a factor of 16 in the adapted regions.

A value of zero leaves this parameter unbounded, and you should use a suitable limit for **Min Cell Volume**. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the Theory Guide. For guidelines for limiting cell sizes and number of cells during dynamic gradient adaption, see [Dynamic Gradient Adaption Approach](#) (p. 1450).

30.13. Improving the Mesh by Smoothing and Swapping

Smoothing and face swapping are tools that complement mesh adaption by increasing the quality of the final numerical mesh. Smoothing repositions the nodes, and face swapping modifies the cell connectivity to achieve these improvements in quality.

Important

Face swapping is applicable only to meshes with triangular or tetrahedral cells.

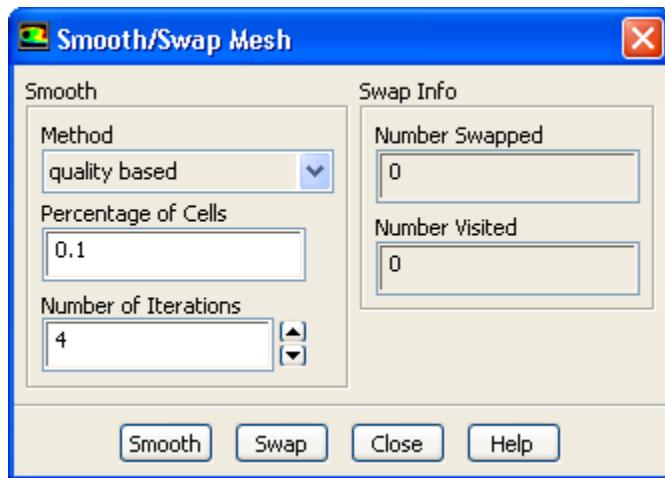

Important

Face swapping and most methods of smoothing are available only for serial cases; only quality-based smoothing can be used for parallel cases.

Both smoothing and swapping are performed using the *Smooth/Swap Mesh Dialog Box* (p. 2293) (*Figure 30.15* (p. 1466)).

Adapt → Smooth/Swap...

Figure 30.15 The Smooth/Swap Mesh Dialog Box

For additional information, please see the following sections:

- [30.13.1. Smoothing](#)
- [30.13.2. Face Swapping](#)
- [30.13.3. Combining Skewness-Based Smoothing and Face Swapping](#)

30.13.1. Smoothing

The three smoothing methods that are available in ANSYS FLUENT are:

- quality-based smoothing
 - This method is recommended for all types of meshes.
- Laplacian smoothing

This method can be applied to all types of meshes, but it is recommended to use it for quadrilateral and hexahedral meshes.

- skewness-based smoothing

This method is recommended for triangular and tetrahedral meshes, and can be used alternatively with face swapping (see [Combining Skewness-Based Smoothing and Face Swapping \(p. 1472\)](#)).

30.13.1.1. Quality-Based Smoothing

When you use the quality-based smoothing method, ANSYS FLUENT will divide the mesh into a number of “bins”, each of which contain a certain number of cells. Improvements are attempted on the cells in those bins that exhibit the lowest orthogonal quality (as defined in [Mesh Quality \(p. 145\)](#)). As part of this method, you specify the percentage of the total number of cells, in order to determine how many bins are modified.

Note that the method employed during quality-based smoothing is similar to when you use the `mesh/repair-improve/improve` text command. The advantage of using the **Smooth/Swap Mesh** dialog box rather than the text command is that you can control the percentage of the cells that ANSYS FLUENT attempts to improve.

To perform quality-based smoothing, do the following steps:

- In the [Smooth/Swap Mesh Dialog Box \(p. 2293\)](#) ([Figure 30.15 \(p. 1466\)](#)), select **quality based** in the **Method** drop-down list in the **Smooth** group box.
- Enter the **Percentage of Cells** to which you want improvements made.

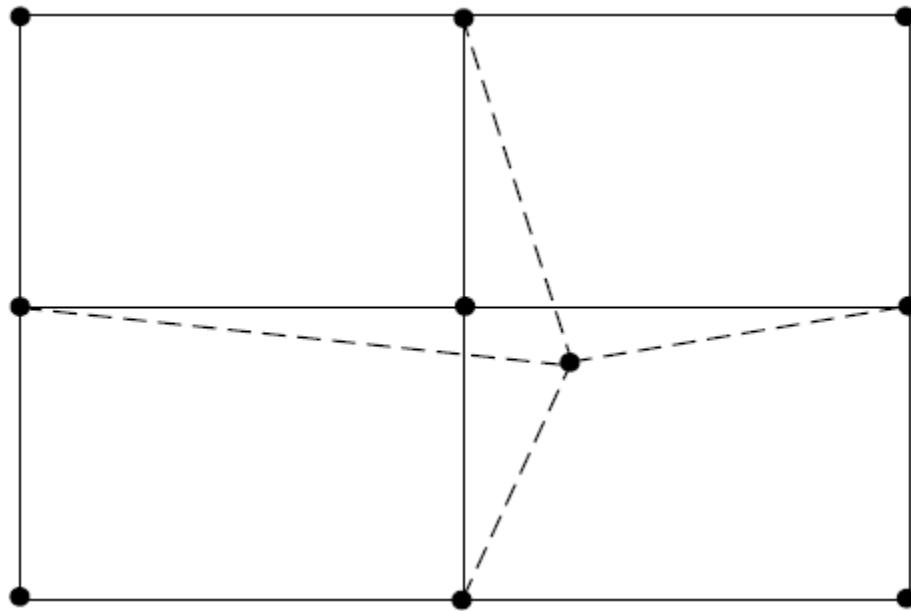

Important

Quality-based smoothing will be CPU intensive if you specify a large value for the **Percentage of Cells**. It is recommended that you enter a small value initially, and then perform the smoothing process multiple times, if necessary. Note that the maximum percentage allowed is 10%.

- Specify the number of successive smoothing sweeps to be performed on the mesh in the **Number of Iterations** number-entry box. The default value is 4.
- Click the **Smooth** button.

30.13.1.2. Laplacian Smoothing

When you use this method, a Laplacian smoothing operator is applied to the unstructured mesh to re-position nodes. The new node position is the average of the positions of its node neighbors. The computed node position increment is multiplied by the relaxation factor (which is set to a value between 0.0 and 1.0). A value of zero for the relaxation factor results in no movement of the node, and a value of unity results in movement equivalent to the entire computed increment. [Figure 30.16 \(p. 1468\)](#) illustrates the new node position for a typical configuration of quadrilateral cells. The dashed line is the original mesh and the solid line is the final mesh.

Figure 30.16 Result of Smoothing Operator on Node Position

This repositioning strategy improves the skewness of the mesh, but relaxes the clustering of node points. In extreme circumstances, the present operator may create mesh lines that cross over the boundary, creating negative cell volumes. This is most likely to occur near sharp or coarsely resolved convex corners, especially if you perform multiple smoothing operations with a large relaxation factor. [Figure 30.17 \(p. 1468\)](#) illustrates an initial tetrahedral mesh before one unrelaxed smoothing iteration creates mesh lines that cross over each other ([Figure 30.18 \(p. 1469\)](#)).

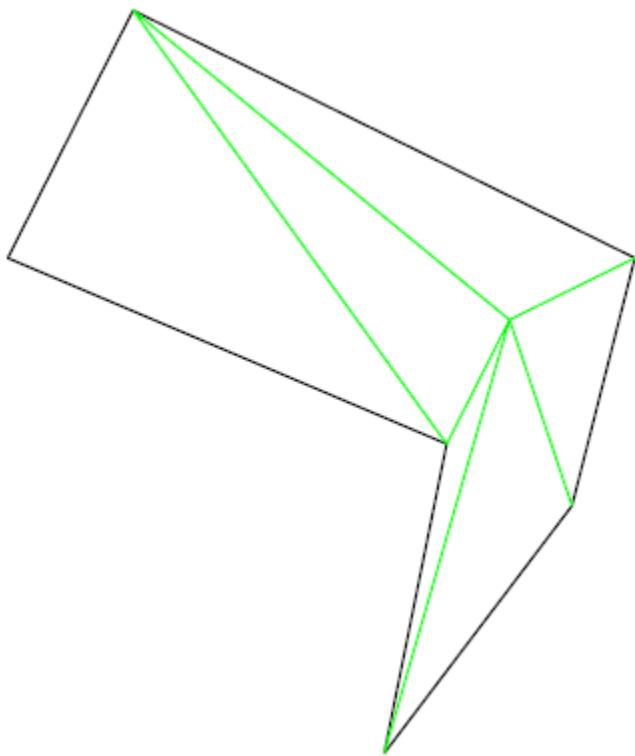

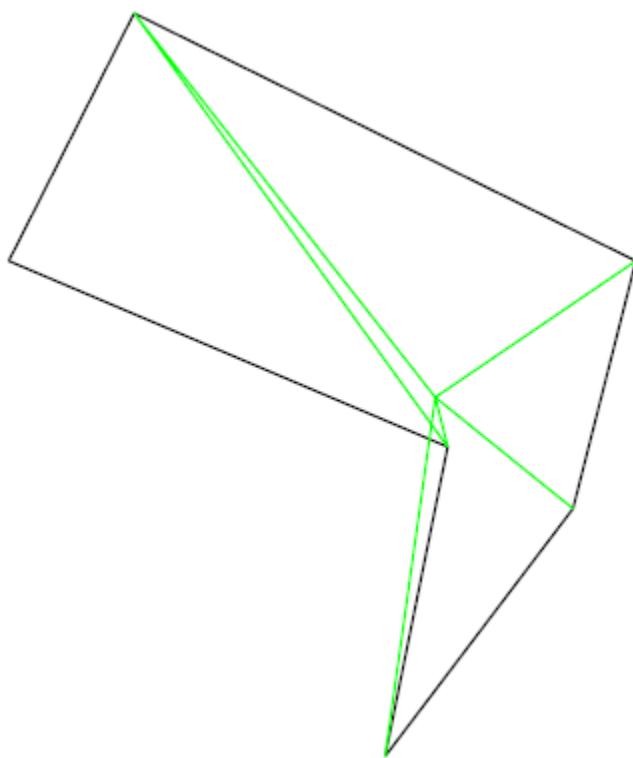

Figure 30.17 Initial Mesh Before Smoothing Operation

Figure 30.18 Mesh Smoothing Causing Mesh-Line Crossing

The default smoothing parameters are designed to improve mesh quality with minimal adverse effects, but it is recommended that you save a case file before smoothing the mesh. If you apply a conservative relaxation factor and start with a good quality initial mesh, the frequency of failure due to smoothing is extremely low in two dimensions. However, corruption of the mesh topology occurs much more frequently in three dimensions, particularly with tetrahedral meshes.

The smoothing operator can also be applied repeatedly, but as the number of smoothing sweeps increase, the node points have a tendency to pull away from boundaries and the mesh tends to lose any clustering characteristics.

To perform Laplacian smoothing, do the following steps:

1. In the *Smooth/Swap Mesh Dialog Box* (p. 2293) (*Figure 30.15* (p. 1466)), select **laplace** from the **Method** drop-down list in the **Smooth** group box.
2. Set the factor by which to multiply the computed position increment for the node in the **Relaxation Factor** field. The lower the factor, the more reduction in node movement.
3. Specify the number of successive smoothing sweeps to be performed on the mesh in the **Number of Iterations** field. The default value is 4.
4. Click the **Smooth** button.

30.13.1.3. Skewness-Based Smoothing

When you use skewness-based smoothing, ANSYS FLUENT applies a smoothing operator to the mesh, repositioning interior nodes to lower the maximum skewness of the mesh. ANSYS FLUENT will try to move interior nodes to improve the skewness of cells with skewness greater than the specified “skewness

threshold." This process can be very time consuming, so perform smoothing only on cells with high skewness.

Improved results can be obtained by smoothing the nodes several times. There are internal checks that will prevent a node from being moved if moving it causes the maximum skewness to increase, but it is common for the skewness of some cells to increase when a cell with a higher skewness is being improved. Thus, you may see the average skewness increase while the maximum skewness is decreasing.

Important

Carefully consider whether the improvements to the mesh due to a decrease in the maximum skewness are worth the potential increase in the average skewness. Performing smoothing only on cells with very high skewness (e.g., 0.8 or 0.9) may reduce the adverse effects on the average skewness.

To perform skewness-based smoothing, do the following:

1. In the *Smooth/Swap Mesh Dialog Box* (p. 2293) (*Figure 30.15* (p. 1466)), select **skewness** from the **Method** drop-down list in the **Smooth** group box.
2. Set the minimum cell skewness value for which node smoothing will be attempted in the **Skewness Threshold** field. ANSYS FLUENT will try to move interior nodes to improve the skewness of cells with skewness greater than this value. By default, **Skewness Threshold** is set to 0.4 for 2D and 0.8 for 3D.
3. Specify the number of successive smoothing sweeps to be performed on the mesh in the **Number of Iterations** field. The default value is 4.
4. Click the **Smooth** button.

30.13.2. Face Swapping

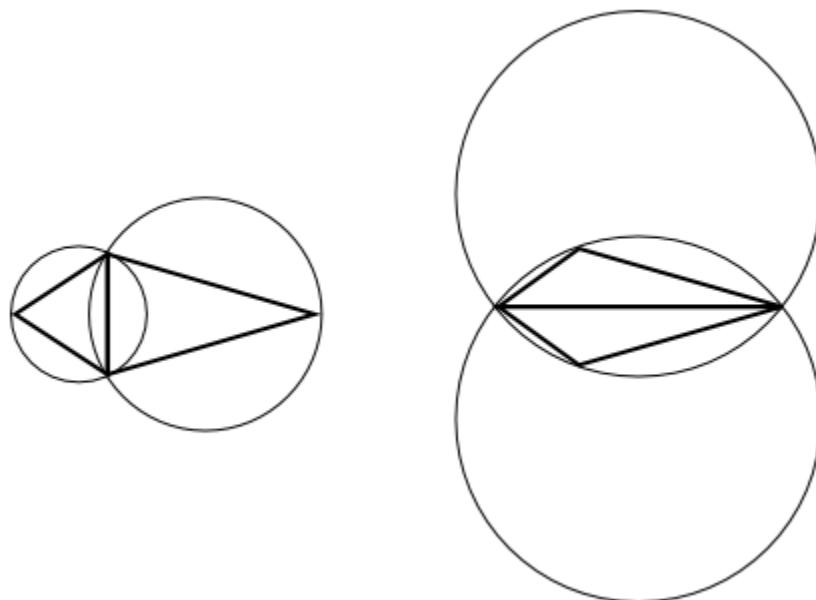

Face swapping is used to improve the quality of a triangular or tetrahedral mesh.

To perform face swapping, click the **Swap** button in the *Smooth/Swap Mesh Dialog Box* (p. 2293) until the reported **Number Swapped** is 0. The **Number Visited** indicates the total number of faces that were visited and tested for possible face swapping.

Face swapping is applicable only to meshes with triangular or tetrahedral cells.

30.13.2.1. Triangular Meshes

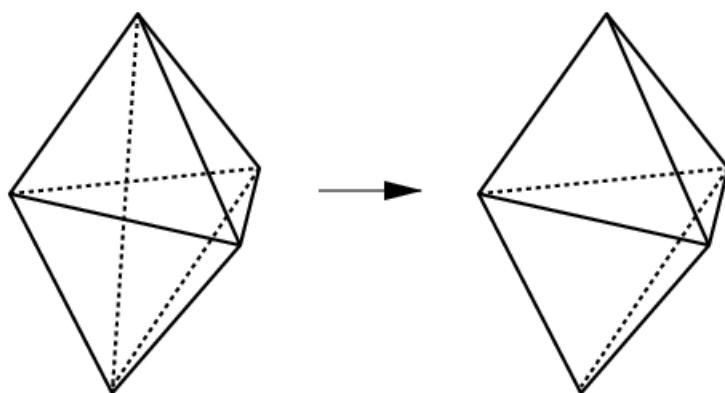

The approach for triangular meshes is to use the Delaunay circle test to decide if a face shared by two triangular cells should be swapped. A pair of cells sharing a face satisfies the circle test if the circumcircle of one cell does not contain the unshared node of the second cell. *Figure 30.19* (p. 1471) illustrates cell neighbors in the circle test. In cases where the circle test is not satisfied, the diagonal or face is swapped, as illustrated in *Figure 30.20* (p. 1471).

Figure 30.19 Examples of Cell Configurations in the Circle Test**Figure 30.20 Swapped Faces to Satisfy the Delaunay Circle Test**

Repeated application of the face-swapping technique will produce a constrained Delaunay mesh. If you have a Delaunay mesh, it is a unique triangulation that maximizes the minimum angles in the mesh. Thus, the triangulation tends toward equilateral cells, providing the most equilateral mesh for the given node distribution. For more information on Delaunay mesh generation, see the Theory chapter in the TGrid User's Guide.

30.13.2.2. Tetrahedral Meshes

For tetrahedral meshes, face swapping consists of searching for configurations of three cells sharing an edge and converting them into two cells sharing a face to decrease skewness and the cell count (see *Figure 30.21* (p. 1472)).

Figure 30.21 3D Face Swapping

30.13.3. Combining Skewness-Based Smoothing and Face Swapping

As mentioned in [Skewness-Based Smoothing \(p. 1469\)](#), skewness-based smoothing should usually be alternated with face swapping. Guidelines for this procedure are presented here.

- Perform four smoothing iterations using a **Skewness Threshold** of 0.8 for 3D, or 0.4 for 2D.
- Swap until the **Number Swapped** decreases to 0.
- For 3D meshes, decrease the **Skewness Threshold** to 0.6 and repeat the smoothing/swapping procedure.

Chapter 31: Creating Surfaces for Displaying and Reporting Data

ANSYS FLUENT enables you to select portions of the domain to be used for visualizing the flow field. The domain portions are called *surfaces*, and there are many ways to create them. Surfaces are required for graphical analysis of 3D problems because you cannot display vectors, contours, and so on, or create an XY plot for the entire domain at once. In 2D you can usually visualize the flow field on the entire domain, but to create an XY plot of a variable in a portion of the interior of the domain, you must generate a surface. In addition, in both 2D and 3D, you will need one or more surfaces if you want to generate a surface-integral report. Note that ANSYS FLUENT will automatically create a surface for each boundary zone in the domain. Surface information is stored in the case file.

The following sections explain how to create, rename, group, and delete surfaces, and how to determine their sizes.

- 31.1. Using Surfaces
- 31.2. Zone Surfaces
- 31.3. Partition Surfaces
- 31.4. Point Surfaces
- 31.5. Line and Rake Surfaces
- 31.6. Plane Surfaces
- 31.7. Quadric Surfaces
- 31.8. Isosurfaces
- 31.9. Clipping Surfaces
- 31.10. Transforming Surfaces
- 31.11. Grouping, Renaming, and Deleting Surfaces

31.1. Using Surfaces

In order to visualize the internal flow of a 3D problem or create XY plots of solution variables for 3D results, you must select portions of the domain (surfaces) on which the data is to be displayed. Surfaces can also be used for visualizing or plotting data for 2D problems, and for generating surface-integral reports.

ANSYS FLUENT provides methods for creating several kinds of surfaces, and stores all surfaces in the case file. These surfaces and their uses are described briefly below:

Zone Surfaces:

If you want to create a surface that will contain the same cells/faces as an existing cell/face zone, you can generate a zone surface. This kind of surface is useful for displaying results on boundaries.

Partition Surfaces:

When you are using the parallel version of ANSYS FLUENT, you may find it useful to create surfaces that are defined by the boundaries between mesh partitions. You can then display data on each side of a partition boundary.

See [Parallel Processing \(p. 1715\)](#) for more information about running the parallel solver.

Point Surfaces:

To monitor the value of some variable or function at a particular location in the domain, you can create a surface consisting of a single point.

Line and Rake Surfaces:

To generate and display pathlines, you must specify a surface from which the particles are released. Line and rake surfaces are well-suited for this purpose and for obtaining data for comparison with wind tunnel data. A rake surface consists of a specified number of points equally spaced between two specified endpoints. A line surface is simply a line that includes the specified endpoints and extends through the domain; data points will be at the centers of the cells through which the line passes, and consequently will not be equally spaced.

Plane Surfaces:

If you want to display flow-field data on a specific plane in the domain, you can create a plane surface. A plane surface is simply a plane that passes through three specified points.

Quadric Surfaces:

To display data on a line (2D), plane (3D), circle (2D), sphere (3D), or quadric surface you can specify the surface by entering the coefficients of the quadric function that defines it. This feature provides you with an explicit method for defining surfaces.

Isosurfaces:

You can use an isosurface to display results on cells that have a constant value for a specified variable. Generating an isosurface based on x , y , or z coordinate, for example, will give you an x , y , or z cross-section of your domain. Generating an isosurface based on pressure will enable you to display data for another variable on a surface of constant pressure.

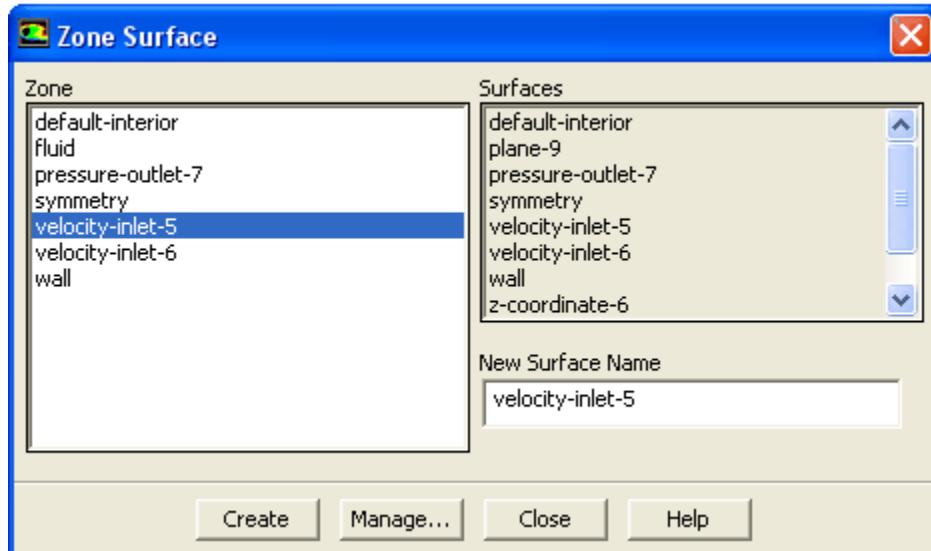

31.2. Zone Surfaces

Zone surfaces are useful for displaying results on boundaries. For example, you may want to plot contours of velocity magnitude at the inlet and outlet of the problem domain, or temperature contours on the domain's walls. To do so, you need to have a surface that contains the same faces (or cells) as an existing face (or cell) zone. Zone surfaces are created automatically for all boundary face zones in the domain, so you will generally not need to create any zone surfaces unless you accidentally delete one.

To create a zone surface, you will use the *Zone Surface Dialog Box* (p. 2295) (*Figure 31.1* (p. 1474)).

Surface → Zone...

Figure 31.1 The Zone Surface Dialog Box

The steps for creating the zone surface are as follows:

1. In the **Zone** list, select the zone for which you want to create a surface.
2. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, zone-surface-6). If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If your surface name begins with any other character or number, ANSYS FLUENT rejects the entry.

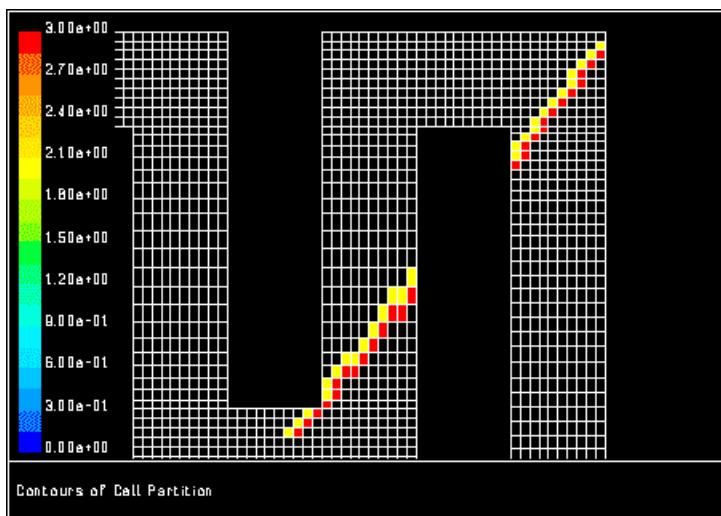

3. Click **Create**. The new surface name is added to the **Surfaces** list in the dialog box.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). For details, see *Grouping, Renaming, and Deleting Surfaces* (p. 1495).

31.3. Partition Surfaces

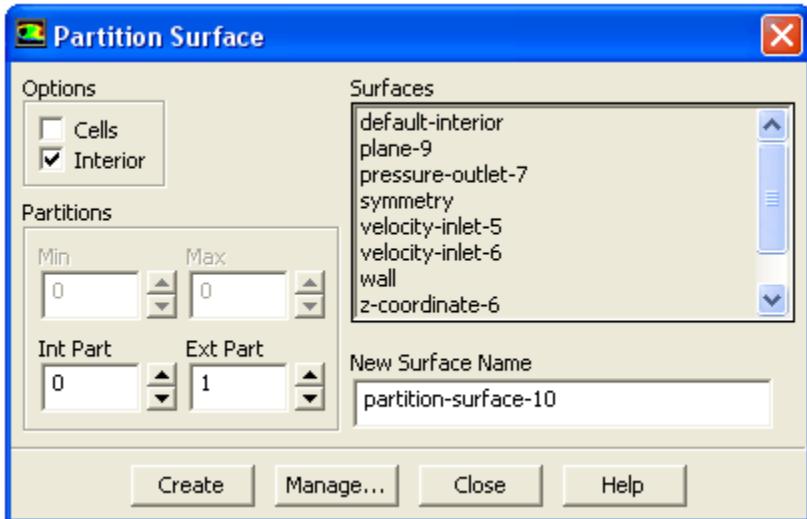

If you are using the parallel version of ANSYS FLUENT (see *Parallel Processing* (p. 1715)), you may find it useful to create data surfaces defined by the boundaries of mesh partitions. As described in *Mesh Partitioning and Load Balancing* (p. 1733), partitioning the mesh divides it into groups of cells that can be solved on separate processors when you use a parallel solver. A partition surface will contain faces or cells on the boundary of two mesh partitions. For example, you can plot solution values on the partition surface to determine how the solution is changing across a partition interface, as shown in the following figure:

Figure 31.2 Contours of Cell Partitions on Partition Surface Overlaid on Mesh

To create a partition surface, you will use the *Partition Surface Dialog Box* (p. 2295) (*Figure 31.3* (p. 1476)).

Surface → Partition...

Figure 31.3 The Partition Surface Dialog Box

The procedure for creating the partition surface are as follows:

1. Specify the partition boundary in which you are interested by indicating the two bordering partitions under the **Partitions** heading. The boundary that defines the partition surface is the boundary between the "interior partition" and the "exterior partition". **Int Part** indicates the ID number of the interior partition (that is, the partition under consideration), and **Ext Part** indicates the ID number of the bordering (exterior) partition. The **Min** and **Max** fields will indicate the minimum and maximum ID numbers of the mesh partitions. The minimum is always zero, and the maximum is one less than the number of processors. If there are more than two mesh partitions, each interior partition will share boundaries with several exterior partitions. By setting the appropriate values for **Int Part** and **Ext Part**, you can create surfaces for any of these boundaries.
2. Choose interior or exterior faces or cells to be contained in the partition surface by selecting or clearing **Cells** and **Interior** under **Options**. To obtain a surface consisting of cells that are on the "interior" side of the partition boundary, select both **Cells** and **Interior**. To create one consisting of cells that are on the "exterior" side, select **Cells** and clear **Interior**. If you want the surface to contain the faces on the boundary instead of the cells, clear the **Cells** option. To have the faces reflect data values for the interior cells, select the **Interior** check box, and to have them reflect values for the exterior cells, clear it.
3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `partition-surface-6`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.)

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

4. Click **Create**. The new surface name is added to the **Surfaces** list in the dialog box.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). For details, see *Grouping, Renaming, and Deleting Surfaces* (p. 1495).

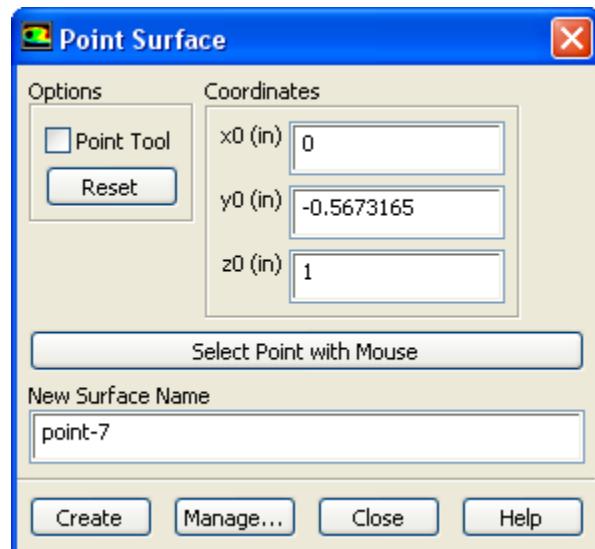

31.4. Point Surfaces

You may often be interested in displaying results at a single point in the domain. For example, you may want to monitor the value of some variable or function at a particular location. To do this, you must first create a "point" surface, which consists of a single point. When you display node-value data on a point surface, the value displayed is a linear average of the neighboring node values. If you display cell-value data, the value at the cell in which the point lies is displayed.

To create a point surface, use the *Point Surface Dialog Box* (p. 2078) (Figure 31.4 (p. 1477)).

Surface → Point...

Figure 31.4 The Point Surface Dialog Box

Create a point surface as follows:

1. Specify the location of the point. There are three different ways to do this:
 - Enter the coordinates (**x0**, **y0**, **z0**) under **Coordinates**.
 - Click **Select Point With Mouse** and then select the point by clicking on a location in the active graphics window with the mouse-probe button. (See *Controlling the Mouse Button Functions* (p. 1548) for information about setting mouse button functions.)
 - Use the **Point Tool** option to interactively position a point in the graphics window. You can set the initial location of this point using one of the two methods described above for specifying the point's position (or you can start from the position defined by the default **Coordinates**). See *Using the Point Tool* (p. 1478) for information about using the point tool.
2. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `point-5`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.)

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

3. Click **Create** to create the new surface.

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). For details, see *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

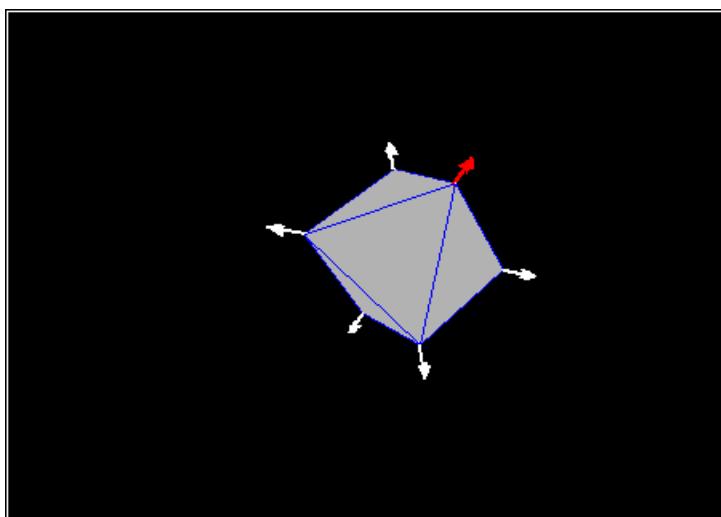

31.4.1. Using the Point Tool

The point tool enables you to interactively fine-tune the definition of a point using graphics. Starting from an initial point, you can translate the point until its position is as desired. For example, if you need to position a point surface at the center of a duct, just past the inlet, you can start with the point tool near the desired location (such as on the inlet), and translate it until it is in the proper place. (You may find it helpful to display mesh faces to ensure that the point tool is correctly positioned inside the domain.)

31.4.1.1. Initializing the Point Tool

Before enabling the **Point Tool** option, set the **Coordinates** to suitable starting values. You can enter values manually, or use the **Select Point With Mouse** button. Often it is convenient to display the mesh for an inlet or isosurface on or near which the point is to be located, and then select a point on that mesh to specify the initial position of the point tool. Once you have specified the appropriate **Coordinates**, activate the tool by turning on the **Point Tool** option. The point tool, an eight-sided polygon, will appear in the graphics window, as shown in *Figure 31.5* (p. 1478).

Figure 31.5 The Point Tool

You can then translate the point tool as described below. The point surface you create will be located at the center of the point tool.

31.4.1.2. Translating the Point Tool

To translate the point tool in the direction along the red axis, click the mouse-probe button (the right button by default) anywhere on the gray part of the point tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion. For information about changing the mouse functions, see [Controlling the Mouse Button Functions \(p. 1548\)](#).

To translate the tool in the transverse directions (that is, along either of the other axes), press **Shift**, click the mouse-probe button anywhere on the gray part of the point tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. In 2D, there will be only one set of green arrows because there is only one other direction for translation. If you find the perspective distracting when performing this type of translation, you can turn it off in the [Camera Parameters Dialog Box \(p. 2162\)](#) (opened from the [Views Dialog Box \(p. 2157\)](#)), as described in [Controlling Perspective and Camera Parameters \(p. 1559\)](#).

31.4.1.3. Resetting the Point Tool

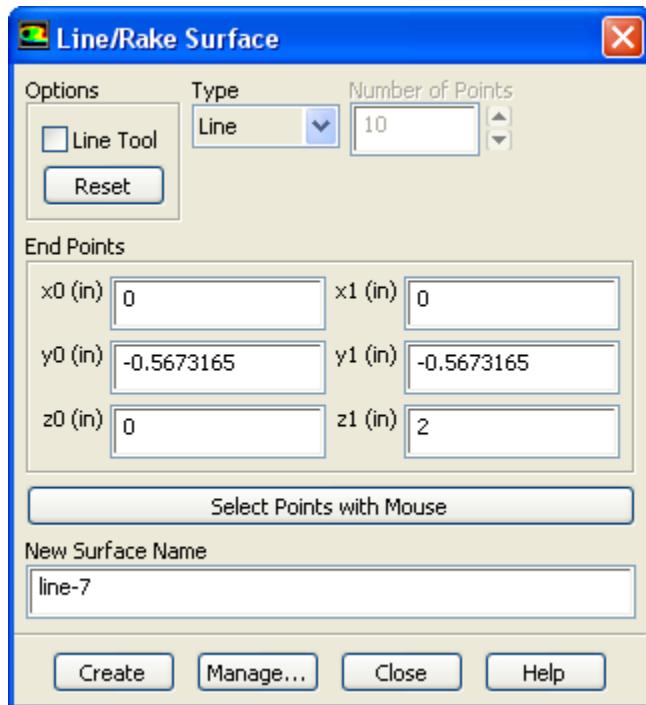

If you "lose" the point tool, or want to reset it for any other reason, you can either click **Reset** to return the point tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the point tool will lie at the center of the domain.

31.5. Line and Rake Surfaces

You can create lines and rakes in the domain for releasing particles, obtaining data for comparison with tunnel data, and so on. A rake consists of a specified number of points equally spaced between two specified endpoints. A line is simply a line that extends up to and includes the specified endpoints; data points will be located where the line intersects the faces of the cell, and consequently may not be equally spaced.

To create a line or rake surface, you will use the [Line/Rake Surface Dialog Box \(p. 2079\)](#) (*Figure 31.6 (p. 1480)*).

Surface → Line/Rake...

Figure 31.6 The Line/Rake Surface Dialog Box

The steps for creating the line or rake surface are as follows:

1. Indicate whether you are creating a **Line** surface or a **Rake** surface by selecting the appropriate item in the **Type** drop-down list.
2. If you are creating a rake surface, specify the **Number of Points** to be equally spaced between the two endpoints.
3. Specify the location of the line or rake surface. There are three different ways to define the location:
 - Enter the coordinates of the first point (**x0, y0, z0**) and the last point (**x1, y1, z1**) under **End Points**.
 - Click **Select Points With Mouse** and then select the endpoints by clicking on locations in the active graphics window with the mouse-probe button. (See *Controlling the Mouse Button Functions* (p. 1548) for information about setting mouse button functions.)
 - Use the **Line Tool** option to interactively position a line in the graphics window. You can set the initial location of this line using one of the two methods described above for specifying endpoints (or you can start from the position defined by the default **End Points**). See *Using the Line Tool* (p. 1481) for information about using the line tool.

Note that when you use the second or third method described above, the coordinates of the **End Points** are updated automatically.

4. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `line-5` or `rake-6`). If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

5. Click **Create** to create the new surface.

If you want to check that the new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). See *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

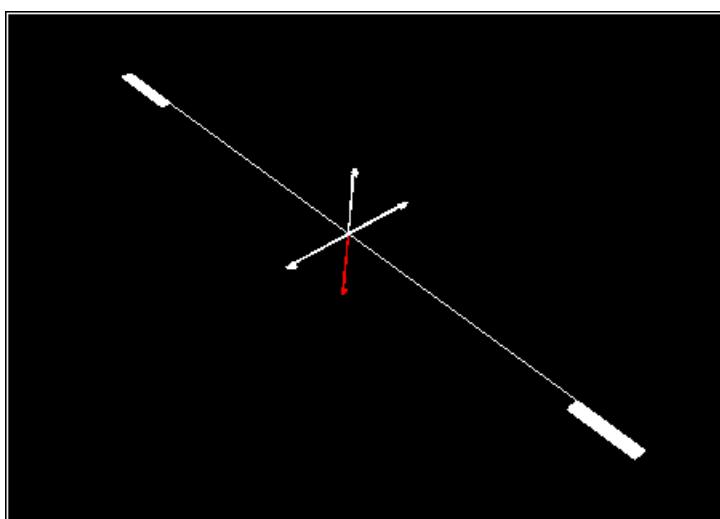

31.5.1. Using the Line Tool

The line tool enables you to interactively fine-tune the definition of a line or rake using graphics. Starting from an initial line, you can translate, rotate, and resize the line until its position, orientation, and length are as desired. For example, if you need to position a rake surface just inside the inlet to a duct, you can start with the line tool near the desired location (such as on the inlet), and translate, rotate, and resize it until you are satisfied. You may find it helpful to display mesh faces to ensure that the line tool is correctly positioned inside the domain.

31.5.1.1. Initializing the Line Tool

Before enabling the **Line Tool** option, set the **End Points** to suitable starting values. You can enter values manually, or use the **Select Points With Mouse** button. Often it is convenient to display the mesh for an inlet or isosurface on or near which you want to place the line or rake surface and then select two points on that mesh to specify the initial position of the line tool. Once you have specified the appropriate **End Points**, activate the **Line Tool** option. The line tool appears in the graphics window, as shown in *Figure 31.7* (p. 1481).

Figure 31.7 The Line Tool

You can then translate, rotate, and/or resize the line tool as described in the following sections.

31.5.1.2. Translating the Line Tool

To translate the line tool in the direction along the red axis, click the mouse-probe button (the right button by default) anywhere on the "line" part of the tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion. For information about changing the mouse functions see [Controlling the Mouse Button Functions \(p. 1548\)](#).

Important

Do not click on the axes of the line tool that have arrows on the ends. These axes control rotation of the tool. Click only on the portion of the tool that represents the prospective line surface. This portion is designated by the rectangles attached to each end.

To translate the tool in the transverse directions (that is, along either of the axes within the plane perpendicular to the red axis), press **Shift**, click the mouse-probe button anywhere on the "line" part of the tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. In 2D, there will be only one set of green arrows because there is only one other direction for translation. If you find the perspective distracting when performing this type of translation, you can disable it in the [Camera Parameters Dialog Box \(p. 2162\)](#) (opened from the [Views Dialog Box \(p. 2157\)](#)), as described in [Controlling Perspective and Camera Parameters \(p. 1559\)](#).

31.5.1.3. Rotating the Line Tool

To rotate the line tool, you click the mouse-probe button on one of the white axes with arrows. When you click on one of these axes, a green ribbon will encircle the other arrowed axis, designating it as the axis of rotation. As you drag the mouse along the circle to rotate the tool, the green circle will become yellow.

Important

Do not click on the red axis to rotate the line tool.

31.5.1.4. Resizing the Line Tool

If you plan to generate a rake surface, you can resize the line tool to define the length of the rake. Click the mouse-probe button in one of the white rectangles at the ends of the "line" part of the tool (shown in black in [Figure 31.7 \(p. 1481\)](#)) and drag the mouse to lengthen or shorten the tool. Green arrows will show the direction of stretching/shrinking.

31.5.1.5. Resetting the Line Tool

If you "lose" the line tool, or want to reset it for any other reason, you can either click **Reset** to return the line tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the line tool will lie midway along the x and y lengths of the domain, spanning the z domain extent.

31.6. Plane Surfaces

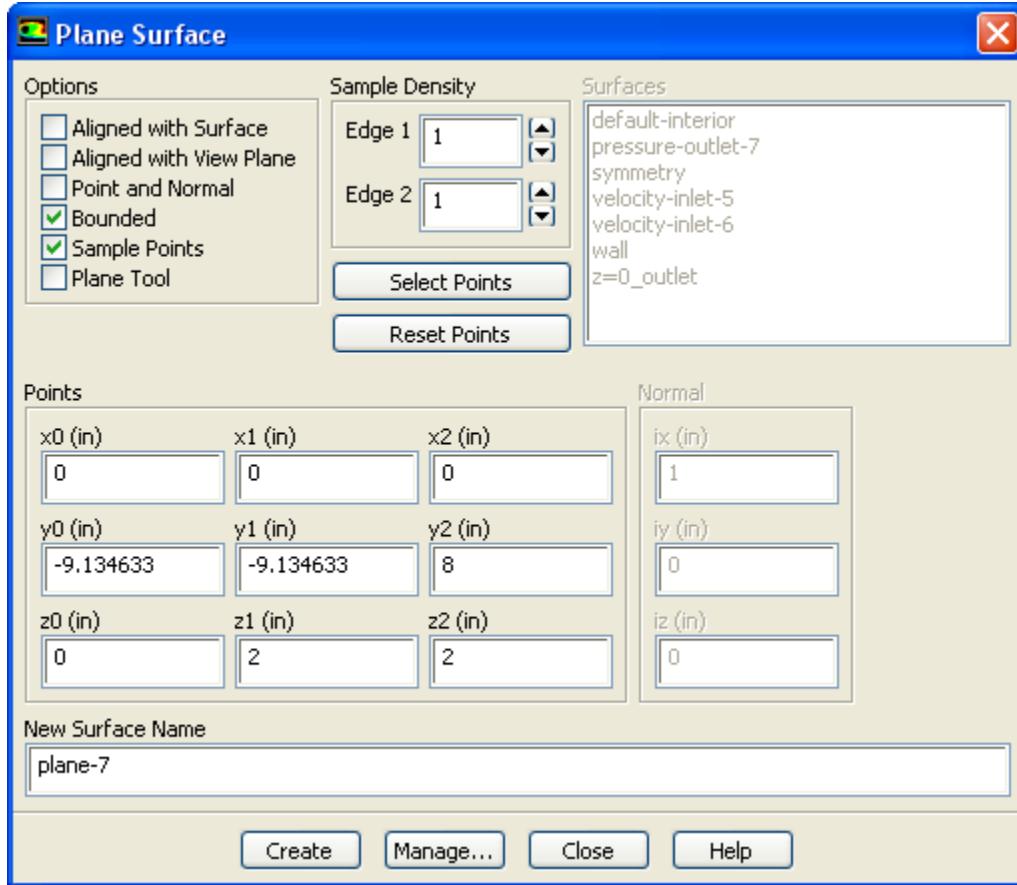

To display flow-field data on a specific plane in the domain, you will use a plane surface. You can create surfaces that cut through the solution domain along arbitrary planes only in 3D; this feature is not available in 2D.

There are six types of plane surfaces that you can create:

- Intersection of the domain with the infinite plane: This is the default plane surface created. The extents of the plane is determined by the extents of the domain. Because the plane is slicing through the domain, the data points will, by default, be located where the plane intersects the faces of a cell, and consequently may not be equally spaced.
- Bounded plane: This plane will be a bounded parallelepiped, for which 3 of the 4 corners are the 3 points that define the plane equation (or the 4 corners are the corners of the "plane tool"). Like the default plane surface described above, this type of surface will also have unequally spaced data points.
- Bounded plane with equally spaced data points: This plane is the same as the bounded plane described above, except you will specify the density of points along the two directions of the parallelepiped, creating a uniform distribution of data points.
- Plane having a certain normal vector and passing through a specified point: To create this type of plane, define a normal vector and a point. A plane with the specified normal and passing through the specified point will be created.
- Plane aligned with an existing surface: To create this type of plane, you will define a single point and a surface. A plane parallel to the selected surface and passing through the specified point will be created.
- Plane aligned with the view in the graphics window: To create this type of plane, you will define a single point. A plane parallel to the current view in the active graphics window and passing through the specified point will be created.

To create a plane surface, you will use the [Plane Surface Dialog Box \(p. 2080\)](#) ([Figure 31.8 \(p. 1484\)](#)).

Surface → Plane...

Figure 31.8 The Plane Surface Dialog Box

The procedure for creating the plane surface is as follows:

1. Decide which of the six types of planes you want to create.
 - To create the default plane type (the intersection of the infinite plane with the domain), go directly to step 2.
 - To create a bounded plane, select **Bounded** under **Options**.
 - To create a bounded plane with equally spaced data points, select both **Bounded** and **Sample Points**, and then set the number of data points under **Sample Density**. You will specify the point density in each direction by entering the appropriate values for **Edge 1** and **Edge 2**. Edge 1 extends from point 0 to point 1, and edge 2 extends from point 1 to point 2.
 - To define a plane aligned with an existing surface, select **Aligned With Surface**, and then choose the surface in the **Surfaces** list and specify a single point using one of the first two methods described below in step 2.
 - To define a plane aligned with the view plane, select **Aligned With View Plane**, and then choose a single point using one of the first two methods described below in step 2.
 - To define a plane having a certain normal vector and passing through a specified point, select **Point And Normal**, and then specify the normal vector by entering values in the **ix**, **iy**, and **iz** fields under **Normal**, and a single point using one of the first two methods described below in step 2.
2. Specify the location of the plane surface. There are three different ways to define the location:

- Enter the coordinates of the three **Points** defining the planar surface: (x_0, y_0, z_0), (x_1, y_1, z_1), and (x_2, y_2, z_2).
- Click **Select Points** and then select the three points by clicking on locations in the active graphics window with the mouse-probe button. (See [Controlling the Mouse Button Functions \(p. 1548\)](#) for information about setting mouse button functions.)
- Use the **Plane Tool** option to interactively position a plane in the graphics window. You can set the initial location of this plane using one of the two methods described above for specifying the defining points. You can also start from the position defined by the default **Points**. See [Using the Plane Tool \(p. 1485\)](#) for information about using the plane tool.

Note that when you use the second or third method described above, the coordinates of the **End Points** are updated automatically.

3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `plane-7`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.)

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

4. Click **Create** to create the new surface.

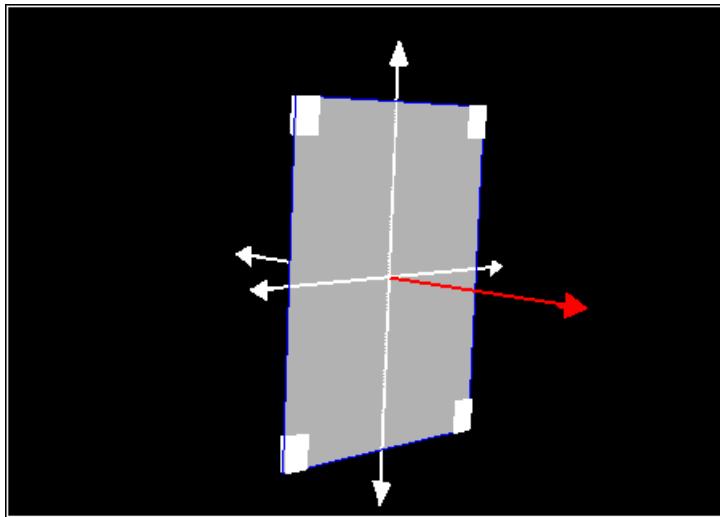

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the [Surfaces Dialog Box \(p. 2087\)](#). See [Grouping, Renaming, and Deleting Surfaces \(p. 1495\)](#) for details.

31.6.1. Using the Plane Tool

The plane tool enables you to interactively fine-tune the definition of a plane using graphics. Starting from an initial plane, you can translate, rotate, and resize the plane until its position, orientation, and size are as desired. For example, if you need to position a plane surface at a cross-section of an irregularly-shaped, curved duct, you can start with the plane tool near the desired location, resize it, translate it until it is within the duct walls, and rotate it to the proper orientation. You may find it helpful to display mesh faces to ensure that the plane tool is correctly positioned inside the domain.

31.6.1.1. Initializing the Plane Tool

Before enabling the **Plane Tool** option, set the **Points** to suitable starting values. You can enter values manually, or use the **Select Points** button. Often it is convenient to display the mesh for an inlet or isosurface that is similar to the desired plane surface, and then select three points on that mesh to position the initial plane. Once you have specified the appropriate **Points**, activate the **Plane Tool** option. The plane tool will appear in the graphics window, as shown in [Figure 31.9 \(p. 1486\)](#).

Figure 31.9 The Plane Tool

You can then translate, rotate, and/or resize the plane tool as described in the following sections.

31.6.1.2. Translating the Plane Tool

To translate the plane tool in the direction normal to the plane, click the mouse-probe button (the right button by default) anywhere on the gray part of the plane tool and drag the mouse until the tool reaches the desired location. Green arrows will show the direction of motion. For information about changing the mouse functions see [Controlling the Mouse Button Functions \(p. 1548\)](#).

To translate the tool in the transverse directions (that is, along either of the axes that lie within the plane), press **Shift**, click the mouse-probe button anywhere on the gray part of the plane tool, and drag the mouse until the tool reaches the desired location. Two sets of green arrows will show the possible directions of motion. If you find the perspective distracting when performing this type of translation, you can turn it off in the [Camera Parameters Dialog Box \(p. 2162\)](#) (opened from the [Views Dialog Box \(p. 2157\)](#)), as described in [Controlling Perspective and Camera Parameters \(p. 1559\)](#).

31.6.1.3. Rotating the Plane Tool

To rotate the plane tool, click the mouse-probe button on one of the white arrows at the tips of the plane's axes. Clicking on any arrow rotates the tool about either of the other two axes: when you click on the arrow, two green ribbons will encircle the plane tool, forming circles about each of the two possible axes of rotation. Drag the mouse along the desired circle to rotate the tool. As you do so, the circle along which the tool is rotating will become yellow.

The following notes may help you when you are rotating the plane tool:

- Once you move your mouse along one circle, you cannot change the direction of rotation unless you release the mouse-probe button and try again. Be careful to start moving your mouse very steadily so that you can choose the correct direction.
- Do not click on the red arrow to rotate.
- Do not try to rotate by clicking on an arrow that is pointing away from you. It will be very difficult for you to judge which direction of rotation is correct from this point of view. Because there are two arrows on each axis, there will always be an appropriate arrow available.

- Do not rotate the plane tool more than 90° or so at once. If you rotate the tool by a large angle, the arrow on which you are clicking will begin to point away from you, and you will have trouble controlling the rotation (as discussed in the item above).

31.6.1.4. Resizing the Plane Tool

If you plan to generate a bounded plane, you can resize the plane tool to define the plane's boundaries. Click the mouse-probe button in one of the white squares at the plane tool's corners (shown in black in [Figure 31.9 \(p. 1486\)](#)) and drag the mouse to stretch or shrink the tool. Green arrows will show the direction of the plane's diagonal.

Important

Be careful not to drag your mouse across any of the axes while resizing the tool. This will flip the tool over and corrupt it. If you accidentally do this, reset the plane tool and start again.

31.6.1.5. Resetting the Plane Tool

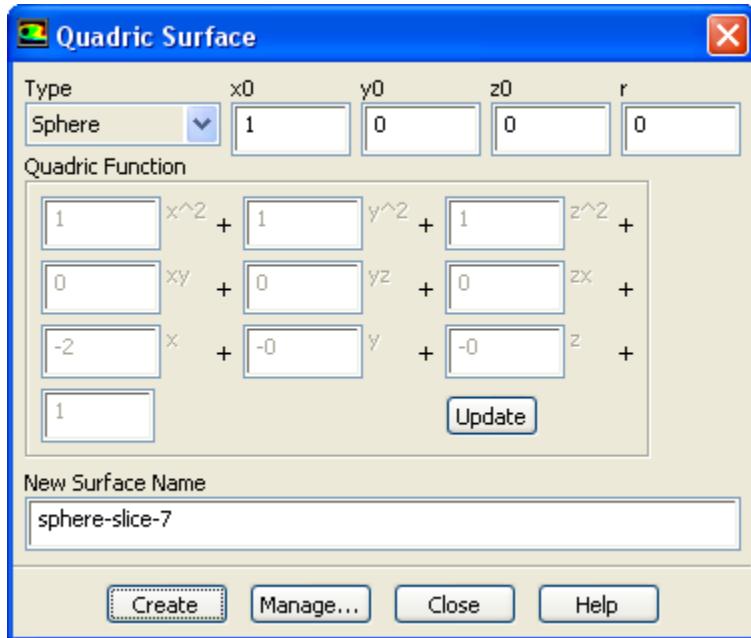

If you "lose" the plane tool, or want to reset it for any other reason, you can either click **Reset Points** to return the plane tool to the default position and start from there, or turn the tool off and re-initialize it as described above. In the default position, the plane tool will lie midway along the x length of the domain, spanning the y and z domain extents.

31.7. Quadric Surfaces

If you want to display data on a line (2D), plane (3D), circle (2D), sphere (3D), or general quadric surface, you can specify the surface by entering the coefficients of the quadric function that defines it. This feature provides you with an explicit method for defining surfaces. See [Line and Rake Surfaces \(p. 1479\)](#) and [Plane Surfaces \(p. 1482\)](#) for additional methods for creating line and plane surfaces.

To create a quadric surface, you will use the [Quadric Surface Dialog Box \(p. 2082\)](#) ([Figure 31.10 \(p. 1488\)](#)).

Surface → Quadric...

Figure 31.10 The Quadric Surface Dialog Box

The steps for creating the quadric surface are as follows:

1. Decide which type of quadric surface you want to create. In 3D, choose **Plane**, **Sphere**, or (general) **Quadric** in the **Type** drop-down list. In 2D, choose **Line**, **Circle**, or **Quadric**.
2. Specify the defining equation for the surface *in SI units*.
 - Line or plane surface: If you have selected **Line** (in 2D) or **Plane** (in 3D) as the surface type, the surface will consist of all points on the domain that satisfy the equation $ix * x + iy * y + iz * z = \text{distance}$. You will input **ix** (the coefficient of *x*), **iy** (the coefficient of *y*), **iz** (the coefficient of *z*), and **distance** (the distance of the line or plane from the origin) in the fields to the right of the **Type** drop-down list. When you click **Update** under the **Quadratic Function** heading, the display of the quadric function coefficients will change to reflect your inputs.
 - Circle or sphere surface: If you have selected **Circle** (in 2D) or **Sphere** (in 3D) as the surface type, the surface will consist of all points on the domain that satisfy the equation $(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2 = r^2$. You will input **x0**, **y0**, **z0** (the *x*, *y*, and *z* coordinates of the sphere or circle's center) and **r** (the radius) in the fields to the right of the **Type** drop-down list. When you click **Update** under the **Quadratic Function** heading, the display of the quadric function coefficients will change to reflect your inputs.
 - Quadric surface: If you have selected **Quadric** as the surface type, the surface will consist of all points in the domain that satisfy the general quadric function $Q = \text{value}$. You will input the coefficients of the quadric function Q (the coefficients of the terms x^2 , y^2 , z^2 , xy , yz , zx , x , y , z and the constant term) directly in the **Quadratic Function** box, and you will set **value** to the right of the **Type** drop-down list. Note that the **Update** button will be disabled when you choose this type of surface.
3. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, *sphere-slice-7* or *quadric-slice-10*). If the **New Surface Name**

you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

4. Click **Create** to create the new surface.

If you want to check that your new surface has been added to the list of all defined surfaces, or you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). See *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

31.8. Isosurfaces

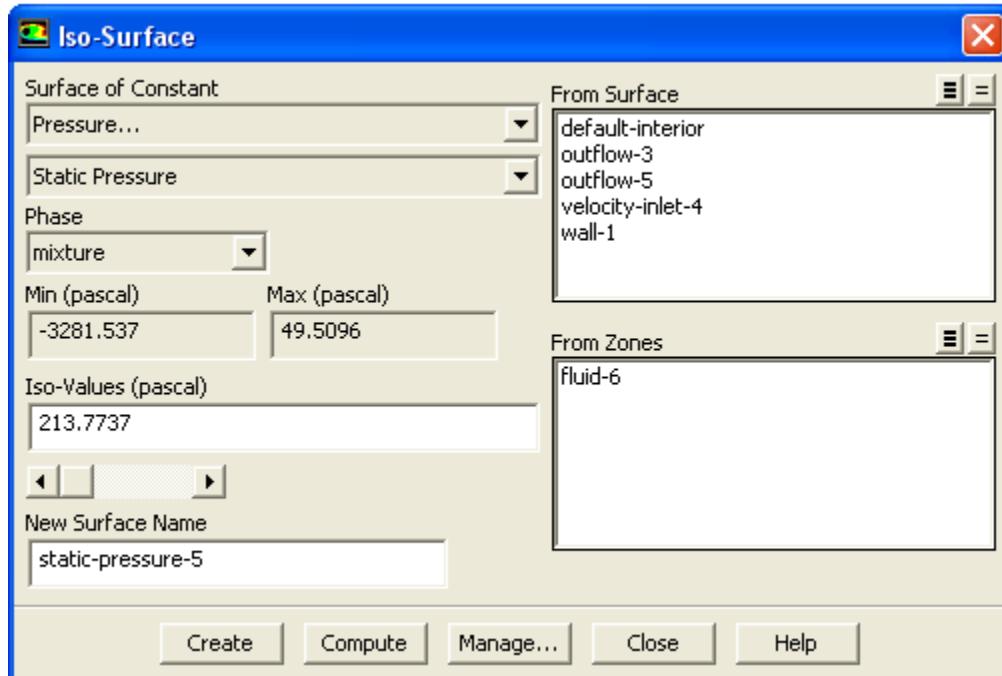

If you want to display results on cells that have a constant value for a specified variable, you will need to create an isosurface of that variable. Generating an isosurface based on x , y , or z coordinate, for example, will give you an x , y , or z cross-section of your domain; generating an isosurface based on pressure will enable you to display data for another variable on a surface of constant pressure. You can create an isosurface from an existing surface or from the entire domain. Furthermore, you can restrict any isosurface to a specified cell zone.

Important

Note that you cannot create an isosurface until you have initialized the solution, performed calculations, or read a data file.

To create an isosurface, you will use the *Iso-Surface Dialog Box* (p. 2084) (*Figure 31.11* (p. 1490)).

Surface → Iso-Surface...

Figure 31.11 The Iso-Surface Dialog Box

The steps for creating the isosurface are as follows:

1. Choose the scalar variable to be used for isosurfacing in the **Surface of Constant** drop-down list. First, select the desired category in the upper list. You can then select from related quantities from the lower list. (See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
2. If you want to create an isosurface from an existing surface (that is, generate a new surface of constant x , y , temperature, pressure, and so on that is a subset of another surface), choose that surface in the **From Surface** list. You can specify the cell zone on which you want to create an isosurface by selecting the zone in the **From Zones** list.
 - If you do not select a surface from the list, the isosurfacing will be performed on the entire domain.
 - If you do not select a zone from the list, then the isosurfacing will not be restricted to any cell zone and will run through the entire domain.
3. Click **Compute** to calculate the minimum and maximum values of the selected scalar field in the domain or on the selected surface (in the **From Surface** list). The minimum and maximum values will be displayed in the **Min** and **Max** fields.
4. Set the isovalue using one of the following methods. (Note that the second method will enable you to define multiple isovalue in a single isosurface.)
 - You can set an isovalue interactively by moving the slider with the left mouse button. The value in the **Iso-Values** field will be updated automatically. This method will also create a temporary isosurface in the graphics window. Using the slider enables you to preview an isosurface before creating it.

Important

Even though the isosurface is displayed, it is only a temporary surface. To create an isosurface, use the **Create** button after deciding on a particular isovalue.

- You can type in isovalue in the **Iso-Values** field directly, separating multiple values by white space. Multiple isovalue will be contained in a single isosurface; that is, you cannot select subsurfaces within the resulting isosurface.
5. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, z-coordinate-6). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.)

Important

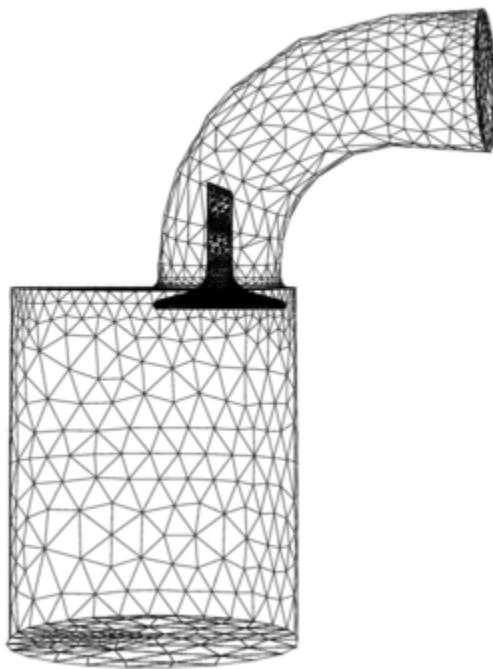

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

6. Click **Create**. The new surface name will be added to the **From Surface** list in the dialog box.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). See *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

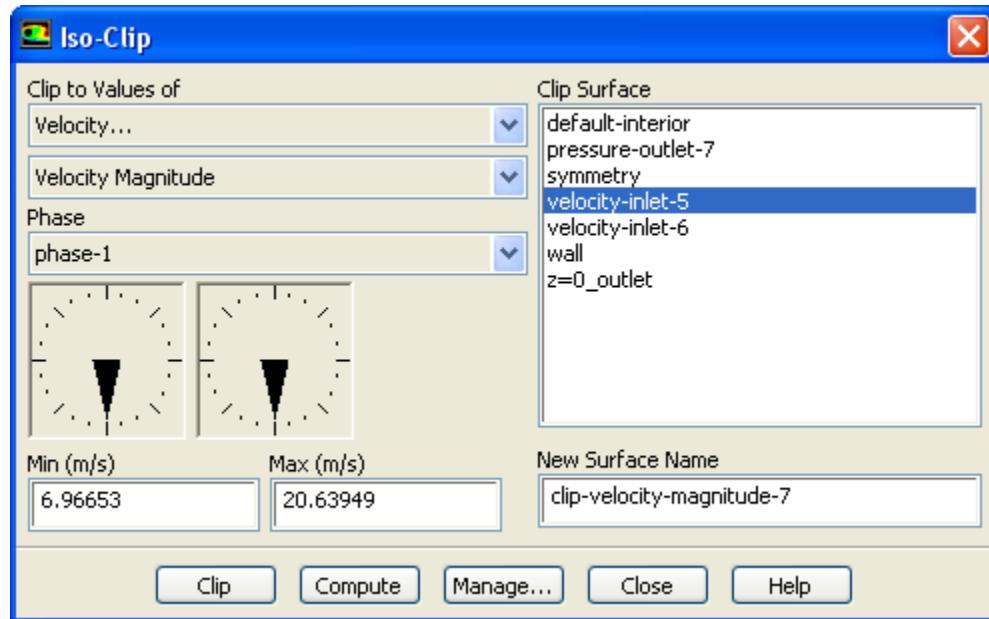

31.9. Clipping Surfaces

If you have created a surface, but you do not want to use the whole surface to display data, you can clip the surface between two isovalue to create a new surface that spans a specified subrange of a specified scalar quantity. The clipped surface consists of those points on the selected surface where the scalar field values are within the specified range. For example, in *Figure 31.12* (p. 1492) the external wall has been clipped to values of *x* coordinate less than 0 to show only the back half of the wall, enabling you to see the valve inside the intake port.

Figure 31.12 External Wall Surface Isoclipped to Values of x Coordinate

To clip an existing surface, you will use the *Iso-Clip Dialog Box* (p. 2086) (*Figure 31.13* (p. 1492)).

Surface → **Iso-Clip...**

Figure 31.13 The Iso-Clip Dialog Box

The steps for clipping a surface are as follows:

1. Choose the scalar variable on which the clipping will be based in the **Clip To Values Of** drop-down list. First, select the desired category in the upper list. You can then select from related quantities from the lower list. See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.
2. Select the surface to be clipped in the **Clip Surface** list.
3. Click **Compute** to calculate the minimum and maximum values of the selected scalar field on the selected surface. The minimum and maximum values are displayed in the **Min** and **Max** fields.
4. Define the clipping range using one of the following methods.
 - You can set the upper and lower limits of the clipping range interactively by moving the indicator in each dial (that is, the dial above the **Min** or **Max** field) with the left mouse button. The value in the corresponding **Min** or **Max** field is updated automatically. This method will also create a temporary surface in the graphics window. Using the dials enables you to preview a clipped surface before creating it.

Important

Even though the clipped surface is displayed, it is only a temporary surface. To create the new surface, use the **Clip** button after deciding on the clipping range.

- You can type the minimum and maximum values in the clipping range directly in the **Min** and **Max** fields.
5. If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, `clip-density-8`). (If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.)

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

6. Click **Clip**. The new surface name is added to the **Clip Surface** list in the dialog box. (The original surface will remain unchanged.)

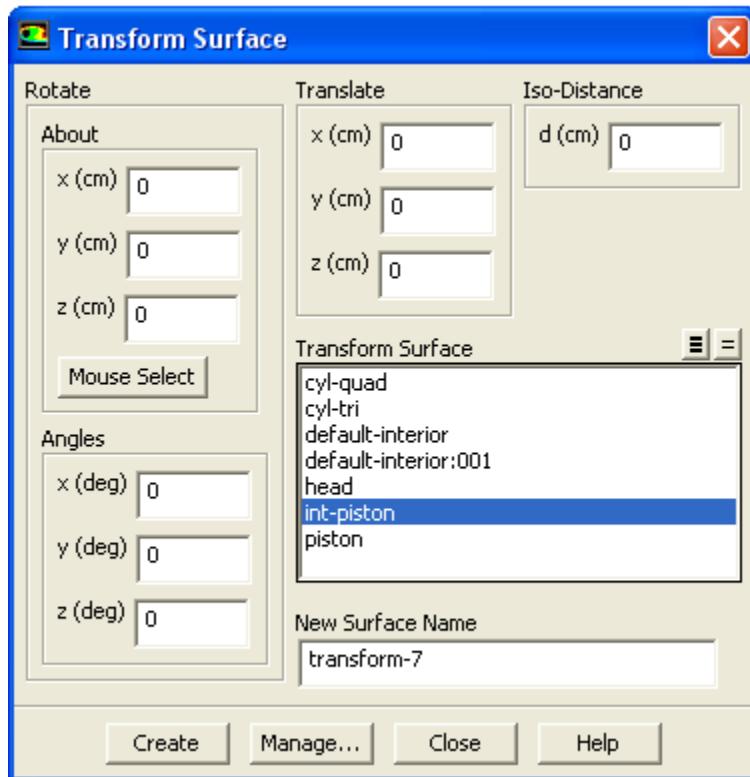

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). See *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

31.10. Transforming Surfaces

You can create a new data surface from an existing surface by rotating and/or translating the original surface. For example, you can rotate the surface of a complicated turbomachinery blade to plot data in the region between blades. You can also create a new surface at a constant normal distance from the original surface.

To transform an existing surface to create a new one, you will use the *Transform Surface Dialog Box* (p. 2297) (*Figure 31.14* (p. 1494)).

Surface → Transform...

Figure 31.14 The Transform Surface Dialog Box

The steps for transforming a surface are as follows:

1. Select the surface to be transformed in the **Transform Surface** list.
2. Set the appropriate transformation parameters, as described below. You can perform any combination of translation, rotation, and "isodistancing" on the surface.
 - Rotation: To rotate a surface, you will specify the origin about which the rotation is performed, and the angle by which the surface is rotated.

In the **About** box under **Rotate**, you will specify a point, and the origin of the coordinate system for the rotation will be set to that point. (The *x*, *y*, and *z* directions will be the same as for the global coordinate system.) For example, if you specified the point (1,5,3) in 3D, rotation would be about the *x*, *y*, and *z* axes anchored at (1,5,3). You can either enter the point's coordinates in the **x,y,z** fields or click **Mouse Select** and select a point in the graphics window using the mouse-probe button. See [Controlling the Mouse Button Functions \(p. 1548\)](#) for information about mouse button functions.

In the **Angles** box under **Rotate**, you will specify the angles about the *x*, *y*, and *z* axes (that is, the axes of the coordinate system with the origin defined under **About**) by which the surface is rotated. For 2D problems, you can specify rotation about the *z* axis only.

- Translation: To translate a surface, you will simply define the distance by which the surface is translated in each direction. Set the **x**, **y**, and **z** translation distances under **Translate**.
- Isodistancing: To create a surface positioned at a constant normal distance from the original surface, you need to set only that normal distance between the original surface and the transformed surface. Set the value for **d** under **Iso-Distance**.

- If you do not want to use the default name assigned to the surface, enter a new name under **New Surface Name**. The default name is the concatenation of the surface type and an integer that is the new surface ID (for example, transform-9). If the **New Surface Name** you enter is the same as the name of a surface that already exists, ANSYS FLUENT will automatically assign the default name to the new surface when it is created.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

- Click **Create**. The new surface name is added to the **Transform Surface** list in the dialog box. The original surface will remain unchanged.

If you want to delete or otherwise manipulate any surfaces, click **Manage...** to open the *Surfaces Dialog Box* (p. 2087). See *Grouping, Renaming, and Deleting Surfaces* (p. 1495) for details.

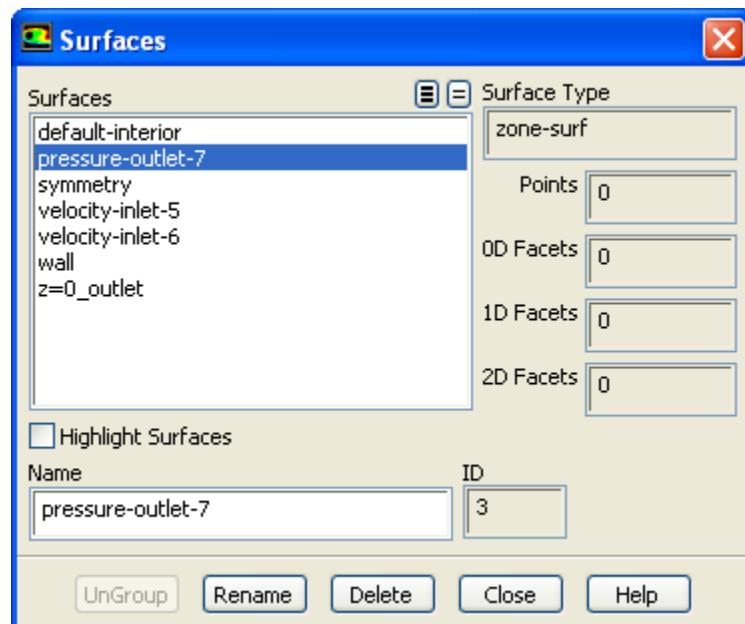

31.11. Grouping, Renaming, and Deleting Surfaces

Once you have created a number of surfaces, you can interactively rename, delete, and group surfaces and obtain information about their components. Grouping surfaces is useful if you want to perform postprocessing on a number of surfaces at a time. For example, you may want to group several wall surfaces together to generate a contour plot of temperature on all walls. To postprocess results on each wall surface individually, "ungroup" the surfaces.

Manipulation of existing surfaces is performed with the *Surfaces Dialog Box* (p. 2087) (*Figure 31.15* (p. 1495)).

Surface → Manage...

Figure 31.15 The Surfaces Dialog Box

You can also open this dialog box by clicking **Manage...** in one of the surface creation dialog boxes described in the previous sections.

For additional information, please see the following sections:

- [31.11.1. Grouping Surfaces](#)
- [31.11.2. Renaming Surfaces](#)
- [31.11.3. Deleting Surfaces](#)
- [31.11.4. Surface Statistics](#)

31.11.1. Grouping Surfaces

As mentioned above, you may want to group several surfaces together in order to perform postprocessing on all of them at once. To create a surface group, select the surfaces to be grouped in the **Surfaces** list. You can define a new name for the group in the **Name** field, or you can use the default name, which is the name of the first surface you selected in the **Surfaces** list. Then click **Group**. The selected surfaces disappear from the **Surfaces** list, and the name of the surface group is added to the list.

Important

The **Group** button will not appear until you have selected at least two surfaces. As soon as you choose a second surface in the **Surfaces** list, the **Rename** button will change to the **Group** button.

To ungroup the surfaces, simply select the surface group in the **Surfaces** list and click **UnGroup**. The group name will disappear from the list and the names of the original surfaces in the group will reappear in the list.

31.11.2. Renaming Surfaces

To change the name of an existing surface, select the surface in the **Surfaces** list, enter a new name in the **Name** field, and then click **Rename**. The new name replaces the old name in the **Surfaces** list and the surface is otherwise unchanged.

If you have selected more than one surface, the **Rename** button will not appear in the dialog box. When more than one surface is selected, the **Rename** button is replaced by the **Group** button.

Important

The surface name that you enter must begin with an alphabetical letter. If the name of the surface begins with any other character or number, ANSYS FLUENT rejects the entry.

31.11.3. Deleting Surfaces

If you find that a surface is no longer useful, you may want to delete it to prevent the list of surfaces from becoming too cluttered. Select the surface or surfaces to be deleted in the **Surfaces** list, and then click **Delete**. The delete operation is not reversible, so if you want to get a deleted surface back again you will need to recreate it using one of the surface-creation dialog boxes described in the previous sections.

31.11.4. Surface Statistics

You can also use the [Surfaces Dialog Box \(p. 2087\)](#) to retrieve topological information about surfaces. **Points** is the total number of nodes in a surface. **0D Facets** is the number of isolated nodes in a surface (that is, nodes that have no connectivity, such as point surfaces or nodes in a rake), **1D Facets** is the number of linear faces (consisting of two connected nodes) in a surface in a 2D problem, and **2D Facets** is the number of 2D faces (triangular or quadrilateral) in a surface in a 3D problem. Note that an **interior** zone surface in a 3D problem consists of 2D facets, and similarly an **interior** zone surface in a 2D problem consists of 1D facets.

These statistics are listed for the surface(s) selected in the **Surfaces** list. If more than one surface is selected, the sum over all selected surfaces is displayed for each quantity.

Note that if you want to check these statistics for a surface that was read from a case file, you will need to first display it.

Chapter 32: Displaying Graphics

Graphics tools available in ANSYS FLUENT enable you to process the information contained in your CFD solution and easily view the results. The following sections explain how to use these tools to examine your solution. The procedure for saving picture files of graphics displays is described in *Saving Picture Files* (p. 119).

- 32.1. Basic Graphics Generation
- 32.2. Customizing the Graphics Display
- 32.3. Controlling the Mouse Button Functions
- 32.4. Viewing the Application Window
- 32.5. Modifying the View
- 32.6. Composing a Scene
- 32.7. Animating Graphics
- 32.8. Creating Videos
- 32.9. Histogram and XY Plots
- 32.10. Turbomachinery Postprocessing
- 32.11. Fast Fourier Transform (FFT) Postprocessing

32.1. Basic Graphics Generation

In ANSYS FLUENT, you can generate graphics displays showing meshes, contours, profiles, vectors, and pathlines. Some graphics are generated using variables that are plotted directly from the ANSYS FLUENT data file once the file has been read. The variables listed in the data file depend on the models active at the time the file is written. Variables that are required by the solver, based on the current model settings, but are missing from the data file are set to their default values. For those missing variables, one iteration should be performed in order to obtain the required values for generating the plot. A complete list of variables stored in the data file is available in (`xfile.h`) and can be accessed as stated in *Data Sections* (p. 2360). The following sections describe how to create these plots. (Generation of histogram and XY plots is discussed in *Histogram and XY Plots* (p. 1587).)

Important

If your model includes a discrete phase, you can also display the particle trajectories, as described in *Displaying of Trajectories* (p. 1143).

This section discusses the following topics:

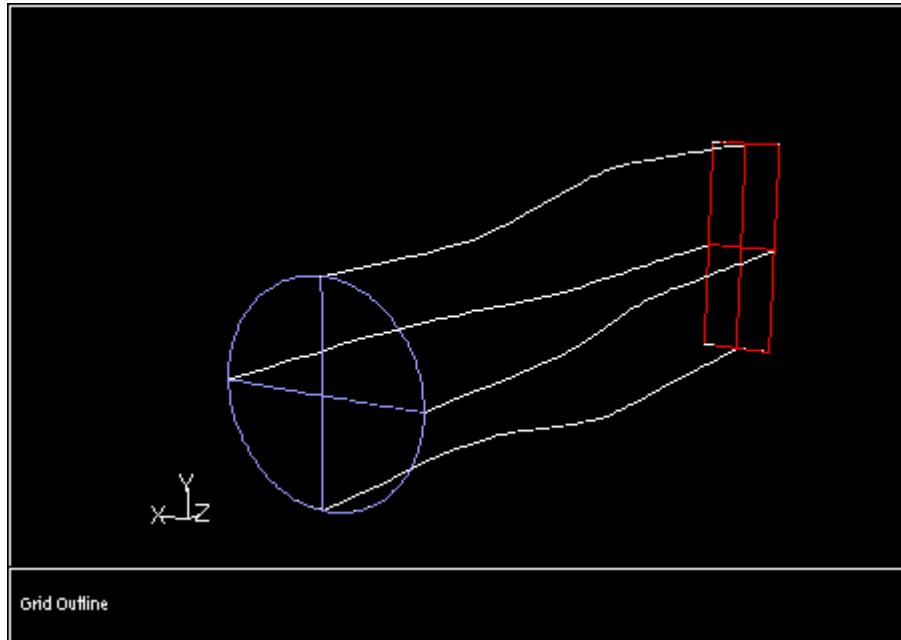

- 32.1.1. Displaying the Mesh
- 32.1.2. Displaying Contours and Profiles
- 32.1.3. Displaying Vectors
- 32.1.4. Displaying Pathlines
- 32.1.5. Displaying Results on a Sweep Surface
- 32.1.6. Hiding the Graphics Window Display

32.1.1. Displaying the Mesh

During the problem setup or when you are examining your solution, you may want to look at the mesh associated with certain surfaces. You can do the following:

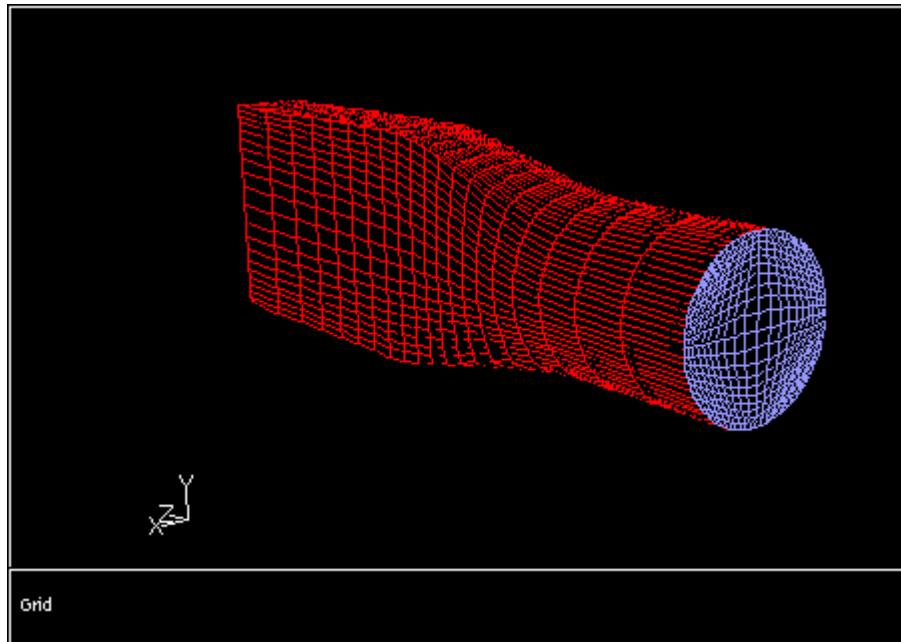

- Display the outline of all or part of the domain, as shown in *Figure 32.1* (p. 1500).

Figure 32.1 Outline Display

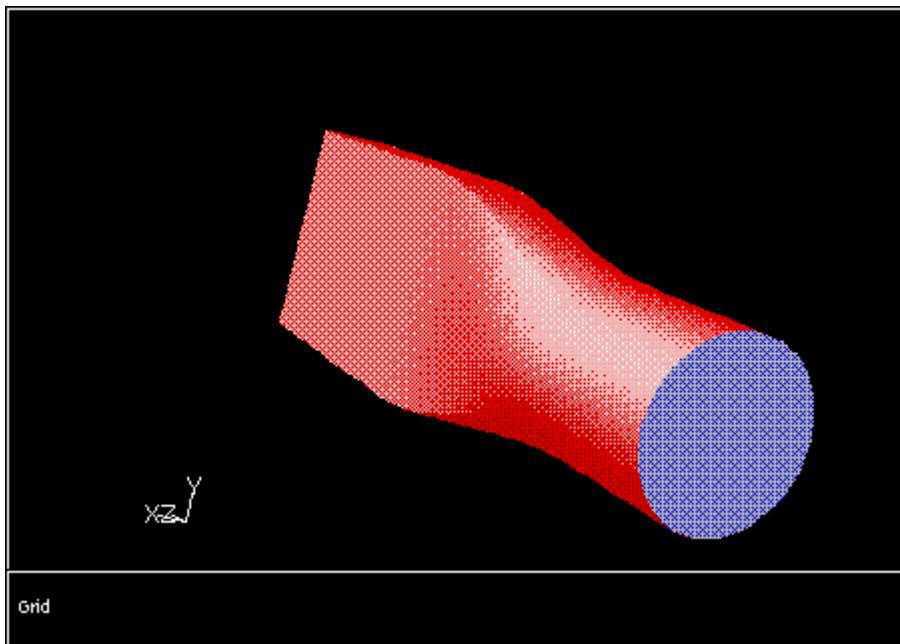

- Draw the mesh lines (edges), as shown in *Figure 32.2* (p. 1500).

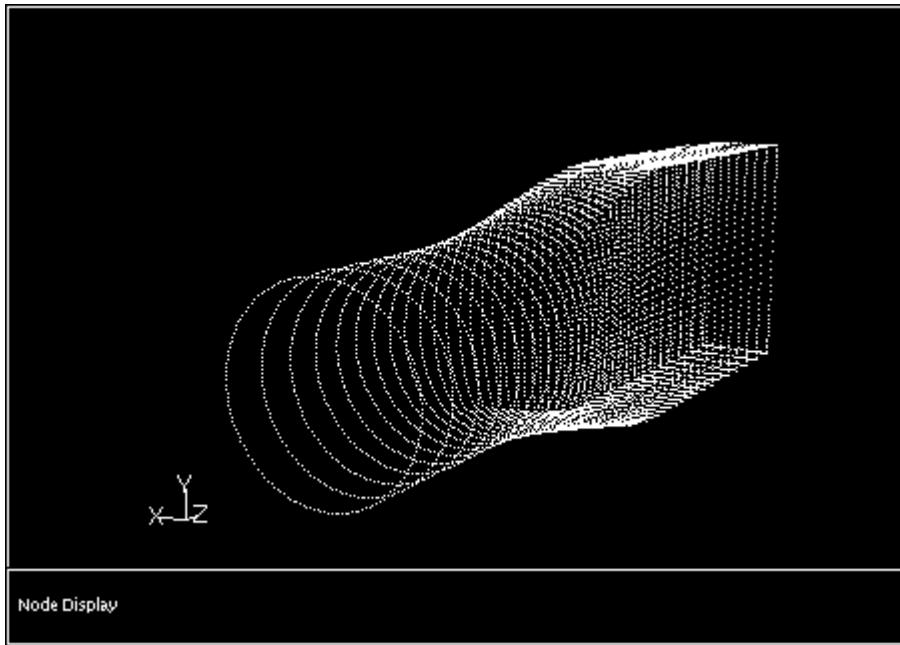

Figure 32.2 Mesh Edge Display

- Draw the solid surfaces (filled meshes) for a 3D domain, as shown in *Figure 32.3* (p. 1501).

Figure 32.3 Mesh Face (Filled Mesh) Display

- Draw the nodes on the domain surfaces, as shown in [Figure 32.4 \(p. 1501\)](#).

Figure 32.4 Node Display

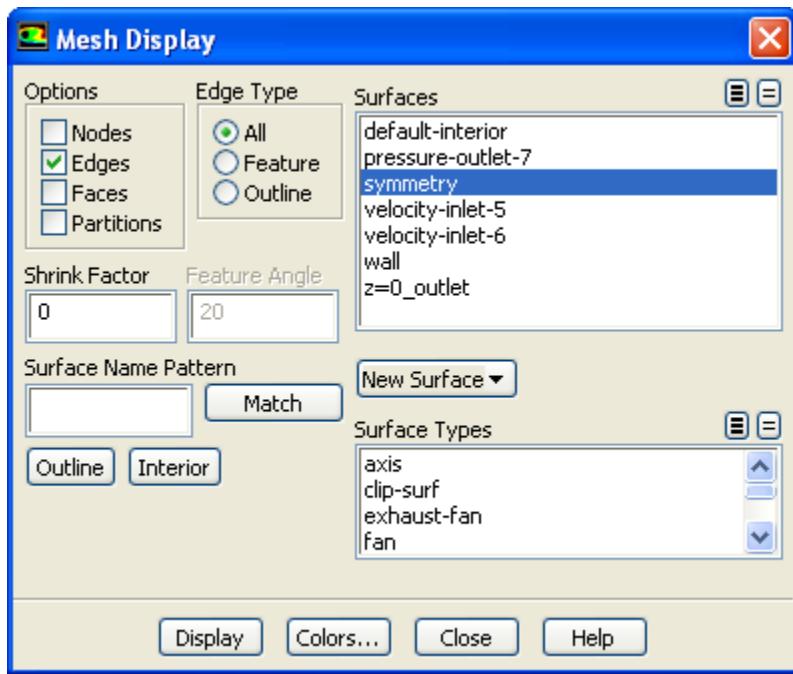

For information about displaying the mesh on a surface that sweeps through the domain, see [Displaying Results on a Sweep Surface \(p. 1529\)](#).

32.1.1.1. Generating Mesh or Outline Plots

You can draw the mesh or outline for all or part of your domain using the [Mesh Display Dialog Box \(p. 1767\)](#) ([Figure 32.5 \(p. 1502\)](#)).

General → Display...

Figure 32.5 The Mesh Display Dialog Box

The basic steps for generating a mesh or outline plot are as follows:

1. Choose the surfaces for which you want to display the mesh or outline in the **Surfaces** list.

If you want to select several surfaces of the same type, select that type in the **Surface Types** list instead. All of the surfaces of that type will be selected automatically in the **Surfaces** list (or deselected, if they are all selected already).

Another shortcut is to specify a **Surface Name Pattern** and click **Match** to select surfaces with names that match the specified pattern. For example, if you specify **wall***, all surfaces whose names begin with **wall** (for example, **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all surfaces whose names consist of **wall** followed by a single character will be selected (or deselected, if they are all selected already).

To choose all “outline” surfaces (that is, surfaces on the outer boundary of the domain), click **Outline** below the **Surface Types** list. If all outline surfaces are already selected, this will deselect them. To choose all “interior” surfaces, click **Interior**. If all interior surfaces are already selected, this will deselect them.

2. Depending on what you want to draw, do one or more of the following:

- To draw an outline of the selected surfaces (as in [Figure 32.1 \(p. 1500\)](#)), select **Edges** under **Options** and **Outline** under **Edge Type**. If you need more detail in the outline display of a complex geometry, see the description of the **Feature** option, below.
- To draw the mesh edges (as in [Figure 32.2 \(p. 1500\)](#)), select **Edges** under **Options** and **All** under **Edge Type**.
- To generate a filled-mesh display (as in [Figure 32.3 \(p. 1501\)](#)), select **Faces** under **Options**.

- To draw the nodes on the selected surfaces (as in [Figure 32.4 \(p. 1501\)](#)), select **Nodes** under **Options**.
3. Set any of the mesh and outline display options described in the following section.
 4. Click **Display** to draw the specified mesh or outline in the active graphics window.

To display filled meshes, with smoothly shaded display, enable lighting and select a lighting interpolation method other than **Flat** in the [Display Options Dialog Box \(p. 2148\)](#) or the [Lights Dialog Box \(p. 2162\)](#).

If you display nodes, and you want to change the symbol representing the nodes, you can change the **Point Symbol** in the [Display Options Dialog Box \(p. 2148\)](#). See [Modifying the Rendering Options \(p. 1546\)](#) for details.

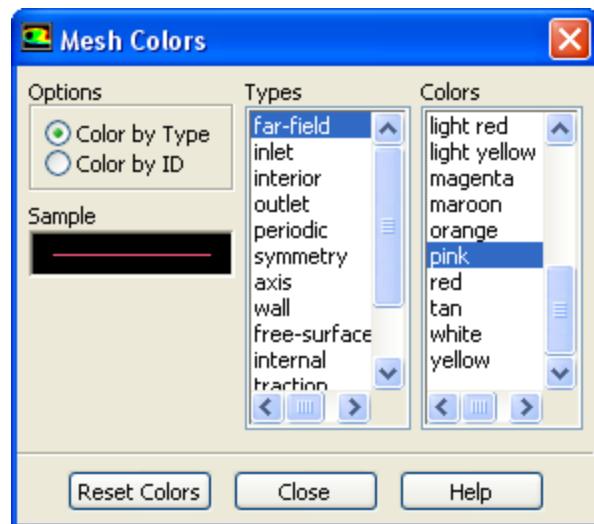

32.1.1.2. Mesh and Outline Display Options

The options mentioned in the procedure in the previous section include modifying the mesh colors, adding the outline of important features to an outline display, drawing partition boundaries, and shrinking the faces and/or cells in the display.

32.1.1.2.1. Modifying the Mesh Colors

ANSYS FLUENT enables you to control the colors that are used to render the meshes for each zone type or surface. This capability can help you to understand mesh plots quickly and easily. To modify the colors, open the [Mesh Colors Dialog Box \(p. 1770\)](#) ([Figure 32.6 \(p. 1503\)](#)) by clicking **Colors...** in the [Mesh Display Dialog Box \(p. 1767\)](#).

Figure 32.6 The Mesh Colors Dialog Box

You can set colors individually for the meshes displayed on each surface, using the [Scene Description Dialog Box \(p. 2151\)](#).

By default, the **Color by Type** option is turned on, enabling you to assign colors based on zone type. To change the color used to draw the mesh for a particular zone type, select the zone type in the **Types** list and then select the new color in the **Colors** list. You will see the effect of your change when you next display the mesh. Note that the **surface** type in the **Types** list applies to all surface meshes (i.e., meshes that are drawn for surfaces created using the dialog boxes opened from the **Surface** menu) except zone surfaces.

If you prefer to use the colors ANSYS FLUENT assigns by zone ID, then you can display the mesh using the **Color by ID** option.

32.1.1.2.2. Adding Features to an Outline Display

For closed 3D geometries such as cylinders, the standard outline display often will not show enough detail to accurately depict the shape. This is because for each boundary, only those edges on the "outside" of the geometry (that is, those that are used by only one face on the boundary) are drawn. In [Figure 32.7 \(p. 1504\)](#), which shows the outline display for a complicated duct geometry, only the inlet and outlet are visible.

Figure 32.7 Standard Outline of Complex Duct

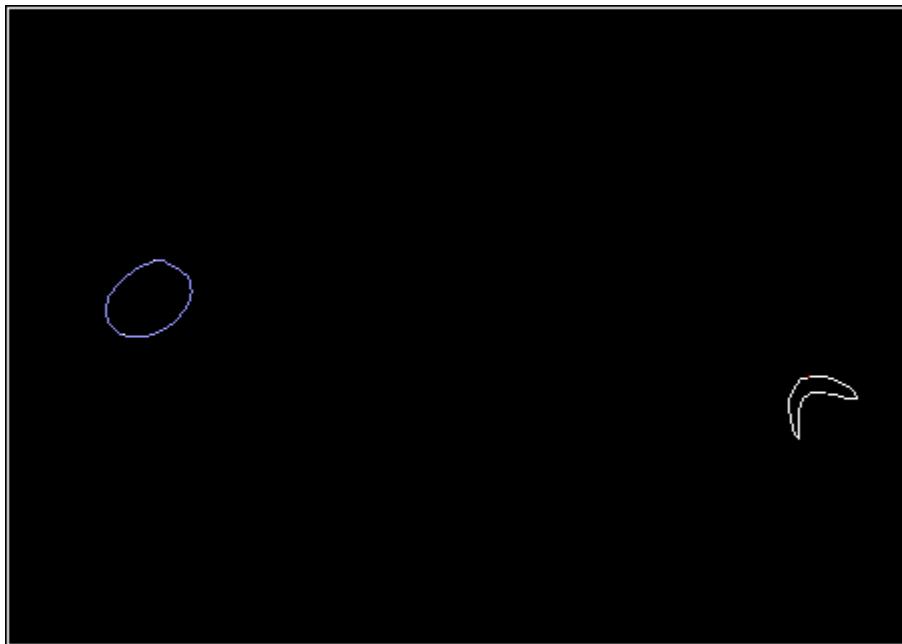

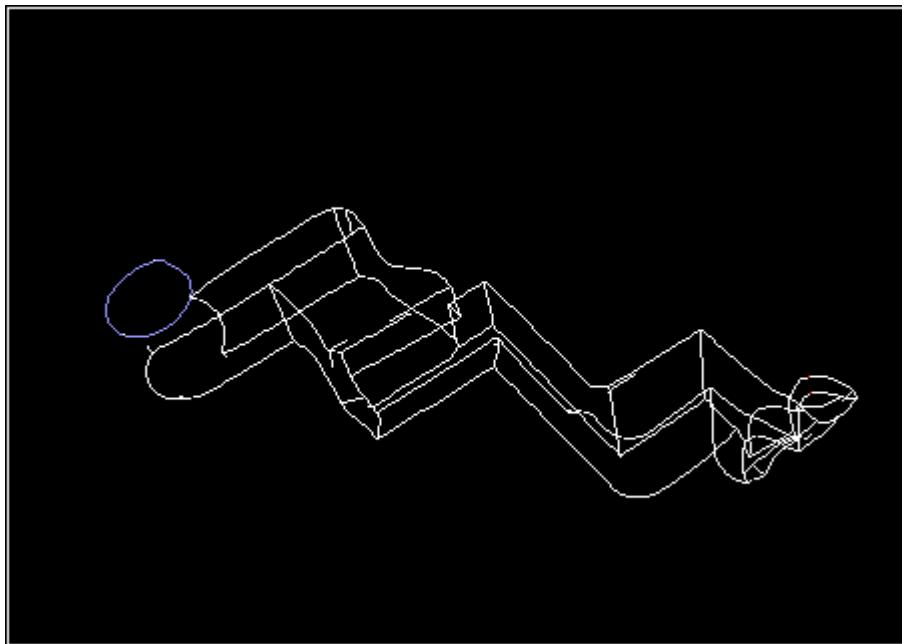

Figure 32.8 Feature Outline of Complex Duct

You can capture additional features using the **Feature** option in the *Mesh Display Dialog Box* (p. 1767). (See *Figure 32.8* (p. 1504).) Enable **Feature** under **Edge Type**, and then set the **Feature Angle**. With the default **Feature Angle** of 20, if the difference between the normal directions of two adjacent faces is more than 20°, the edge between those faces will be drawn. Decreasing the **Feature Angle** will result in more edge lines (that is, more detail) being added to the outline display. The appropriate angle for your geometry will depend on its curvature and complexity. You can modify the **Feature Angle** until you find the value that yields the best outline display.

32.1.1.2.3. Drawing Partition Boundaries

If you have partitioned your mesh for parallel processing, you can add the display of partition boundaries to the mesh display by turning on the **Partitions** option in the *Mesh Display Dialog Box* (p. 1767).

32.1.1.2.4. Shrinking Faces and Cells in the Display

To distinguish individual faces or cells in the display, enlarge the space between adjacent faces or cells by increasing the **Shrink Factor** in the *Mesh Display Dialog Box* (p. 1767). The default value of zero produces a display in which the edges of adjacent faces or cells overlap. A value of 1 creates the opposite extreme: each face or cell is represented by a point and there is considerable space between each one. A small value such as 0.01 may be large enough to enable you to distinguish one face or cell from its neighbor. Displays with different **Shrink Factor** values are shown in *Figure 32.9* (p. 1505) and *Figure 32.10* (p. 1506). Click **Display** to see the effect of the change in **Shrink Factor**.

Figure 32.9 Mesh Display with Shrink Factor = 0

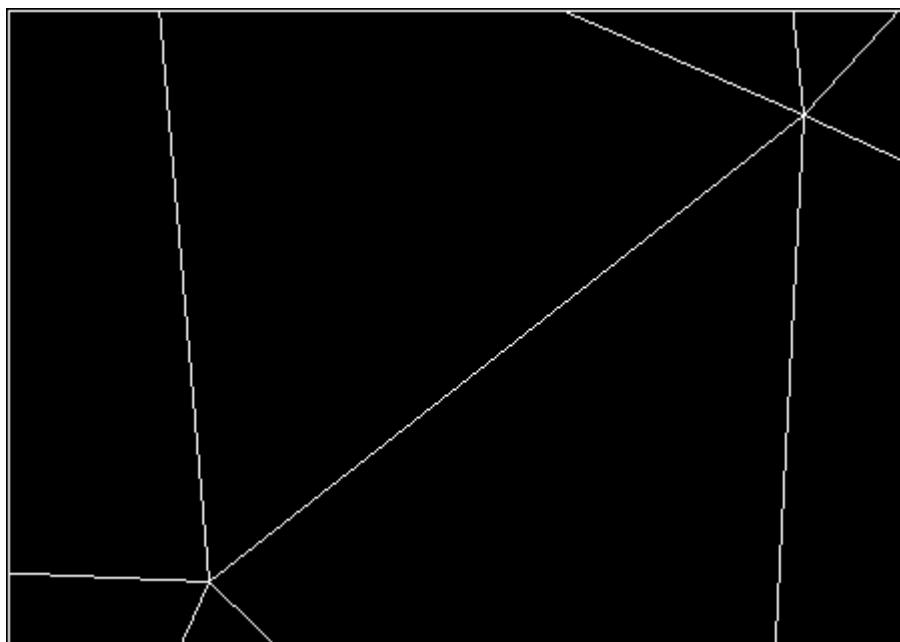

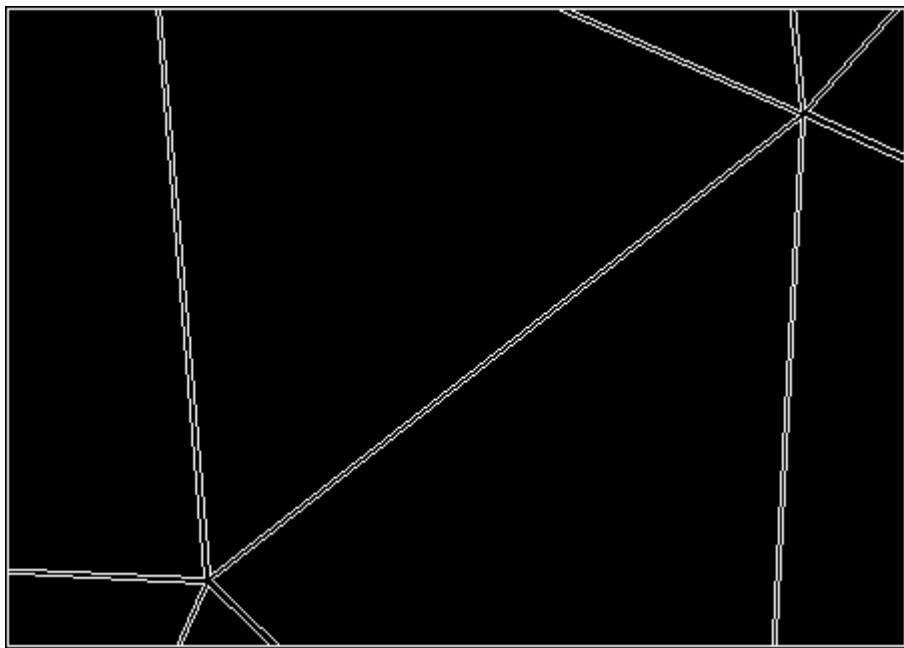

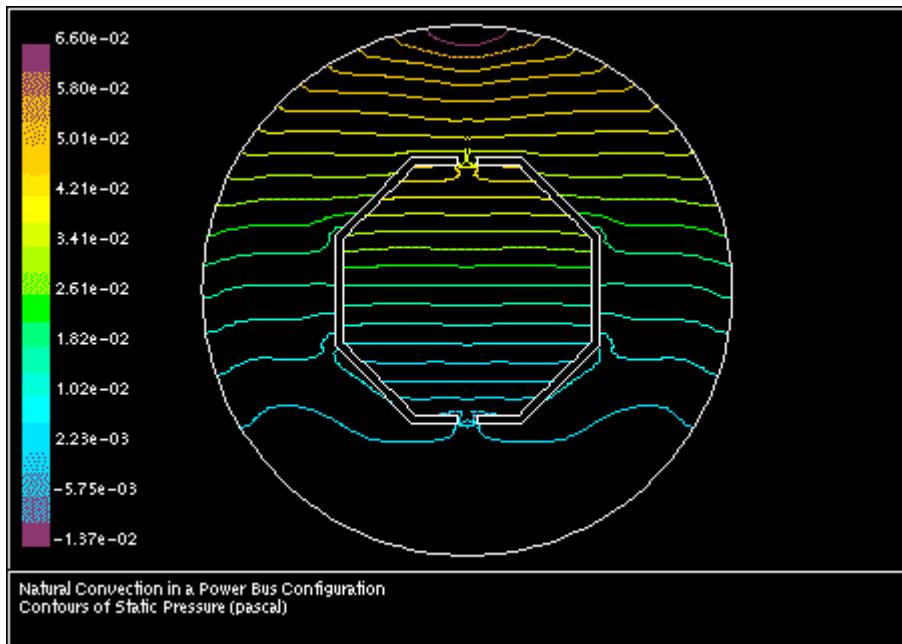

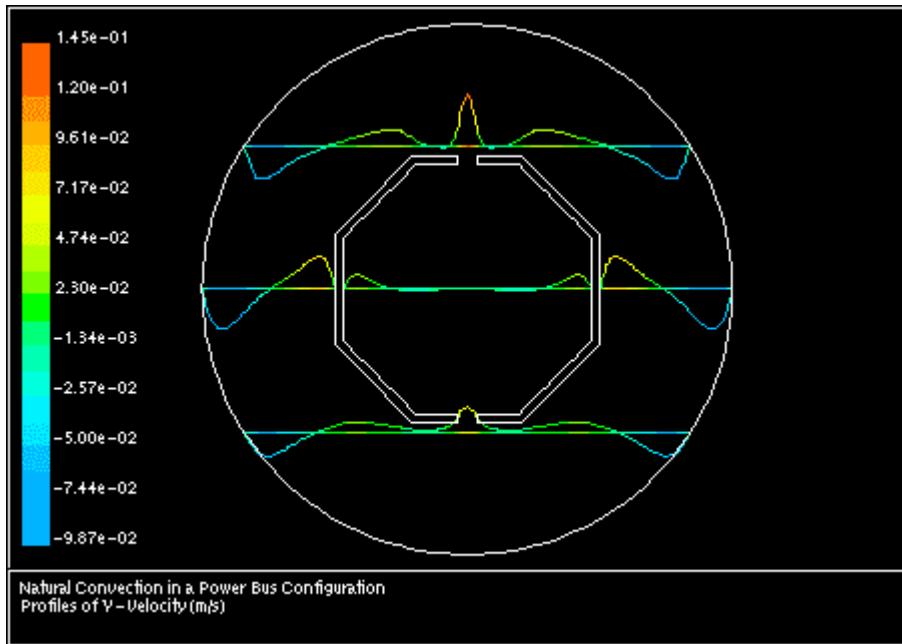

Figure 32.10 Mesh Display with Shrink Factor = 0.01

32.1.2. Displaying Contours and Profiles

ANSYS FLUENT enables you to plot contour lines or profiles superimposed on the physical domain. Contour lines are lines of constant magnitude for a selected variable (isotherms, isobars, and so on). A profile plot draws these contours projected off the surface along a reference vector by an amount proportional to the value of the plotted variable at each point on the surface. Sample plots are shown in [Figure 32.11 \(p. 1507\)](#) and [Figure 32.12 \(p. 1507\)](#).

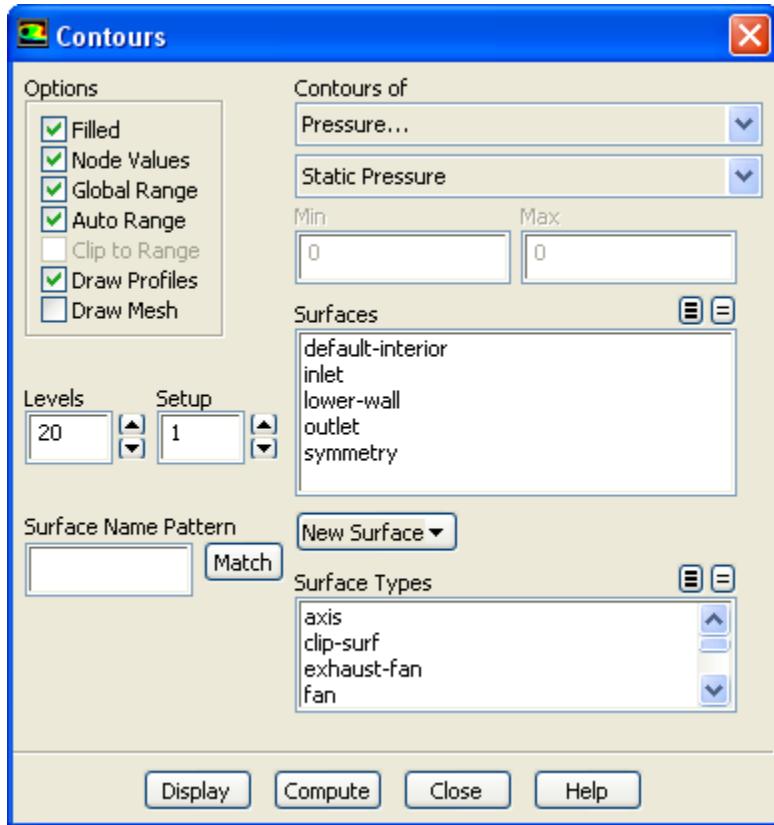

For information about displaying contours or profiles on a surface that sweeps through the domain, see [Displaying Results on a Sweep Surface \(p. 1529\)](#).

Figure 32.11 Contours of Static Pressure**Figure 32.12 Profile Plot of y Velocity**

32.1.2.1. Generating Contour and Profile Plots

You can plot contours or profiles using the [Contours Dialog Box \(p. 2120\)](#) ([Figure 32.13 \(p. 1508\)](#)).

❖ **Graphics and Animations** → **Contours** → **Set Up...**

Figure 32.13 The Contours Dialog Box

The basic steps for generating a contour or profile plot are as follows:

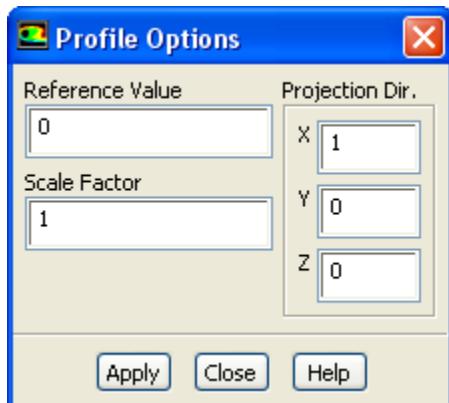

1. Select the variable or function to be contoured or profiled in the **Contours of** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
2. Choose the surface or surfaces on which to draw the contours or profiles in the **Surfaces** list. For 2D cases, if no surface is selected, contouring or profiling is done on the entire domain. For 3D cases, you must always select at least one surface.

If you want to select several surfaces of the same type, you can select that type in the **Surface Types** list instead. All of the surfaces of that type will be selected automatically in the **Surfaces** list (or deselected, if they are all selected already).

Another shortcut is to specify a **Surface Name Pattern** and click **Match** to select surfaces with names that match the specified pattern. For example, if you specify **wall***, all surfaces whose names begin with **wall** (e.g., **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all surfaces whose names consist of **wall** followed by a single character will be selected (or deselected, if they are all selected already).

3. Specify the number of contours or profiles in the **Levels** field. The maximum number of levels allowed is 100.
4. If you are generating a profile plot, enable the **Draw Profiles** option. In the resulting *Profile Options Dialog Box* (p. 2123) (*Figure 32.14* (p. 1509)) you will define the profiles.

Figure 32.14 The Profile Options Dialog Box

- Set the “zero height” reference value for the profile (**Reference Value**) and the length scale factor for projection (**Scale Factor**). Any point on the profile with a value equal to the **Reference Value** will be plotted exactly on the defining surface. Values greater than the **Reference Value** will be projected ahead of the surface (in the direction of **Projection Dir.**) and scaled by **Scale Factor**), and values less than the **Reference Value** will be projected behind the surface and scaled.

These parameters can be used to create fuller profiles when you need to display the variation in a variable which is small compared to the absolute value of the variable. Consider, for example, the display of temperature profiles when the temperature range in the domain is from 300 K to 310 K. The 10 K range in the temperature will be hard to detect when profiles are drawn using the default scaling (which will be based on the absolute magnitude of 310 K). To create a fuller profile, you can set the **Reference Value** to 300 and the profile **Scaling Factor** to 5 (for example) to magnify the display of the remaining 10 K range. In subsequent display of the profiles, the reference value of 300 will be effectively subtracted from the data before display so that the temperatures of 300 K will not be offset from the baselines. The profiles will then reflect only the variation of temperature from 300 K.

- Set the direction in which profiles are projected (**Projection Dir.**). In 2D, for example, a contour plot of pressure on the entire domain can be projected in the z direction to form a carpet plot, or a contour plot of y velocity on a sequence of y -co-ordinate slice lines can be projected in the y direction to form a series of velocity profiles (as shown in [Figure 32.12 \(p. 1507\)](#)).
 - Click **Apply** and close the [Profile Options Dialog Box \(p. 2123\)](#).
- Set any of the contour and profile plot options described below.
 - Click **Display** to draw the specified contours or profiles in the active graphics window.

The resulting display will include the specified number of contours or profiles of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

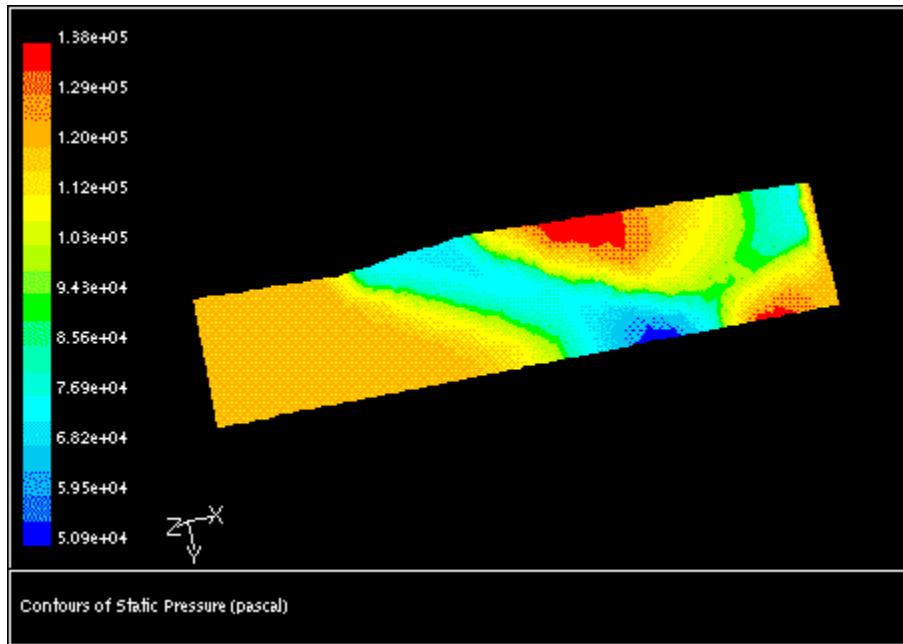

32.1.2.2. Contour and Profile Plot Options

The options mentioned in the procedure above include drawing color-filled contours/profiles (instead of the default line contours/profiles), specifying a range of values to be contoured or profiled, including portions of the mesh in the contour or profile display, choosing node or cell values for display, and storing the contour or profile plot settings.

32.1.2.2.1. Drawing Filled Contours or Profiles

Color-filled contour or profile plots show a contour or profile display containing a continuous color display (see [Figure 32.15 \(p. 1510\)](#)), instead of just drawing lines representing specific values. Note that a color-filled profile display is often referred to as a “carpet plot”. To generate a filled contour or profile plot, enable the **Filled** option in the [Contours Dialog Box \(p. 2120\)](#) during step 5 in the previous section.

Figure 32.15 Filled Contours of Static Pressure

To display smoothly shaded filled contours, you must enable lighting and select a lighting interpolation method other than **Flat** in the [Display Options Dialog Box \(p. 2148\)](#) or the [Lights Dialog Box \(p. 2162\)](#). You will not get smooth shading of filled contours if the **Clip to Range** option is turned on. Smooth shading of filled profiles is not available.

32.1.2.2.2. Specifying the Range of Magnitudes Displayed

By default, the minimum and maximum values contoured or profiled are set based on the range of values in the entire domain. This means that the color scale will start at the smallest value in the domain (shown in the **Min** field) and end at the largest value (shown in the **Max** field). If you are plotting contours or profiles on a subset of the domain (that is, on a surface), your plot may cover only the midrange of the color scale. For example, if blue corresponds to 0 and red corresponds to 10, and the values on your surface range only from 4 to 6, your plot will contain mostly green contours or profiles, since green is the color at the middle of the default color scale.

- To focus in on a smaller range of values, so that blue corresponds to 4 and red to 6, manually reset the range to be displayed. You can also use the minimum and maximum values on the selected surfaces—rather than in the entire domain—to determine the range. Another reason to manually set the range is if you are interested only in certain values. For example, if you want to determine the region where pressure exceeds a certain value, you can increase the minimum value for display so that the lower pressure values are not displayed.
- To manually set the contour/profile range, turn off the **Auto Range** option in the [Contours Dialog Box \(p. 2120\)](#). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be displayed.

- To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.
- If you are drawing filled contours or profiles you can control whether or not values outside the prescribed **Min/ Max** range are displayed.
- To leave areas in which the value is outside the specified range empty (that is, draw no contours or profiles), enable the **Clip to Range** option. This is the default setting. If you turn **Clip to Range** off, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. [Figure 32.16 \(p. 1511\)](#) and [Figure 32.17 \(p. 1512\)](#) show the results of enabling/disabling the **Clip to Range** option.
- To base the minimum and maximum values on the range of values on the selected surfaces, rather than in the entire domain, turn off the **Global Range** option in the [Contours Dialog Box \(p. 2120\)](#). The **Min** and **Max** values will be updated when you next click **Compute** or **Display**.

Figure 32.16 Filled Contours with Clip to Range On

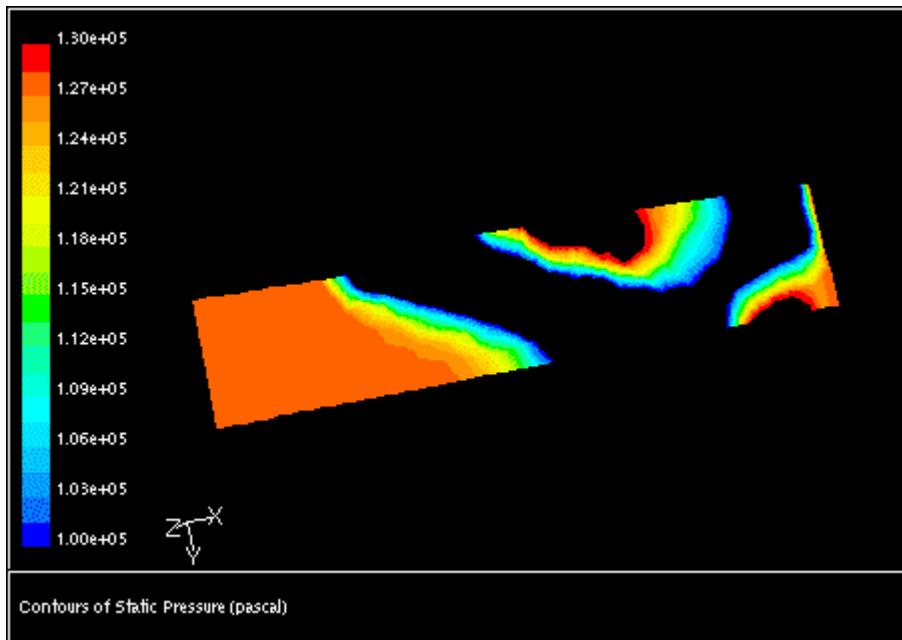

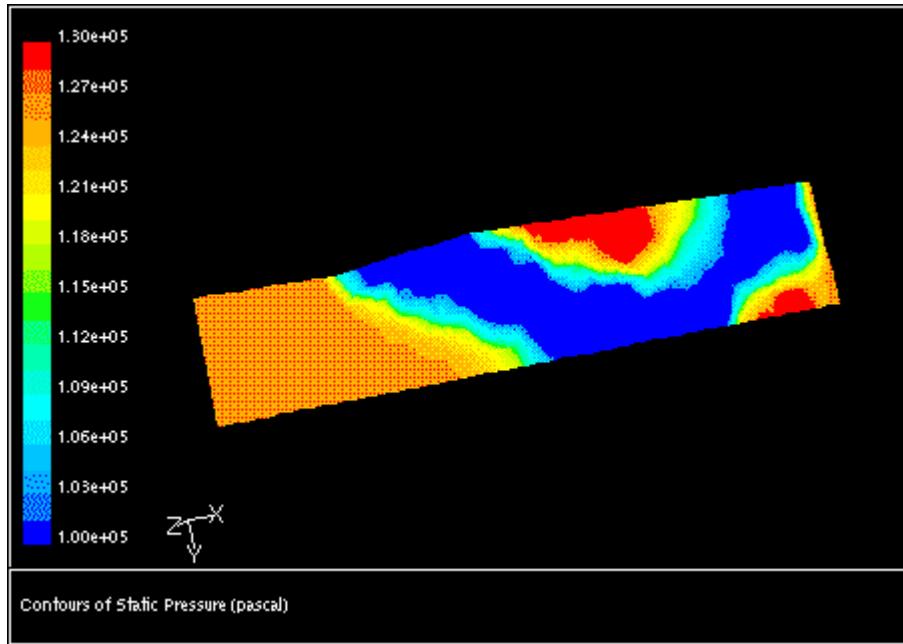

Figure 32.17 Filled Contours with Clip to Range Off

32.1.2.2.3. Including the Mesh in the Contour Plot

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your contour or profile plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the contours. This is accomplished by turning on the **Draw Mesh** option in the *Contours Dialog Box* (p. 2120). The *Mesh Display Dialog Box* (p. 1767) will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the *Contours Dialog Box* (p. 2120), the mesh display, as defined in the *Mesh Display Dialog Box* (p. 1767), will be included in the contour or profile plot.

32.1.2.2.4. Choosing Node or Cell Values

In ANSYS FLUENT you can choose to display the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are displayed. For line contours or profiles, node values are always used. To display filled contours or profiles and to display the cell values, turn off the **Node Values** option. Filled contours/profiles of node values will show a smooth gradation of color, while filled contours/profiles of cell values may show sharp changes in color from one cell to the next.

For face-only functions (for example, **Wall Shear Stress**), the cell values that are displayed for boundary zone surfaces will actually be the face values. This is only true in the case of boundary zone surfaces created for postprocessing, where the actual cell values are used for the part of the surface which lies in the interior. These face values are more accurate, as face-only functions are computed on the faces and not on the cells. For more information about cell values, see *Cell Values* (p. 1653).

If you are plotting contours to show the effect of a porous medium or fan, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

32.1.2.2.5. Storing Contour Plot Settings

For frequently used combinations of contour variables and options, you can store the information needed to generate the contour plot by specifying a **Setup** number and setting up the desired information in the [Contours Dialog Box \(p. 2120\)](#). When you click **Display**, the settings for **Options**, **Contours of**, **Min**, **Max**, and **Surfaces** will be saved. You can then change the **Setup** number to an unused value (that is, an ID for which no information has been saved) and generate a different contour plot. To generate a plot using the saved setup information, change the **Setup** number back to the value for which you saved contour information and click **Display**. You can save up to 10 different setups.

Important

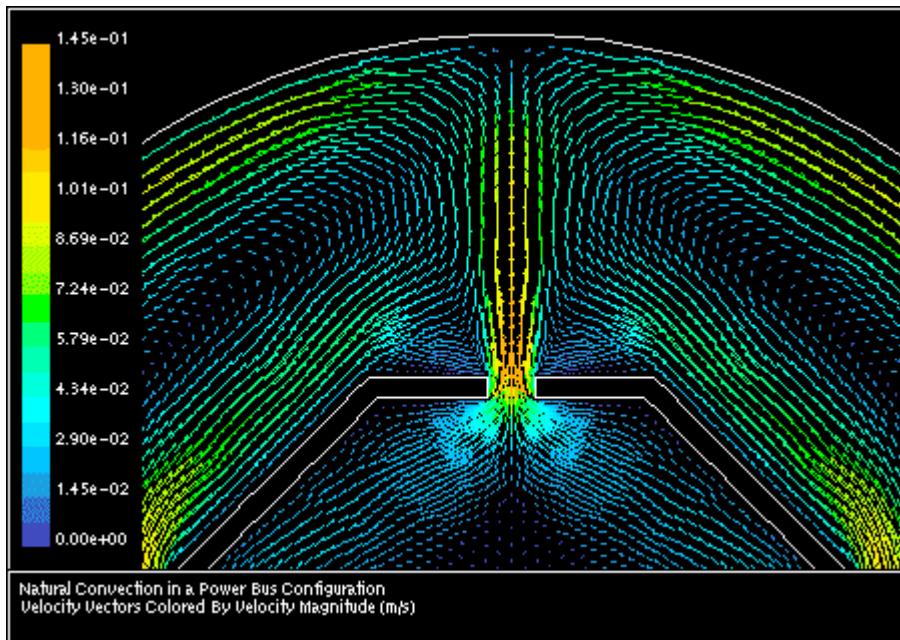

Note that the number of contour **Levels**, the surfaces selected for display in the [Mesh Display Dialog Box \(p. 1767\)](#) (when the **Draw Mesh** option is activated), and the settings for profiles in the [Profile Options Dialog Box \(p. 2123\)](#) (when the **Draw Profiles** option is activated) will *not* be saved in the **Setup**, nor will the **Setup** be saved in the case file.

32.1.3. Displaying Vectors

You can draw vectors in the entire domain, or on selected surfaces. By default, one vector is drawn at the center of each cell (or at the center of each facet of a data surface), with the length and color of the arrows representing the velocity magnitude ([Figure 32.18 \(p. 1513\)](#)). The spacing, size, and coloring of the arrows can be modified, along with several other vector plot settings. Velocity vectors are the default, but you can also plot vector quantities other than velocity. Note that cell-center values are always used for vector plots; you cannot plot node-averaged values.

For information about displaying vectors on a surface that sweeps through the domain, see [Displaying Results on a Sweep Surface \(p. 1529\)](#).

Figure 32.18 Velocity Vector Plot

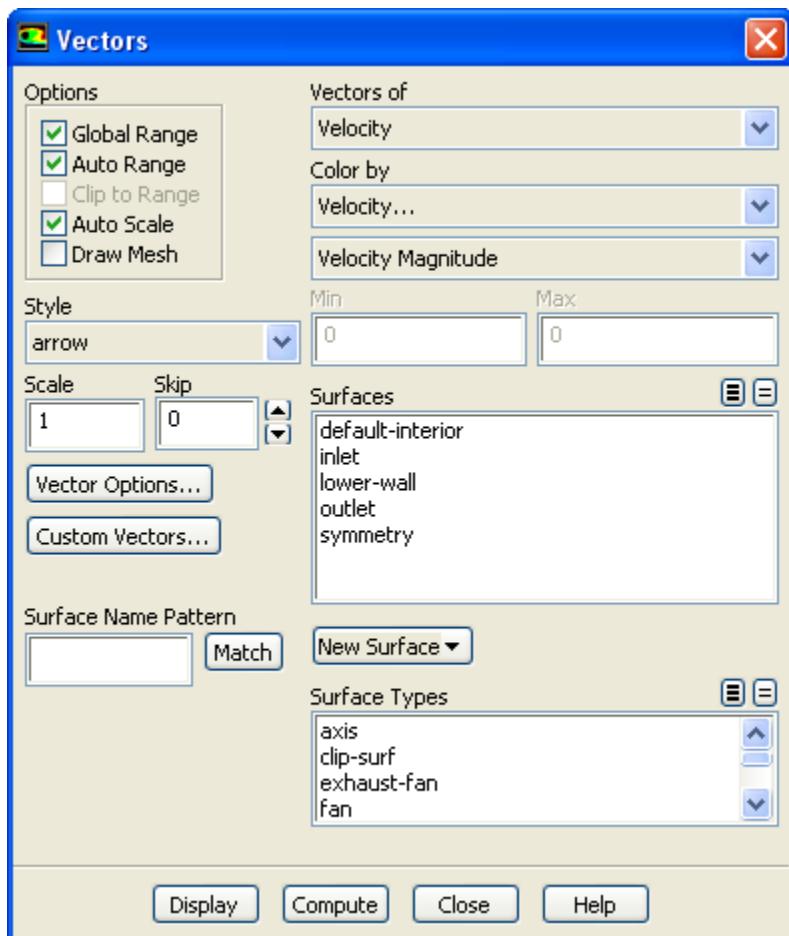

32.1.3.1. Generating Vector Plots

You can plot vectors using the *Vectors Dialog Box* (p. 2123) (*Figure 32.19* (p. 1514)).

↳ **Graphics and Animations** → **Vectors** → **Set Up...**

Figure 32.19 The Vectors Dialog Box

The procedure for generating a vector plot is as follows:

1. In the **Vectors of** drop-down list, select the vector quantity to be plotted. By default, only velocity and relative velocity are available, but you can create your own custom vectors as described in *Creating and Managing Custom Vectors* (p. 1518).
2. In the **Surfaces** list, choose the surface(s) on which you want to display vectors. If you want to display vectors on the entire domain, select none of the surfaces in the list.

If you want to select several surfaces of the same type, you can select that type in the **Surface Types** list instead. All of the surfaces of that type will be selected automatically in the **Surfaces** list (or deselected, if they are all selected already).

Another short cut is to specify a **Surface Name Pattern** and click **Match** to select surfaces with names that match the specified pattern. For example, if you specify **wall***, all surfaces whose names begin with **wall** (for example, **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all surfaces whose names consist

- of **wall** followed by a single character will be selected (or deselected, if they are all selected already).
3. Set any of the vector plot options as described in [Vector Plot Options \(p. 1515\)](#).
 4. Click **Display** to draw the vectors in the active graphics window.

32.1.3.2. Displaying Relative Velocity Vectors

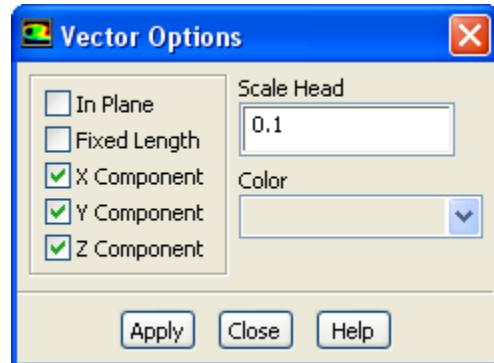

If you are solving your problem using one or more moving reference frames or moving meshes, you will have the option to display either the absolute vectors or the relative vectors. If you select **Velocity** (the default) in the **Vectors of** list, the vectors will be drawn based on the absolute, stationary reference frame. If you select **Relative Velocity**, the vectors will be drawn based on the reference frame of the **Reference Zone** in the [Reference Values Task Page \(p. 2046\)](#). See [Setting the Reference Zone \(p. 1650\)](#) for details. (If you are modeling a single moving reference frame, you need not specify the **Reference Zone**; the vectors will be drawn based on the moving reference frame.)

32.1.3.3. Vector Plot Options

The options mentioned in the procedure above include scaling the vector arrows, skipping the display of some vectors, displaying vectors in the plane of the data surface, displaying fixed-length or fixed-color vectors, displaying directional components of the vectors, specifying a range of values to be displayed, coloring the vectors by a different scalar field, including portions of the mesh in the vector display, and changing the style of the arrows or the scale of the arrowheads.

The most common options are set in the [Vectors Dialog Box \(p. 2123\)](#), and others are set in the [Vector Options Dialog Box \(p. 2126\)](#) ([Figure 32.20 \(p. 1515\)](#)), which you can open by clicking **Vector Options...** in the [Vectors Dialog Box \(p. 2123\)](#).

Figure 32.20 The Vector Options Dialog Box

32.1.3.3.1. Scaling the Vectors

By default, vectors are scaled automatically so that the arrows overlap minimally when no vectors are skipped. For instructions on thinning the vector display, see ["Thinning" Pathlines \(p. 1524\)](#). With the **Auto Scale** option, you can modify the **Scale** factor (which is set to 1 by default) to increase or decrease the vector scale from the default "auto scale". The main advantage of autoscaling is that the vector display with a scale factor of 1 will always be appropriate, regardless of the size of the domain, giving you a better starting point for fine-tuning the vector scale.

If you turn off the **Auto Scale** option, the vectors will be drawn at their actual sizes scaled by the scale factor (**Scale**, which is set to 1 by default). The "actual" size of a vector is the magnitude of the vector variable (velocity, by default) at the point where it is drawn. A vector drawn at a point where the velocity

magnitude is 100 m/s is drawn 100 m long, whether the domain is 0.1 m or 1000 m. You can modify the vector scale by changing the value of **Scale** in the *Vectors Dialog Box* (p. 2123) until the size of the vectors (that is, the actual size multiplied by **Scale**) is satisfactory.

32.1.3.3.2. Skipping Vectors

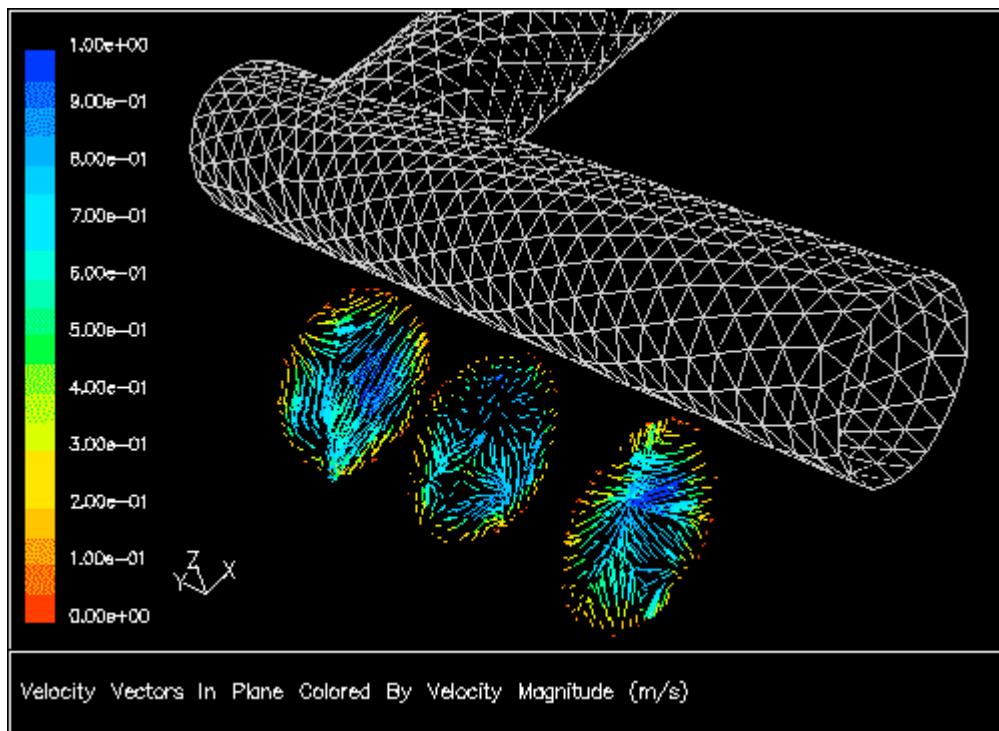

If your vector display is difficult to understand because there are too many arrows displayed, you can “thin out” the vectors by changing the **Skip** value in the *Vectors Dialog Box* (p. 2123). By default, **Skip** is set to 0, indicating that a vector will be drawn for each cell in the domain or for each face on the selected surface (for example, n vectors). If you increase **Skip** to 1, every other vector will be displayed, yielding $n/2$ vectors. If you increase **Skip** to 2, every third vector will be displayed, yielding $n/3$ vectors, and so on. The order of faces on the selected surface (or cells in the domain) will determine which vectors are skipped or drawn; thus adaption and reordering will change the appearance of the vector display when a non-zero **Skip** value is used.

32.1.3.3.3. Drawing Vectors in the Plane of the Surface

For some problems, you may be interested in visualizing velocity (or other vector) components that are normal to the flow. These “secondary flow” components are usually much smaller than the components in the flow direction and are difficult to see when the flow direction components are also visible. To easily view the normal flow components, you can enable the **In Plane** option in the *Vector Options Dialog Box* (p. 2126). When this option is on, ANSYS FLUENT will display only the vector components in the plane of the surface selected for display. If the selected surface is a cross-section of the flow domain, you will be displaying the components normal to the flow.

Figure 32.21 (p. 1516) shows velocity vectors generated using the **In Plane** option. Note that these vectors have been translated outside the domain, as described in *Transforming Geometric Objects in a Scene* (p. 1569), so that they can be seen more easily.

Figure 32.21 Velocity Vectors Generated Using the In Plane Option

32.1.3.3.4. Displaying Fixed-Length Vectors

By default, the length of a vector is proportional to its velocity magnitude. If you want all of the vectors to be displayed with the same length, you can enable the **Fixed Length** option in the [Vector Options Dialog Box \(p. 2126\)](#). To modify the vector length, adjust the value of the **Scale** factor in the [Vectors Dialog Box \(p. 2123\)](#).

32.1.3.3.5. Displaying Vector Components

All Cartesian components of the vectors are drawn by default, so that the arrow points along the resultant vector in physical space. However, sometimes one of the components, say, the x component, is relatively large. In such cases, you may want to suppress the x component and scale up the vectors, in order to visualize the smaller y and z components. To suppress one or more of the vector components, turn off the appropriate button(s) (**X**, **Y**, or **Z Component**) in the [Vector Options Dialog Box \(p. 2126\)](#).

32.1.3.3.6. Specifying the Range of Magnitudes Displayed

By default, the minimum and maximum vectors included in the vector display are set based on the range of vector-variable (velocity, by default) magnitudes in the entire domain. If you want to focus in on a smaller range of values, you can restrict the range to be displayed. The color scale for the vector display will change to reflect the new range of values. (You can also use the minimum and maximum values on the selected surfaces—rather than on the entire domain—to determine the range, or change the scalar field by which the vectors are colored from velocity magnitude to any other scalar, as described below.)

To manually set the range of velocity magnitudes (or the range of whatever scalar field is selected in the **Color by** drop-down list), turn off the **Auto Range** option in the [Vectors Dialog Box \(p. 2123\)](#). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be displayed. For example, if you want to display velocity vectors only in regions where the velocity magnitude exceeds 150 m/s but is less than 300 m/s, you will change the value of **Min** to 150 and the value of **Max** to 300. Similarly, if you are coloring the vectors by static pressure, you can choose to display velocity vectors only in regions where the pressure is within a specified range. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

When you restrict the range of vectors displayed, you can also control whether or not values outside the prescribed **Min/ Max** range are displayed. To leave areas in which the value is outside the specified range empty (that is, draw no vectors), enable the **Clip to Range** option. This is the default setting. If you turn **Clip to Range** off, values below the **Min** value will be colored with the lowest color on the color scale, and values above the **Max** value will be colored with the highest color on the color scale. This feature is the same as the one available for displaying filled contours (see [Figure 32.16 \(p. 1511\)](#) and [Figure 32.17 \(p. 1512\)](#)).

You can also choose to base the minimum and maximum values on the range of values on the selected surfaces, rather than the entire domain. To do this, turn off the **Global Range** option in the [Vectors Dialog Box \(p. 2123\)](#). The **Min** and **Max** values will be updated when you next click **Compute** or **Display**.

32.1.3.3.7. Changing the Scalar Field Used for Coloring the Vectors

If you want to color the vectors by a scalar field other than velocity magnitude (the default), you can select a different variable or function in the **Color by** drop-down list. Select the desired category in the upper list, and then choose one of the related quantities from the lower list. If you choose static pressure, for example, the length of the vectors will still correspond to the velocity magnitude, but the color of the vectors will correspond to the value of pressure at each point where a vector is drawn.

32.1.3.3.8. Displaying Vectors Using a Single Color

If you want all of the vectors to be the same color, you can select the color to be used in the **Color** drop-down list in the [Vector Options Dialog Box \(p. 2126\)](#). If no color is selected (that is, if you choose the empty space at the top of the drop-down list—the default selection), the vector color will be determined by the **Color by** field specified in the [Vectors Dialog Box \(p. 2123\)](#). Single color vectors are useful in displays that overlay contours and vectors.

32.1.3.3.9. Including the Mesh in the Vector Plot

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your vector plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the vectors. This is accomplished by turning on the **Draw Mesh** option in the [Vectors Dialog Box \(p. 2123\)](#). The [Mesh Display Dialog Box \(p. 1767\)](#) will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the [Vectors Dialog Box \(p. 2123\)](#), the mesh display, as defined in the [Mesh Display Dialog Box \(p. 1767\)](#), will be included in the vector plot.

32.1.3.3.10. Changing the Arrow Characteristics

There are five different styles available for drawing the vector arrows. Choose **cone**, **filled-arrow**, **arrow**, **harpoon**, or **headless** in the **Style** drop-down list in the [Vectors Dialog Box \(p. 2123\)](#). The default arrow style is **harpoon**.

If you choose a vector arrow style that includes heads, you can control the size of the arrowhead by modifying the **Scale Head** value in the [Vector Options Dialog Box \(p. 2126\)](#).

32.1.3.4. Creating and Managing Custom Vectors

In addition to the velocity vector quantity provided by ANSYS FLUENT, you can also define your own custom vectors to be plotted. This capability is available with the [Custom Vectors Dialog Box \(p. 2126\)](#).

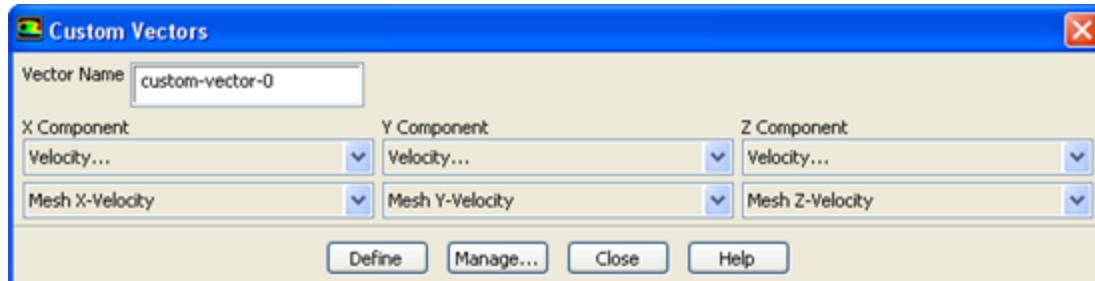

Any custom vectors that you define will be saved in the case file the next time that you save it. You can also save your custom vectors to a separate file, so that they can be used with a different case file.

32.1.3.4.1. Creating Custom Vectors

To create your own custom vector, you will use the [Custom Vectors Dialog Box \(p. 2126\)](#) ([Figure 32.22 \(p. 1518\)](#)). This dialog box enables you to define custom vectors based on existing quantities. Any vectors that you define will be added to the **Vectors of** list in the [Vectors Dialog Box \(p. 2123\)](#).

To open the [Custom Vectors Dialog Box \(p. 2126\)](#), click **Custom Vectors...** in the [Vectors Dialog Box \(p. 2123\)](#).

Figure 32.22 The Custom Vectors Dialog Box

The steps for creating a custom vector are as follows:

1. Specify the name of the custom vector in the **Vector Name** field.

Important

Do not specify a name that is already used for a standard vector (for example, velocity or relative-velocity).

2. Select the variable or function for the x component of the vector in the **X Component** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. For an explanation of the variables in the list, see *Field Function Definitions* (p. 1653).
3. Repeat the step above to select the variable or function for the y component (and, in 3D, the z component) of the custom vector.

Important

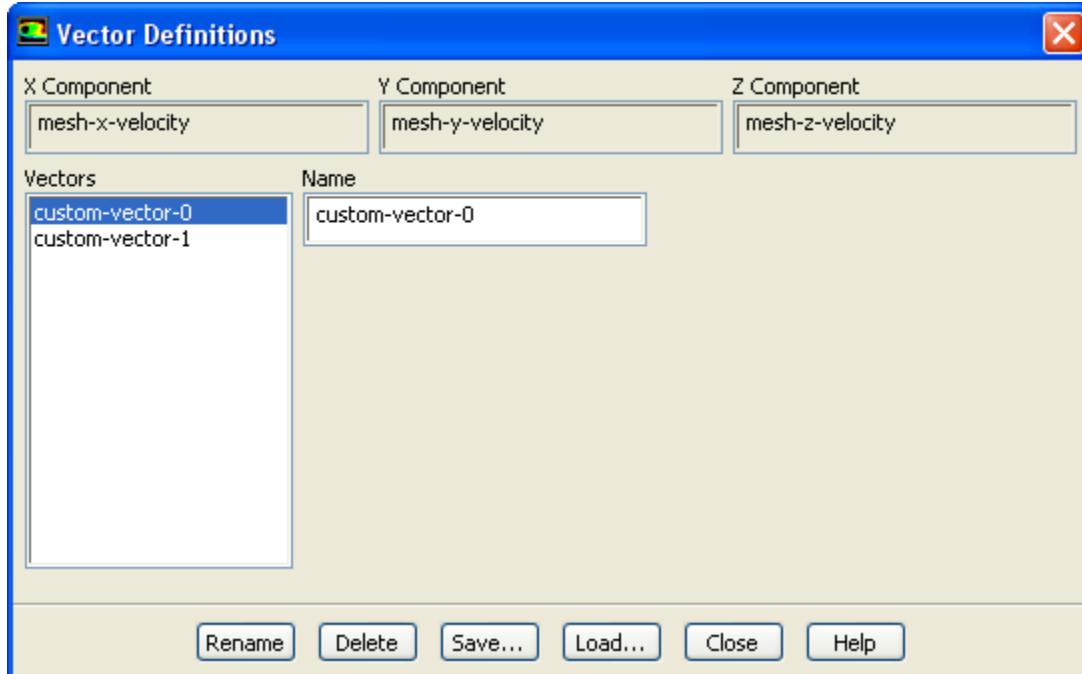

You can use the **Custom Vectors** option to plot vectors in solid cell zones. The scalars that are selected in the x , y (and, in 3D, the z) components, and that are valid in solid regions, will have vector plots displayed in the solid cell zones. Note that if a vector has no valid components in the solid region, then that vector will not be plotted in the solid region. However, if at least one component of the vector is valid in the solid region, then only that component of the vector will be plotted.

4. Click **Define**.

32.1.3.4.2. Manipulating, Saving, and Loading Custom Vectors

Once you have defined your vectors, you can manipulate them using the *Vector Definitions Dialog Box* (p. 2127) (*Figure 32.23* (p. 1520)). You can display a vector definition to be sure that it is correct, delete the vector if you decide that it is incorrect and needs to be redefined, or give the vector a new name. You can also save custom vectors to a file or read them from a file. The custom vector file enables you to transfer custom vectors between case files.

To open the *Vector Definitions Dialog Box* (p. 2127), click **Manage...** in the *Custom Vectors Dialog Box* (p. 2126).

Figure 32.23 The Vector Definitions Dialog Box

The following actions can be performed in the *Vector Definitions Dialog Box* (p. 2127):

- To check the definition of a vector, select it in the **Vectors** list. Its definition will be displayed in the **X Component**, **Y Component**, and **Z Component** fields at the top of the dialog box. This display is for informational purposes only; you cannot edit it. If you want to change a vector definition, you must delete the vector and define it again in the *Custom Vectors Dialog Box* (p. 2126).
- To delete a vector, select it in the **Vectors** list and click **Delete**.
- To rename a vector, select it in the **Vectors** list, enter a new name in the **Name** field, and click **Rename**.

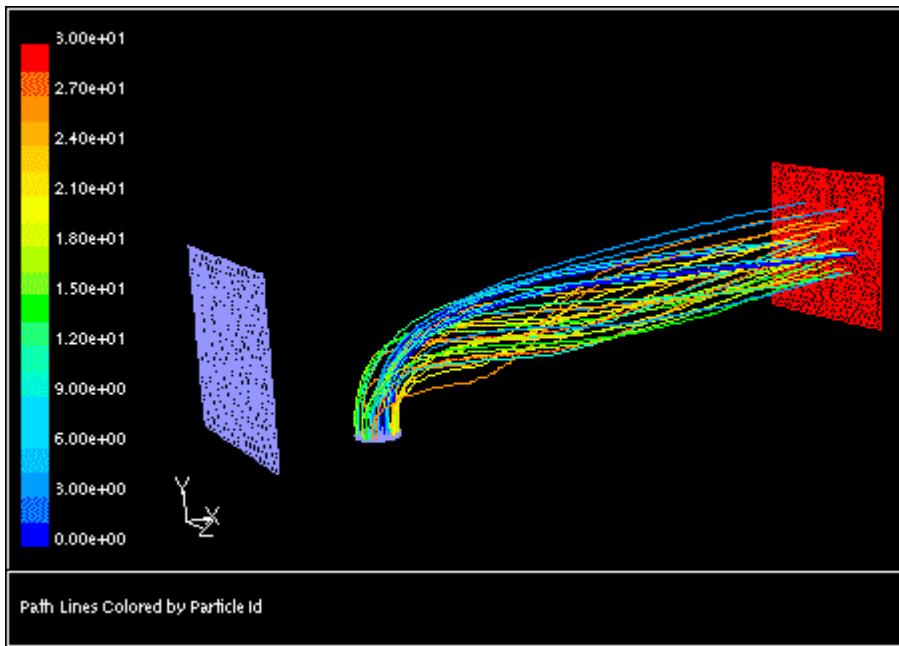

Important

Do not specify a name that is already used for a standard vector (for example, `velocity` or `relative-velocity`).

- To save all the vectors in the **Vectors** list to a file, click **Save...** and specify the file name in *The Select File Dialog Box* (p. 33).
- To read custom vectors from a file that you saved as described above, click **Load** and specify the file name in *The Select File Dialog Box* (p. 33). (Custom vectors are valid Scheme functions, and can also be loaded with the **File/Read/Scheme...** menu item, as described in *Reading Scheme Source Files* (p. 75).)

32.1.4. Displaying Pathlines

Pathlines are used to visualize the flow of massless particles in the problem domain. The particles are released from one or more surfaces that you have created with the tools in the **Surface** menu (see *Creating Surfaces for Displaying and Reporting Data* (p. 1473)). A **line** or **rake** surface (see *Line and Rake Surfaces* (p. 1479)) is most commonly used. *Figure 32.24* (p. 1521) shows a sample plot of pathlines.

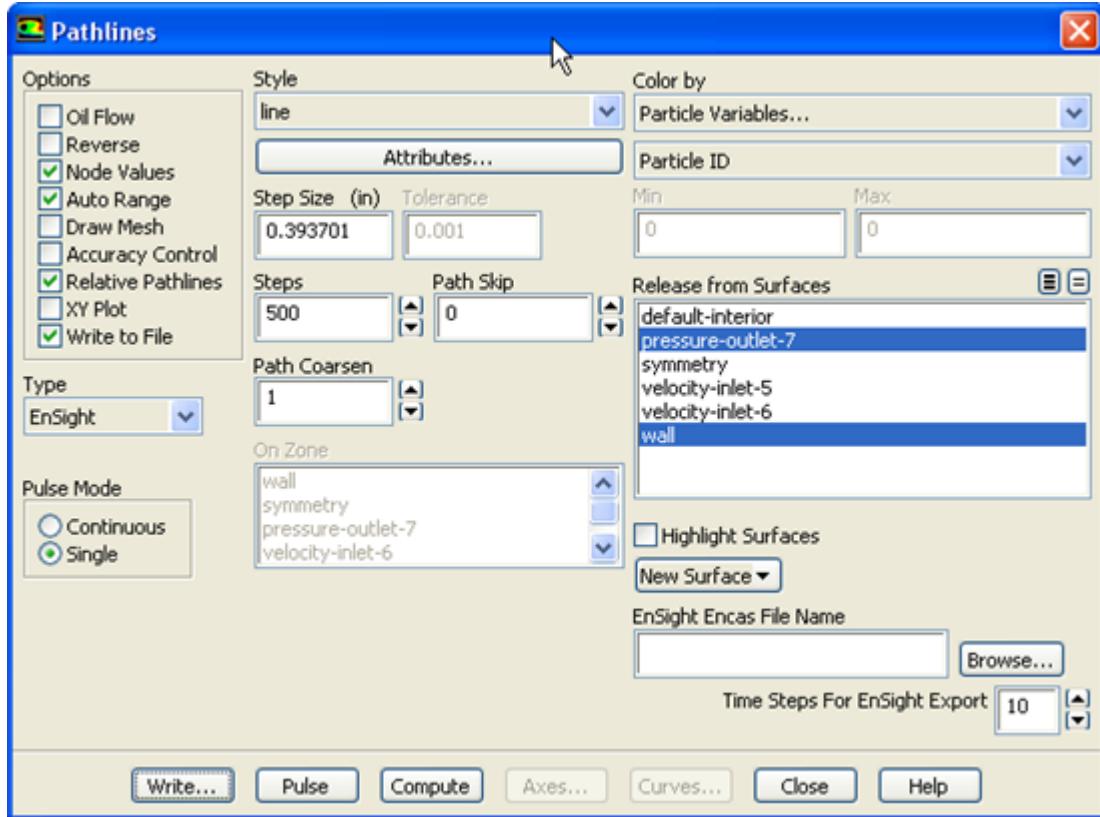

Figure 32.24 Pathline Plot

Note that the display of discrete-phase particle trajectories is discussed in *Displaying of Trajectories* (p. 1143).

32.1.4.1. Steps for Generating Pathlines

You can plot pathlines using the *Pathlines Dialog Box* (p. 2128) (*Figure 32.25* (p. 1522)).

◆ **Graphics and Animations** → **Pathlines** → **Set Up...**

Figure 32.25 The Pathlines Dialog Box

The basic steps for generating pathlines are as follows:

1. Select the surface(s) from which to release the particles in the **Release From Surfaces** list.
2. Set the step size and the maximum number of steps. The **Step Size** sets the length interval used for computing the next position of a particle. Note that particle positions are always computed when particles enter/leave a cell; even if you specify a very large step size, the particle positions at the entry/exit of each cell will still be computed and displayed. The value of **Steps** sets the maximum number of steps a particle can advance. A particle will stop when it has traveled this number of steps or when it leaves the domain. One simple rule of thumb to follow when setting these two parameters is that if you want the particles to advance through a domain of length L , the **Step Size** times the number of **Steps** should be approximately equal to L .
3. Set any of the pathline plot options described in *Options for Pathline Plots* (p. 1522).
4. Click **Display** to draw the pathlines, or click **Pulse** to animate the particle positions. The **Pulse** button will become the **Stop!** button during the animation, and you must click **Stop!** to stop the pulsing.

32.1.4.2. Options for Pathline Plots

You can include the mesh in the pathline display, control the style of the pathlines (including the twisting of ribbon-style pathlines), and color them by different scalar fields and control the color scale. You can also “thin” the pathline display, trace the particle positions in reverse, and draw “oil-flow” pathlines. If you are “pulsing” the pathlines, you can control the pulse mode. If you are using larger time step size for calculations then you can control the accuracy of the pathline by specifying tolerance. In addition to the regular pathline display, you can also generate an XY plot of a specified quantity along the pathline trajectories. Finally, you can choose node or cell values for display (or plotting).

32.1.4.2.1. Including the Mesh in the Pathline Display

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your pathline display as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the pathlines (as in [Figure 32.24 \(p. 1521\)](#)). This is accomplished by turning on the **Draw Mesh** option in the [Pathlines Dialog Box \(p. 2128\)](#). The [Mesh Display Dialog Box \(p. 1767\)](#) will appear when you enable the **Draw Mesh** option, where you can set the mesh display parameters. When you click **Display** in the [Pathlines Dialog Box \(p. 2128\)](#), the mesh display, as defined in the [Mesh Display Dialog Box \(p. 1767\)](#), will be included in the plot of pathlines.

32.1.4.2.2. Controlling the Pathline Style

Pathlines can be displayed as lines (with or without arrows), ribbons, cylinders (coarse, medium, or fine), triangles, spheres, or a set of points. You can choose **line**, **line-arrows**, **point**, **sphere**, **ribbon**, **triangle**, **coarse-cylinder**, **medium-cylinder**, or **fine-cylinder** in the **Style** drop-down list in the [Pathlines Dialog Box \(p. 2128\)](#). Pulsing can be done only on **point**, **sphere**, or **line** styles.

Once you have selected the pathline style, click **Style Attributes...** to set the pathline thickness and other parameters related to the selected **Style**:

- If you are using the **line** or **line-arrows** style, set the **Line Width** in the [Path Style Attributes Dialog Box \(p. 2132\)](#) that appears when you click **Style Attributes...**. For **line-arrows** you will also set the **Spacing Factor**, which controls the spacing between the lines. The size of the arrow heads can be adjusted by entering a value in the **Scale** text-entry box.
- If you are using the **point** style, you will set the **Marker Size** in the [Path Style Attributes Dialog Box \(p. 2132\)](#). The thickness of the pathline will be the thickness of the marker.
- If you are using the **sphere** style, you will set the **Diameter** and the **Detail** in the [Path Style Attributes Dialog Box \(p. 2132\)](#).

The best diameter to use will depend on the dimensions of the domain, the view, and the particle density. However, an adequate starting point would be a diameter on the order of 1/4 of the average cell size or 1/4 step size. Units for the **Diameter** field correspond to the mesh dimensional units.

The level of detail applied to the graphical rendering of the spheres can be controlled using the **Detail** field in the [Path Style Attributes Dialog Box \(p. 2132\)](#). The level of detail uses integer values ranging from 4 to 50. Note that the performance of the graphical rendering will be better when using a small level of detail, that is, very coarse spheres, such as 6 or 8. The rendering performance significantly decreases with higher levels of detail. You should gradually increase the detail to determine the best-case scenario between performance and quality.

Also note that to take full advantage of spherical rendering, lighting should be turned on in the view. The Gouraud setting provides much smoother looking spheres than the Flat setting and better performance than the Phong setting. For more information on lighting, see [Adding Lights \(p. 1544\)](#).

- If you are using the **triangle** or any of the **cylinder** styles, you will set the **Width** in the [Path Style Attributes Dialog Box \(p. 2132\)](#). For triangles, the specified value will be half the width of the triangle's base, and for cylinders, the value will be the cylinder's radius.
- If you are using the **ribbon** style, clicking **Style Attributes...** opens the [Ribbon Attributes Dialog Box \(p. 2132\)](#), in which you can set the ribbon's **Width**. You can also specify parameters for twisting the ribbon pathlines. In the **Twist By** drop-down list, you can select a scalar field on which the pathline twisting is based (for example, helicity). Select the desired category in the upper list and then select a related quantity in the lower list. The twisting may not be displayed smoothly because the scalar field

by which you are twisting the pathline is calculated at cell centers only (and not interpolated to a particle's position). The **Twist Scale** sets the amount of twist for the selected scalar field. To magnify the twist for a field with very little change, increase this factor; to display less twist for a field with dramatic changes, decrease this factor.

When you click **Compute**, the **Min** and **Max** fields will be updated to show the range of the **Twist By** scalar field.

32.1.4.2.3. Controlling Pathline Colors

By default, the pathlines are colored by the particle ID number. That is, each particle's path will be a different color. You can also choose the color based on the surface from where the pathlines were released from using the surface ID as the particle variable. You can choose to color the pathlines by any of the scalar fields in the **Color by** drop-down list. Select the desired category in the upper list and then select a related quantity in the lower list. If you color the pathlines by velocity magnitude, for example, each particle's path will be colored depending on the speed of the particle at each point in the path.

The range of values of the selected scalar field will, by default, be the upper and lower limits of that field in the entire domain. The color scale will map to these values accordingly. If you prefer to restrict the range of the scalar field, turn off the **Auto Range** option (under **Options**) and set the **Min** and **Max** values manually beneath the **Color by** list. If you color the pathlines by velocity, and you limit the range to values between 30 and 60 m/s, for example, the "lowest" color will be used when the particle speed falls below 30 m/s and the "highest" color will be used when the particle speed exceeds 60 m/s. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

32.1.4.2.4. "Thinning" Pathlines

If your pathline plot is difficult to understand because there are too many paths displayed, you can "thin out" the pathlines by changing the **Path Skip** value in the *Pathlines Dialog Box* (p. 2128). By default, **Path Skip** is set to 0, indicating that a pathline will be drawn from each face on the selected surface (for example, n pathlines). If you increase **Path Skip** to 1, every other pathline will be displayed, yielding $n/2$ pathlines. If you increase **Path Skip** to 2, every third pathline will be displayed, yielding $n/3$, and so on. The order of faces on the selected surface will determine which pathlines are skipped or drawn; thus adaption and reordering will change the appearance of the pathline display when a non-zero **Path Skip** value is used.

32.1.4.2.5. Coarsening Pathlines

To further simplify pathline plots, and reduce plotting time, a coarsening factor can be used to reduce the number of points that are plotted. Providing a coarsening factor of n , will result in each n th point being plotted for a given pathline in any cell. This coarsening factor is specified in the *Pathlines Dialog Box* (p. 2128), in the **Path Coarsen** field. For example, if the coarsening factor is set to 2, then ANSYS FLUENT will plot alternate points.

Important

Note that if any particle or pathline enters a new cell, this point will always be plotted.

32.1.4.2.6. Reversing the Pathlines

If you are interested in determining the source of a particle for which you know the final destination (for example, a particle that leaves the domain through an exit boundary), you can reverse the pathlines

and follow them from their destination back to their source. To do this, enable the **Reverse** option in the [Pathlines Dialog Box \(p. 2128\)](#). All other inputs for defining the pathlines will be exactly the same as for forward pathlines; the only difference is that the surface(s) selected in the **Release From Surfaces** list will be the final destination of the particles instead of their source.

32.1.4.2.7. Plotting Oil-Flow Pathlines

If you want to display “oil-flow” pathlines (that is, pathlines that are constrained to lie on a particular boundary), enable the **Oil Flow** option in the [Pathlines Dialog Box \(p. 2128\)](#). You will then need to select a single boundary zone in the **On Zone** list. The selected zone is the boundary on which the oil-flow pathlines will lie.

32.1.4.2.8. Controlling the Pulse Mode

If you are going to use the **Pulse** button in the [Pathlines Dialog Box \(p. 2128\)](#) to animate the pathlines, you can choose one of two pulse modes for the release of particles that follow the pathlines. To release a single wave of particles, select the **Single** option under **Pulse Mode**. To release particles continuously from the initial positions, select the **Continuous** option.

32.1.4.2.9. Controlling the Accuracy

If you are using large time step size for the calculation, there might be significant error introduced while calculating the pathlines. To control this error, select **Accuracy Control** and specify the value of **Tolerance**. The tolerance value will be taken into consideration while calculating the pathlines for each time step.

32.1.4.2.10. Plotting Relative Pathlines

If you want to display the pathlines relative to the moving reference frame, enable the **Relative Pathlines** option in the [Pathlines Dialog Box \(p. 2128\)](#). You will then need to select the surfaces from the **Release from Surfaces** list.

32.1.4.2.11. Generating an XY Plot Along Pathline Trajectories

If you want to generate an XY plot along the trajectories of the pathlines you have defined, enable the **XY Plot** option in the [Pathlines Dialog Box \(p. 2128\)](#). The **Color by** drop-down list will be replaced by **Y Axis Function** and **X Axis Function** lists. Select the variable to be plotted on the *y* axis in the **Y Axis Function** list, and specify whether you want to plot this quantity as a function of the **Time** elapsed along the trajectory, or the **Path Length** along the trajectory by selecting the appropriate item in the **X Axis Function** drop-down list. Specify the **Step Size**, number of **Steps**, and other parameters as usual for a standard pathline display. Then click **Plot** to display the XY plot.

Once you have generated an XY plot, you may want to save the plot data to a file. You can read this file into ANSYS FLUENT at a later time and plot it alone using the [File XY Plot Dialog Box \(p. 2173\)](#), as described in [XY Plots of File Data \(p. 1593\)](#), or add it to a plot of solution data, as described in [Including External Data in the Solution XY Plot \(p. 1593\)](#).

To save the plot data to a file, enable the **Write to File** option in the [Pathlines Dialog Box \(p. 2128\)](#). The **Plot** button changes to a **Write...** button. Clicking **Write...** opens [The Select File Dialog Box \(p. 33\)](#), in which you can specify a name and save a file containing the plot data. The format of this file is described in [XY Plot File Format \(p. 1599\)](#).

32.1.4.2.12. Saving Pathline Data

To save pathline data to a file, perform the following steps:

1. Enable the **Write to File** option in the *Pathlines Dialog Box* (p. 2128) (*Figure 32.25* (p. 1522)).
 2. In the **Type** drop-down list, select one of the following types of files:
 - **Standard** for **FIELDVIEW** (.fvp) format
 - **Geometry** for .ibl format (which can be read by **GAMBIT**)
 - **EnSight** format
-

Important

If you plan to write the pathline data in **EnSight** format, you should first verify that you have already written the files associated with the **EnSight Case Gold** file type by using the **File/Export...** menu option (see *EnSight Case Gold Files* (p. 94)).

For further information about the files that are written for any of these types, refer to the appropriate section following these steps.

3. Choose to color the pathlines by any of the scalar fields in the **Color by** drop-down lists.
4. Select the surface(s) from which to release the particles in the **Release From Surfaces** list.
5. If you selected **EnSight** under **Type**, you will need to specify the **EnSight Encas File Name**. Use **Browse...** to select the .encas file that was created when you exported the file with the **File/Export...** menu option. If you do not make a selection, then you will need to create an appropriate .encas file manually.

You can also select the number of **Time Steps For EnSight Export**. This number directly determines how many time levels will be available for animation in EnSight.

6. Click **Write...** to open *The Select File Dialog Box* (p. 33), in which you can specify a name and save a file containing the pathline data.

To initiate saving pathline data through the text command interface enter the following TUI command:

```
display/path-lines/write-to-files
```

In addition to pathline data, you can also export particle data in either **Standard**, **EnSight** or **Geometry** type. For information on exporting particle data in **FIELDVIEW** (standard), **EnSight** or .ibl (geometry) format, refer to *Exporting Steady-State Particle History Data* (p. 100).

32.1.4.2.12.1. Standard Type

If **Standard** is selected under **Type**, ANSYS FLUENT will write the file in **FIELDVIEW** format, which can be exported and read into **FIELDVIEW**. The **FIELDVIEW** ASCII Particle Path Format is licensed from Intelligent Light, proprietor of an independent visualization software package (<http://www.ilight.com>). The file name that you use for saving the data must have a .fvp extension. You also have the ability to retrieve and display the particle and pathline trajectories from the file.

If the case is steady-state, the particle path information will be written in ASCII format. For transient or unsteady-state cases, the BINARY format must be used. The **FIELDVIEW** file contains a set of paths, where each path consists of a series of points. At every point the spatial location and selected variables

are defined. A full description of the ASCII and BINARY formats can be found in Appendix K - Particle Path Formats of FIELDVIEW's Reference Manual [1] ([p. 2367](#)), available to licensed **FIELDVIEW** users.

The following is an example of the **FIELDVIEW** format for a steady-state case:

```
FVPARTICLES 2 1
Tag Names
0
Variable Names
2
time
particle_id
3
0.2 0.8 1.3 0.2 0
0.3 0.9 1.3 0.4 0
0.5 1.1 1.3 0.6 0
```

The beginning of the file displays header information. Tag Names cannot be specified when the file is exported from ANSYS FLUENT, and hence will always be 0. ANSYS FLUENT enables you to export two variables, which are listed under Variable Names: the first is determined by the scalar fields selected in the **Color by** drop-down lists (time in the example above); the second is always particle_id.

The rest of the file contains information about each path. A path section begins by listing the total number of points for the path. Then a line of data is presented for each point, with the X, Y, and Z locations listed in the first three columns and the variable information in the fourth and fifth columns. The example above presents a single pathline consisting of three points; the time ranges from .2 to .6, and the ID of the particle is 0.

32.1.4.2.12.2. Geometry Type

If **Geometry** is selected under **Type**, the file will be written in .ibl format. The resulting file contains particle paths in the form of a curve which can be read in GAMBIT. The following is an example of a **Geometry** file format that contains multiple curves:

```
Closed Index Arclength
Begin section ! 1
Begin curve ! 1
1      185.61      0      23.26
2      88.90000000000001      0      -89.67

Begin curve ! 2
1      88.89999999999569      0      -89.6699999999997
2      76.90221619148909      0      -101.2290490001453
3      62.92208239159677      0      -110.2907424975297
4      47.47166726362848      0      -116.5231659809653
5      31.11689338997181      0      -119.6980363161113
6      14.45680848476821      0      -119.6990633707006
7      -1.898356710978934      0      -116.5262095254603
8      -17.34954014966171      0      -110.2956910520416
9      -31.33079110697006      0      -101.2357213074894
10     -43.3300000000007      0      -89.67815166483965

Begin curve ! 3
1      -43.33      0      -89.67815166485001
2      -175.56      0      64.69066040289
```

The above example demonstrates how multiple curves can be imported; single curves may also be imported. After importing this file into GAMBIT, the file is read by first looking for a **Begin curve** string and then looking for the X, Y, and Z coordinates under the **Begin curve** line.

32.1.4.2.12.3. EnSight Type

By selecting **EnSight** under **Type**, you can generate files with the following extensions:

- .mpg
- .mscl
- .encas

An .mpg file will be written for every time step specified in the **Time Steps For EnSight Export** field. A sequential number will be appended to the .mpg extension to indicate the time step. Each file contains a header which lists the time at which the data was exported, as well as three columns listing the X, Y and Z coordinates for every particle at that particular time step.

The following is an example of a file called `particle.mpg0003`, which contains data for nine particles at the third time step:

```
File is written from fluent in ensight measured particle format for
t = 2.42813e-04
particle coordinates
 9
1-7.27734e-05 1.91710e-03 4.69093e-03
2-1.75772e-04 1.97040e-03 3.92842e-03
3-2.26051e-04 2.10134e-03 5.63228e-03
4-1.16390e-04 2.32442e-03 5.23423e-03
5-6.32735e-04 2.53326e-03 5.70791e-03
6-9.69431e-04 2.37006e-03 5.27602e-03
7-6.77868e-04 2.92054e-03 4.11570e-03
8-9.78029e-04 2.75717e-03 4.13314e-03
9-8.54859e-04 3.73727e-03 2.23796e-03
```

An .mscl file will be written for every time step specified in the **Time Steps For EnSight Export** field. A sequential number will be appended to the .mscl extension to indicate the time step. Each file contains the scalar information (specified under **Color By**) for every particle at a particular time step.

The following is an example of a file called `particle.mscl0006`, which captures **Particle ID** data for nine particles at the sixth time step:

```
particle id
0.00000e+00 6.00000e+00 1.20000e+01 1.80000e+01 2.40000e+01 3.00000e+01
3.60000e+01 4.20000e+01 4.80000e+01
```

A new .encas file will be written if a selection is made under **EnSight Encas File Name**. This new file is a modified version of the .encas file selected with the **Browse...** button, and contains information about all of the related files (including geometry, velocity, scalar and coordinate files). The name of the new file will be the root of the original file with .new appended to it (for example if `test.encas` is selected, a file named `test.new.encas` will be written). It is this new file that should be read into **EnSight**.

The following is an example of a file called `spray2-unsteady.new.encas`, that refers to the files generated when the data was originally exported as an **EnSight Case Gold** file type (.geo, .vel, .sc11, and .sc12) and the files created during the pathline data export (.mpg and .mscl):

```
FORMAT
type: ensight gold
GEOMETRY
model: spray2-unsteady.geo
measured: 1 particle.mpg****
VARIABLE
scalar per measured node: 1 particle-id particle.mscl****
scalar per node: pressure           spray2-unsteady.sc11
```

```

scalar per node: pressure-coefficient
vector per node: velocity
TIME
time set: 1 Model
number of steps: 10
filename start number:    1
filename increment:      1
time values: 0.00000e+00 1.21406e-04 2.42813e-04 3.64219e-04 4.85626e-04
6.07032e-04 7.28438e-04 8.49845e-04 9.71251e-04 1.09266e-03

```

32.1.4.2.13. Choosing Node or Cell Values

In ANSYS FLUENT you can determine the scalar field value at a particle location using the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are used. If you prefer to use the cell values, turn the **Node Values** option off. Note that for face-only functions like **Wall Shear Stress**, the cell value is the area-weighted average from the face values that define that cell as c0.

If you are plotting pathlines to show the effect of a porous medium or fan, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

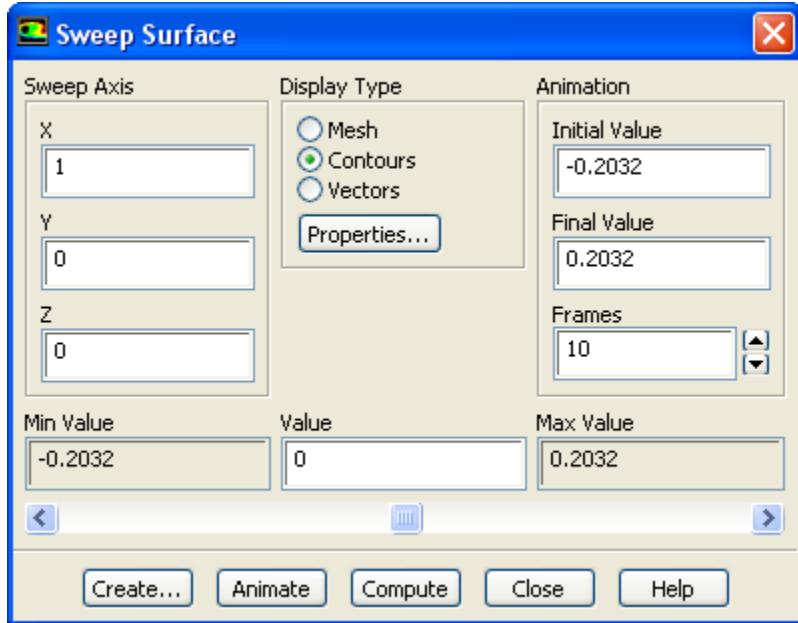

32.1.5. Displaying Results on a Sweep Surface

Sweep surfaces can be used when you want to examine the mesh, contours, or vectors on various sections of the domain without explicitly creating the corresponding surfaces. For example, if you want to display solution results for a 3D combustion chamber, instead of creating numerous surfaces at different cross-sections of the domain, you can use a sweep surface to view the variation of the flow and temperature throughout the chamber.

32.1.5.1. Steps for Generating a Plot Using a Sweep Surface

You can plot meshes, contours, or vectors on a sweep surface using the [Sweep Surface Dialog Box \(p. 2141\)](#) ([Figure 32.26 \(p. 1530\)](#)).

Graphics and Animations → **Sweep Surface** → **Set Up...**

Figure 32.26 The Sweep Surface Dialog Box

The basic steps for generating a mesh, contour, or vector plot using a sweep surface are as follows:

1. Under **Sweep Axis**, specify the (**X**, **Y**, **Z**) vector representing the axis along which the surface should be swept.
2. Click **Compute** to update the **Min Value** and **Max Value** to reflect the extents of the domain along the specified axis.
3. Under **Display Type**, specify the type of display you want to see: **Mesh**, **Contours**, or **Vectors**. The first time that you select **Contours** or **Vectors**, ANSYS FLUENT will open the *Contours Dialog Box* (p. 2120) or the *Vectors Dialog Box* (p. 2123) so you can modify the settings for the display. To make subsequent modifications to the display settings, click **Properties** to open the *Contours Dialog Box* (p. 2120) or *Vectors Dialog Box* (p. 2123).
4. Move the slider under **Value** (which indicates the value of x, y, or z) to move the sweep surface through the domain along the specified **Sweep Axis**. ANSYS FLUENT will update the mesh, contour, or vector display when you release the slider. You can also enter a position in the **Value** field and press **Enter** to update the display.
5. If you want to save the currently displayed sweep surface so that you can use it for a different type of plot (for example, a pathlines plot or an XY plot) or combine it with displays on other surfaces, click **Create...** to open the *Create Surface Dialog Box* (p. 2142) (Figure 32.27 (p. 1530)). Enter the **Surface Name** and click **OK**.

Figure 32.27 The Create Surface Dialog Box

The surface that is created is an isosurface based on the mesh coordinates; the contour or vector settings are not stored in the surface.

You can also animate the sweep surface display, as described below, rather than moving the slide bar yourself.

32.1.5.2. Animating a Sweep Surface Display

The steps for animating a sweep surface display are as follows:

1. Specify the **Sweep Axis** and **Display Type** as described above.
2. Under **Animation**, enter the **Initial Value** and **Final Value** for the animation. These values correspond to the minimum and maximum values along the **Sweep Axis** for which you want to animate the display.
3. Specify the number of **Frames** you want to see in the animation.
4. Click **Animate**.

32.1.6. Hiding the Graphics Window Display

There may be situations where displaying graphics on a local machine is not practical. Therefore, you may decide to hide (or disable) the graphics display window.

To disable the graphics display window when starting ANSYS FLUENT from the command line, you can specify the driver as null:

```
fluent -driver null
```

For an ANSYS FLUENT session that is already in progress, the graphics window display can be disabled using the following TUI command:

```
display → set → rendering-options → driver → null
```

Important

All graphics windows must be closed prior to invoking the above TUI command.

If the graphics window display is disabled, you can continue to save graphics using the **Save Picture** option, as described in [Saving Picture Files \(p. 119\)](#). The saved graphics files will be identical whether the graphics window display is enabled or disabled.

For an ANSYS FLUENT session that is already in progress, to re-enable a graphics window display that had been previously disabled, use the following TUI command:

```
display → set → rendering-options → driver → opengl
```

If any graphics windows are open (which are not visible to you), ANSYS FLUENT will prompt you to close all open windows. You can close them using the following Scheme command:

```
(close-all-open-windows)
```

and then retype the TUI command to enable the graphics windows.

Important

If you happen to be logged on to a machine remotely, then `opengl` may not work on your system. Use `x11` instead to enable your graphics windows.

32.2. Customizing the Graphics Display

There are a number of ways in which you can alter the graphical display once you have generated the basic elements in it (contours, meshes, and so on). For example, you can overlay multiple graphics, add descriptive text or lighting to the plot, and modify the captions or legend layout. These and other customizations are described in this section.

- 32.2.1. Overlay of Graphics
- 32.2.2. Opening Multiple Graphics Windows
- 32.2.3. Changing the Legend Display
- 32.2.4. Adding Text to the Graphics Window
- 32.2.5. Changing the Colormap
- 32.2.6. Adding Lights
- 32.2.7. Modifying the Rendering Options

32.2.1. Overlay of Graphics

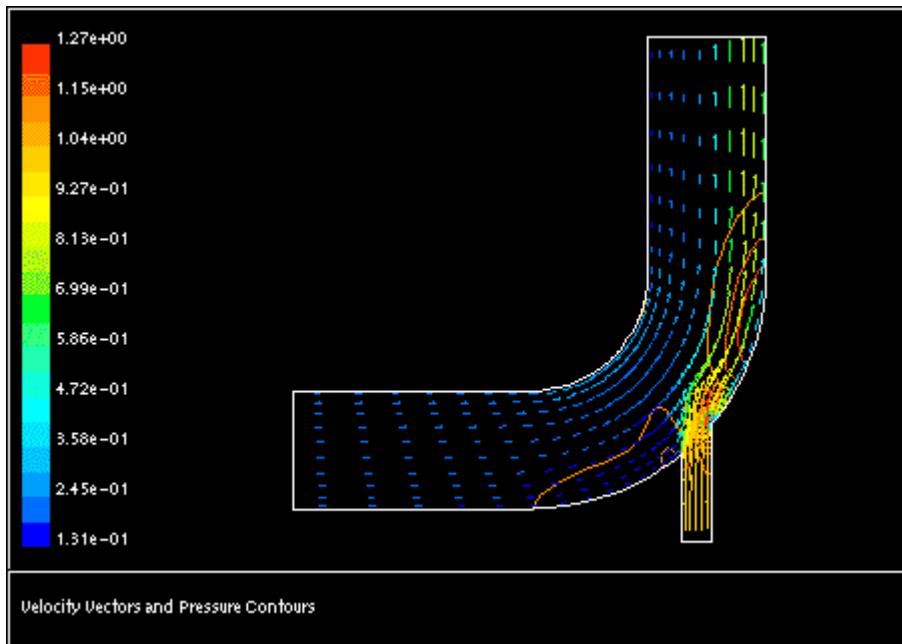

Normally, you can see only one picture at a time in the graphics window; that is, as one plot is generated, the previous plot is erased. Sometimes, however, you may want to see two plots overlaid. For example, you may want to plot vectors and pressure contours on the same plot (see [Figure 32.28 \(p. 1533\)](#)). You can do this by turning on the **Overlays** option (and clicking **Apply**) in the [Scene Description Dialog Box \(p. 2151\)](#).

◀ **Graphics and Animations** → **Scene...**

Once overlaying is enabled, subsequent graphics that you generate will be displayed on top of the existing display in the active graphics window. To generate a plot without overlays, you must turn off the **Overlays** option in the [Scene Description Dialog Box \(p. 2151\)](#) (and remember to click **Apply**).

When you are overlaying multiple graphics, the captions and color scale that will appear in the latest display are those that correspond to the most recently drawn graphic.

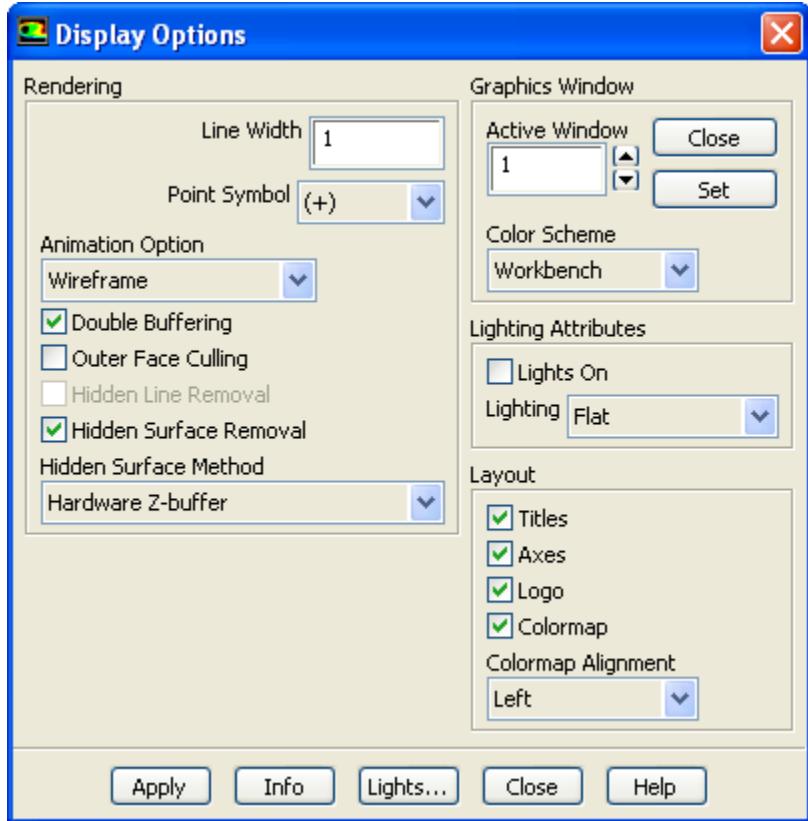

Note that when overlaying is enabled, it will apply to all graphics windows, including those that are not yet open. Turning overlays on and off does so for all graphics windows, not just for the active window. That is, if you enable overlays, open a new graphics window (as described in [Opening Multiple Graphics Windows \(p. 1533\)](#)), and then generate two or more graphics in that window, they will be overlaid.

Figure 32.28 Overlay of Velocity Vectors and Pressure Contours

32.2.2. Opening Multiple Graphics Windows

During your ANSYS FLUENT session, you can open up to 20 graphics windows at one time and they may be viewed within the application window or in separate windows. The windows are numbered 1 through 20 and the ID number for each window will appear at the top of the frame that surrounds it. You can view a specific window by selecting it from the drop-down list next to the ID number. The first time you display graphics, window 1 will be displayed automatically. To open an additional window, you can use the *Display Options Dialog Box* (p. 2148) (Figure 32.29 (p. 1534)).

◆ **Graphics and Animations → Options...**

Figure 32.29 The Display Options Dialog Box

Use the up arrow to increment the window ID in the **Active Window** field under **Graphics Window** and then click **Open**. The **Close** button changes to the **Open** button if the **Active Window** is set to more than 1.

To close an open window, increase or decrease the **Active Window** value to the ID of the window to be closed, and then click **Close** that appears next to the **Active Window** field. The **Open** button changes to a **Close** button if the **Active Window** is open.

To display a different color scheme for the graphics window, select **Classic** or **Workbench** from the drop-down list located below the **Active Window** field. All graphics windows will change.

32.2.2.1. Setting the Active Window

When you have more than one graphics window open, you must identify the active window so that ANSYS FLUENT will know which one to draw the plot in. There are two ways to set the active window: you can simply click any mouse button in the desired graphics window, or you can specify the ID for the desired graphics window in the **Active Window** field (in the *Display Options Dialog Box* (p. 2148)) and click **Set**. Regardless of the method used, this window will remain active until you set a new active window.

32.2.3. Changing the Legend Display

ANSYS FLUENT graphics include, by default, a caption or legend block that consists of fields of text describing the contents of the graphic, the ANSYS FLUENT product identification, an axis triad indicating the orientation of the displayed object, a color key defining the correspondence between each color and the magnitude of the plotted variable, and the ANSYS logo. You can turn off the display of the legend

and color scale, and/or the axis triad. You can also hide the ANSYS logo. You can also display the colormap on any side of the display window as per convenience. In addition you can also edit the captions directly in the graphics window.

32.2.3.1. Enabling/Disabling the Legend, Logo, and Color Scale

You can disable the display of the **Titles**, **Axes**, **Logo**, and the **Colormap** scale by deselecting each of the options under **Layout** in the *Display Options Dialog Box* (p. 2148) (*Figure 32.29* (p. 1534)).

◆◆◆ **Graphics and Animations** → **Options...**

Use the text interface to enable/disable the captions and color scale individually, and to change the size and position of the captions and color scale.

display → set → windows → text →

display → set → windows → scale →

See the separate [Text Command List](#) for details.

32.2.3.2. Editing the Legend

When captions are displayed in the graphics window, you may choose to modify, delete, or add to the text that appears in the caption box. To do so, click the left mouse button in the desired location. A cursor will appear, and you can then type new text or delete the text that was originally there (using the backspace or delete key). Note that changes to existing text in the caption block will be removed when you draw new graphics in the window (unless you are overlaying multiple graphics in the same window), but text that you add on a previously empty line in the caption block will not be removed until the default caption text makes use of that line.

32.2.3.3. Adding a Title to the Caption

You can define a title for your problem using the `title` text command:

display → set → title

The title you define will appear on the top line of the caption, at the far left, in all subsequent plots. It will also be saved in the case file.

Important

You will need to enclose your title in quotation marks (for example, "my title").

32.2.3.4. Enabling/Disabling the Axes

You can disable the display of the axis triad by turning off the **Axes** option under **Layout** in the *Display Options Dialog Box* (p. 2148) (*Figure 32.29* (p. 1534)).

32.2.3.5. Displaying/Hiding the Logo

You can prevent the ANSYS logo from being displayed in the graphics window by disabling the **Logo** option under **Layout** in the *Display Options Dialog Box* (p. 2148) (*Figure 32.29* (p. 1534)).

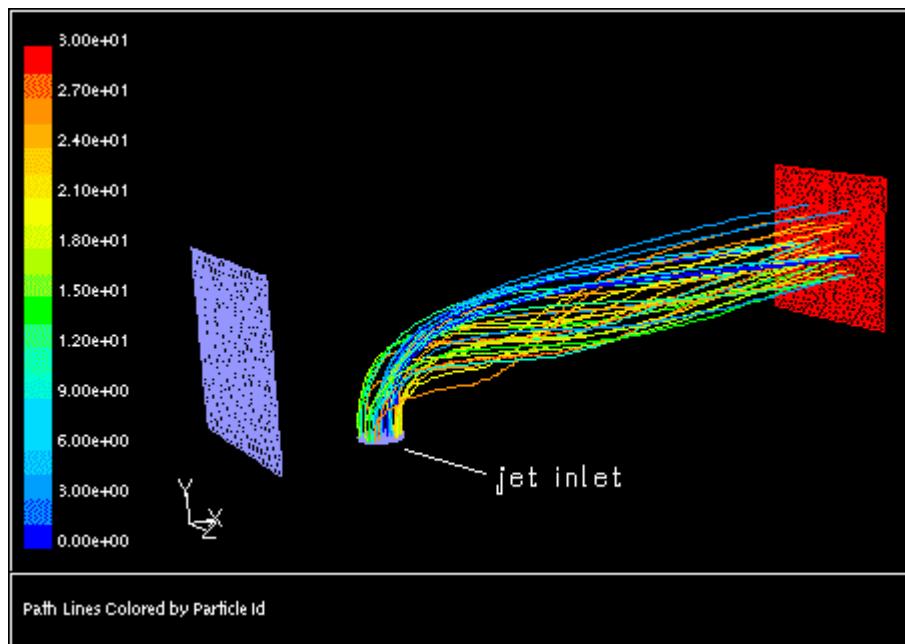

32.2.3.6. Colormap Alignment

You can set the position of the colormap on any side (left, top, bottom, or right) of the display window. Default alignment for the colormap is set to the **Left**. If you wish to change the alignment, select the required direction in the **Colormap Alignment** drop-down list.

32.2.4. Adding Text to the Graphics Window

There are two ways to add text annotations with optional attachment lines to the graphics windows. You can either use the **mouse-annotate** function for one of the mouse buttons, or use the *Annotate Dialog Box* (p. 2167). Both of these methods are described in this section. *Figure 32.30* (p. 1536) shows an example of a graphics display with annotated text in it.

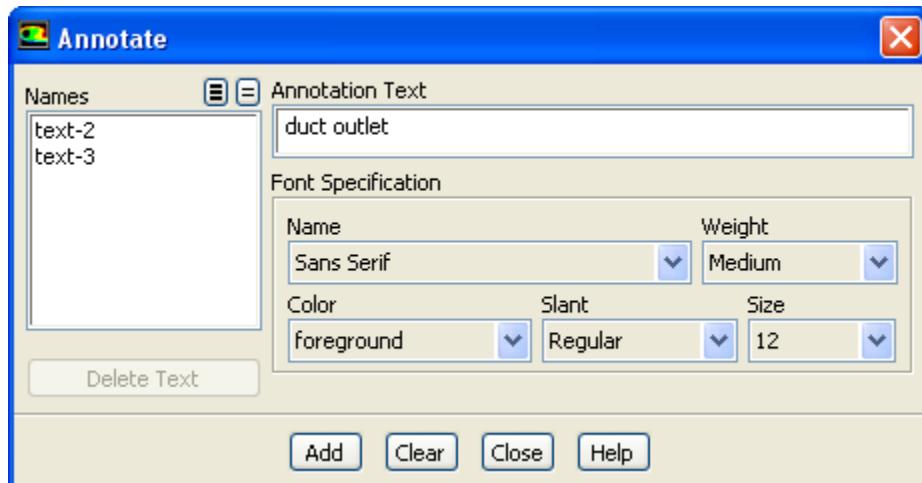

Figure 32.30 Graphics Window with Text Annotation

32.2.4.1. Adding Text Using the Annotate Dialog Box

Adding text to the graphics window using the *Annotate Dialog Box* (p. 2167) (*Figure 32.31* (p. 1537)) enables you to control the font and color of the text.

◀ **Graphics and Animations → Annotate...**

Figure 32.31 The Annotate Dialog Box

The steps for adding text are as follows:

1. Under **Font Specification**, select the font type in the **Name** drop-down list, the font weight (**Medium** or **Bold**) in the **Weight** drop-down list, the size (in points) in the **Size** drop-down list, the color in the **Color** drop-down list, and the slant (**Regular** or **Italic**) in the **Slant** drop-down list.
2. Enter the text to be added in the **Annotation Text** field.
3. Click **Add**. You will be asked to pick the location in the graphics window where you want to place the text, using the mouse-probe button. By default, the mouse-probe button is the right button, but you can change this using the [Mouse Buttons Dialog Box \(p. 2315\)](#), as described in [Controlling the Mouse Button Functions \(p. 1548\)](#).

If you click the mouse button once in the desired location, the text will be placed at that point. Dragging the mouse with the mouse-probe button depressed will draw an attachment line from the point where the mouse was first clicked to the point where it was released. The annotation text will be placed at the point where the mouse button was released.

32.2.4.2. Adding Text Using the Mouse-Annotate Function

To add text annotations to the graphics window using the **mouse-annotate** function, you must first set the function of one of the mouse buttons to be **mouse-annotate** in the [Mouse Buttons Dialog Box \(p. 2315\)](#). (See [Controlling the Mouse Button Functions \(p. 1548\)](#) for details about modifying the mouse button functions.) Then, click the **mouse-annotate** button in the desired location in the graphics window. A cursor will appear and you can type the text directly in the graphics window. Dragging the mouse with the **mouse-annotate** button depressed will draw an attachment line from the point where the mouse was first clicked to the point where it was released. The cursor will then appear at the point where the mouse button was released.

Important

The mouse-annotate button will not function as described above when running ANSYS FLUENT on Linux with the graphics window embedded. To work around this limitation, you can either annotate using the [Annotate Dialog Box \(p. 2167\)](#) (as described in [Adding Text Using the Annotate Dialog Box \(p. 1536\)](#)), or you can first detach your graphics window, so that it becomes a floating window, perform the annotation using the mouse-annotate button, then return to an embedded graphics window (as described in [Embedding the Graphics Windows \(p. 1553\)](#)).

You can use the [Annotate Dialog Box \(p. 2167\)](#) to edit or delete text added using the mouse, as described below.

32.2.4.3. Editing Existing Annotation Text

Once you have added text to the graphics display, using either the [Annotate Dialog Box \(p. 2167\)](#) or the **mouse-annotate** function, you may change the font characteristics of one or more text items, or delete individual text items.

To modify or delete existing text, follow these steps:

1. Select the appropriate item in the **Names** list in the [Annotate Dialog Box \(p. 2167\)](#) (*Figure 32.31 (p. 1537)*). When you select a name, the associated text will be displayed in the **Annotation Text** field, and the **Add** button becomes the **Edit** button.
2. Modify the **Font Specification** entries as desired, and click **Edit** to modify the text, or simply click **Delete Text** below the **Names** list to delete the selected text.

Note that if you want to make changes to all current annotation text, you can select all of the **Names** instead of just one in step 1.

You can move the text in the same way that you move other geometric objects in the display, using the [Scene Description Dialog Box \(p. 2151\)](#) and the [Transformations Dialog Box \(p. 2154\)](#). See [Transforming Geometric Objects in a Scene \(p. 1569\)](#) for details.

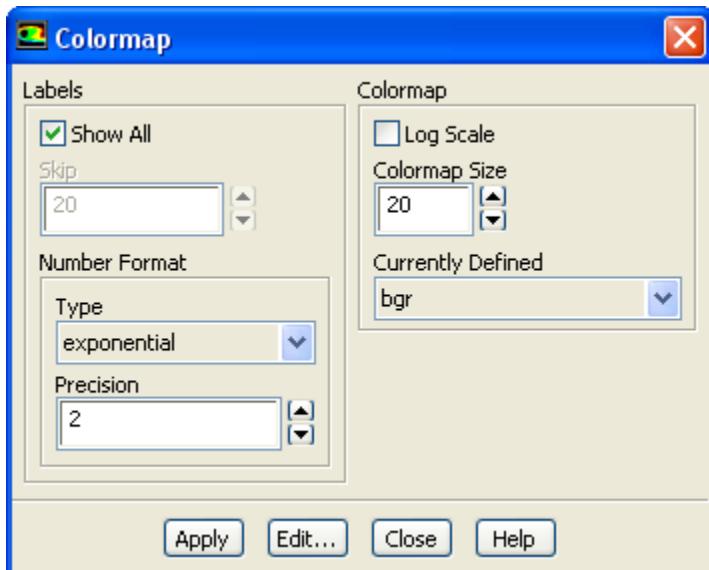

32.2.4.4. Clearing Annotation Text

Annotation text is associated with the active graphics window and is removed only when the annotations are explicitly cleared. To remove the annotations from the graphics window, you must click **Clear** in the [Annotate Dialog Box \(p. 2167\)](#) (even if you use the **mouse-annotate** function to add the text). If you draw new graphics in the window without clearing the annotations, they will remain visible in the new display.

32.2.5. Changing the Colormap

The default colormap used by ANSYS FLUENT to display graphical data (for example, vectors) ranges from blue (minimum value) to red (maximum value). Additional predefined colormaps are available, and you can also create custom colormaps. To make any changes to the colormap, you will use the [Colormap Dialog Box \(p. 2164\)](#) (*Figure 32.32 (p. 1539)*).

◀ **Graphics and Animations → Colormap...**

Figure 32.32 The Colormap Dialog Box

When you plot contours, you can temporarily modify the number of colors in the colormap by changing the number of contour levels in the [Contours Dialog Box \(p. 2120\)](#); you will only need to use the [Colormap Dialog Box \(p. 2164\)](#) if you wish to change other characteristics of the colormap.

Important

Note that if you are using a gray-scale colormap and you wish to save a gray-scale picture, you should save a color picture. When you save a gray-scale picture, ANSYS FLUENT uses an internal gray scale, not the gray scale specified by the colormap. If you save a color picture, the colormap you selected (that is, your gray scale) will be used.

32.2.5.1. Predefined Colormaps

The following colormaps are automatically available in ANSYS FLUENT:

bgr:

Blue represents the minimum value, green the middle, and red the maximum value. Colors in between are interpolated from blue to green, and from green to red. (This is the default colormap.)

bgrb:

Blue represents the minimum and maximum values, and green and red are values 1/3 and 2/3 of the maximum value, respectively. Colors in between are interpolated from blue to green, from green to red, and from red to blue.

blue:

The minimum value is represented by blue-black, and the maximum value by pure blue.

cyan-yellow:

Cyan represents the minimum value and yellow represents the maximum value.

fea:

Blue represents the minimum value and red represents the maximum value. The colors in between are those used in third-party finite element analysis packages.

gray:

Black is used for the minimum value and white for the maximum value.

green:

The minimum value is represented by green-black, and the maximum value by pure green.

purple-magenta:

Purple represents the minimum value and magenta represents the maximum value.

red:

The minimum value is represented by red-black, and the maximum value by pure red.

rgb:

Red represents the minimum value, green the middle, and blue the maximum value. Colors in between are interpolated from red to green, and from green to blue.

The number of colors interpolated between the colors in the scale name (for example, between purple and magenta) will depend on the size of the colormap.

32.2.5.2. Selecting a Colormap

The procedure for selecting a new colormap to be used in graphics displays is as follows:

1. In the *Colormap Dialog Box* (p. 2164) (*Figure 32.32* (p. 1539)), select the desired colormap in the **Currently Defined** drop-down list. This list will contain all of the colormaps predefined by ANSYS FLUENT as well as any custom colormaps that you have created as described in *Creating a Customized Colormap* (p. 1542).
2. Set the colormap size and scale as described in *Specifying the Colormap Size and Scale* (p. 1540).
3. Click **Apply** to update the current graphics display with the new colormap. All future displays will use the newly selected colormap and options.

32.2.5.2.1. Specifying the Colormap Size and Scale

Once you have selected the desired colormap from the **Currently Defined** list, you may modify the **Colormap Size**. This value is the number of distinct colors in the color scale.

You can also choose to use a logarithmic scale instead of a decimal scale by turning on the **Log Scale** option. With a log scale, the color used in the graphics display will represent the log of the value at that location in the domain. The values represented by the colors will, therefore, increase exponentially.

32.2.5.2.2. Changing the Number Format

You can change the format of the labels that define the color divisions at the left of the graphics window using the controls under the **Number Format** heading in the *Colormap Dialog Box* (p. 2164).

- To display the real value with an integral and fractional part (for example, 1.0000), select **float** in the **Type** drop-down list. You can set the number of digits in the fractional part by changing the value of **Precision**.
- To display the real value with a mantissa and exponent (for example, 1.0e-02), select **exponential** in the **Type** drop-down list. You can define the number of digits in the fractional part of the mantissa in the **Precision** field.
- To display the real value with either float or exponential form, depending on the size of the number and the defined **Precision**, choose **general** in the **Type** drop-down list.

32.2.5.3. Displaying Colormap Label

You can customize the number of values displayed on the colormap. The default number of labels that appear alongside the colormap depends on the font size and the colormap size (*Figure 32.33* (p. 1541)).

- To reduce the number of labels that appear alongside the colormap, increase the number of labels skipped. To do so, deselect **Show All** in the *Colormap Dialog Box* (p. 2164) and set the number of labels to be skipped.

To demonstrate what effect this command has on the display, enter a value of 4 under **Skip** (note that the value entered must be an integer). This will result in three intermediate labels being skipped, with the first and the last colormap values always being displayed (*Figure 32.34 (p. 1542)*).

- To reset the original colormap display, simply select **Show All**.

Figure 32.33 The Default Colormap Label Display

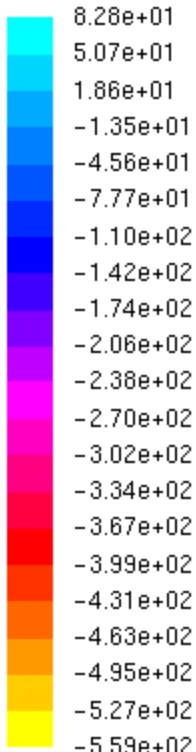

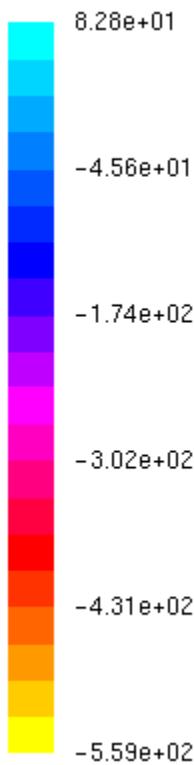

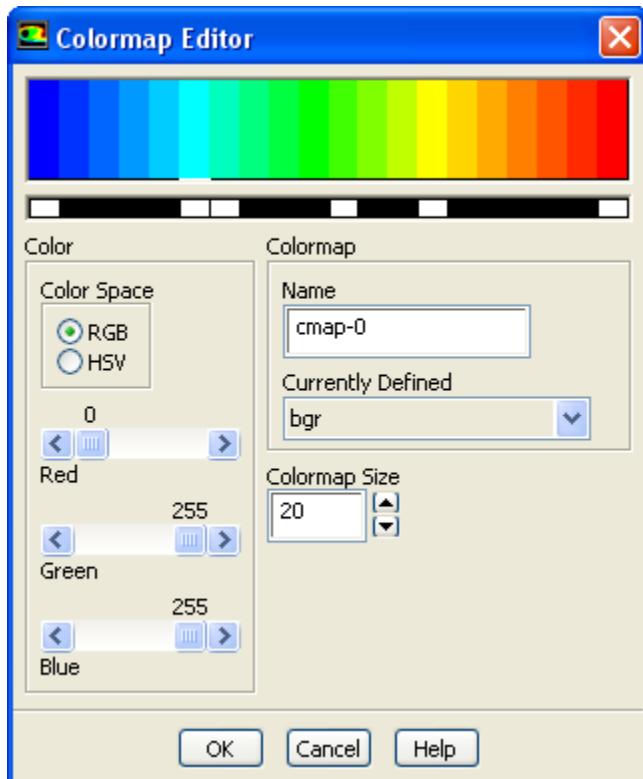

Figure 32.34 The Colormap with Skipped Labels

32.2.5.4. Creating a Customized Colormap

You can create your own colormap by manipulating the “anchor colors” and the colormap size. A color scale is created by linear interpolation between the anchor colors. The color, number, and position of the anchor colors will therefore control the description of the colormap. By increasing the colormap size, you can increase the total number of colors and obtain a color scale that changes more gradually. The procedure is as follows:

1. In the *Colormap Dialog Box* (p. 2164), click **Edit...** to open the *Colormap Editor Dialog Box* (p. 2165) (*Figure 32.35* (p. 1543)).

Figure 32.35 The Colormap Editor Dialog Box

2. In the *Colormap Editor Dialog Box* (p. 2165), select a color scale in the **Currently Defined** list as your starting point. The colors in the scale will be displayed at the top of the dialog box. A white bar below a color is an "anchor point" indicating that this color is an "anchor color".
3. If you want to add more colors to the color scale, increase the **Colormap Size**; to use fewer colors, decrease this value. When you use the counter arrows (or type in a value and press **Enter**), the color scale display at the top of the dialog box will be updated immediately.

Important

The total number of colors must not be less than the number of anchor points.

4. To obtain the desired color scale interpolation, manipulate the anchor colors as needed:
 - To add an anchor point, click any mouse button on the black space directly below the desired anchor color (or click on the color itself). A white bar will appear below the color to identify it as an anchor color, and the color will automatically be selected for color-definition modification.
 - To remove an anchor point, click on the white bar below the anchor color. The white bar will disappear and the color scale will be updated to reflect the new interpolation.
 - To select a current anchor color in order to modify its color definition, click on the color itself at the top of the dialog box.
 - To modify the color of the selected anchor color, you can change either the red/green/blue components (choose **RGB**, the default) or the hue/saturation/value components (choose **HSV**). **HSV** is recommended if you plan to record the graphics display on video, as it enables you to create a more subtle gradation of color and reduce the tendency of bright colors to "bleed". Move the **Red**,

Green, and **Blue** or **Hue**, **Saturation**, and **Value** sliders to obtain the desired color. The color scale at the top of the dialog box will be updated automatically to show the effect of your change.

Important

It is a good idea to note the original value of a color component before moving the slider so that you will be able to return to it if you change your mind. (See [Scales \(p. 31\)](#) for instructions on using a scale slider.)

If you make a mistake while modifying the color scale, you can start over by selecting the starting-point colormap in the **Currently Defined** list.

5. If you want to change the default name of the new colormap, enter the new name in the **Name** field. By default, custom colormaps are called `cmap-0`, `cmap-1`, and so on.
6. Click **OK** to save the new colormap. The colormap name appears in the **Currently Defined** list in the [Colormap Dialog Box \(p. 2164\)](#) and can be selected for use in the graphics display.

Custom colormap definitions will be saved in the case file.

32.2.6. Adding Lights

In ANSYS FLUENT you can add lights with a specified color and direction to your display. These lights can enhance the appearance of the display when it contains 3D geometries. By default one light is defined. You can enable the effect of the existing light(s) using the [Display Options Dialog Box \(p. 2148\)](#) or the [Lights Dialog Box \(p. 2162\)](#), and you can add new lights using the [Lights Dialog Box \(p. 2162\)](#).

32.2.6.1. Turning on Lighting Effects with the Display Options Dialog Box

To enable the effect of lighting, you can use the [Display Options Dialog Box \(p. 2148\)](#).

◆ [Graphics and Animations → Options...](#)

If you enable the **Lights On** option under **Lighting Attributes** and click **Apply**, you will see the lighting effects in the active graphics window. To turn off the lighting effects, simply turn off the **Lights On** option and click **Apply**.

You can also choose the method to be used in lighting interpolation; select **Flat**, **Gouraud**, or **Phong** in the **Lighting** drop-down list. Flat is the most basic method: there is no interpolation within the individual polygonal facets. Gouraud and Phong have smoother gradations of color because they interpolate on each facet.

32.2.6.2. Turning on Lighting Effects with the Lights Dialog Box

You can also enable lighting effects using the [Lights Dialog Box \(p. 2162\)](#) ([Figure 32.36 \(p. 1545\)](#)).

◆ [Graphics and Animations → Lights...](#)

For constant lighting effects in the direction of the view, enable the **Headlight On** option in the [Lights Dialog Box \(p. 2162\)](#). This option has the effect of a light source directly in front of the model, no matter what orientation the model is viewed in. To disable this feature, turn off the **Headlight On** option in the [Lights Dialog Box \(p. 2162\)](#).

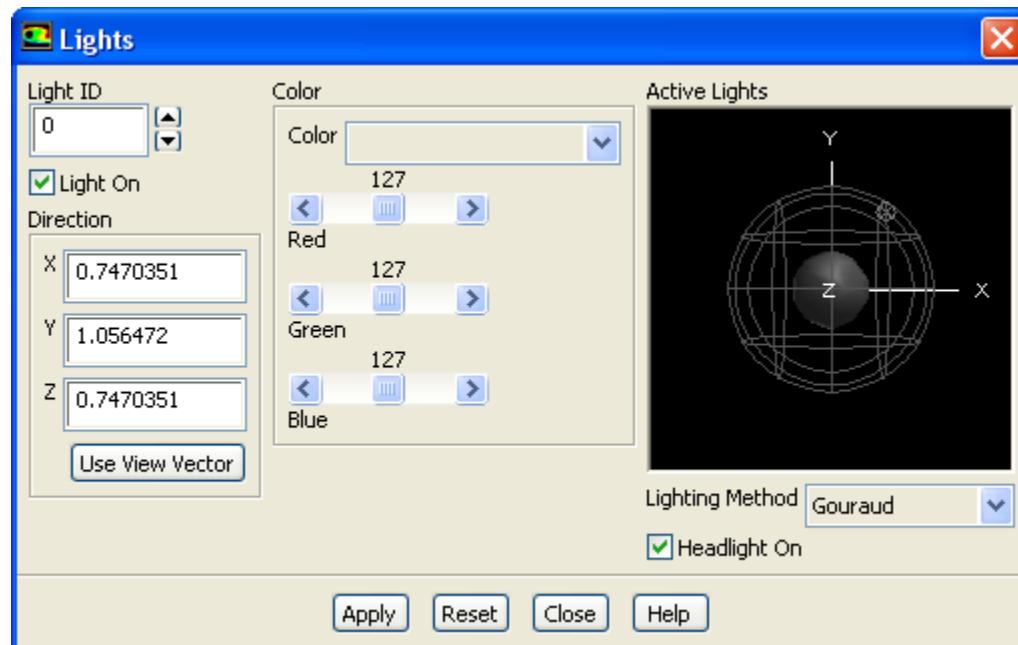

In the **Lighting Method** drop-down list, choose **Flat**, **Gouraud**, or **Phong** to enable the appropriate lighting method. These methods are described in the previous section. To disable lighting, select **Off** in the list. To see the lighting effects in the active graphics window, click **Apply**.

32.2.6.3. Defining Light Sources

You can control individual lights in the *Lights Dialog Box* (p. 2162) (*Figure 32.36* (p. 1545)). The *Lights Dialog Box* (p. 2162) enables you to create a light and then turn it off without deleting it. In this way, you can retain lights that you have defined previously but do not wish to use at present.

◆ **Graphics and Animations** → **Lights...**

Figure 32.36 The Lights Dialog Box

(You can also open the *Lights Dialog Box* (p. 2162) by clicking **Lights...** in the *Display Options Dialog Box* (p. 2148).)

By default, light 0 is defined to be dark gray with a direction of (1,1,1). A light source is a distant light, similar to the sun. The direction (1,1,1) means that the rays from the light will be parallel to the vector from (1,1,1) to the origin. To create an additional light (for example, light 1), follow the steps listed below.

1. Increase **Light ID** to a new value (for example, 1).
2. Enable the **Light On** check box.
3. Define the light color by entering a descriptive string (for example, `lavender`) in the **Color** field, or by moving the **Red**, **Green**, and **Blue** sliders to obtain the desired color. The default color for all lights is dark gray.
4. Specify the light direction by doing one of the following:
 - Enter the **(X, Y, Z)** Cartesian components under **Direction**.
 - Click the middle mouse button in the desired location on the sphere under **Active Lights**. (You can also move the light along the circles on the surface of the sphere by dragging the mouse while

holding down the middle button.) You can rotate the sphere by pressing the left mouse button and moving the mouse (like a trackball).

- Use your mouse to change the view in the graphics window so that your position in reference to the geometry is the position from which you would like a light to shine. Then click **Use View Vector** to update the **X,Y,Z** fields with the appropriate values for your current position and update the graphics display with the new light direction. This method is convenient if you know where you want a light to be, but you are not sure of the exact direction vector.
5. Repeat steps 1–4 to add more lights.
 6. When you have defined all the lights you want, click **Apply** to save their definitions.

32.2.6.3.1. Removing a Light

To remove a light, enter the ID number of the light to be removed in the **Light ID** field and then clear the **Light On** check box. When a light is turned off, its definition is retained, so you can easily add it to the display again at a later time by selecting the **Light On** check box. For example, you may want to define three different lights to be used in different scenes. You can define each of them, and then enable only one or two at a time, using the **Light ID** field and the **Light On** check box. Once you have made all the desired modifications to the lights, remember to click **Apply** to save the changes.

32.2.6.3.2. Resetting the Light Definitions

If you have made changes to the light definitions, but you have not yet clicked **Apply**, you can reset the lights by clicking **Reset**. All lighting characteristics will revert to the last saved state (that is, the lighting that was in effect the last time you opened the dialog box or clicked on **Apply**).

32.2.7. Modifying the Rendering Options

Depending on the objects in your display window and what kind of graphics hardware and software you are using, you may want to modify some of the rendering parameters listed below. All are listed under the **Rendering** heading in the *Display Options Dialog Box* (p. 2148) (*Figure 32.29* (p. 1534)).

❖ Graphics and Animations → Options...

After making a change to any of these rendering parameters, click **Apply** to re-render the scene in the active graphics window with the new attributes. To see the effect of the new attributes on another graphics window, you must redisplay it or make it the active window (see *Setting the Active Window* (p. 1534)) and click **Apply** again.

Line Width:

By default, all lines drawn in the display have a thickness of 1 pixel. If you want to increase the thickness of the lines, increase the value of **Line Width**.

Point Symbol:

By default, nodes displayed on surfaces and data points on line or rake surfaces are represented in the display by a + sign inside a circle. If you want to modify this representation (for example, to make the nodes easier to see), you can select a different symbol in the **Point Symbol** drop-down list.

Animation Options:

There are two animation options which you can choose from. They are as follows:

All

uses a solid-tone shading representation of all geometry during mouse manipulation.

Wireframe

uses a wireframe representation of all geometry during mouse manipulation. If your computer has a graphics accelerator, you may not want to use this option; otherwise, the mouse manipulation may be very slow.

Double Buffering:

Enabling the **Double Buffering** option can dramatically reduce screen flicker during graphics updates. Note, however, that if your display hardware does not support double buffering and you turn this option on, double buffering will be done in software. Software double buffering uses extra memory.

Outer Face Culling:

This option enables you to turn off the display of outer faces in wall zones. **Outer Face Culling** is useful for displaying both sides of a slit wall. By default, when you display a slit wall, one side will “bleed” through to the other. When you enable the **Outer Face Culling** option, the display of a slit wall will show each side distinctly as you rotate the display. This option can also be useful for displaying two-sided walls (that is, walls with fluid or solid cells on both sides).

Hidden Line Removal:

If you do not use hidden line removal, ANSYS FLUENT will not try to determine which lines in the display are behind others; it will display all of them, and a cluttered display will result for most 3D mesh displays. For most 3D problems, therefore, you should enable the **Hidden Line Removal** option. You should turn this option off (for optimal performance) if you are working with a 2D problem or with geometries that do not overlap.

Hidden Surface Removal:

If you do not use hidden surface removal, ANSYS FLUENT will not try to determine which surfaces in the display are behind others; it will display all of them, and a cluttered display will result for most 3D mesh displays. For most 3D problems, therefore, you should enable the **Hidden Surface Removal** option. You should turn this option off (for optimal performance) if you are working with a 2D problem or with geometries that do not overlap.

You can choose one of the following methods for performing hidden surface removal in the **Hidden Surface Method** drop-down list. These options vary in speed and quality, depending on the device you are using.

Hardware Z-buffer

is the fastest method if your hardware supports it. The accuracy and speed of this method is hardware-dependent. Note that if this method is not available on your computer, selecting it will cause the **Software Z-buffer** method to be used.

Painters

will show fewer edge-aliasing effects than **Hardware-Z-buffer**. This method is often used instead of **Software-Z-buffer** when memory is limited.

Software Z-buffer

is the fastest of the accurate software methods available (especially for complex scenes), but it is memory-intensive.

Z-sort only

is a fast software method, but it is not as accurate as **Software-Z-buffer**.

32.2.7.1. Graphics Device Information

If you need to know which graphics driver you are using and what graphics hardware it recognizes, you can click **Info** in the *Display Options Dialog Box* (p. 2148). The graphics device information will be printed in the text (console) window.

32.3. Controlling the Mouse Button Functions

A convenient feature of ANSYS FLUENT is that it enables you to assign a specific function to each of the mouse buttons. According to your specifications, clicking a mouse button in the graphics window will cause the appropriate action to be taken. These functions apply only to the graphics windows; they behave differently when an XY plot or histogram is displayed. For information about the use of mouse buttons in these plots, see [Plot Types \(p. 1587\)](#). Clicking any mouse button in a graphics window will make that window the active window.

Important

3DConnexion Space products (Ball, Mouse, Pilot, and Navigator) are not supported with ANSYS FLUENT.

For additional information, see the following sections:

[32.3.1. Button Functions](#)

[32.3.2. Modifying the Mouse Button Functions](#)

32.3.1. Button Functions

The predefined button functions available are listed below:

mouse-rotate

Enables you to rotate the view by dragging the mouse across the screen. Dragging horizontally rotates the object about the screen's *y* axis; vertical mouse movement rotates the object about the screen's *x* axis. The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-dolly

Enables you to translate the view by dragging the mouse while holding down the button. The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-zoom

Enables you to draw a zoom box, anchored at the point at which the button was pressed, by dragging the mouse with the button held down. When you release the button, if the dragging was from left to right, a magnified view of the area within the zoom box will fill the window. If the dragging was from right to left, the area of the window is shrunk to fit into the zoom box, resulting in a "zoomed out" view. If the mouse button is simply clicked (not dragged), the selected point becomes the center of the window.

mouse-roll-zoom

Enables you to rotate or zoom the view, depending on the direction in which you drag the mouse. If you drag the mouse horizontally, the display will rotate about the axis normal to the screen. If you drag it vertically, the display will be magnified (if you drag it down) or shrunk (if you drag it up). The function completes when the mouse button is released or the cursor leaves the graphics window.

mouse-probe

Enables you to select items from the graphics windows and request information about displayed scenes. If the probe function is turned off and you click the mouse-probe button in the graphics window, only the identity of the item on which you clicked will be printed out in the console window. If the probe function is turned on, more detailed information about a selected item will be printed out.

mouse-annotate

Enables you to insert text into the graphics window. If the mouse button is dragged, an attachment line is drawn. When the button is released (after dragging or clicking), a cursor is displayed in the graphics window, and you can enter your text. When you are finished, press <Enter> or move the cursor out

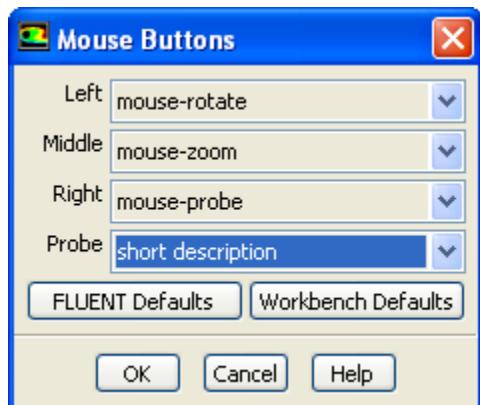

of the graphics window. To modify or remove annotated text and attachment lines, use the **Clear** button in the *Annotate Dialog Box* (p. 2167), as described in *Editing Existing Annotation Text* (p. 1538).

32.3.2. Modifying the Mouse Button Functions

Mouse button functions are specified in the *Mouse Buttons Dialog Box* (p. 2315) (*Figure 32.37* (p. 1549)).

Display → Mouse Buttons...

Figure 32.37 The Mouse Buttons Dialog Box

For each mouse button (**Left**, **Middle**, and **Right**), select the desired function in the drop-down list. The functions are listed above. If you assign the probe function to one of the buttons, select **on** or **off** as the **Probe** status.

The new button functions take effect as soon as you click **OK**. That is, you do not have to redraw the graphics window to use the new functions; the appropriate function will be executed when a mouse button is subsequently clicked in a graphics window.

The **ANSYS FLUENT Defaults** button functions are as follows:

But-ton	2D	3D
Left	mouse-dolly	mouse-ro-tate
Middle	mouse-zoom	mouse-zoom
Right	mouse-probe	mouse-probe

The **Workbench Defaults** button functions are as follows:

But-ton	2D	3D
Left	mouse-dolly	mouse-dolly
Middle	mouse-ro-tate	mouse-probe

Button	2D	3D
Right	mouse-zoom	mouse-zoom

32.4. Viewing the Application Window

In ANSYS FLUENT, the application window will house the menus and console, as well as multiple graphics windows, task pages, and a navigation pane. By default, all components are displayed and one graphics window is visible. You can toggle the visibility of the toolbars, navigation pane, task page, and graphics window. You can also detach or embed the graphics window. The menu bar and the console are never hidden. The graphics windows, when anchored within the application window, will be placed on the right side, immediately below the toolbar. You also have the option of viewing separate graphics windows as described in [Opening Multiple Graphics Windows \(p. 1533\)](#). A description of the **View** menu options which control the layout of the GUI is as follows.

Figure 32.38 The View Menu

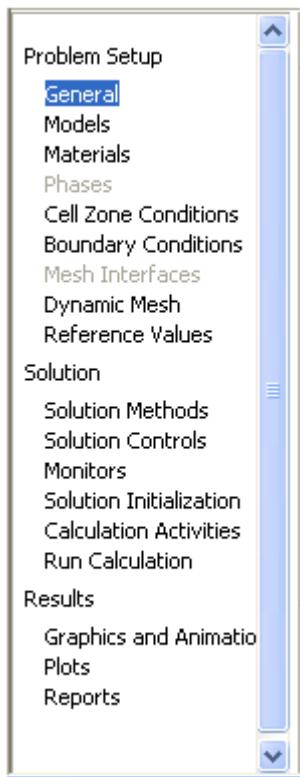

Toolbars

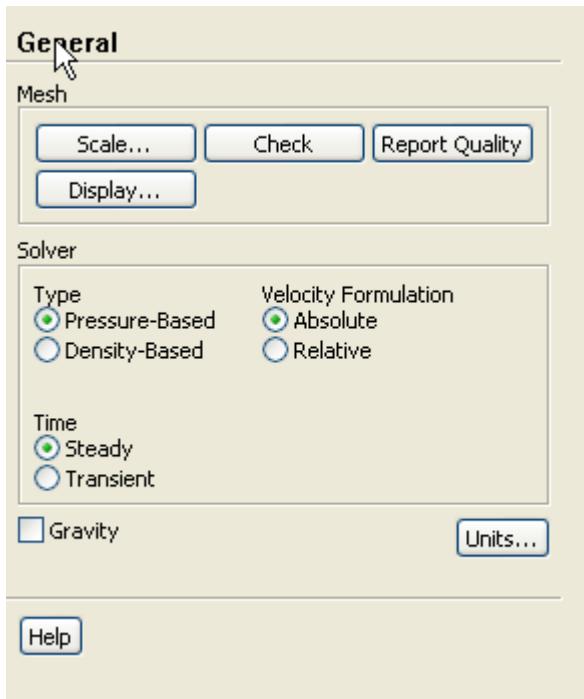

Enables you to customize the appearance of ANSYS FLUENT by displaying or hiding the ANSYS FLUENT toolbars. There are two toolbars. A general toolbar for read case, save and help commands. Another toolbar with commands that apply to the active graphics window. When the graphics window is hidden, the toolbars are visible. By default, all toolbars are visible.

Navigation Pane

Enables you to customize the appearance of ANSYS FLUENT by displaying or hiding the **Navigation Pane** which is a small pane on the left side of the GUI. One row is always highlighted and signifies the task page that is displayed to the right of the **Navigation Page**. Depending on user input, sometimes one or more items are not displayed in the **Navigation Pane**.

Figure 32.39 The Navigation Pane**Task Page**

Enables you to customize the appearance of ANSYS FLUENT by displaying or hiding the task page which is on the right side of the **Navigation Pane**. You can set the controls provided in the task page before running the calculation. The task page can also be opened using menu items. Each task page has a **Help** button which opens the help to the appropriate page in the reference guide.

Figure 32.40 The General Task Page**Graphics Window**

Enables you to customize the appearance of ANSYS FLUENT by displaying or hiding the **Graphics Window** which is on the right side of the GUI, below the toolbar.

Embed Graphics Window

Enables you to anchor the graphics window within ANSYS FLUENT, or detach the windows such that they are free-floating. For more information, refer to *Embedding the Graphics Windows* (p. 1553).

Show All

Enables you to customize the appearance of ANSYS FLUENT by showing all of the GUI components with one command.

Show Only Console

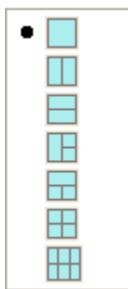

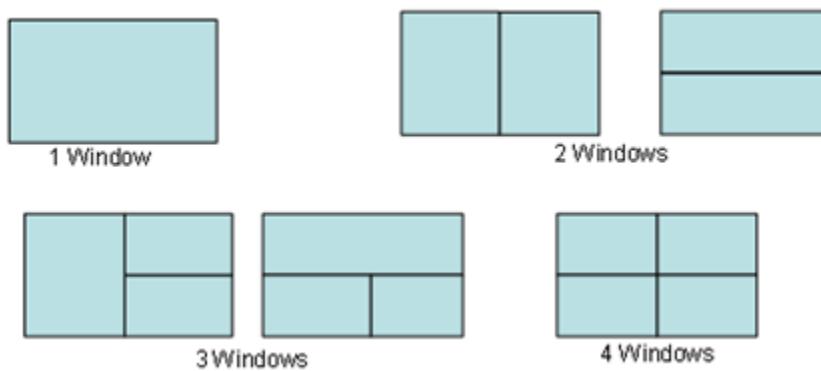

Enables you to customize the appearance of ANSYS FLUENT by showing only the console window along with the menu bar in the application window. The console window is anchored to the lower right corner of the application window. If **Show Only Console** is selected, the menu items of the hidden item (toolbars, navigation pane, task page, and graphics window) are unchecked in the **View** menu. You can resize the console window as you wish with the minimum height being 2 lines. The console window will display messages to the user and provide access to the TUI.

Important

Whenever a GUI component is hidden and you issue a command that requires a hidden GUI component, the view is changed automatically to complete the request.

Graphics Window Layout

Enables you to customize the appearance of ANSYS FLUENT by displaying multiple views. This menu has a submenu with several options. By default, one graphics window is displayed and the window numbering will start at 1. As you can see in *Figure 32.42* (p. 1553), you may display up to 4 windows. You can select any existing window to view through the drop-down menu above the window. You may click on any window to change it from inactive to active.

Figure 32.41 Graphics Window Layout Submenu**Figure 32.42 Graphics Window Layout Options**

Save Layout

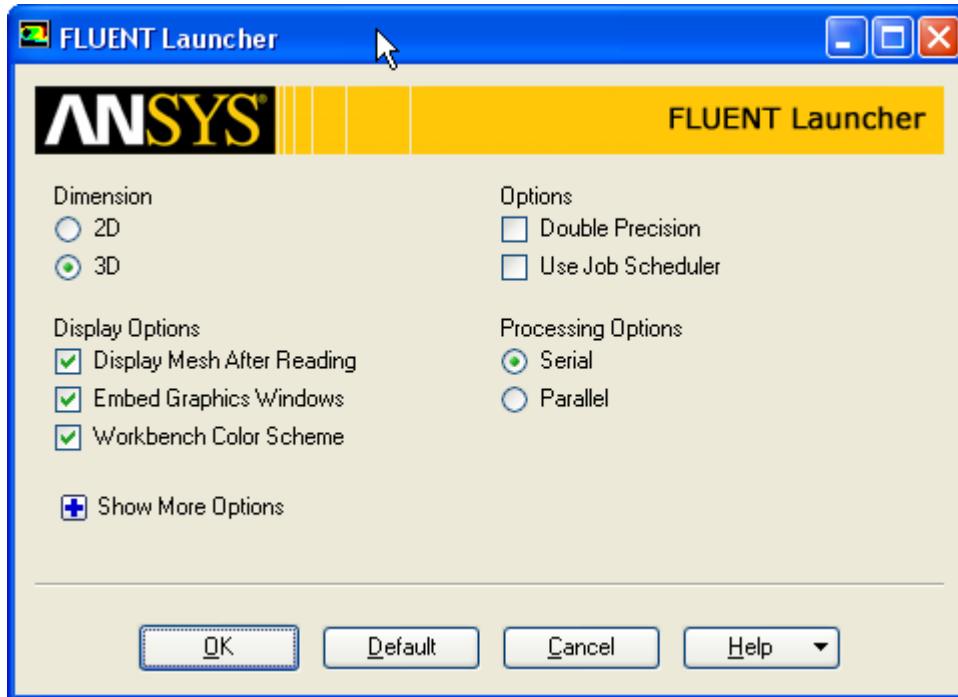

Enables you to save the current layout of the GUI, including the visibility of the current GUI components and the configuration of the dialog boxes and graphics window. This saved layout is applied when you start ANSYS FLUENT, utilizing a .cxlayout file that is written in your home directory. The default position will be used for any dialog box that is not repositioned when you save the layout. The .cxlayout file in your home directory applies to all Cortex applications (that is, ANSYS FLUENT, MixSim, and TGrid).

32.4.1. Embedding the Graphics Windows

When starting ANSYS FLUENT, FLUENT Launcher has an option which enables you to embed the graphics window in the main application or show them as separate windows. The **Embed Graphics Window** option under **Display Options** is enabled by default.

Important

Note that FLUENT Launcher saves your most recent settings. Therefore, if this option was previously disabled, then it will remain disabled the next time you use FLUENT Launcher.

Figure 32.43 The FLUENT Launcher Dialog Box

If you started ANSYS FLUENT with the **Embed Graphics Window** option disabled, and you do not want to have separate, floating graphics windows, you can always embed the graphics windows again. To do so, use the **View/Embed Graphics Window** menu item.

32.5. Modifying the View

ANSYS FLUENT enables you to select and control the view of the scene that is displayed in the graphics window. You can modify the view by scaling, centering, rotating, translating, or zooming the display. You can also save a view that you have created, or restore or delete a view that you saved earlier. These operations are performed in the [Views Dialog Box \(p. 2157\)](#) ([Figure 32.45 \(p. 1556\)](#)) or with the mouse, or simply using the shortcut in the graphics toolbar, as described in [Selecting a View \(p. 1555\)](#).

Important

You can revert to the previous view by pressing **Ctrl-L** while the graphics window has the main focus. You can also use the text command `view last` from the top level of the text command tree. You can use the command to revert to any of the past 20 views.

For additional information, see the following sections:

- [32.5.1. Selecting a View](#)
- [32.5.2. Manipulating the Display](#)
- [32.5.3. Controlling Perspective and Camera Parameters](#)
- [32.5.4. Saving and Restoring Views](#)
- [32.5.5. Mirroring and Periodic Repeats](#)

32.5.1. Selecting a View

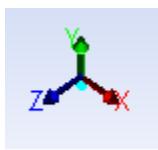

You can use the [Views Dialog Box \(p. 2157\)](#) ([Figure 32.45 \(p. 1556\)](#)) to select the orientation of your display or use the  drop-down available in the graphics toolbar for 3D simulations. Furthermore, you can simply click on the interactive triad ([Figure 32.44 \(p. 1555\)](#)), displayed in the graphics window. The [Table 32.1: Standard Views \(p. 1555\)](#) relates the **Views** listed in the [Views Dialog Box \(p. 2157\)](#) to the views available in the graphics toolbar (see [The Graphics Toolbar \(p. 24\)](#)).

 **Graphics and Animations → Views...**

Table 32.1 Standard Views

View Listed in Dialog Box	View Shortcut in Graphics Toolbar
back	
bottom	
front	
isometric	
left	
right	
top	

Figure 32.44 Using the Triad to Change the Orientation of the Object

To change the orientation of the object in the graphics window using the triad ([Figure 32.44 \(p. 1555\)](#)), you can

- Left-click on an axis to point it in the positive direction.
- Right-click on an axis to point it in the negative direction.
- Left-click on the iso-ball to set the isometric view.

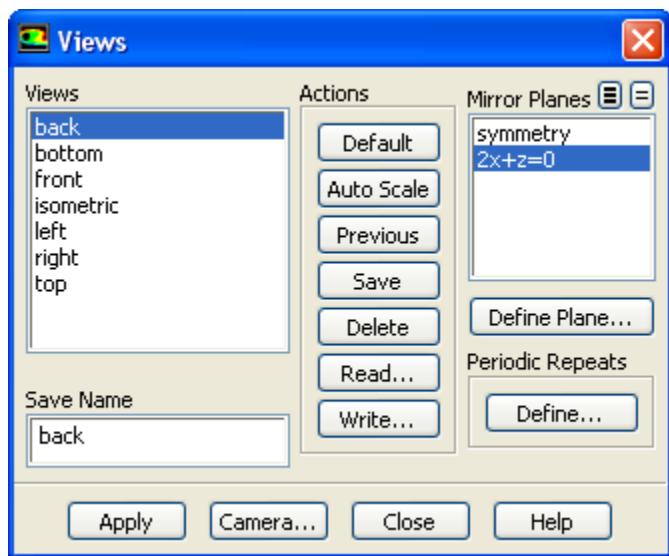

Note that left-clicking on X-axis will result in the +X-axis pointing towards you.

32.5.2. Manipulating the Display

Most of the manipulating activities (like scaling and centering the display) are accomplished using the [Views Dialog Box \(p. 2157\)](#) ([Figure 32.45 \(p. 1556\)](#)).

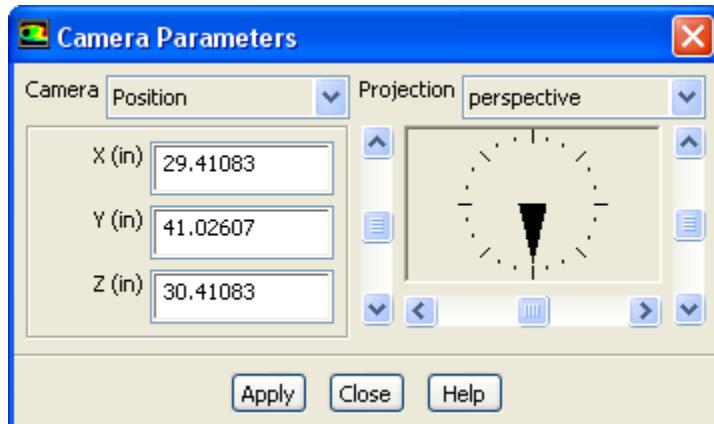

◀ **Graphics and Animations** → **Views...**

Figure 32.45 The Views Dialog Box

You can rotate, translate, and zoom the graphics display using either the mouse or the *Camera Parameters Dialog Box* (p. 2162) (*Figure 32.46* (p. 1556)), which is opened from the *Views Dialog Box* (p. 2157).

Figure 32.46 The Camera Parameters Dialog Box

32.5.2.1. Scaling and Centering

You can scale and center the current display without changing its orientation by clicking **Auto Scale** in the *Views Dialog Box* (p. 2157).

32.5.2.2. Rotating the Display

Use either the mouse or the *Camera Parameters Dialog Box* (p. 2162) to:

- Rotate the display in any direction (in 3D)
- Rotate the display about the axis normal to the screen (in 2D)

To rotate a display with the mouse, use the button with the **mouse-rotate** function (the left button, by default). For information about changing the mouse functions, see [Controlling the Mouse Button Functions \(p. 1548\)](#).

- Click and drag the left mouse button in the graphics window to rotate the geometry in the display.
- You can also click and drag the left mouse button on the (x, y, z) graphics triad in the lower left corner to rotate the display.
- If you press the **Shift** key when you first click the mouse button to begin the rotation, the rotation will be constrained to a single direction (for example, you can rotate about the screen's horizontal axis without changing the position relative to the vertical axis).
- If you want to constrain the rotation of a display to be about the axis normal to the screen, you can also use the **mouse-roll-zoom** function.
- Click the appropriate mouse button and drag the mouse to the left for clockwise rotation, or to the right for counterclockwise rotation.

To rotate a 3D display using the [Camera Parameters Dialog Box \(p. 2162\)](#) ([Figure 32.46 \(p. 1556\)](#)) use the dial and the slider of the scales.

- To rotate about the horizontal axis at the center of the screen, move the slider on the scale to the left of the dial up or down (see [Scales \(p. 31\)](#) or instructions on using the scale).
- To rotate about the vertical axis at the center of the screen, move the slider on the scale below the dial to the left or right.
- To rotate about the axis at the center of and perpendicular to the screen, click the left mouse button on the indicator in the dial and drag it around the dial.

Important

The position of the slider or the dial indicator does not reflect the cumulative rotation about the axis as the slider/indicator will return to its original position when you release the mouse button.

32.5.2.2.1. Spinning the Display with the Mouse

When you use the mouse for rotation, you have the option to “push” the display into a continuous spin. This feature can be used in conjunction with video recording, or simply for interactive viewing of the domain from different angles. To activate this option, use the `auto-spin?` text command:

```
display → set → rendering-options → auto-spin?
```

Then display the graphics (or, if the graphics are already displayed, you can click **Apply** in the [Display Options Dialog Box \(p. 2148\)](#)). The **mouse-rotate** button will then have two uses:

- To perform the standard rotation, stop dragging the mouse before you release the **mouse-rotate** button.
- To start the continuous spin, release the **mouse-rotate** button while you are still dragging the mouse. The display will continue to rotate on its own until you click any mouse button in the graphics window again. The speed of the rotation will depend on how fast you are dragging the mouse when you release the button.

For smoother rotation, enable the **Double Buffering** option in the [Display Options Dialog Box \(p. 2148\)](#) (see [Modifying the Rendering Options \(p. 1546\)](#)). This will reduce screen flicker during graphics updates.

32.5.2.3. Translating the Display

By default the left mouse button is set to **mouse-dolly** in 2D. For information about changing the mouse functions, see [Controlling the Mouse Button Functions \(p. 1548\)](#). Click and drag the left mouse button in the graphics window to translate the geometry in the display.

In 3D, you can either change one of the button functions to **mouse-dolly** and follow the instructions above for 2D, or use the **mouse-zoom** button (the middle button by default). Click the middle button once on the point in the display that you want to move to the center of the screen. ANSYS FLUENT will redisplay the graphic with that point in the center of the window. This method can also be used in 2D.

32.5.2.4. Zooming the Display

In both 2D and 3D you will use the mouse button with the **mouse-zoom** function (the middle button by default) or the **mouse-roll-zoom** function (see [Controlling the Mouse Button Functions \(p. 1548\)](#) for information about enabling this optional function), or the [Camera Parameters Dialog Box \(p. 2162\)](#) to magnify and shrink the display.

With the **mouse-zoom** function, click the middle mouse button and drag it from left to right (creating a "zoom box") to magnify the display. [Figure 32.47 \(p. 1558\)](#) displays the correct dragging of the mouse, from upper left to lower right on the display, in order to zoom. You can also drag from lower left to upper right. After you release the mouse button, ANSYS FLUENT will redisplay the graphic, filling the graphics window with the portion of the display that previously occupied the zoom box.

Figure 32.47 Zooming In (Magnifying the Display)

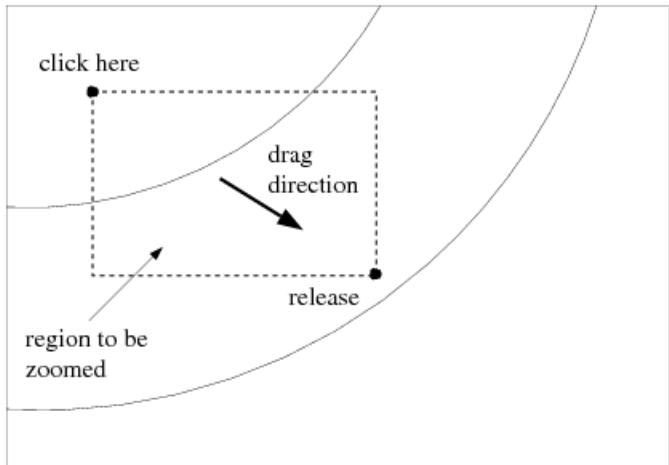

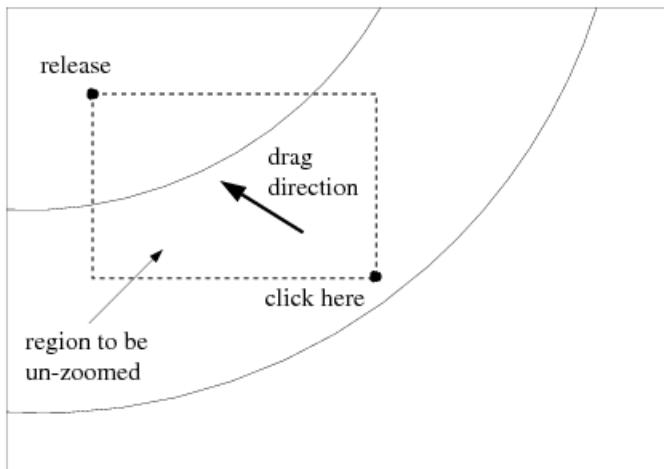

Figure 32.48 Zooming Out (Shrinking the Display)

Click the middle mouse button and drag it from right to left to shrink the display. [Figure 32.48 \(p. 1559\)](#) displays the correct dragging of the mouse, from lower right to upper left on the display, in order to "zoom out". You can also drag from upper right to lower left. After you release the mouse button, ANSYS FLUENT will redisplay the graphic, shrinking the graphical display by the ratio of sizes of the zoom box you created and the previous display.

With the **mouse-roll-zoom** function, click the appropriate mouse button and drag the mouse down to zoom in continuously, or up to zoom out. In the [Camera Parameters Dialog Box \(p. 2162\)](#) ([Figure 32.46 \(p. 1556\)](#)), use the scale to the right of the dial to zoom the display. Move the slider bar up to zoom in and down to zoom out.

32.5.3. Controlling Perspective and Camera Parameters

Perspective and other camera parameters are defined in the [Views Dialog Box \(p. 2157\)](#), which you can open by clicking **Camera...** in the [Camera Parameters Dialog Box \(p. 2162\)](#) ([Figure 32.45 \(p. 1556\)](#)).

◆ **Graphics and Animations** → **Views...**

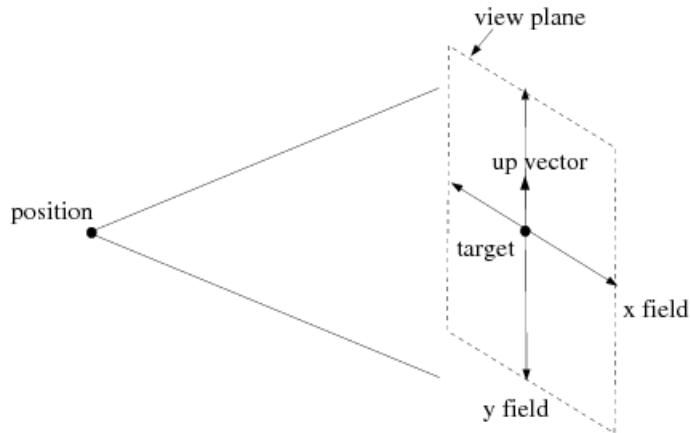

32.5.3.1. Perspective and Orthographic Views

You may choose to display either an orthographic view or a perspective view of your graphics. To show a perspective view (the default), select **Perspective** in the **Projection** drop-down list in the [Views Dialog Box \(p. 2157\)](#) ([Figure 32.46 \(p. 1556\)](#)). To turn off perspective, select **Orthographic** in the **Projection** drop-down list.

32.5.3.2. Modifying Camera Parameters

Instead of translating, rotating, and zooming the display as described in [Manipulating the Display \(p. 1555\)](#), you may sometimes want to modify the "camera" through which you are viewing the graphics display.

The camera is defined by four parameters: position, target, up vector, and field, as illustrated in [Figure 32.49 \(p. 1560\)](#). "Position" is the camera's location. "Target" is the location of the point the camera is looking at, and "up vector" indicates to the camera which way is up. "Field" indicates the field of view (width and height) of the display.

Figure 32.49 Camera Definition

To modify the camera's position, select **Position** in the **Camera** drop-down list and specify the **X**, **Y**, and **Z** coordinates of the desired point. To modify the target location, select **Target** in the **Camera** drop-down list and specify the coordinates of the desired point. Select **Up Vector** to change the up direction. The up vector is the vector from (0,0,0) to the specified (**X,Y,Z**) point. Finally, to change the field of view, select **Field** in the **Camera** list and enter the **X** (horizontal) and **Y** (vertical) field distances.

Important

Click **Apply** after you change each camera parameter (**Position**, **Target**, **Up Vector**, and **Field**).

32.5.4. Saving and Restoring Views

After you make changes to the view shown in your graphics window, you may want to save the view so that you can return to it later. Several default views are predefined for you, and can be easily restored. All saving and restoring functions are performed with the *Views Dialog Box* (p. 2157) (*Figure 32.45* (p. 1556)).

❖ **Graphics and Animations** → **Views...**

Important

Note that settings for mirroring and periodic repeats are not saved in a view.

32.5.4.1. Restoring the Default View

When experimenting with different view manipulation techniques, you may accidentally "lose" your geometry in the display. You can easily return to the default (front) view by clicking **Default** in the *Views Dialog Box* (p. 2157).

32.5.4.2. Returning to Previous Views

After manipulating the display and viewing it from different angles, you can return to previous displays by clicking **Previous** in the *Views Dialog Box* (p. 2157).

32.5.4.3. Saving Views

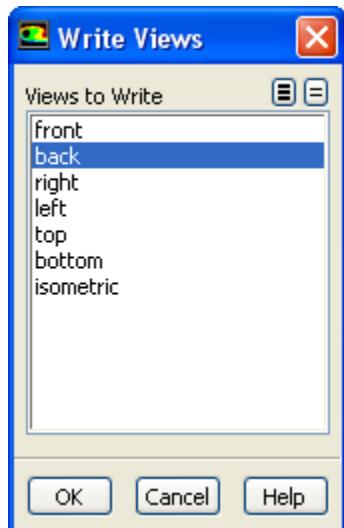

Once you have created a new view that you want to save for future use, enter a name for it in the **Save Name** field in the [Views Dialog Box \(p. 2157\)](#) and click **Save**. Your new view will be added to the list of **Views**, and you can restore it later as described below.

If a view with the same name already exists, you will be asked in a [Question Dialog Box \(p. 33\)](#) if it is OK to overwrite the existing view. If you overwrite one of the default views (top, left, right, front, and so on), be sure to save it in a view file if you wish to use it in a later session. Although all views are saved to the case file, the default views are recomputed automatically when a case file is read in. Any custom view with the same name as a default view will be overwritten at that time.

As mentioned previously, all defined views will be saved in the case file when you write one. If you plan to use your views with another case file, you can write a “view file” containing just the views. You can read this view file into another solver session involving a different case file and restore any of the defined views, as described below.

To save a view file, click **Write...** in the [Views Dialog Box \(p. 2157\)](#). In the resulting [Write Views Dialog Box \(p. 2159\)](#) ([Figure 32.50 \(p. 1561\)](#)), select the views you want to save in the **Views to Write** list and click **OK**. You will then use the [The Select File Dialog Box \(p. 33\)](#) to specify the file name and save the view file.

Figure 32.50 The Write Views Dialog Box

32.5.4.4. Reading View Files

If you have saved views to a view file (as described above), you can read them into your current solver session by clicking **Read...** in the [Views Dialog Box \(p. 2157\)](#), and indicating the name of the view file in [The Select File Dialog Box \(p. 33\)](#). If a view that you read has the same name as a view that already exists, you will be asked in a [Question Dialog Box \(p. 33\)](#) if it is OK to overwrite (that is, replace) the existing view.

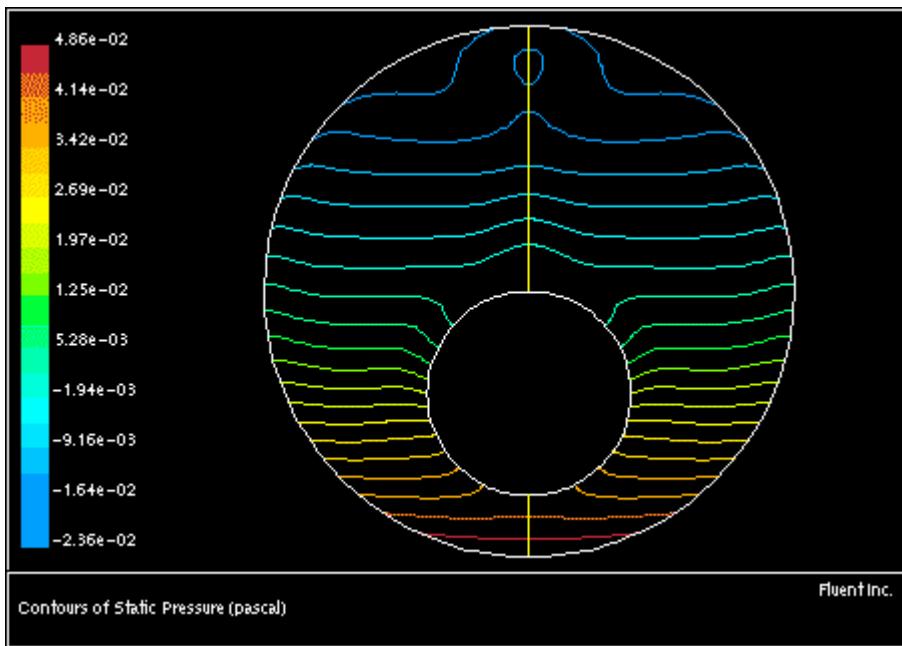

32.5.4.5. Deleting Views

If you decide that you no longer want to keep a particular view, you can delete it by selecting it in the **Views** list and clicking on **Delete**. Use this option carefully, so that you do not accidentally delete one of the predefined views.

32.5.5. Mirroring and Periodic Repeats

If you model the problem domain as a subset of the complete geometry using symmetry or periodic boundaries, you can display results on the complete geometry by mirroring or repeating the domain. For example, only one half of the annulus shown in [Figure 32.51 \(p. 1562\)](#) was modeled, but the graphics are displayed on both halves. You can also define mirror planes or periodic repeats just for graphical display, even if you did not model your problem using symmetry or periodic boundaries.

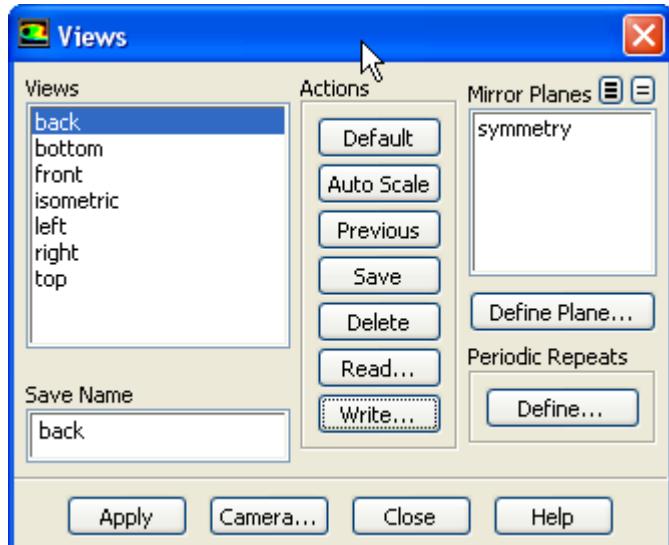

Figure 32.51 Mirroring Across a Symmetry Boundary

Display of symmetry and periodic repeats is controlled in the [Views Dialog Box \(p. 2157\)](#) ([Figure 32.52 \(p. 1562\)](#)).

↳ **Graphics and Animations → Views...**

Figure 32.52 The Views Dialog Box

For a symmetric domain, all symmetry boundaries are listed in the **Mirror Planes** list. Select one or more of these boundaries as the plane(s) about which to mirror the display.

For a periodic domain, click **Define...** to open the *Graphics Periodicity Dialog Box* (p. 2160), to access the periodicity parameters. Specify the number of times to repeat the modeled portion by increasing the value of **Number of Repeats**. If, for example, you modeled a 90° sector of a duct and you wanted to display results on the entire duct, you would set **Number of Repeats** to 4.

In some cases, there may be multiple zones with different periodicity in the domain. For example, in turbomachinery problems with multiple blade rows using the mixing plane model, the periodic angles are different for each blade row. One blade may contain 20 blades (18° periodic angle) and other may contain 15 blades (24° periodic angle). In such cases select the required cell zone and specify the number of repeats for that particular cell zone.

When you click **Set** in the *Graphics Periodicity Dialog Box* (p. 2160) the graphics display will be immediately updated to show the requested periodic repeats.

Figure 32.53 (p. 1563) and *Figure 32.54* (p. 1563) shows the display for the sample geometry before and after applying the periodic repeats respectively. In this case the value of **Number of Repeats** is set to 6 for the 60° sector (outer part) and to a value of 4 is set for the 90° sector (inner part) of the geometry.

Figure 32.53 Before Applying Periodicity

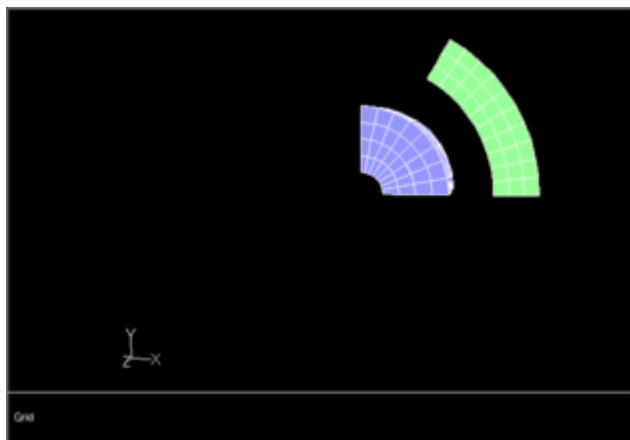

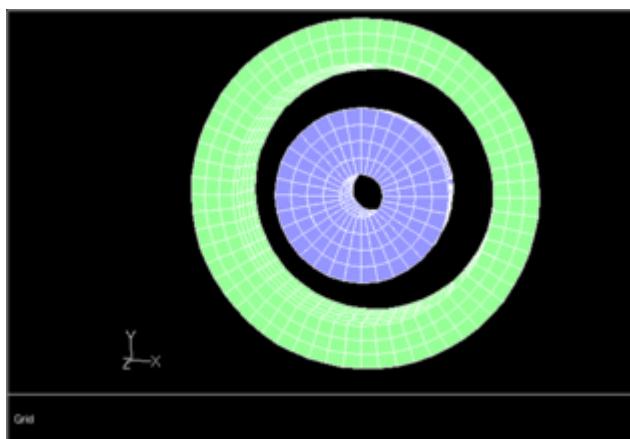

Figure 32.54 After Applying Periodicity

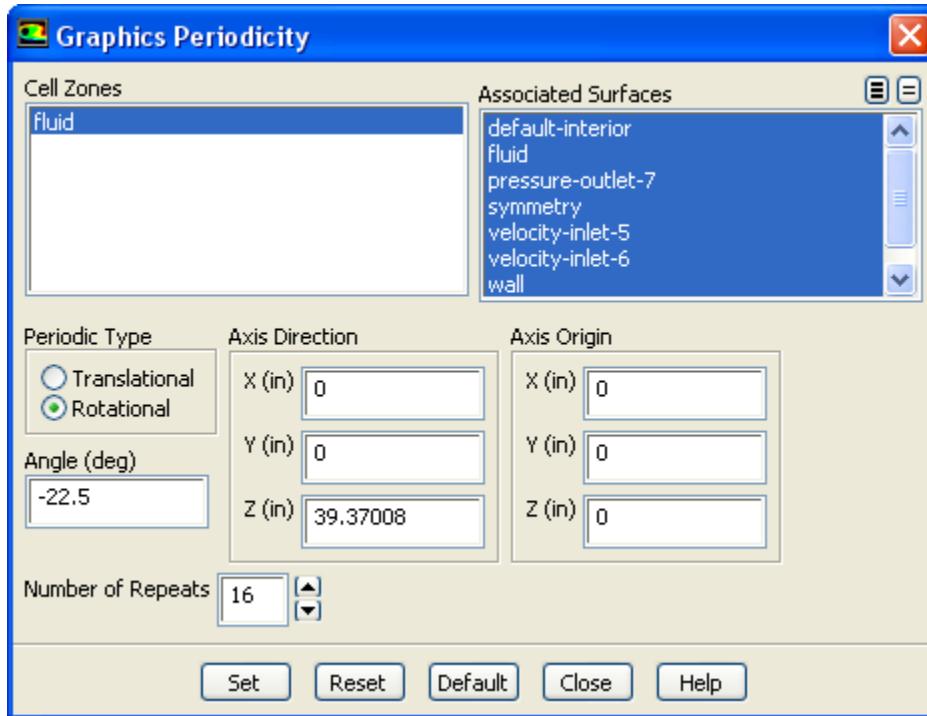

32.5.5.1. Periodic Repeats for Graphics

To define graphical periodicity for a non-periodic domain, do the following:

1. Click **Define...** under **Periodic Repeats** in the *Views Dialog Box* (p. 2157).

Figure 32.55 The Graphics Periodicity Dialog Box

2. In the resulting *Graphics Periodicity Dialog Box* (p. 2160) (Figure 32.55 (p. 1564)), select the **Cell Zone** for which you want to specify the number of repeats.

Associated Surfaces list contains the surfaces associated with the selected cell zone. This is only informative and you cannot edit the selection of surfaces in this box.

3. Specify **Rotational** or **Translational** as the **Periodic Type**.
4. For translational periodicity, specify the **Translation** distance of the repeated domain in the **X**, **Y**, and **Z** directions. For rotational periodicity, specify the axis about which the periodicity is defined and the **Angle** by which the domain is rotated to create the periodic repeat. For 3D problems, the axis of rotation is the vector passing through the specified **Axis Origin** and parallel to the vector from (0,0,0) to the (**X**,**Y**,**Z**) point specified under **Axis Direction**. For 2D problems, you will specify only the **Axis Origin**; the axis of rotation is the z-direction vector passing through the specified point.
5. Specify **Number of Repeats** for the selected cell zone.
6. Click **Set** in the *Graphics Periodicity Dialog Box* (p. 2160).
7. Follow the same procedure for other cell zones.
8. Click **Apply** in the *Views Dialog Box* (p. 2157) to visualize the modified display.

You can delete the definition of any periodicity you have defined for graphics by clicking **Reset** in the *Graphics Periodicity Dialog Box* (p. 2160).

Note

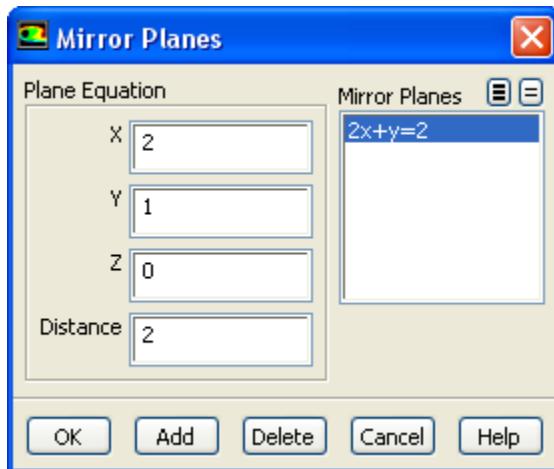

For the 3D domain with multiple periodic zones having different periodicity, ANSYS FLUENT can repeat only mesh, contour and vector plots, and not the pathlines and particle tracks. Also if such domain contains, isosurfaces and clip-surfaces, that are associated with a particular cell zone, they are repeated using the same periodicity that is defined for that cell zone. However, if the surface is not associated with any cell zone, you cannot specify the periodicity for that surface.

32.5.5.2. Mirroring for Graphics

To define a mirror plane for a non-symmetric domain, do the following:

1. Click **Define Plane...** under **Mirror Planes** in the *Views Dialog Box* (p. 2157).

Figure 32.56 The Mirror Planes Dialog Box

2. In the resulting *Mirror Planes Dialog Box* (p. 2159) (Figure 32.56 (p. 1565)), set the coefficients of **X**, **Y**, and **Z** and the **Distance** (of the plane from the origin) in the following equation for the mirror plane:

$$Ax + By + Cz = \text{distance} \quad (32-1)$$

3. Click **Add** to add the defined plane to the **Mirror Planes** list. When you are done creating mirror planes, click **OK**. The newly defined plane(s) will now appear in the **Mirror Planes** list in the *Views Dialog Box* (p. 2157). To include the mirroring in the display, select the plane(s) and click **Apply**, as described above.

If you want to delete a mirror plane that you have defined, select it in the **Mirror Planes** list in the *Mirror Planes Dialog Box* (p. 2159) and click **Delete**. When you click **OK** in this dialog box, the deleted plane will be removed permanently from the **Mirror Planes** list in the *Views Dialog Box* (p. 2157).

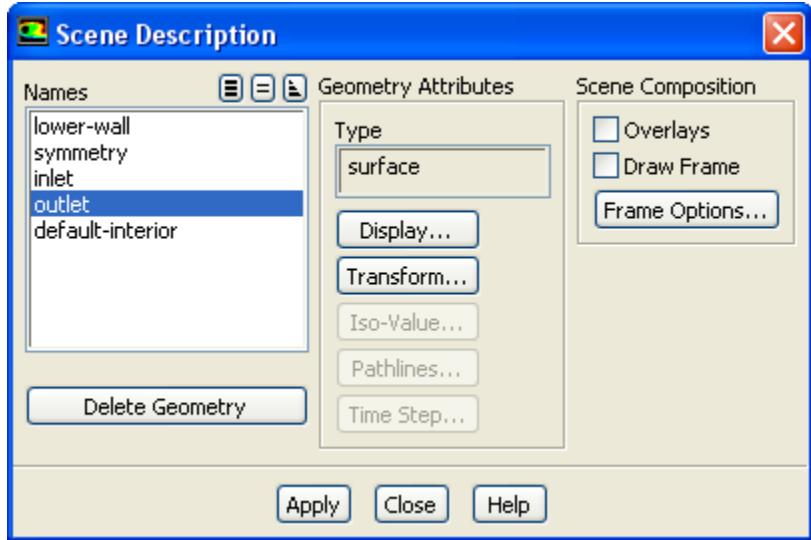

32.6. Composing a Scene

Once you have displayed some geometric objects (meshes, surfaces, contours, vectors, and so on) in your graphics window, you may want to move them around and change their characteristics to increase the effectiveness of the scene displayed. You can use the *Scene Description Dialog Box* (p. 2151) (Figure 32.57 (p. 1566)) and the *Display Properties Dialog Box* (p. 2153) (Figure 32.58 (p. 1567)) and *Transformations*

[Dialog Box \(p. 2154\)](#) ([Figure 32.60 \(p. 1570\)](#)), which are opened from within it, to rotate, translate, and scale each object individually, as well as change the color and visibility of each object.

↔ **Graphics and Animations** → **Scene...**

Figure 32.57 The Scene Description Dialog Box

The [Iso-Value Dialog Box \(p. 2155\)](#) ([Figure 32.61 \(p. 1571\)](#)), which is also opened from within the [Scene Description Dialog Box \(p. 2151\)](#), enables you to change the isovalue of a selected isosurface. The [Pathline Attributes Dialog Box \(p. 2156\)](#) ([Figure 32.62 \(p. 1572\)](#)) lets you set some pathline attributes. The ability to make geometric objects visible and invisible is especially useful when you are creating an animation (see [Animating Graphics \(p. 1575\)](#)) because it enables you to add or delete objects from the scene one at a time. The ability to change the color and position of an object independently of the others in the scene is also useful for setting up animations, as is the ability to change isosurface isovales. You will find the features in the [Scene Description Dialog Box \(p. 2151\)](#) useful even when you are not generating animations because they enable you to manage your graphics window efficiently. The procedure for overlaying graphics, which uses the **Scene Description** dialog box, is described in [Overlay of Graphics \(p. 1532\)](#). (Note that you cannot use the [Scene Description Dialog Box \(p. 2151\)](#) to control XY plot and histogram displays.)

For additional information, see the following sections:

- 32.6.1. Selecting the Object(s) to be Manipulated
- 32.6.2. Changing an Object's Display Properties
- 32.6.3. Transforming Geometric Objects in a Scene
- 32.6.4. Modifying Iso-Values
- 32.6.5. Modifying Pathline Attributes
- 32.6.6. Deleting an Object from the Scene
- 32.6.7. Adding a Bounding Frame

32.6.1. Selecting the Object(s) to be Manipulated

In order to manipulate the objects in the scene, you will begin by selecting the object or objects of interest in the **Names** list in the [Scene Description Dialog Box \(p. 2151\)](#) ([Figure 32.57 \(p. 1566\)](#)). The **Names** list is a list of the geometric objects that currently exist in the scene (including those that are presently invisible). If you select more than one object at a time, any operation (transformation, color specification, and so on) will apply to all the selected objects. You can also select objects by clicking on them in the

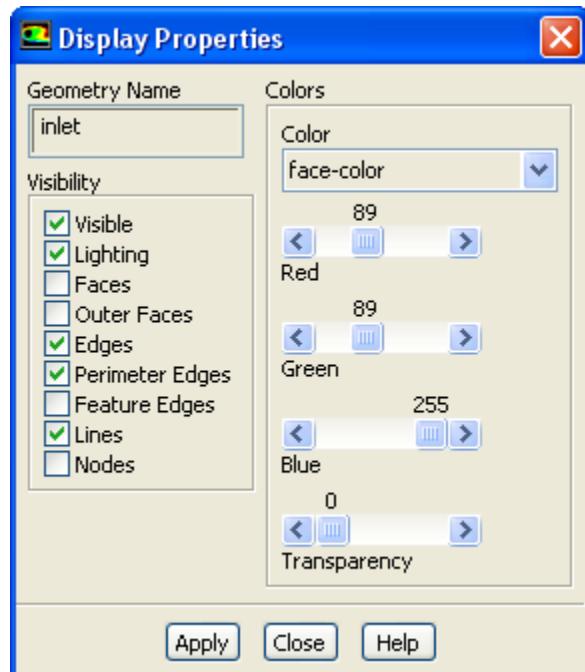

graphics display using the mouse-probe button, which is, by default, the right mouse button. (See [Controlling the Mouse Button Functions \(p. 1548\)](#) for information about mouse button functions.) To deselect a selected object, simply click on its name in the **Names** list.

When you select one or more objects (either in the **Names** list or in the display), the **Type** field will report the type of the selected object(s). Possible types for a single object include mesh, surface, contour, vector, path, and text (that is, annotation text). This information is especially helpful when you need to distinguish two or more objects with the same name. When more than one object is selected, the type displayed is Group.

32.6.2. Changing an Object's Display Properties

To enhance the scene in the graphics window, you can change the color, visibility, and other display properties of each geometric object in the scene. You can specify different colors for displaying the edges and faces of a mesh object to show the underlying mesh (edges) when the faces of the mesh are filled and shaded. You can also make a selected object temporarily invisible. If, for example, you are displaying the entire mesh for a complicated problem, you can make objects visible or invisible to display only certain boundary zones of the mesh without regenerating the mesh display using the [Mesh Display Dialog Box \(p. 1767\)](#). You can also use the visibility controls to manipulate geometric objects for efficient graphics display or for the creation of animations. These features, plus several others, are available in the [Display Properties Dialog Box \(p. 2153\)](#) (*Figure 32.58 (p. 1567)*).

Figure 32.58 The Display Properties Dialog Box

To set the display properties described above, select one or more objects in the **Names** list in the [Scene Description Dialog Box \(p. 2151\)](#) and then click **Display...** to open the [Display Properties Dialog Box \(p. 2153\)](#) for that object or group of objects.

32.6.2.1. Controlling Visibility

There are several ways for you to control the visibility of an object. All visibility options are listed under the **Visibility** heading in the [Display Properties Dialog Box \(p. 2153\)](#).

- To make the selected object(s) invisible, turn off the **Visible** option. To “undo” invisibility, enable the **Visible** option again.
- To turn the effect of lighting for the selected object(s) on or off, use the **Lighting** check box. You can choose to have lighting affect only certain objects instead of all of them. Note that if **Lighting** is turned on for an object such as a contour or vector plot, the colors in the plot will not be exactly the same as those in the colormap at the left of the display.
- To toggle the filled display of faces for the selected mesh or surface object(s), use the **Faces** option. Turning **Faces** on here has the same effect as turning it on for the entire mesh in the *Mesh Display Dialog Box* (p. 1767).
- To turn the display of outer edges on or off, use the **Outer Faces** option. This option is useful for displaying both sides of a slit wall. By default, when you display a slit wall, one side will “bleed” through to the other. When you turn off the **Outer Faces** option, the display of a slit wall will show each side distinctly as you rotate the display. This option can also be useful for displaying two-sided walls (that is, walls with fluid or solid cells on both sides).
- To turn the display of interior and exterior edges of the geometric object(s) on or off, use the **Edges** option.
- To turn the display of the outline of the geometric object(s) on or off, use the **Perimeter Edges** check box.
- To toggle the display of feature lines (described in *Adding Features to an Outline Display* (p. 1504)), if any, for the selected object(s), use the **Feature Edges** option.
- To toggle the display of the lines (if any) in the geometric object(s), use the **Lines** check box. Pathlines, line contours, and vectors are “lines”.
- To toggle the display of nodes (if any) in the geometric object(s), use the **Nodes** check box.

Once you have set the appropriate display parameters, click **Apply** to update the graphics display.

32.6.2.2. Controlling Object Color and Transparency

The *Display Properties Dialog Box* (p. 2153) also lets you control an object’s color and how transparent it is. All color and transparency options are listed under the **Colors** heading.

- To modify the color of faces, edges, or lines in the selected object(s), choose **face-color**, **edge-color**, **line-color**, or **node-color** in the **Color** drop-down list. The **Red**, **Green**, and **Blue** color scales will show the RGB components of the face, edge or line color, which you can modify by moving the sliders on the color scales. When you are satisfied with the color specification, click **Apply** to save it and update the display. The ability to set the colors for faces and edges can be useful when you wish to have a filled display for the mesh or surface, but you also want to be able to see the mesh lines. You can achieve this effect by specifying different colors for the faces and the edges.
- To set the relative transparency of an object, select **face-color** in the **Color** drop-down list. Move the slider on the **Transparency** scale and click **Apply** to update the graphics display. An object with a transparency of 0 is opaque, and an object with a transparency of 100 is transparent. By specifying a high transparency value for the walls of a pipe, for example, you will be able to see contours that you have displayed on cross-sections inside the pipe. This feature is available on all platforms when the software z buffer is used for hidden surface removal, but if your display hardware supports transparency, it will be more efficient to use the hardware z buffer as the hidden surface method instead. You can select these methods in the *Display Options Dialog Box* (p. 2148), as described in *Modifying the Rendering Options* (p. 1546).

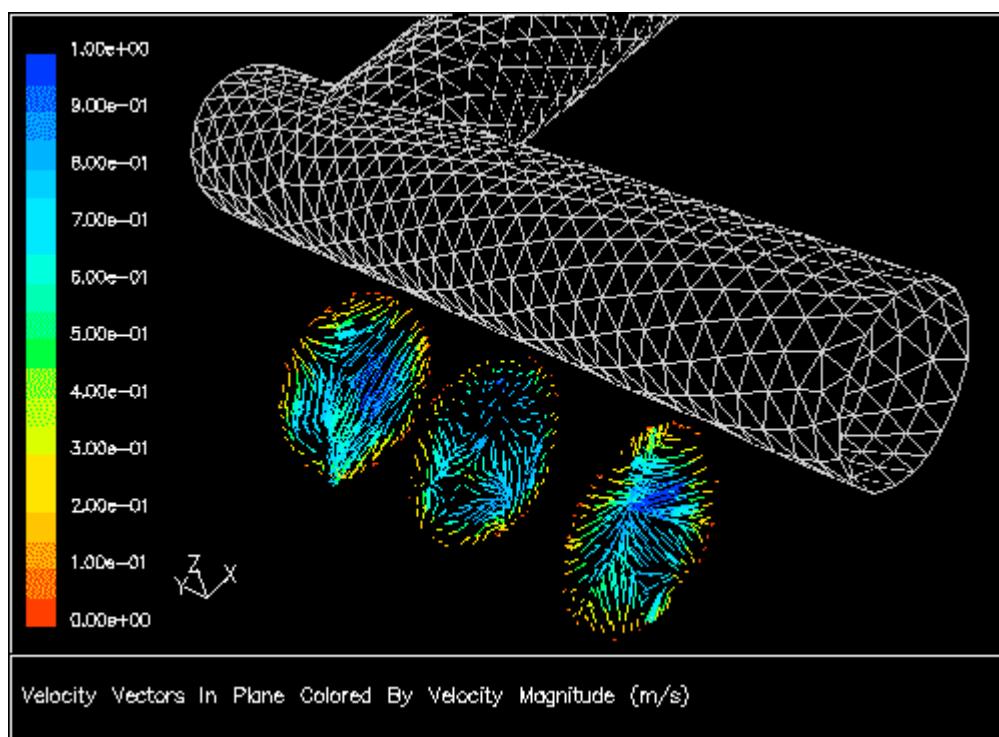

Important

If you save a picture of a display with transparent surfaces, you should *not* set the **File Type** in the *Save Picture Dialog Box* (p. 2144) to **Vector**.

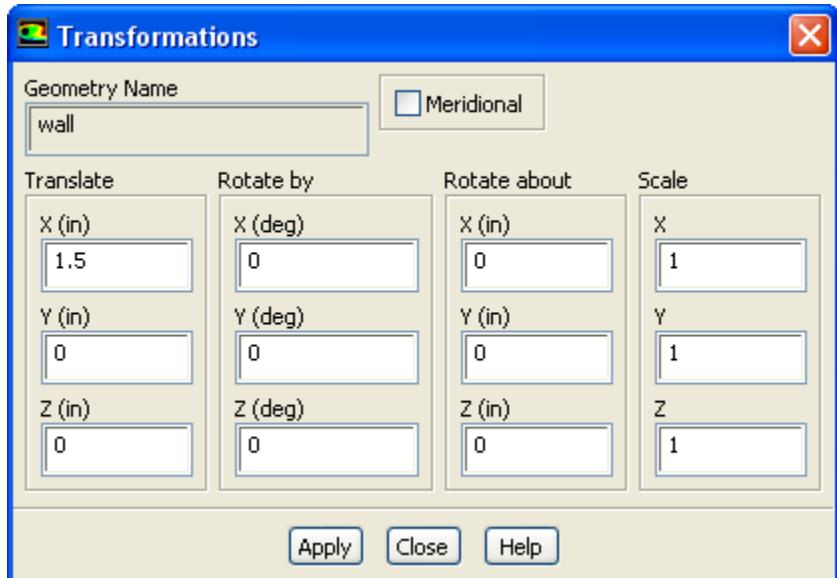

32.6.3. Transforming Geometric Objects in a Scene

When you are composing a scene in your graphics window, you might find it helpful to move a particular object from its original position or to increase or decrease its size. For example, if you have displayed contours or vectors on cross-sections of an internal flow domain (such as a pipe), you might want to translate these cross-sections so that they will appear outside of the pipe, where they can be seen and interpreted more easily. *Figure 32.59* (p. 1569) shows such an example.

Figure 32.59 Velocity Vectors Translated Outside the Domain for Better Viewing

You can also move an object by rotating it about the x , y , or z axis. If you want to display one object more prominently than the others, you can scale its size. If your geometry is rotating or has rotational symmetry, you can display the meridional view. All of these capabilities are available in the *Transformations Dialog Box* (p. 2154) (*Figure 32.60* (p. 1570)).

Figure 32.60 The Transformations Dialog Box

To perform the transformations described above, select one or more objects in the **Names** list in the *Scene Description Dialog Box* (p. 2151) and then click **Transform...** to open the *Transformations Dialog Box* (p. 2154) for that object or group of objects.

32.6.3.1. Translating Objects

To translate the selected object(s), enter the translation distance in each direction in the **X**, **Y**, and **Z** real number fields under **Translate**. Note that you can check the domain extents in the *Scale Mesh Dialog Box* (p. 1766) or the *Iso-Surface Dialog Box* (p. 2084). Translations are not cumulative, so you can easily return to a known state. To return to the original position, simply enter 0 in all three real number fields.

32.6.3.2. Rotating Objects

To rotate the selected object(s), enter the number of degrees by which to rotate about each axis in the **X**, **Y**, and **Z** integer number fields under **Rotate By**. You can enter any value between –360 and 360. By default, the rotation origin will be (0,0,0). If you want to spin an object about its own origin, or about some other point, specify the **X**, **Y**, and **Z** coordinates of that point under **Rotate About**.

Rotations are not cumulative, so you can easily return to a known state. To return to the original position, simply enter 0 in all three integer number fields under **Rotate By**.

32.6.3.3. Scaling Objects

To scale the selected object(s), enter the amount by which to scale in each direction in the **X**, **Y**, and **Z** real number fields under **Scale**. To avoid distortion of the object's shape, be sure to specify the same value for all three entries. Scaling is not cumulative, so you can easily return to a known state. To return the object to its original size, simply enter 1 in all three real number fields.

32.6.3.4. Displaying the Meridional View

To display the meridional view of the selected object(s), enable the **Meridional** option. This option is available only for 3D models. It is applicable to cases with a defined axis of rotation and is especially useful in turbomachinery applications.

The meridional transformation projects the selected entities onto a surface of constant angular coordinate, θ . The resultant projection thus lies in an (r, ζ) plane where ζ is in the direction of the rotation axis and r is normal to it. The value of θ used for the projection is taken as that corresponding to the minimum (r, ζ) point of the entity.

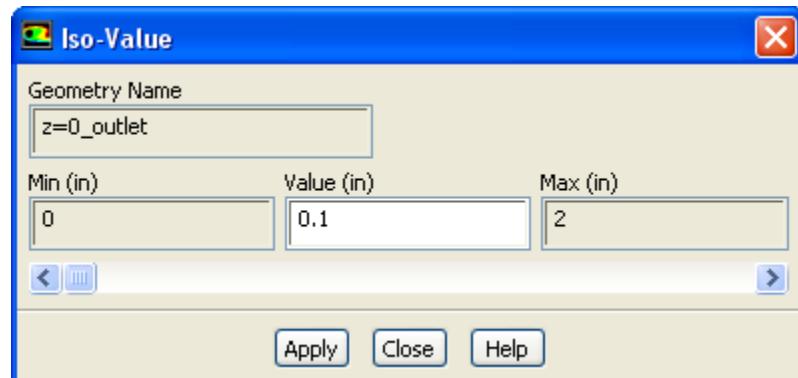

32.6.4. Modifying Iso-Values

One convenient feature that you can use to generate effective animations is the ability to generate surfaces with intermediate values between two isosurfaces with different isovalue. If the surfaces have contours, vectors, or pathlines displayed on them, ANSYS FLUENT will generate and display contours, vectors, or pathlines on the intermediate surfaces that it creates.

32.6.4.1. Steps for Modifying Iso-Values

You can modify an isosurface's isovalue directly by selecting it in the *Scene Description Dialog Box* (p. 2151)'s **Names** list or indirectly by selecting an object displayed on the isosurface. Then click **Iso-Value...** to open the *Iso-Value Dialog Box* (p. 2155) (*Figure 32.61* (p. 1571)) for the selected object. Note that this button is available only if the geometric object selected in the **Names** list is an isosurface or an object on an isosurface (contour on an isosurface, for example); otherwise it is grayed out.

Figure 32.61 The Iso-Value Dialog Box

In the *Iso-Value Dialog Box* (p. 2155), set the new isovalue in the **Value** field, and click **Apply**. Contours, vectors, or pathlines that were displayed on the original isosurface will be displayed for the new isovalue.

32.6.4.2. An Example of Iso-Value Modification for an Animation

The ability to generate intermediate surfaces with data displayed on them is especially convenient if you want to create an animation that shows data on successive slices of the problem domain. For example, if you have solved the flow through a pipe junction and you want to create an animation that moves through one of the pipes (along their axis) and displays pressure contours on several cross-sections, you can use the following procedure:

1. Generate a surface of constant coordinate (such as the y coordinate at the pipe inlet) using the [Iso-Surface Dialog Box \(p. 2084\)](#).
2. Use the [Contours Dialog Box \(p. 2120\)](#) to generate contours of static pressure on this isosurface and manipulate the graphics display to the desired view.
3. Open the [Animate Dialog Box \(p. 2142\)](#) and create key frame 1.
4. In the [Scene Description Dialog Box \(p. 2151\)](#), select the contour in the **Names** list and click **Iso-Value...** to open the [Iso-Value Dialog Box \(p. 2155\)](#).
5. Change the value of the isovalue to the y coordinate at the other end of the pipe, and click **Apply**. You will see the contours of static pressure at the new y coordinate.
6. Set key frame 10 in the [Animate Dialog Box \(p. 2142\)](#).
7. Play back the animation.

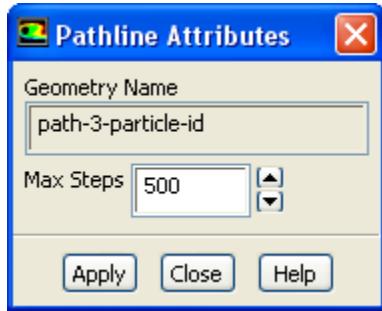

When you play back the animation, ANSYS FLUENT will create the intermediate frames showing contours of static pressure on the slices between the two ends of the pipe. Ten slices will be shown in succession, all with contours displayed on them.

Using the [Sweep Surface Dialog Box \(p. 2141\)](#) to animate the display of contours or vectors on a surface that sweeps through the domain may be more convenient than the procedure described above. See [Displaying Results on a Sweep Surface \(p. 1529\)](#) for details.

32.6.5. Modifying Pathline Attributes

If you are creating animations of existing pathlines, you may want to change the number of steps used in the computation of the pathlines. This enables you to animate pathlines advancing through the domain. To do so, select the pathlines in the **Names** list in the [Scene Description Dialog Box \(p. 2151\)](#) and then click **Pathlines...** to open the [Pathline Attributes Dialog Box \(p. 2156\)](#) ([Figure 32.62 \(p. 1572\)](#)).

Figure 32.62 The Pathline Attributes Dialog Box

In the [Pathline Attributes Dialog Box \(p. 2156\)](#), set the new maximum number of steps for pathline computation (**Max Steps**). After you change the value and click **Apply**, the selected pathline will be recomputed and redrawn.

32.6.5.1. An Example of Pathline Modification for an Animation

You can use the following procedure to animate pathlines from step 2 to step 101 (for example):

1. Generate the plot of pathlines using the [Pathlines Dialog Box \(p. 2128\)](#).
2. In the [Scene Description Dialog Box \(p. 2151\)](#), select the pathlines in the **Names** list and click **Pathlines...** to open the [Pathline Attributes Dialog Box \(p. 2156\)](#).

3. Change the value of the maximum number of steps to 2, and click **Apply**.
4. Open the *Animate Dialog Box* (p. 2142) and create key frame 1.
5. In the *Pathline Attributes Dialog Box* (p. 2156), change the value of the maximum number of steps to 101, and click **Apply**.
6. Set key frame 100 in the *Animate Dialog Box* (p. 2142).
7. Play back the animation.

When you play back the animation, ANSYS FLUENT will animate the pathlines so that they advance one step in each frame.

32.6.6. Deleting an Object from the Scene

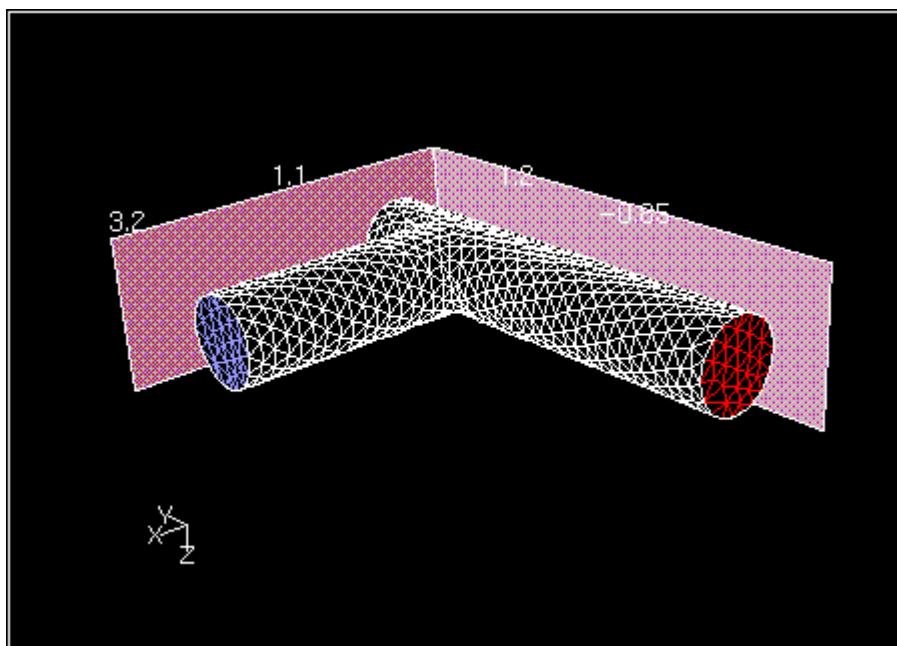

If you are composing a complex scene with overlays and find that you no longer want to keep one of the objects, it is possible to delete it without affecting any of the other objects in the scene. The ability to delete individual objects is especially useful if you have overlays on and you generate an unwanted object (for example, if you generate contours of the wrong variable). You can simply delete the unwanted object and continue your scene composition, instead of starting over from the beginning. Note that it is also possible to make objects temporarily invisible, as described in *Controlling Visibility* (p. 1567).

Object deletion is performed in the *Scene Description Dialog Box* (p. 2151) (*Figure 32.57* (p. 1566)). To delete an object from the scene, select it in the **Names** list and then click **Delete Geometry**. The selected name will disappear from the **Names** list, and the display will be updated immediately.

32.6.7. Adding a Bounding Frame

ANSYS FLUENT enables you to add a bounding frame around your displayed domain. You may also include measure markings on the bounding frame to indicate the length, height, and/or width of the domain, as shown in *Figure 32.63* (p. 1573).

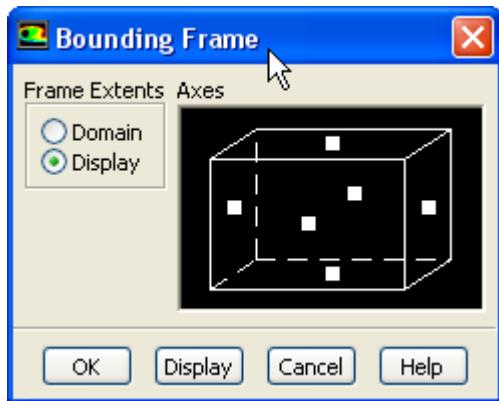

Figure 32.63 Graphics Display with Bounding Frame

To add a bounding frame to your display, you will follow the procedure below:

1. Click **Frame Options...** in the *Scene Description Dialog Box* (p. 2151) (*Figure 32.57* (p. 1566)) to open the *Bounding Frame Dialog Box* (p. 2157) (*Figure 32.64* (p. 1574)).

Figure 32.64 The Bounding Frame Dialog Box

2. Under **Frame Extents** in the *Bounding Frame Dialog Box* (p. 2157), select **Domain** or **Display** to indicate whether the bounding frame should encompass the domain extents or only the portion of the domain that is shown in the display.
3. In the **Axes** portion of the *Bounding Frame Dialog Box* (p. 2157), specify the frame boundaries and measurements to be shown in the display:
 - Indicate the bounding plane(s) (for example, the x-z and y-z planes shown in *Figure 32.63* (p. 1573)) to be displayed by clicking on the white square on the appropriate plane of the box shown under the **Axes** heading. You can use any of the mouse buttons. The square will turn red to indicate that the associated bounding plane will be displayed in the graphics window.
 - Specify where you would like to see the measurement annotations by clicking on the appropriate edge of the box. The edge will turn red to indicate that the markings will be displayed along that edge of the displayed geometry.

Important

If you have trouble determining which square or edge corresponds to which location in your domain, you can easily find out by displaying one or two bounding planes to get your bearings. You can then select the appropriate objects to obtain the final display.

4. Click **Display** to update the display with the current settings. If you are not satisfied with the frame, repeat steps 2 and/or 3 and click **Display** again.
5. Once you are satisfied with the bounding frame that is displayed, click **OK** to close the *Bounding Frame Dialog Box* (p. 2157) and save the frame settings for future displays.
6. If you wish to include the bounding frame in all subsequent displays, enable the **Draw Frame** option in the *Scene Description Dialog Box* (p. 2151) and click **Apply**. If this option is not enabled, the bounding box will appear only in the current display; it will not be redisplayed when you generate a new display (unless you have overlays enabled).

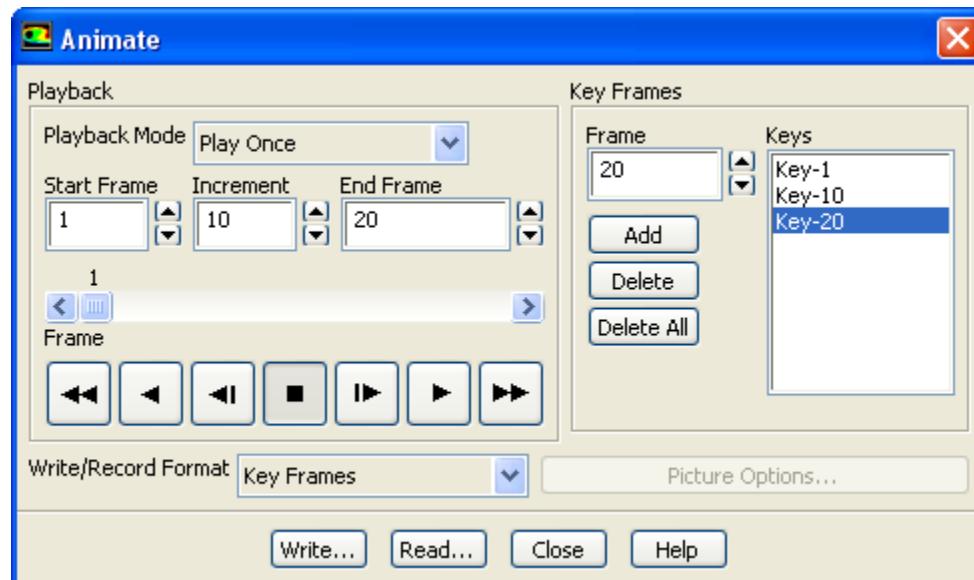

The bounding planes and axis annotations will appear in the **Names** list of the *Scene Description Dialog Box* (p. 2151), and you can manipulate them in the same way as any other geometric object in the display. For example, you can use the *Display Properties Dialog Box* (p. 2153) to change the face color of a bounding plane or to make it transparent (see *Changing an Object's Display Properties* (p. 1567)).

32.7. Animating Graphics

To generate animations that progress from one static view of the graphics display to the next, you can set up “key frames” (individual static images) using the *Animate Dialog Box* (p. 2142) (*Figure 32.65* (p. 1575)).

◆ **Graphics and Animations → Scene Animation**

Figure 32.65 The Animate Dialog Box

You can compose a scene in the graphics window and define it as a single key frame. Then, modify the scene by moving or scaling objects, making some objects invisible or visible, changing colors, changing the view, or making other changes, and define the new scene as another key frame. ANSYS FLUENT can then interpolate smoothly between the two frames that you defined, creating a specified number of intermediate frames.

Another method of generating animations is to automatically generate surfaces with intermediate values between two isosurfaces with different isovalue. See *Modifying Iso-Values* (p. 1571) for details. See *Displaying Results on a Sweep Surface* (p. 1529) for information about displaying the mesh, contours, or vectors on a surface that sweeps through the domain. If you want to create a graphical animation of the solution over time, you can use the *Solution Animation Dialog Box* (p. 2105) to set up the graphical displays that you want to use in the animation. You can choose the type of display you want to animate by choosing **Mesh, Contours, Pathlines, Particle Tracks, Vectors, XY Plot, or Monitor**. For details on animating the solution, see *Animating the Solution* (p. 1409). For more information on generating, displaying, and saving pathlines and particle tracks, refer to *Displaying Pathlines* (p. 1520).

For additional information, see the following sections:

- [32.7.1. Creating an Animation](#)
- [32.7.2. Playing an Animation](#)
- [32.7.3. Saving an Animation](#)
- [32.7.4. Reading an Animation File](#)
- [32.7.5. Notes on Animation](#)

32.7.1. Creating an Animation

You can define any number of key frames (up to 3000) to create your animation. By assigning the appropriate numbers to the key frames, you provide the information ANSYS FLUENT needs to create the correct number of intermediate frames. For example, to create a simple animation that begins with a front view of an object, moves to a side view, and ends with a rear view of the object, you would follow the procedure outlined below:

1. Determine the number of frames that you want in the animation. For this example, consider the animation to be 31 frames.
2. Determine the number of key frames that you need to specify. In this example, you will specify three: one showing the front view, one showing the side view, and one showing the rear view.
3. Determine the appropriate key frame numbers to assign to the 3 specified frames. Here, the front view will be specified as key frame 1, the side view will be key frame 16, and the rear view will be key frame 31.
4. Compose the scenes for each view to be used as a key frame. You can use the *Scene Description Dialog Box* (p. 2151) (see *Composing a Scene* (p. 1565)) and the *Views Dialog Box* (p. 2157) (see *Modifying the View* (p. 1554)) to modify the display, and any other dialog boxes or commands to create contours, vectors, pathlines, and so on to be included in each scene. After you complete each scene, create the appropriate key frame by setting the **Frame** number and clicking **Add** under **Key Frames** in the *Animate Dialog Box* (p. 2142). For special considerations related to key frame definition, see *Notes on Animation* (p. 1579).

Important

Be sure to change the **Frame** number before clicking **Add**, or you will overwrite the last key frame that you created.

You can check any of the key frames that you have created by selecting it in the **Keys** list. The selected key frame will be displayed in the graphics window.

5. When you complete the animation, you can play it back as described in *Playing an Animation* (p. 1576) and/or save it as described in *Saving an Animation* (p. 1578).

32.7.1.1. Deleting Key Frames

If, during the creation of your animation, you want to remove one of the key frames that you have defined, select the key frame in the **Keys** list and click **Delete**. If you want to delete all key frames and start over again, click **Delete All**.

32.7.2. Playing an Animation

Once you have defined the key frames (as described in *Creating an Animation* (p. 1576)) or read in a previously created animation file (as described in *Reading an Animation File* (p. 1579)), you can play back the animation and ANSYS FLUENT will interpolate between the frames that you specified to complete the animation.

To play the animation once through from start to finish, click the “play” button under the **Playback** heading in the *Animate Dialog Box* (p. 2142). (The buttons function in a way similar to those on a standard video cassette player. “Play” is the second button from the right—a single triangle pointing to the right.) To play the animation backwards once, click the “play reverse” button (the second from the left—a single triangle point to the left). As the animation plays, the **Frame** scale shows the number of the

frame that is currently displayed, as well as its relative position in the entire animation. If, instead of playing the complete animation, you want to jump to a particular key frame, move the **Frame** slider bar to the desired frame number, and the frame corresponding to the new frame number will be displayed in the graphics window.

Additional options for playing back animations are described below. Be sure to check [Notes on Animation \(p. 1579\)](#) as well for important notes about playing back animations.

32.7.2.1. Playing Back an Excerpt

You may sometimes want to play only one portion of a long animation. To do this, you can modify the **Start Frame** and the **End Frame** under the **Playback** heading in the [Animate Dialog Box \(p. 2142\)](#). For example, if your animation contains 50 frames, but you want to play only frames 20 to 35, you can set **Start Frame** to 20 and **End Frame** to 35. When you play the animation, it will start at frame 20 and finish at frame 35.

32.7.2.2. "Fast-Forwarding" the Animation

You can "fast-forward" or "fast-reverse" the animation by skipping some of the frames during playback. To fast-forward the animation, set the **Increment** and click the fast-forward button. If, for example, your **Start Frame** is 1, your **End Frame** is 15, and your **Increment** is 2, when you click the fast-forward button (the last button on the right—two triangles pointing to the right), the animation will show frames 1, 3, 5, 7, 9, 11, 13 and 15. Clicking on the fast-reverse button (the first button on the left—two triangles pointing to the left) will show frames 15, 13, 11,...1.

32.7.2.3. Continuous Animation

If you want the playback of the animation to repeat continuously, there are two options available.

- To continuously play the animation from beginning to end (or from end to beginning, if you use one of the reverse play buttons), select **Auto Repeat** in the **Playback Mode** drop-down list in the [Animate Dialog Box \(p. 2142\)](#).
- To play the animation back and forth continuously, reversing the playback direction each time, select **Auto Reverse** in the **Playback Mode** drop-down list.

To turn off the continuous playback, select **Play Once** in the **Playback Mode** list. This is the default setting.

32.7.2.4. Stopping the Animation

To stop the animation during playback, click the "stop" button (the square in the middle of the playback control buttons). If your animation contains very complicated scenes, there may be a slight delay before the animation stops.

32.7.2.5. Advancing the Animation Frame by Frame

To advance the animation manually frame by frame, use the third button from the right (a vertical bar with a triangle pointing to the right). Each time you click this button, the next frame will be displayed in the graphics window. To reverse the animation frame by frame, use the third button from the left (a left-pointing triangle with a vertical bar). Frame-by-frame playback enables you to freeze the animation at points that are of particular interest.

32.7.3. Saving an Animation

Once you have created your animation, you can save it in any of the following formats:

- Animation file containing the key frame descriptions
- Picture files, each containing a frame of the animation
- MPEG file containing each frame of the animation
- Video (see [Creating Videos \(p. 1579\)](#))

32.7.3.1. Animation File

You can save the key frame definitions to a file that can be read back into ANSYS FLUENT (see [Reading an Animation File \(p. 1579\)](#)) when you want to replay the animation. Since the animation file will contain only the key frame definitions, you must be sure that you have a case and data file containing the necessary surfaces and other information referred to by the key frame descriptions.

To write an animation file, select **Key Frames** in the **Write/Record Format** drop-down list in the [Animate Dialog Box \(p. 2142\)](#), and click **Write....** In [The Select File Dialog Box \(p. 33\)](#), specify the name of the file and save it.

32.7.3.2. Picture File

You can also generate a picture file for each frame in the animation. This feature enables you to save your animation frames to picture files used by an external animation program such as ImageMagick. To save the animation as a picture file, follow these steps:

1. Select **Picture Files** in the **Write/Record Format** drop-down list in the [Animate Dialog Box \(p. 2142\)](#).
2. If necessary, click **Picture Options...** to open the [Save Picture Dialog Box \(p. 2144\)](#) and set the appropriate parameters for saving the picture files. (If you are saving picture files for use with ImageMagick, for example, you may want to select the window dump format. See [Window Dumps \(Linux Systems Only\) \(p. 122\)](#) for details.) Click **Apply** in the [Save Picture Dialog Box \(p. 2144\)](#) to save your modified settings.

Important

Do not click **Save...** in the [Save Picture Dialog Box \(p. 2144\)](#). You will save the picture files from the [Animate Dialog Box \(p. 2142\)](#) in the next step.

3. In the [Animate Dialog Box \(p. 2142\)](#), click **Write....** In [The Select File Dialog Box \(p. 33\)](#), specify the filename and click **OK** to save the files. (See [Window Dumps \(Linux Systems Only\) \(p. 122\)](#) for information about specifying filenames that increment automatically as additional pictures are saved.) ANSYS FLUENT will replay the animation, saving each frame to a separate file.

32.7.3.3. MPEG File

It is also possible to save all of the frames of the animation in an MPEG file, which can be viewed using an MPEG decoder such as **mpeg_play**. Saving the entire animation to an MPEG file will require less disk space than storing the individual window dump files (using the picture method), but the MPEG file will yield lower-quality images. To save the animation to an MPEG file, follow these steps:

1. Select **MPEG** in the **Write/Record Format** drop-down list in the [Animate Dialog Box \(p. 2142\)](#).

2. In the *Animate Dialog Box* (p. 2142), click **Write....** In *The Select File Dialog Box* (p. 33), specify the filename, and click **OK** to save the files.

ANSYS FLUENT replays the animation and saves each frame to a separate scratch file; it then combines all of the files into a single MPEG file.

32.7.4. Reading an Animation File

If you have saved the key frames defining an animation to an animation file (as described in *Saving an Animation* (p. 1578)), you can read that file back in at a later time (or in different session) and play the animation. Before reading in an animation file, be sure that the current case and data contain the surfaces and any other information that the key frame description refers to.

To read an animation file, click **Read...** in the *Animate Dialog Box* (p. 2142). In *The Select File Dialog Box* (p. 33), specify the name of the file to be read.

32.7.5. Notes on Animation

When you are creating and playing back animations, note the following:

- For smoother animations, enable the **Double Buffering** option in the *Display Options Dialog Box* (p. 2148) (see *Modifying the Rendering Options* (p. 1546)). This will reduce screen flicker during graphics updates.
- When you are defining key frames, you must create all geometric objects that will be used in the animation before you create any key frames. You cannot create a key frame using one set of geometric objects and then generate a new geometry (such as a vector plot) and include that in another key frame. Create all geometric objects first, and then use the *Display Properties Dialog Box* (p. 2153) to control the visibility of the objects in each key frame (see *Controlling Visibility* (p. 1567)).
- A single animation sequence can contain up to 3000 key frames.
- When you play back an animation, the colormap used will be the one that is currently active, *not* the one that was active during “recording.”

32.8. Creating Videos

Tools are available for creating videos from ANSYS FLUENT. This section is a guide to video creation using the new video capabilities. It assumes that you have a ready-to-use video system, and that you are familiar with this system, including the special video hardware and software installed on your computer. The main use for this feature is to record an animation that you have created using the *Animate Dialog Box* (p. 2142) (as described in *Animating Graphics* (p. 1575)). This section will describe issues involved in recording animations to video, the kind of video equipment you will need, and the procedures for creating a video using ANSYS FLUENT.

Important

Video creation is not currently available in Windows versions of ANSYS FLUENT.

For additional information, see the following sections:

- 32.8.1. Recording Animations To Video
- 32.8.2. Equipment Required
- 32.8.3. Recording an Animation with ANSYS FLUENT

32.8.1. Recording Animations To Video

Recording an animation involves copying the computer-generated images to videotape so that you can view the animation with a VCR, or another type of tape player. This task is not an easy one, as there are several issues that should be addressed in order to create an acceptable video. A couple of these issues are described in the following sections.

32.8.1.1. Computer Image vs. Video Image

The computer monitor uses a different video signal than the video tape recorder (VTR). Most computers use an RGB-component, non-interlaced signal with high resolution and a high refresh rate. A VTR typically uses a standard broadcast video signal (such as NTSC or PAL), which has an interlaced, composite signal with lower resolution and a lower refresh rate. In order to send the computer image to the VTR for recording, the computer has to produce a video signal in the proper format. This requires extra hardware, which, in many cases, converts RGB component video to standard broadcast video, resulting in a lower quality image. A solution to this problem is to make sure that the image you are recording does not have small text, or too much small detail that will be hard to see on video. Sometimes it is best to zoom in on an area of interest in a large image and animate just that portion.

Another problem is that RGB-component video has a larger color space (or color gamut) than standard broadcast video. This means that some colors may get “clipped” when an image is converted to broadcast video, resulting in washed-out colors, or color bleeding. The solution is to try to make sure that the colors fall within the color space of the video format, and are not oversaturated. Some picture controls that can help you do this are available in ANSYS FLUENT. These controls will be discussed in *Check the Picture Quality* (p. 1586).

32.8.1.2. Real-Time vs. Frame-By-Frame

If the images in the animation can be rendered fast enough on the computer screen, it may be possible to record the animation in real-time. This is as simple as placing the video tape recorder (VTR) in record mode, and playing the animation on the computer screen. This also requires scan-converting hardware that will convert the scan lines of the computer screen to a video signal sent to the VTR.

In many cases, however, the animation cannot be played back on the computer screen in real-time. To create a video that plays the animation at a desirable speed, the animation must be recorded frame-by-frame. This involves sending one frame to the VTR, instructing it to record the frame at a specific point on the tape, then backing up the VTR to repeat the procedure with the next frame. This process takes quite a bit longer than real-time recording, but the result can be a much smoother video animation.

32.8.2. Equipment Required

In general, recording an animation to video requires a system with the following hardware components:

Computer

with video hardware to produce the video signal.

Editing VTR

(video tape recorder) that supports frame-accurate recording.

VTR Controller

which enables computer software to control the recording process.

Two VTR controller models are supported by ANSYS FLUENT: the V-LAN controller developed by Videomedia, Inc., and the MiniVAS/MiniVAS-2 controller developed by the V.A.S. Group. ANSYS FLUENT

assumes that your recording system is set up as shown in [Figure 32.66 \(p. 1581\)](#) for a system with a V-LAN controller or as shown in [Figure 32.67 \(p. 1581\)](#) for a system with a MiniVAS controller.

Figure 32.66 Recording System with V-LAN Controller

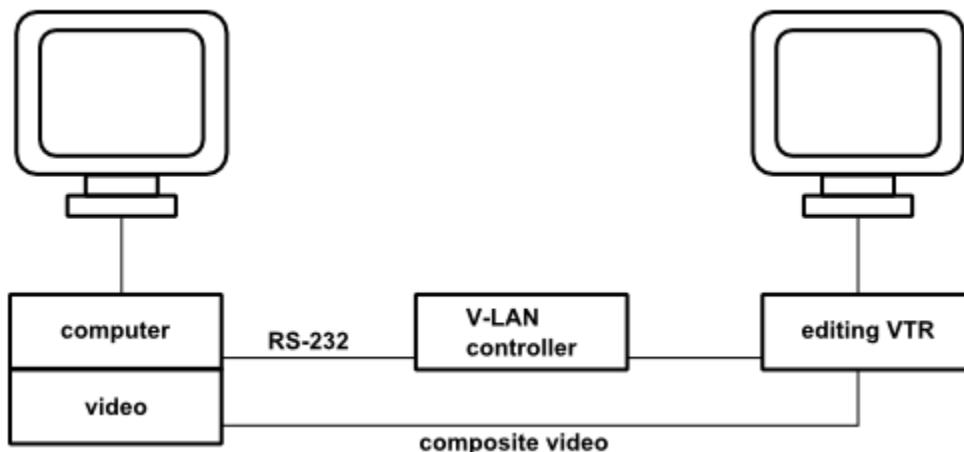

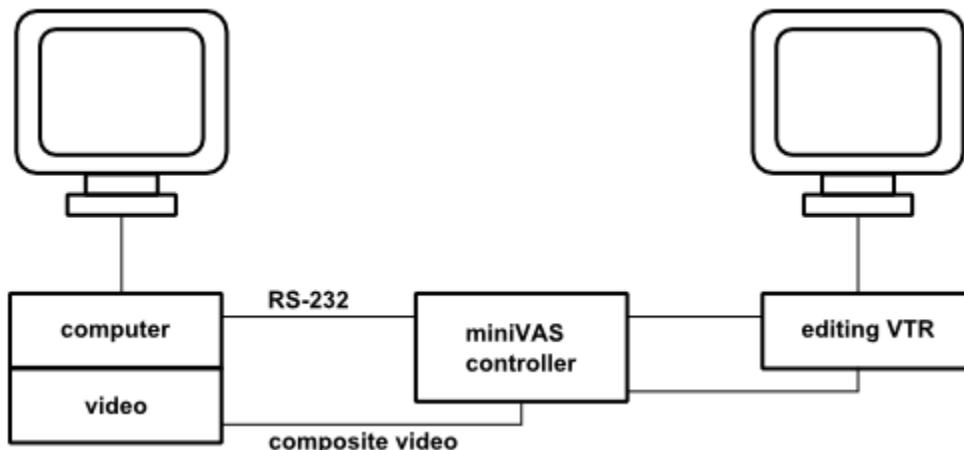

Figure 32.67 Recording System with MiniVAS/MiniVAS-2 Controller

32.8.3. Recording an Animation with ANSYS FLUENT

The procedure for recording an animation using ANSYS FLUENT is as follows:

- [Create an Animation \(p. 1582\)](#)
- [Open a Connection to the VTR Controller \(p. 1582\)](#)
- [Set Up Your Recording Session \(p. 1583\)](#)
- [Check the Picture Quality \(p. 1586\)](#)
- [Make Sure Your Tape is Formatted \(Preblacked\) \(p. 1586\)](#)
- [Start the Recording Session \(p. 1587\)](#)

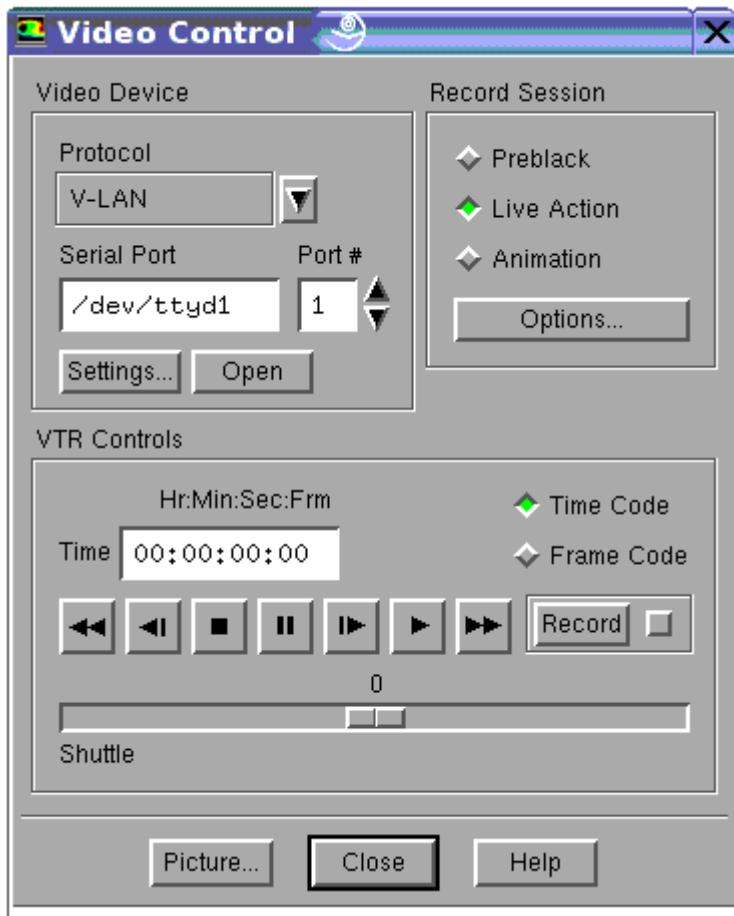

Each step is described in detail in the following sections.

32.8.3.1. Create an Animation

When recording animations to video, you must first create your animation. It's also a good idea to play it back a couple times to make sure you are satisfied with it, and to save the animation key frame definitions to a file for later use (see [Creating an Animation \(p. 1576\)](#)).

When you are ready to record the animation, you can select **Video** in the **Write/Record Format** drop-down list found in the [Animate Dialog Box \(p. 2142\)](#). When you do so, the name of the **Write...** button will change to **Record...**, and you can click **Record...** to display the [Video Control Dialog Box \(p. 2306\)](#) ([Figure 32.68 \(p. 1582\)](#)) used for video creation. This dialog box can also be displayed by selecting the **Video Control...** menu item in the **Display** pull-down menu.

Figure 32.68 The Video Control Dialog Box

32.8.3.2. Open a Connection to the VTR Controller

The procedure for connecting to your VTR controller is as follows:

1. Select the protocol used by your VTR controller using the **Protocol** drop-down list.
2. Check the settings for your VTR controller by clicking on the **Settings...** button. For V-LAN, this will display the [V-LAN Settings Dialog Box \(p. 2309\)](#), and for MiniVAS, it will display the [MiniVAS Settings Dialog Box \(p. 2310\)](#).
3. Select the RS-232 serial port used to connect the VTR controller to your computer. Usually, the serial port is identified by a file name such as `/dev/ttymd1` for serial port 1, and `/dev/ttymd2` for serial port 2. If this is the case on your system, you can simply set the value of **Port #**; otherwise, you can

- type a new file name in the **Serial Port** text entry. Make sure that you have the proper Linux read/write permissions for the file.
4. Open a connection to the VTR controller by clicking the **Open** button. If successful, a line will be printed out in the console window that reports the VTR controller protocol version and the VTR device ID.

32.8.3.3. Set Up Your Recording Session

Once you have established a connection to the VTR controller, you can set up your recording session. There are three types of recording sessions, as described below:

Preblack

is the process of formatting a tape by laying down a time code onto the tape. A tape must be formatted before any frame-accurate editing, including frame-by-frame animation, can be performed. During this process, one usually records a black video signal onto the tape as well, thus the name "preblack". When you select this option, the current graphics window will be cleared to black. You can use the window to send your black video signal to the VTR.

Important

When you preblack a previously formatted tape, a new time code will be written and any previously recorded video will be destroyed.

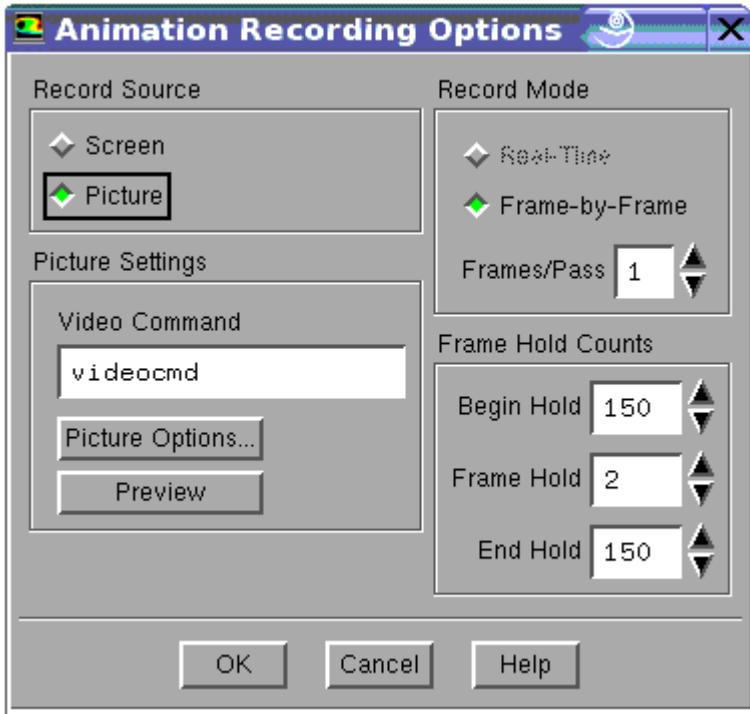

Live Action

Enables you to record a live ANSYS FLUENT session which can be used for demonstration. This option requires your computer's video hardware to have a scan converter that will send the computer display image to your VTR system.

Animation

Plays an animation that you have created, and record it onto your VTR system.

The **Options...** button in the *Video Control Dialog Box* (p. 2306) is used to display the *Animation Recording Options Dialog Box* (p. 2312) (*Figure 32.69* (p. 1584)):

Figure 32.69 The Animation Recording Options Dialog Box

There are three parts to setting up your animation recording session:

1. Select the recording source.
2. Choose real-time or frame-by-frame recording.
3. Set the video frame hold counts.

32.8.3.3.1. Select the Recording Source

There are two possible video sources that can be used for recording an animation: **Screen** and **Picture**. The choice of video source depends on what your video hardware/software provides. Here is a description of each:

Screen

can be used if your computer's video hardware can send all or a portion of the computer screen as a video signal to the VTR using a scan converter and associated software. With this option, you are responsible for setting up the scan converter and sending the video signal to the VTR.

Picture

instructs ANSYS FLUENT to create a picture of each frame of animation and send the picture file to the computer's video hardware using a system command. This option assumes that your computer's video system includes a frame buffer that can store an image and send it as a video signal to the video recording system.

When using the picture option, a shell script will be called that will send the picture file to the video frame buffer. The default setting is `videocmd`, which is a shell script that is included in your ANSYS FLUENT distribution. It is located in `path /Fluent.Inc/bin`, where `path` is the folder in which you have placed the release folder, `Fluent.Inc`. This shell script will execute your system's command to send an image file to the video frame buffer. The script `videocmd` is set up to call the SGI system command `memtovid`. If you have a different system, you must copy the shell script `videocmd` to a

new file and modify it to perform the proper task on your system (see the comments in `videocmd` for details). You can specify the name of your shell script using the **Video Command** text entry in the *Animation Recording Options Dialog Box* (p. 2312).

In order to send a picture file of the proper format to the video frame buffer, you must set up the picture format using the *Save Picture Dialog Box* (p. 2144), which can be displayed by clicking the **Picture Options...** button in the *Animation Recording Options Dialog Box* (p. 2312). If you choose to perform a window dump to create the picture file, the default window dump command used will also be `videocmd`. You can change this setting to use your own command. After setting the picture options, click **Apply** instead of **Save...** in the *Save Picture Dialog Box* (p. 2144) to apply the change.

Once you have set up the picture format and system command, you can test the configuration by sending the picture in the current graphics window to the video frame buffer. This is done by clicking on **Preview** in the *Animation Recording Options Dialog Box* (p. 2312). Note that this is another way to send a black video signal to your VTR when you are preblacking a tape.

32.8.3.3.2. Choose Real-Time or Frame-By-Frame Recording

There are two methods for recording an animation: real-time and frame-by-frame.

Real-Time

can be used if the animation playback speed is fast enough to provide a reasonably smooth animation in real-time. This is only available if the selected record source is **Screen**. In this mode, ANSYS FLUENT will simply turn VTR recording on, play the animation, then stop the recording.

Frame-By-Frame

is used to produce a higher-quality video animation by recording one frame at a time. For each animation frame, this method will 1) play the frame on the screen (and generate the picture file, if needed), 2) preroll the VTR, and 3) record the frame. If the animation has 50 frames, this procedure is repeated 50 times, that is, 50 record passes are made. This is the recommended method, because the real-time playback of the animation will usually be too slow and choppy.

When recording in frame-by-frame mode, there is an optional setting called **Frames/Pass**, which can be used to try and speed up the frame-by-frame recording process. It specifies the number of animation frames recorded to tape per record pass. If the animation is long enough (200 frames or more), you can try setting this value to 2 or higher. For example, if you set this value to 2 for a 202-frame animation, it will record animation frame 1 during the first pass, frames 2 and 102 during the second pass, frames 3 and 103 during the third pass, and so on. This is possible only if the animation frames can be rendered in time to be inserted onto the tape during a record pass, so use this setting with caution.

32.8.3.3.3. Set the Video Frame Hold Counts

The video standard NTSC has a frame rate of 30 frames/sec (and the PAL standard has a rate of 25 frames/sec). At the NTSC rate, a 150-frame animation will take only 5 seconds to play. To stretch out the animation, you can record the same animation frame over 2 or more video frames. This is done by setting video frame hold counts for the beginning, middle, and end of the animation, using the *Animation Recording Options Dialog Box* (p. 2312) controls.

Begin Hold

specifies the number of video frames to hold the first animation frame. It helps to hold the first frame for about 5 seconds (150 video frames for NTSC, or 125 for PAL) so that the viewer can get accustomed to the picture before the animation begins.

Frame Hold

specifies the number of video frames to hold each animation frame, other than the first and last. To slow down your recorded animation, try setting this value to 2 or 3.

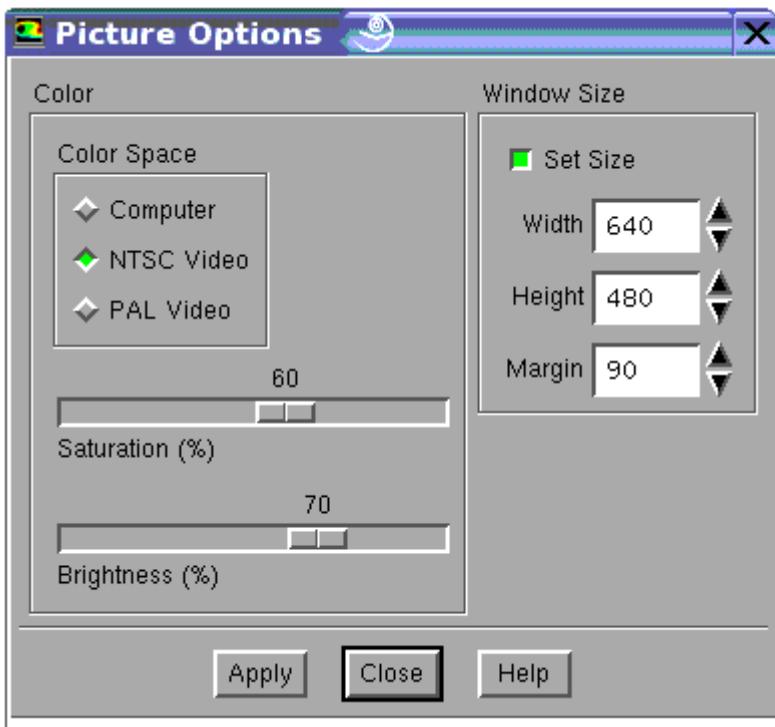

End Hold

specifies the number of video frames to hold the last animation frame. You may want to hold the last animation frame for about 5 seconds to provide closure.

32.8.3.4. Check the Picture Quality

As described in *Recording Animations To Video* (p. 1580), there are several sacrifices made when sending a computer image to video, including loss of color and resolution. Some steps can be taken to minimize the problem using the *Picture Options Dialog Box* (p. 2314) (*Figure 32.70* (p. 1586)). Display this dialog box by clicking the **Picture...** button in the *Video Control Dialog Box* (p. 2306).

Figure 32.70 The Picture Options Dialog Box

**Color**

Use these controls to ensure that all colors fall into the proper color space for your video device. Also, for best results, set the saturation and brightness levels to 80% or less.

Window Size

If you have a scan converter that converts a portion of the computer screen, you can set the graphics window to a particular pixel size to match the scan converter's window size. You can also create a margin around the picture in the window to keep unwanted parts of the screen (such as the window border) out of the video image.

32.8.3.5. Make Sure Your Tape is Formatted (Preblacked)

Before you can start the recording session, you need to make sure the tape has been preblacked with a time code or frame code. When you start with a brand new tape, you need to take time out and preblack the whole tape first. This can be done using the following procedure:

1. Rewind the tape to the beginning.
2. Select a preblack recording session by clicking on the **Preblack** radio button in the *Video Control Dialog Box* (p. 2306).
3. Send the VTR a black video signal using a scan converter or a picture by clicking on the **Preview** button in the *Animation Recording Options Dialog Box* (p. 2312).
4. Click **Preblack** in the **VTR Controls** section of the *Video Control Dialog Box* (p. 2306) to start the preblacking.

32.8.3.6. Start the Recording Session

Make sure you have the proper recording session selected. If you are recording an animation, the **Animation** radio button should be selected.

To start recording onto tape, you must first go to the "in point" on tape where you want the recording to begin. With a blank tape, it is important to start at about 20 seconds into the tape, so the VTR has a chance to preroll up to the in point. You can use the VTR button controls to position the tape, but an easier way to go to a certain point is to type the time code or frame code in the **Time** or **Frame** counter and press **Enter**. For example, a time code of 00 : 02 : 36 : 07 is 2 minutes, 36 seconds, and 7 frames. In order to go to this position on the tape, you can enter the time code as 2 : 36 : 07, leaving out the leading zeros, or you can simply enter 23607, leaving out the leading zeros and colons.

Once your tape is at the start position for your recording session, click **Record** to start recording.

32.9. Histogram and XY Plots

In addition to the many graphics tools already discussed, ANSYS FLUENT also provides tools that enable you to generate XY plots and histograms of solution, file, profile, and residual data. You can modify the colors, titles, legend, and axis and curve attributes to customize your plots. The following sections describe the XY and histogram plotting features in ANSYS FLUENT.

- 32.9.1. Plot Types
- 32.9.2. XY Plots of Solution Data
- 32.9.3. XY Plots of File Data
- 32.9.4. XY Plots of Profiles
- 32.9.5. XY Plots of Circumferential Averages
- 32.9.6. XY Plot File Format
- 32.9.7. Residual Plots
- 32.9.8. Histograms
- 32.9.9. Modifying Axis Attributes
- 32.9.10. Modifying Curve Attributes

32.9.1. Plot Types

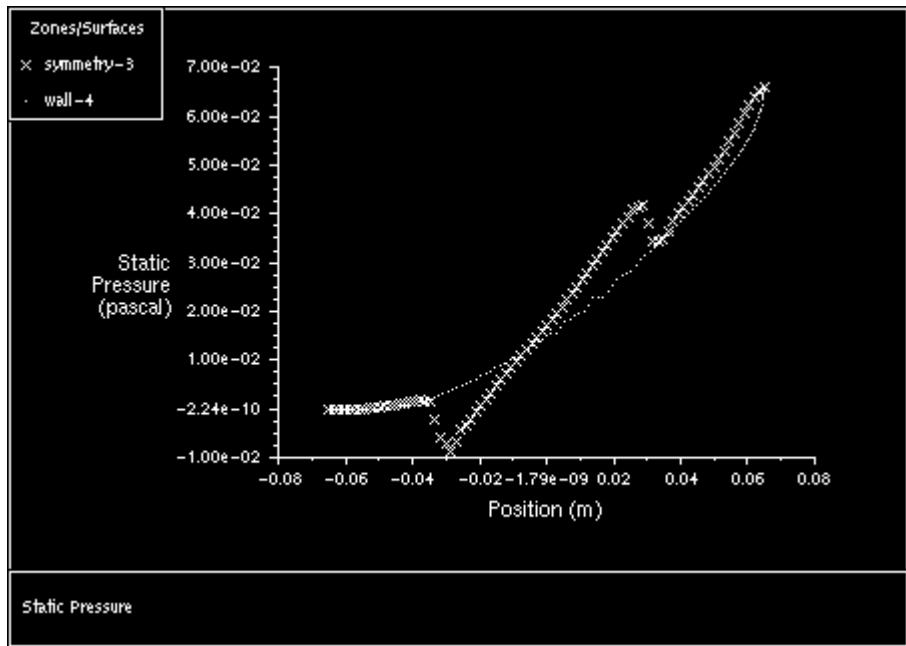

Data can be plotted in XY (abscissa/ordinate) form or histogram form. Each form is described below.

32.9.1.1. XY Plots

An XY (abscissa/ordinate) plot is a line and/or symbol chart of data. Virtually any defined variable or function is accessible for this type of plot. Furthermore, you may read in an externally-generated data file in order to compare your results with experimental data. You can also use the XY-plot facility to plot out profile data, the residual histories of variables, or the time histories if you have a transient problem.

ANSYS FLUENT provides tools for controlling many aspects of the XY plot, including background color, legend, and axis and curve attributes. [Figure 32.71 \(p. 1588\)](#) shows a sample XY plot.

Figure 32.71 Sample XY Plot

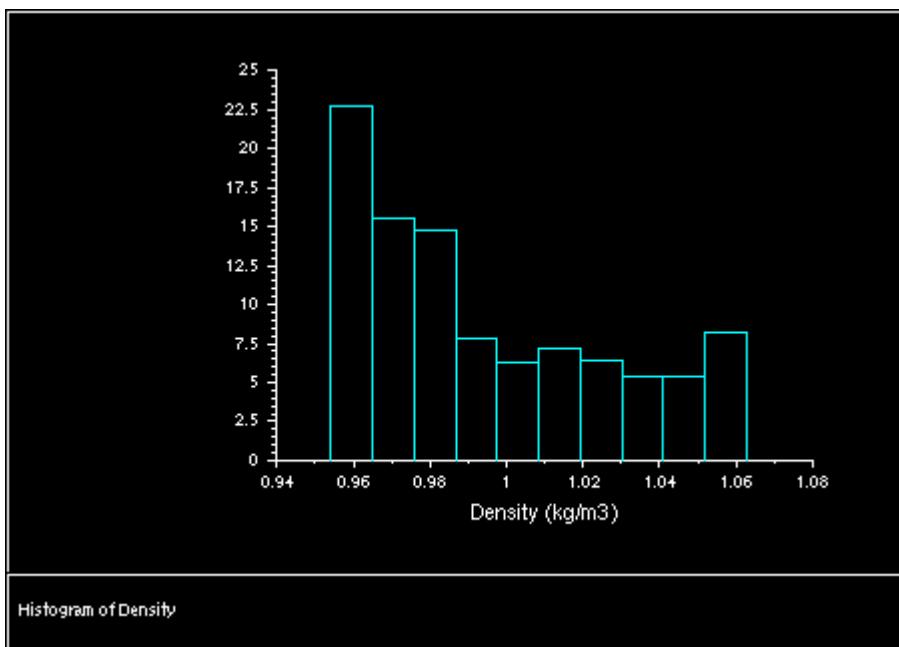

To differentiate the data being displayed, you can customize the pattern, color and weight of the data lines and the shape, color, and size of the data markers.

When an XY plot is displayed in the graphics window, you can either use the **mouse-probe** or **mouse-annotate** functions to add text annotations to the plot. All other functions are inactive for XY plots. For more information about the mouse-annotate function, see [Adding Text Using the Mouse-Annotate Function \(p. 1537\)](#). In addition, you can use any of the mouse buttons to move and resize the legend box.

32.9.1.2. Histograms

A histogram plot is a bar chart of data. It is a representation of a frequency of distribution by means of rectangles of widths representing class intervals and with areas proportional to the corresponding frequencies. When a histogram plot is displayed in the graphics window, you can either use the **mouse-probe** or **mouse-annotate** functions to add text annotations to the plot. All other functions are inactive for histogram plots. (See [Adding Text Using the Mouse-Annotate Function \(p. 1537\)](#) for more information about the mouse-annotate function.) [Figure 32.72 \(p. 1589\)](#) shows a sample histogram.

Figure 32.72 Sample Histogram

See *Histogram Reports* (p. 1647) for information about printing histogram reports. For more information on histogram plots, see *Histograms* (p. 1600).

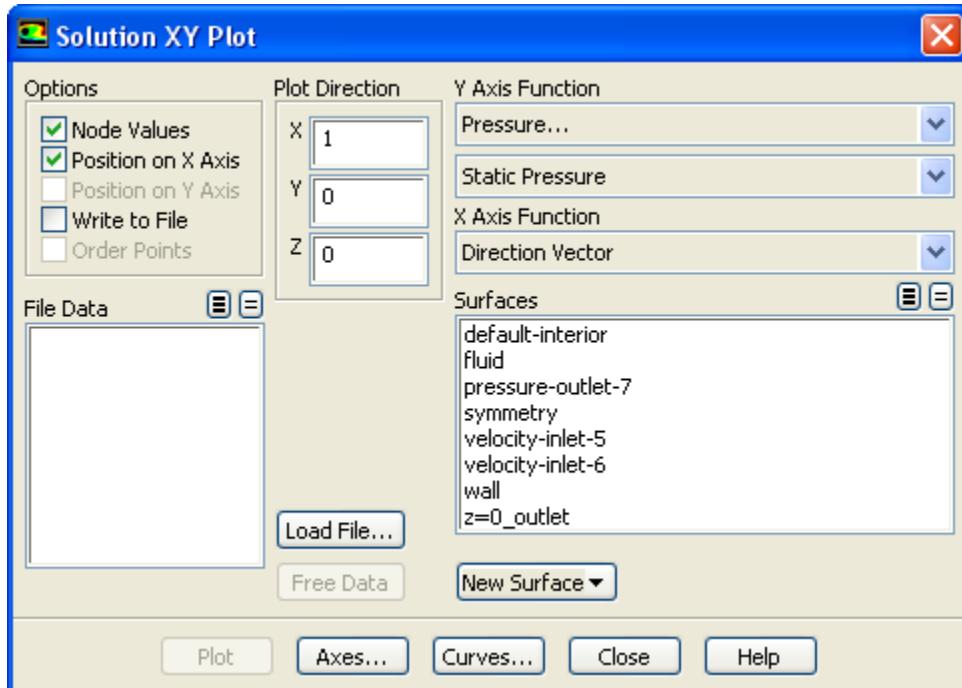

32.9.2. XY Plots of Solution Data

You can produce a very sophisticated XY plot by using data from several zones, surfaces, or files and modifying the axis and curve attributes. Using the capability for loading external data files, you can create plots that compare your ANSYS FLUENT results with data from other sources. To get further information about the solution, you can investigate the frequency of distribution of the data using a histogram (see *Histograms* (p. 1600)).

32.9.2.1. Steps for Generating Solution XY Plots

You can create an XY plot of solution data using the *Solution XY Plot Dialog Box* (p. 2169) (*Figure 32.73* (p. 1590)).

◆ **Plots** → **XY Plot** → **Set Up...**

Figure 32.73 The Solution XY Plot Dialog Box

The basic steps for generating a solution XY plot are as follows:

1. Specify the variable(s) you are plotting:
 - To plot a variable on the y axis as a function of position on the x axis, enable the **Position on X Axis** option and choose the variable to be plotted on the y axis in the **Y Axis Function** drop-down list. Select a category from the upper list and then choose the desired quantity in the lower list. For an explanation of the variables in the list, see *Field Function Definitions* (p. 1653).
 - To plot a variable on the x axis as a function of position on the y axis, enable the **Position on Y Axis** option and choose the variable to be plotted on the x axis in the **X Axis Function** drop-down list.
 - To plot one variable as a function of another, turn off both the **Position on X Axis** and **Position on Y Axis** options and select the variables to be plotted in the **X Axis Function** and **Y Axis Function** drop-down lists.
2. Specify the plot direction:
 - To plot a variable as a function of position along a specified direction vector, select **Direction Vector** in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis), and specify the components of the direction vector for plotting under **Plot Direction**. The position axis of the plot is indicated by the selection of **Position on X Axis** or **Position on Y Axis**. The positions plotted will have coordinate values that correspond to the dot product of the data coordinate vector with the plot direction vector. For example, if you are plotting a variable at the pressure outlet of the geometry shown in *Figure 32.74* (p. 1591), you would specify the **Plot Direction** vector (1,0,0) since you are interested in how the variable changes as a function of x. *Figure 32.75* (p. 1592) shows the resulting XY plot. (If you specified (0,1,0) as the plot direction, all variable values would be plotted at the same position (see *Figure 32.76* (p. 1592)), because the y value is the same at every point on the pressure outlet.)

- It is also possible to plot a variable as a function of position along the length of a specified curvilinear surface. The curvilinear surface must be piecewise linear and it cannot contain more than one closed curve, such as a complete circle. To plot a variable in this way, select **Curve Length** in the **X Axis Function** or **Y Axis Function** drop-down list (whichever is the position axis). Then specify the plot direction along the surface: to plot the variable along the direction of increasing curve length, select **Default** under **Plot Direction**; to plot the variable in the direction of decreasing surface length, select **Reverse**. To check the direction in which the variable will be plotted along a surface, select the surface in the **Surfaces** list and click **Show** under **Plot Direction**. ANSYS FLUENT will display the selected surface in the graphics window, marking the start of the surface with a blue dot and the end of the surface with a red dot. ANSYS FLUENT will also display arrows on the surface showing the direction in which the variable will be plotted.
- Choose the surface(s) on which to plot data in the **Surfaces** list. Note that if you are plotting a variable as a function of position along the length of a curvilinear surface, you can select only one surface in the **Surfaces** list.
 - Set any of the options described below, or modify the attributes of the axes or curves as described in *Modifying Axis Attributes* (p. 1601) and *Modifying Curve Attributes* (p. 1603).
 - Click **Plot** to generate the XY plot in the active graphics window.

You can use any of the mouse buttons to annotate the XY plot (see *Adding Text to the Graphics Window* (p. 1536)) or move the plot legend from its default position in the upper left corner of the graphics window.

Figure 32.74 Geometry Used for XY Plot

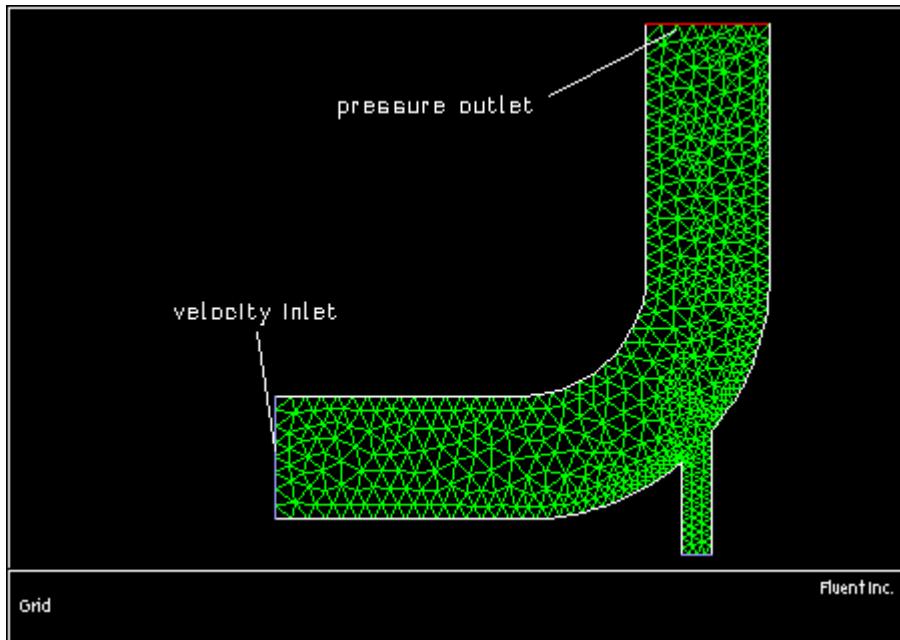

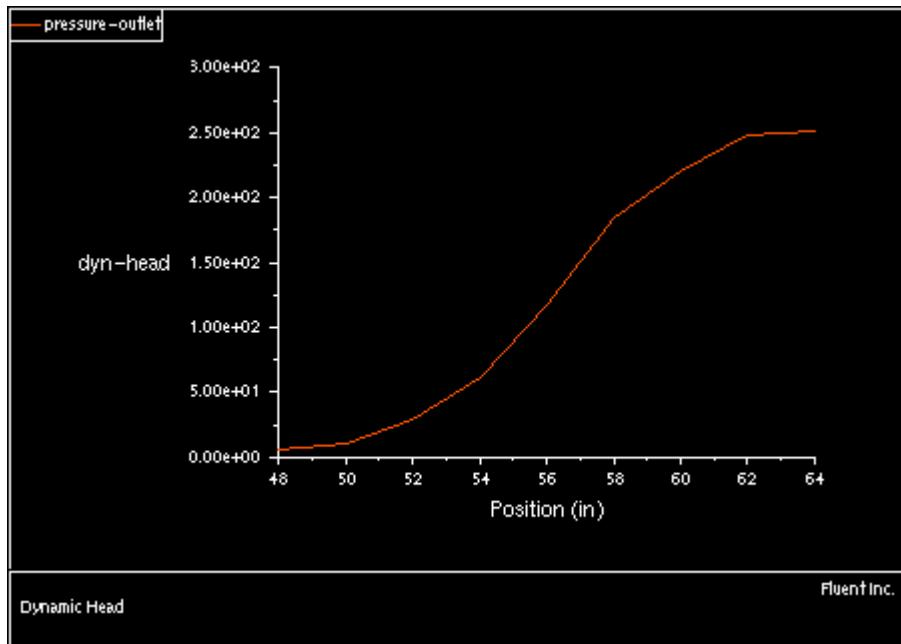

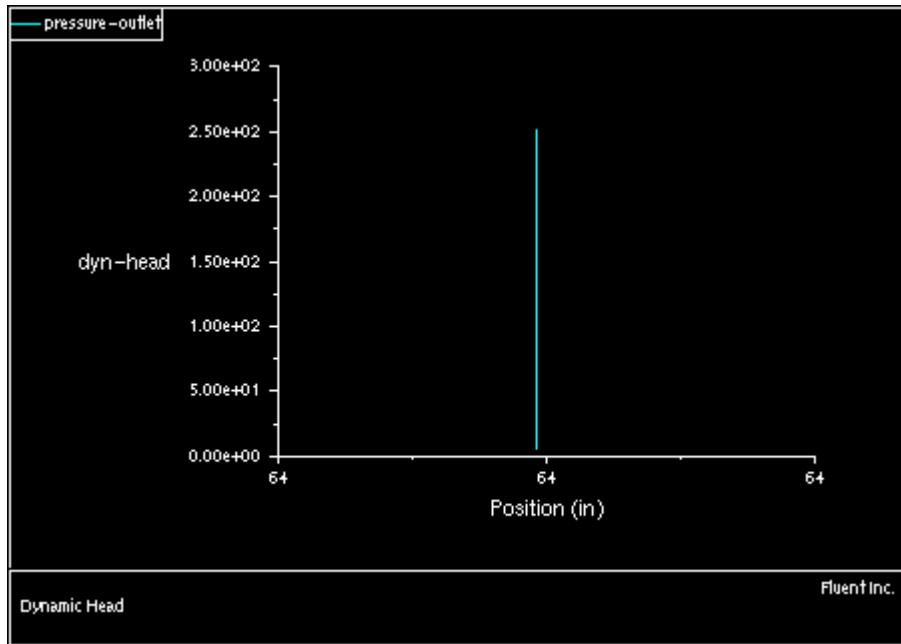

Figure 32.75 Data Plotted at Outlet Using a Plot Direction of (1,0,0)**Figure 32.76 Data Plotted at Outlet Using a Plot Direction of (0,1,0)**

32.9.2.2. Options for Solution XY Plots

The options mentioned in *Steps for Generating Solution XY Plots* (p. 1589) include the following.

- You can include data from an external file in the solution XY plot to compare your results with experimental data.
- You can also choose node or cell values to be plotted, and save the plot data to a file.

32.9.2.2.1. Including External Data in the Solution XY Plot

To add external data to your XY plot for comparison with your results, you must first ensure that any external data files are in the format described in [XY Plot File Format \(p. 1599\)](#). You can then load the file(s) by clicking on the **Load File...** button and specifying the file(s) to be read in [The Select File Dialog Box \(p. 33\)](#). Once a file has been loaded, its title will appear in the **File Data** list. You can choose the data file(s) to be included in your plot from the titles in this list.

To remove a file from the **File Data** list, select it and then click **Free Data**.

32.9.2.2.2. Choosing Node or Cell Values

In ANSYS FLUENT you can choose to display the computed cell-center values or values that have been interpolated to the nodes. By default, the **Node Values** option is turned on, and the interpolated values are displayed. If you prefer to display the cell values, turn the **Node Values** option off. Node-averaged data curves may be somewhat smoother than curves for cell values.

For face-only functions (for example, **Wall Shear Stress**), the cell values that are displayed for boundary zone surfaces will actually be the face values. These face values are more accurate, as face-only functions are computed on the faces and not on the cells. For these face-only functions, the cell values on post-processing surfaces will display the values in the cell. For more information about cell values, see [Cell Values \(p. 1653\)](#).

If you are displaying the XY plot to show the effect of a porous medium or fan, to depict a shock wave, or to show any other discontinuities or jumps in the plotted variable, you should use cell values; if you use node values in such cases, the discontinuity will be smeared by the node averaging for graphics and will not be shown clearly in the plot.

32.9.2.2.3. Saving the Plot Data to a File

Once you have generated an XY plot, you may want to save the plot data to a file. You can read this file into ANSYS FLUENT at a later time and plot it alone using the [File XY Plot Dialog Box \(p. 2173\)](#), as described in [XY Plots of File Data \(p. 1593\)](#), or add it to a plot of solution data, as described above.

To save the plot data to a file, enable the **Write to File** option in the [Solution XY Plot Dialog Box \(p. 2169\)](#). The **Plot** button will change to the **Write...** button. Clicking on the **Write...** button will invoke [The Select File Dialog Box \(p. 33\)](#), in which you can specify a name and save a file containing the plot data. The format of this file is described in [XY Plot File Format \(p. 1599\)](#).

To sort the saved plot data in order of ascending x axis value, enable the **Order Points** option in the [Solution XY Plot Dialog Box \(p. 2169\)](#) before you click **Write....** This option is available only when the **Write to File** option is enabled.

32.9.3. XY Plots of File Data

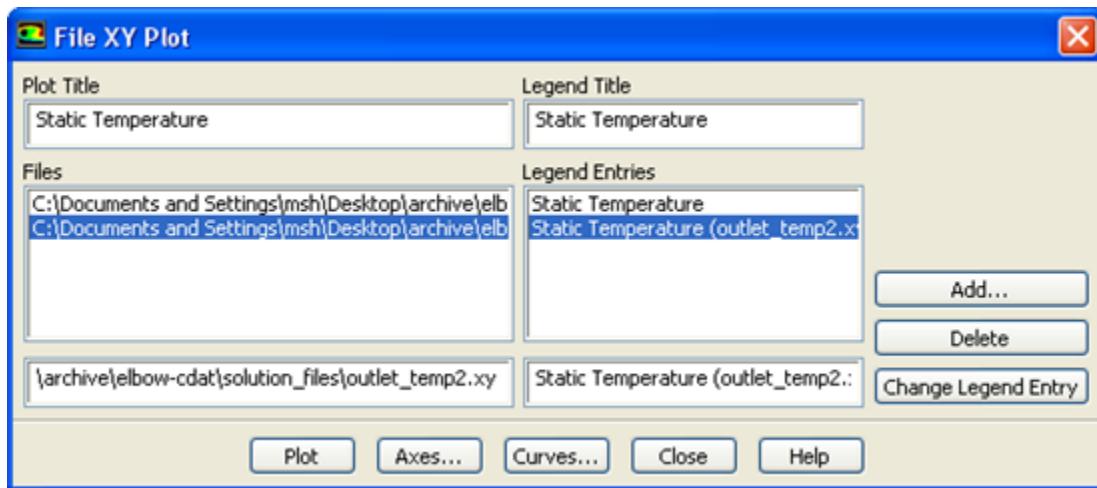

You can produce XY plots using data contained in external files. The [File XY Plot Dialog Box \(p. 2173\)](#) enables you to display data read from external files in an abscissa/ordinate plot form. The format of the plot file is described in [XY Plot File Format \(p. 1599\)](#).

32.9.3.1. Steps for Generating XY Plots of Data in External Files

You can create an XY plot of data contained in one or more external files using the [File XY Plot Dialog Box \(p. 2173\)](#) ([Figure 32.77 \(p. 1594\)](#)).

Plots → File → Set Up...

Figure 32.77 The File XY Plot Dialog Box

The steps for generating a file XY plot are as follows:

1. Load each external data file (with the format described in *XY Plot File Format* (p. 1599)) by entering its name in the text field beneath the **Files** list and clicking **Add...** (or pressing **Enter**). If you click **Add...** without specifying a name under **Files** (or if you specify an incorrect or duplicate name), *The Select File Dialog Box* (p. 33) will appear and you can specify one or more files there. When a file is loaded, its name will appear in the **Files** list and its title will appear in the **Legend Entries** list. Data in all loaded files will be plotted, so if you decide not to include one of the loaded files in the plot you must select it and click **Delete** to remove it.
2. Set any of the options described below, or modify the attributes of the axes or curves as described in *Modifying Axis Attributes* (p. 1601) and *Modifying Curve Attributes* (p. 1603).
3. Click **Plot** to generate an XY plot of the data associated with all loaded files.

32.9.3.2. Options for File XY Plots

The options mentioned in the procedure above include the following. You can change the plot title, legend title, or legend entry.

32.9.3.2.1. Changing the Plot Title

The plot title will appear in the caption box at the bottom of the graphics window. You can modify the plot title by changing the entry in the **Plot Title** text box in the *File XY Plot Dialog Box* (p. 2173) (or by editing the caption box manually, as described in *Changing the Legend Display* (p. 1534)).

32.9.3.2.2. Changing the Legend Entry

When you plot data from a single file, the y axis of the plot will be labeled by the "legend entry." To modify this label, click on the text in the **Legend Entries** list, edit the text that appears in the text field below the list, and then click **Change Legend Entry** (or hit **Enter**). When you next plot the data, the new legend entry will appear in the plot.

32.9.3.2.3. Changing the Legend Title

When you plot data from more than one file, a legend will appear in the upper left corner of the graphics window. By default, the legend will have no title. If you want to add a title, enter it in the **Legend Title** text field. The title will appear above the legend the next time you plot the data.

Note that you can use any of the mouse buttons to annotate the plot (see *Adding Text to the Graphics Window* (p. 1536)) or move the legend from its default position.

32.9.4. XY Plots of Profiles

ANSYS FLUENT enables two options for generating XY plots of data related to boundary profiles. Using the *Plot Profile Data Dialog Box* (p. 2174), you can plot the original data points from the profile file you have read into ANSYS FLUENT. Alternatively, you can plot the values assigned to the cell faces on the boundary after the profile file has been interpolated, by using the *Plot Interpolated Data Dialog Box* (p. 2175).

Important

Note that you must have valid data when trying to use the profile plotting options.

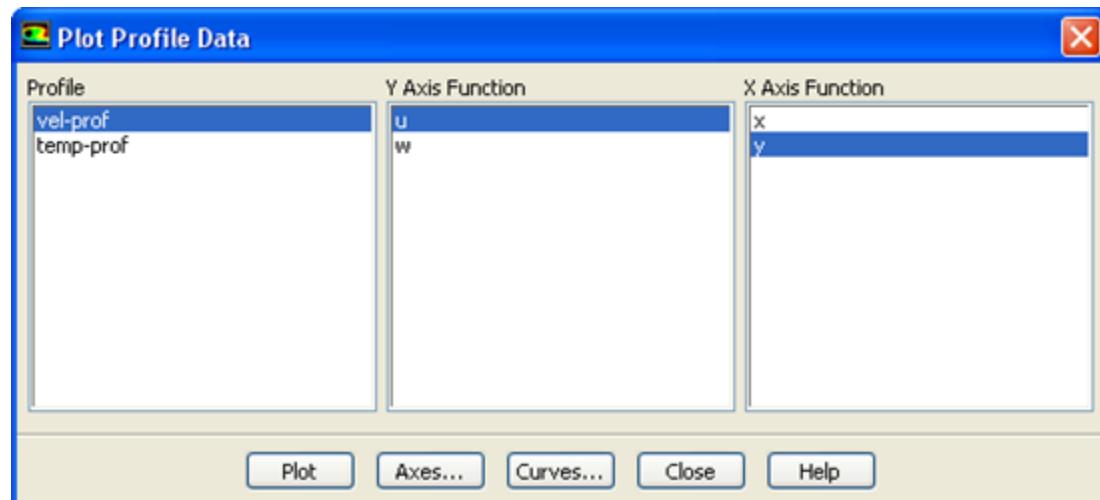

For more information about boundary profiles, see *Profiles* (p. 382).

32.9.4.1. Steps for Generating Plots of Profile Data

Once you have read a profile file, it is available for plotting by using the *Plot Profile Data Dialog Box* (p. 2174).

◆ Plots →  **Profile Data** → Set Up...

Figure 32.78 The Plot Profile Data Dialog Box

The procedure for generating a XY plot of the original profile data is as follows:

1. Select one of the profiles you have read from the **Profile** selection list.
2. Select a field of the profile from the **Y Axis Function** selection list.

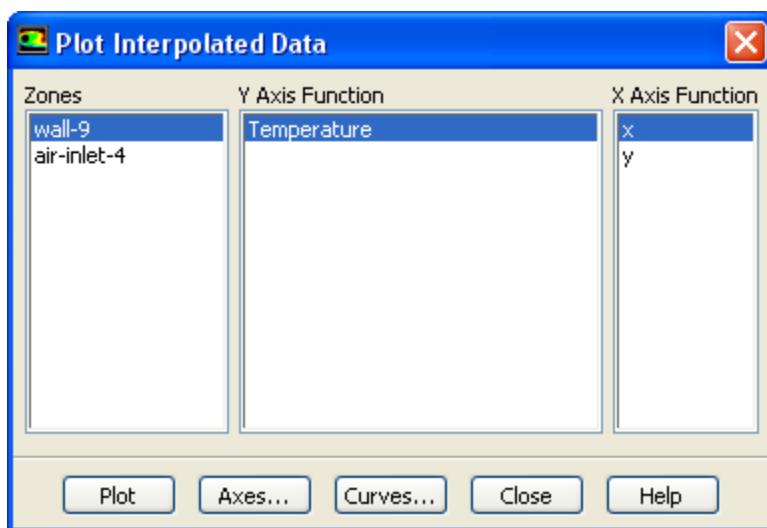

3. Choose a variable against which you want to plot the field data, and select it from the **X Axis Function** selection list. The available variables will vary depending on the profile, and include **x**, **y**, **z**, **r**, and **time**.
4. Modify the attributes of the axes or curves as described in *Modifying Axis Attributes* (p. 1601) and *Modifying Curve Attributes* (p. 1603).
5. Click **Plot** to generate an XY plot of the profile field data.

32.9.4.2. Steps for Generating Plots of Interpolated Profile Data

To interpolate a profile you must first read a profile file for the case, and select a profile field in a boundary conditions dialog box (for example, the *Velocity Inlet Dialog Box* (p. 2006)). After the flow solution has been initialized, the cell face values of the boundary zone can be plotted by using the *Plot Interpolated Data Dialog Box* (p. 2175).

Plots →  Interpolated Data → Set Up...

Figure 32.79 The Plot Interpolated Data Dialog Box

The procedure for generating an XY plot of the interpolated data is as follows:

1. Select a zone from the **Zones** selection list. Only the zones for which you have set a profile field as one or more of the parameters will be available in this list.
2. Select a profile-related parameter of the zone from the **Y Axis Function** selection list. The name of the parameter will be the same as that of the drop-down list in the boundary condition dialog box from which the profile field was selected.
3. Choose a variable against which you want to plot the field data, and select it from the **X Axis Function** selection list. The available variables are **x**, **y**, and (for 3D cases) **z**.
4. Modify the attributes of the axes or curves as described in *Modifying Axis Attributes* (p. 1601) and *Modifying Curve Attributes* (p. 1603).
5. Click **Plot** to generate an XY plot of the cell face values on the boundary.

32.9.5. XY Plots of Circumferential Averages

You can also generate a plot of circumferential averages in ANSYS FLUENT. This enables you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS FLUENT com-

putes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate.

32.9.5.1. Steps for Generating an XY Plot of Circumferential Averages

You can generate an XY plot of circumferential averages in the radial direction using the `circum-avg-radial` text command:

```
plot → circum-avg-radial
```

or you can use the `circum-avg-axial` text command to generate an average in the axial direction:

```
plot → circum-avg-axial
```

The procedure for generating an XY plot of circumferential averages is as follows:

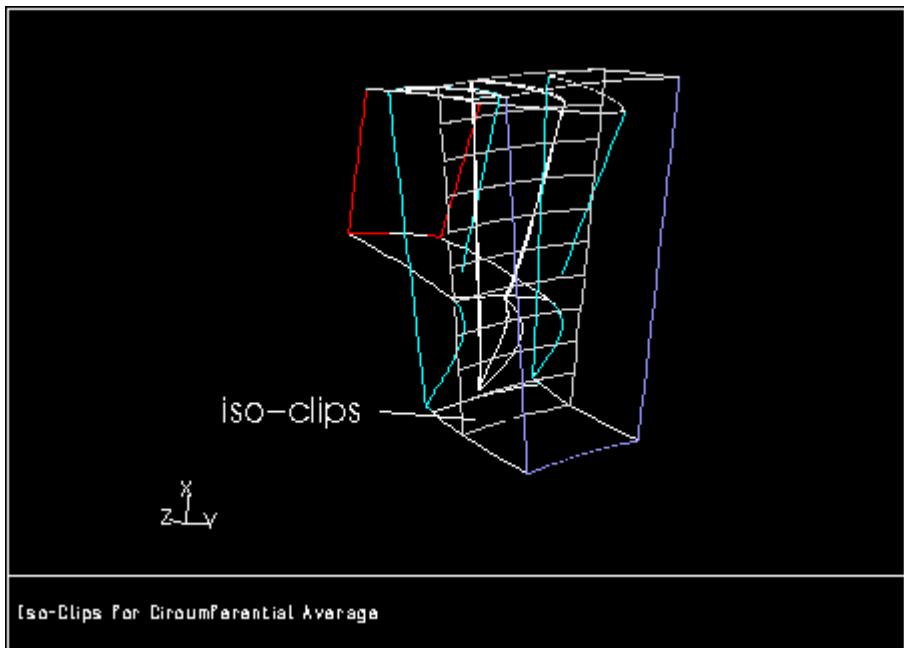

1. Specify the variable to be averaged by typing its name when ANSYS FLUENT prompts you for averages of. You can press **Enter** to see a list of available variables.
2. Choose the surface on which to plot data by typing its name when ANSYS FLUENT prompts you for on surface.

Important

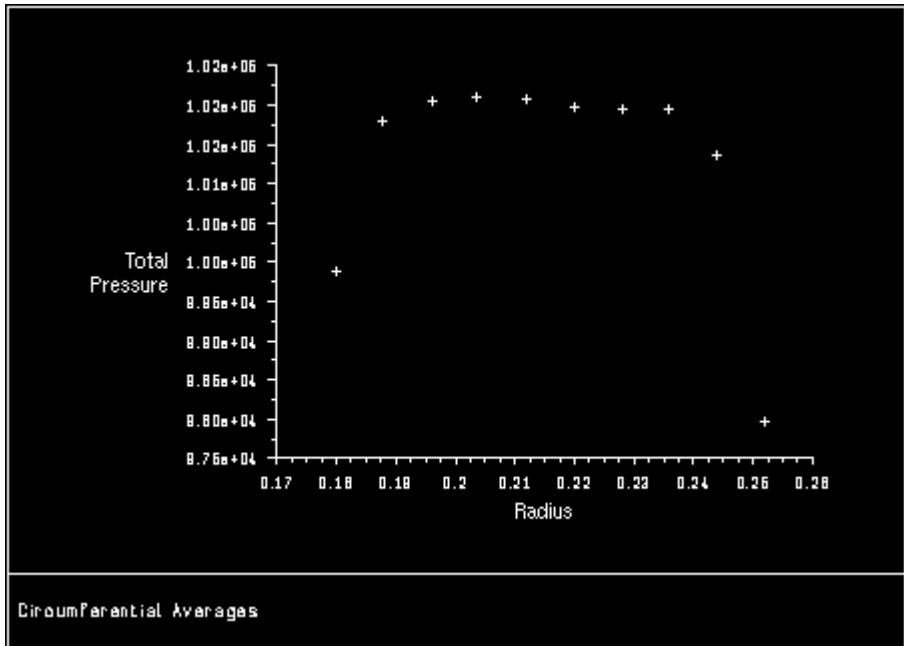

Use the [Mesh Display Dialog Box \(p. 1767\)](#) to see a list of surfaces on which you can plot data. Pressing **Enter** will not show a list of available surfaces.

3. Specify the number of bands to be created. The default number of bands is 5.

ANSYS FLUENT will create circumferential bands by isoclipping the specified surface into equal bands of radial or axial coordinate. An example of the iso-clips created is shown in [Figure 32.80 \(p. 1598\)](#). The radial or axial coordinate is derived from the rotation axis of the **Reference Zone** specified in the [Reference Values Task Page \(p. 2046\)](#).

Figure 32.80 Iso-Clips Created For Circumferential Averaging

ANSYS FLUENT then computes the average of the variable for each band using the area-weighted average described in [Computing Surface Integrals](#) of the Theory Guide. Finally, it plots the average of the variable as a function of radial or axial coordinate. [Figure 32.81 \(p. 1598\)](#) shows an example of an XY plot of circumferential averages using radial coordinates.

Figure 32.81 XY Plot of Circumferential Averages

When the circumferential average plot is generated, ANSYS FLUENT also creates a new surface called radial-bands or axial-bands, which contains the iso-clips described above (see [Figure 32.80 \(p. 1598\)](#)). You can use this surface to generate other XY plots. For more information on the creation and manipulation of surfaces, see [Creating Surfaces for Displaying and Reporting Data \(p. 1473\)](#).

32.9.5.2. Customizing the Appearance of the Plot

If you want to customize the appearance of the axes or curves in a circumferential average plot, you can save the plot data to a file (using the `plot-to-file` text command, as described in [XY Plot File Format \(p. 1599\)](#)), read the file into ANSYS FLUENT and plot it again (using the [File XY Plot Dialog Box \(p. 2173\)](#), as described in [XY Plots of File Data \(p. 1593\)](#)), and then use the [Axes Dialog Box \(p. 2179\)](#) and [Curves Dialog Box \(p. 2181\)](#) (as described in [Modifying Axis Attributes \(p. 1601\)](#) and [Modifying Curve Attributes \(p. 1603\)](#)) to modify the appearance of the plot.

To save the plot data to a file, first use the `plot-to-file` text command to specify the name of the file.

```
plot → file-set → plot-to-file
```

Then generate the circumferential average XY plot as described above. ANSYS FLUENT will display the plot in the graphics window, and also save the plot data to the specified file.

32.9.6. XY Plot File Format

The XY file format read or written by ANSYS FLUENT includes the following information:

- The title of the plot
- The label for the abscissa and the ordinate
- Cortex variables and pairs of abscissa/ordinate data for each curve in the plot

The following sample file illustrates the XY file format:

```
(title "Velocity Magnitude")
(labels "Position" "Velocity Magnitude")

((xy/key/label "pressure-inlet-8")
 (xy/key/visible? #t)
 (xy/line/pattern "--")
 0.0000 230.097 0.
 0.625 160.551
 0.1250 149.205
 ...
 0.5000 183.007
)
```

Similar to the case file format, parentheses bound the various pieces of information in the formatted, ASCII file. The title (`title " "`) and labels (`labels " "`) must be first in the file, then each curve has information in the form `((cxvar value) x y x y x y...)`, where there may be zero or more Cortex variables defined for each curve.

You do not have to include Cortex variables to import your XY data. For example, you may wish to import experimental data to compare with the ANSYS FLUENT solution. The following example would use the default Cortex variables in the code to define the data. After you import the file into ANSYS FLUENT, you could then use the [Axes Dialog Box \(p. 2179\)](#) and the [Curves Dialog Box \(p. 2181\)](#) to customize the XY plot, as described in [Modifying Axis Attributes \(p. 1601\)](#) and [Modifying Curve Attributes \(p. 1603\)](#).

```
(title "Experiment, Run 11")
(labels "X, m" "Cp")
( 0 1.5
 1.5 1.3
 3.2 1.5
 5.1 1.2
)
```

32.9.7. Residual Plots

Residual history can be displayed using an XY plot. The abscissa of the plot corresponds to the number of iterations and the ordinate corresponds to the log-scaled residual values.

To plot the current residual history, click **Plot** in the *Residual Monitors Dialog Box* (p. 2065).

↳ **Monitors** → **Residuals** → **Edit...**

For additional information about using the *Residual Monitors Dialog Box* (p. 2065) to plot residuals, see *Printing and Plotting Residuals* (p. 1383).

32.9.8. Histograms

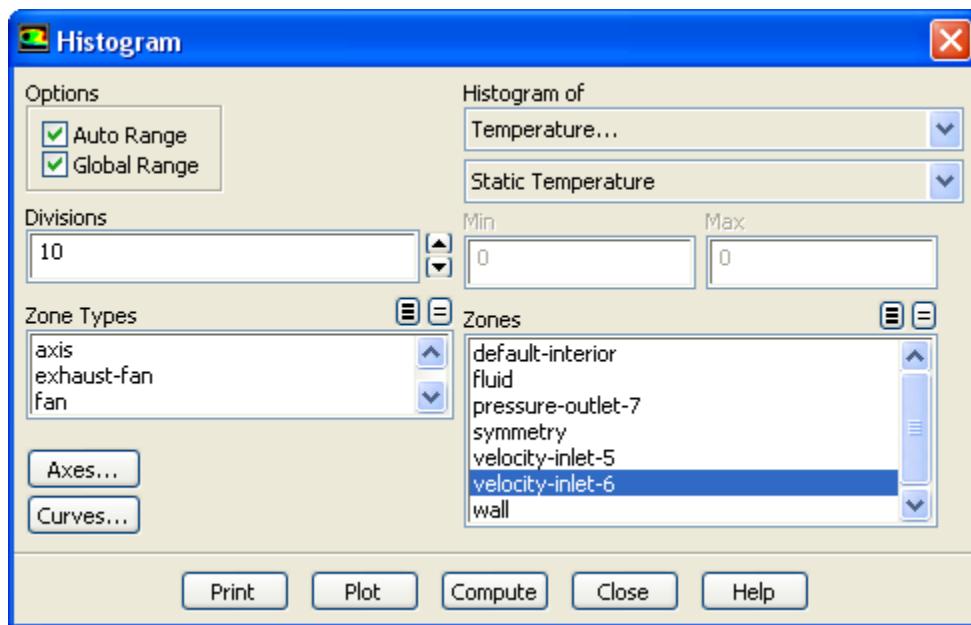

Histograms can be displayed in a graphics window using a bar chart (or printed in the console window, as described in *Histogram Reports* (p. 1647)). The abscissa of the chart is the desired solution quantity and the ordinate is the percentage of the total number of cells.

32.9.8.1. Steps for Generating Histogram Plots

You can create a histogram plot of solution data using the *Histogram Dialog Box* (p. 2172) (*Figure 32.82* (p. 1600)).

↳ **Plots** → **Histogram** → **Set Up...**

Figure 32.82 The Histogram Dialog Box

The steps for generating a histogram plot are as follows:

1. Choose the scalar quantity to be plotted in the **Histogram Of** drop-down list. Select a category in the upper list and then select the desired quantity in the lower list. (See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)

2. Set the number of data intervals that will be plotted in the histogram in the **Divisions** field. By default there will be 10 intervals (“bars”) in the histogram plot to finer intervals, increase the number of **Divisions**. You may want to click **Compute** to update the **Min** and **Max** fields when you are trying to decide how many divisions to plot.
3. Select the face or cell zone under **Zones** for which you want results plotted or printed. If all zones are selected, then the entire domain will be plotted. You can also plot histograms based on the selected **Zone Types**.
4. Set the option described below, if desired, or modify the attributes of the axes or curves as described in [Modifying Axis Attributes \(p. 1601\)](#) and [Modifying Curve Attributes \(p. 1603\)](#).
5. Click **Plot** to generate the histogram plot in the active graphics window.
6. Click **Print** to print out your histogram results on individual zones, or the entire domain. Similarly, you can click **Compute** to calculate your histogram results on individual zones, or the entire domain.

32.9.8.2. Options for Histogram Plots

Other than the axis and curve attribute controls mentioned in the procedure above, the only option for histogram plotting is the ability to specify a subrange of values to be plotted.

32.9.8.2.1. Specifying the Range of Values Plotted

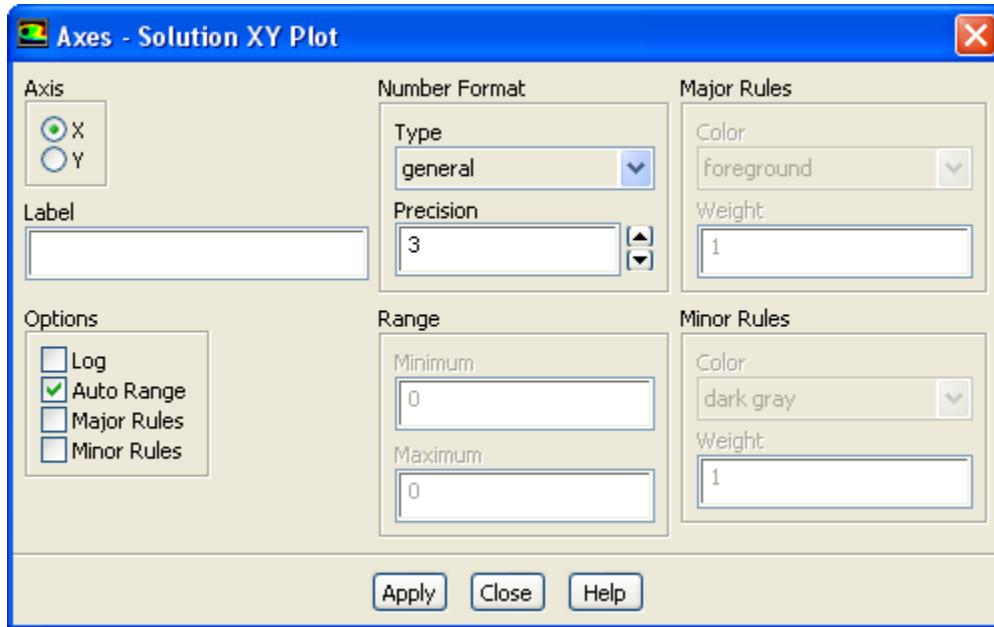

By default, the range of values included in the histogram plot is automatically set to the range of values in the entire domain for the selected variable. If you want to focus in on a smaller range of values, you can restrict the range to be displayed.

To manually set the range of values, turn off the **Auto Range** option in the [Histogram Dialog Box \(p. 2172\)](#). The **Min** and **Max** fields will become editable, and you can enter the new range of values to be plotted. To show the default range at any time, click **Compute** and the **Min** and **Max** fields will be updated.

You can also choose to base the minimum and maximum values on the range of values on the selected surfaces, rather than in the entire domain. To do this, turn off the **Global Range** option in the [Histogram Dialog Box \(p. 2172\)](#). The **Min** and **Max** values will be updated when you next click **Compute**.

32.9.9. Modifying Axis Attributes

You can modify the appearance of the XY and parameters that control the labels, scale, range, numbers, and major and minor rules. For each type of plot (solution XY, file XY, profile, residual, histogram, and so on), you can set different axis parameters in the [Axes Dialog Box \(p. 2179\)](#) ([Figure 32.83 \(p. 1602\)](#)). Note that the title following **Axes** in the dialog box indicates which plot environment you are changing (for example, the **Axes - Solution XY Plot** dialog box controls parameters for solution XY plots).

Figure 32.83 The Axes Dialog Box

To open the *Axes Dialog Box* (p. 2179) for a particular plot type, click **Axes...** in the appropriate dialog box (for example, the **Solution XY Plot**, **File XY Plot**, **Plot Profile Data**, **Plot Interpolated Data**, or **Residual Monitors** dialog box).

32.9.9.1. Using the Axes Dialog Box

The *Axes Dialog Box* (p. 2179) enables you to independently control the characteristics of the ordinate (y axis) and abscissa (z axis) on an XY plot or parameters for one axis or the other, by following the procedure below:

1. Choose the axis for which you want to modify the attributes by selecting **X** or **Y** under **Axis**.
2. Set the desired parameters.
3. Click **Apply** and then choose the other axis and repeat the steps, if desired.

The changes to the axis attributes will appear in the graphics window the next time you generate a plot.

32.9.9.1.1. Changing the Axis Label

If you want to modify the label for the axis, you can do so by editing the **Label** text field in the *Axes Dialog Box* (p. 2179).

32.9.9.1.2. Changing the Format of the Data Labels

You can change the format of the labels that define the primary data divisions on the axes using the controls under the **Number Format** heading in the *Axes Dialog Box* (p. 2179).

- To display the real value with an integral and fractional part (for example, 1.0000), select **float** in the **Type** drop-down list. You can set the number of digits in the fractional part by changing the value of **Precision**.

- To display the real value with a mantissa and exponent (for example, 1.0e-02), select **exponential** in the **Type** drop-down list. You can define the number of digits in the fractional part of the mantissa in the **Precision** field.
- To display the real value with either float or exponential form, depending on the size of the number and the defined **Precision**, choose **general** in the **Type** drop-down list.

32.9.9.1.3. Choosing Logarithmic or Decimal Scaling

By default, decimal scaling is used for both axes (except for the *y* axis in residual plots, which uses a log scale). If you want to change to a logarithmic scale, enable the **Log** option in the *Axes Dialog Box* (p. 2179). To return to a decimal scale, turn off the **Log** option. Note that when you are using the logarithmic scale, the **Range** values are the exponents; to specify a logarithmic range from 1 to 10000, for example, you will specify a minimum value of 1 and a maximum value of 4.

32.9.9.1.4. Resetting the Range of the Axis

By default, the extents of the axis will range from the minimum value plotted to the maximum value plotted. If you want to change the range or extents of the axis, you can do so by turning off the **Auto Range** option in the *Axes Dialog Box* (p. 2179) and setting the new **Minimum** and **Maximum** values for the **Range**. This feature is useful when you are generating a series of plots and you want the extents of one or both of the axes to be the same, even if the range of plotted values differs. For example, if you are generating plots of temperature on several different wall zones, you might want the minimum and maximum temperature on the *y* axis to be the same in every plot so that you can easily compare one plot with another. You would determine a temperature range that includes the temperatures on all walls, and use that as the range for the *y* axis in each plot.

32.9.9.1.5. Controlling the Major and Minor Rules

ANSYS FLUENT enables you to display major and/or minor rules on the axes. Major and minor rules are the horizontal or vertical lines that mark, respectively, the primary and secondary data divisions and span the whole plot window to produce a “mesh.” To add major or minor rules to the plot, enable the **Major Rules** or **Minor Rules** option. You can then specify a color and weight for each type of rule.

Under the **Major Rules** or **Minor Rules** heading, select the desired color for the lines in the **Color** drop-down list and specify the line thickness in the **Weight** field. A line of weight 1.0 is normally 1 pixel wide. A weight of 2.0 would make the line twice as thick (that is, 2 pixels wide).

32.9.10. Modifying Curve Attributes

The data curves in XY plots and histograms can be represented by any combination of lines and markers. You can modify the attributes of the curves, including the patterns, weights, and colors of the lines, and the symbols, sizes, and colors of the markers. For each type of plot (solution XY, file XY, profile, residual, parameters in the *Curves Dialog Box* (p. 2181) (*Figure 32.84* (p. 1604))). Note that the title following **Curves** in the dialog box indicates which plot environment you are changing (for example, the **Curves - Solution XY Plot** dialog box controls curve parameters for solution XY plots).

Figure 32.84 The Curves Dialog Box

To open the [Curves Dialog Box \(p. 2181\)](#) for a particular plot type, click **Curves...** in the appropriate dialog box (for example, **Solution XY Plot**, **File XY Plot**, **Plot Profile Data**, **Plot Interpolated Data**, or **Residual Monitors** dialog box).

32.9.10.1. Using the Curves Dialog Box

The [Curves Dialog Box \(p. 2181\)](#) enables you to independently control the characteristics of each data curve in an XY plot or parameters for a curve, you will follow the procedure below:

1. Specify the curve for which you want to modify the attributes by increasing or decreasing the **Curve #** counter. The curves are numbered sequentially, starting from 0. For example, if you were plotting flow-field values on two surfaces, the first surface would be curve 0, and the second, curve 1. If the plot contains only one curve, the **Curve #** is set to 0 and is not editable.
2. Set the desired line and/or marker parameters as described below.
3. Click **Apply** and then choose another **Curve #** and repeat the steps, if desired.

Your changes to the curve attributes will appear in the graphics window the next time you generate a plot.

32.9.10.1.1. Changing the Line Style

You can control the pattern, color, and weight of the line using the controls under the **Line Style** heading:

- To set the line pattern for the curve, choose one of the items in the **Pattern** drop-down list. Except for **center** and **phantom** lines, the list displays examples of the pattern choices. A **center** line alternates a very long dash and a short dash and a **phantom** line alternates a very long dash and a double short dash. Note that selecting the second item in the drop-down list, represented by 4 short dashes, will result in a solid-line curve.

Important

If you do not want the data points to be connected by any type of line (that is, if you plan to use just markers), select the “blank” choice, which is the first item in the **Pattern** list.

- To set the color of the line, pick one of the choices in the **Color** drop-down list.
- To define the line thickness, set the value of **Weight**. A line weight of 1.0 is normally 1 pixel wide. Therefore, a weight of 2.0 would make the line twice as thick (that is, 2 pixels wide).

32.9.10.1.2. Changing the Marker Style

You can control the symbol, color, and size for the data marker using the controls under the **Marker Style** heading:

- To set the symbol used to mark data, choose one of the items in the **Symbol** drop-down list. The list displays examples of the symbol choices. For example, in plotting pressure-coefficient data on the upper and lower surfaces of an airfoil, the symbol $/*\backslash$ (filled-in upward-pointing triangle) could be used for the marker representing the upper surface data, and the symbol $\backslash*/$ (filled-in downward-pointing triangle) could be used for the marker representing the lower surface data.

Important

If you do not want the data points to be represented by markers (that is, if you plan to use just a line connecting the data points), select the “blank” choice, which is the first item in the **Style** list.

- To set the color of the marker, pick one of the choices in the **Color** drop-down list.
- To define the size of the data marker, set the value of **Size**. A symbol of size 1.0 is 3.0% of the height of the display screen, except for the “.” symbol, which is always one pixel.

32.9.10.1.3. Previewing the Curve Style

To see what a particular setting will look like in the plot, you can preview it in the **Sample** window of the [Curves Dialog Box \(p. 2181\)](#). A single marker and/or line will be shown with the specified style attributes.

32.10. Turbomachinery Postprocessing

In addition to the many graphics tools already discussed, ANSYS FLUENT also provides turbomachinery-specific postprocessing features which can be accessed once you have defined the topology of the problem. Information on postprocessing for turbomachinery applications is provided in the following sections:

- [32.10.1. Defining the Turbomachinery Topology](#)
- [32.10.2. Generating Reports of Turbomachinery Data](#)
- [32.10.3. Displaying Turbomachinery Averaged Contours](#)
- [32.10.4. Displaying Turbomachinery 2D Contours](#)
- [32.10.5. Generating Averaged XY Plots of Turbomachinery Solution Data](#)
- [32.10.6. Globally Setting the Turbomachinery Topology](#)
- [32.10.7. Turbomachinery-Specific Variables](#)

32.10.1. Defining the Turbomachinery Topology

In order to establish the turbomachinery-specific coordinate system used in subsequent postprocessing functions, ANSYS FLUENT requires you to define the topology of the flow domain. The procedure for defining the topology is described further in this section, along with details about the boundary types.

The current implementation of the turbomachinery topology definition for postprocessing is no longer limited to one row of blades at a time. If your geometry contains multiple rows of blades, you can define all turbomachinery topologies simultaneously. You can name and/or manage all topologies and perform various turbomachinery postprocessing tasks on a single topology or on all topologies at once.

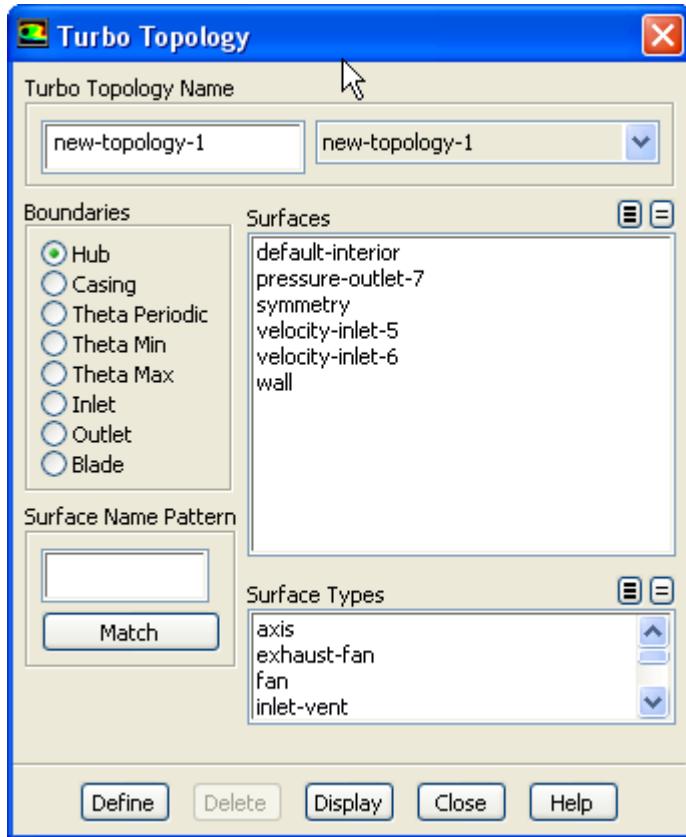

Important

The turbo coordinates can only be generated properly if the correct rotation axis is specified in the boundary conditions dialog box for the fluid zone (see [Specifying the Rotation Axis \(p. 223\)](#)).

To define the turbomachinery topology in ANSYS FLUENT, you will use the [Turbo Topology Dialog Box \(p. 2252\)](#) ([Figure 32.85 \(p. 1606\)](#)).

Define → Turbo Topology...

Figure 32.85 The Turbo Topology Dialog Box

The procedure for defining topology for your turbomachinery application are as follows:

1. Select a boundary type under **Boundaries** (for example, **Hub** in [Figure 32.85 \(p. 1606\)](#)). The boundary types are described in detail in [Boundary Types \(p. 1607\)](#).
2. In the **Surfaces** list, choose the surface(s) that represent the boundary type you selected in step 1.

If you want to select several surfaces of the same type, you can select that type in the **Surface Types** list instead. All of the surfaces of that type will be selected automatically in the **Surfaces** list (or deselected, if they are all selected already). Another shortcut is to specify a **Surface Name**

Pattern and click **Match** to select surfaces with names that match the specified pattern. For example, if you specify **wall***, all surfaces whose names begin with **wall** (for example, **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all surfaces whose names consist of **wall** followed by a single character will be selected (or deselected, if they are all selected already).

3. Repeat the steps 1 and 2 for all the boundary types that are relevant for your model.

Important

For a complete turbo topology definition the surfaces defined as inlet, outlet, hub, casing, periodic, theta min, and theta max (if available) should form a closed domain.

4. Enter a name in the **Turbo Topology Name** field or keep the default name.
5. Click **Define** to complete the definition of the boundaries.

ANSYS FLUENT will inform you that the turbomachinery postprocessing functions have been activated, and the **Turbo** menu will appear in ANSYS FLUENT's menu bar at the top of the console window.

6. Specify a position vector that is defined as $\theta = 0$. This position vector should be outside the domain, for example, if your domain lies in the first and second quadrant, specify negative y axis as the zero θ line. This will ensure that there is no discontinuity in angular coordinates within the domain. This can be done using the `display/set/zero-angle-dir` command.

Default zero θ line is +y axis. If this axis passes through the domain, you should define the zero θ line, so as to satisfy above criteria.

7. To view a defined topology, select the topology from the **Turbo Topology Name** drop-down list and click **Display**. The defined topology is shown in the active graphics window. This enables you to visually check the boundaries to ensure that you have defined them correctly.
8. To edit a defined topology, select the topology from the **Turbo Topology Name** drop-down list, make the appropriate changes and click **Modify**.
9. To remove a defined topology, select the topology from the **Turbo Topology Name** drop-down list and click **Delete**.

Important

Note that the topology setup that you define will be saved to the case file when you save the current model. Thus, if you read this case back into ANSYS FLUENT, you do not need to set up the topology again.

However, use of a boundary condition file to set the turbo topology for two similar cases may not work properly. In that case you need to set the turbo topology manually.

32.10.1.1. Boundary Types

The boundaries for the turbomachinery topology are as follows (see [Figure 32.86 \(p. 1608\)](#)):

Hub

is the wall zone(s) forming the lower boundary of the flow passage (generally toward the axis of rotation of the machine).

Casing

is the wall zone(s) forming the upper boundary of the flow passage (away from the axis of rotation of the machine).

Theta Periodic

is the periodic boundary zone(s) on the circumferential boundaries of the flow passage.

Theta Min

and **Theta Max** are the wall zones at the minimum and maximum angular (θ) positions on a circumferential boundary.

Inlet

is the inlet zone(s) through which the flow enters the passage.

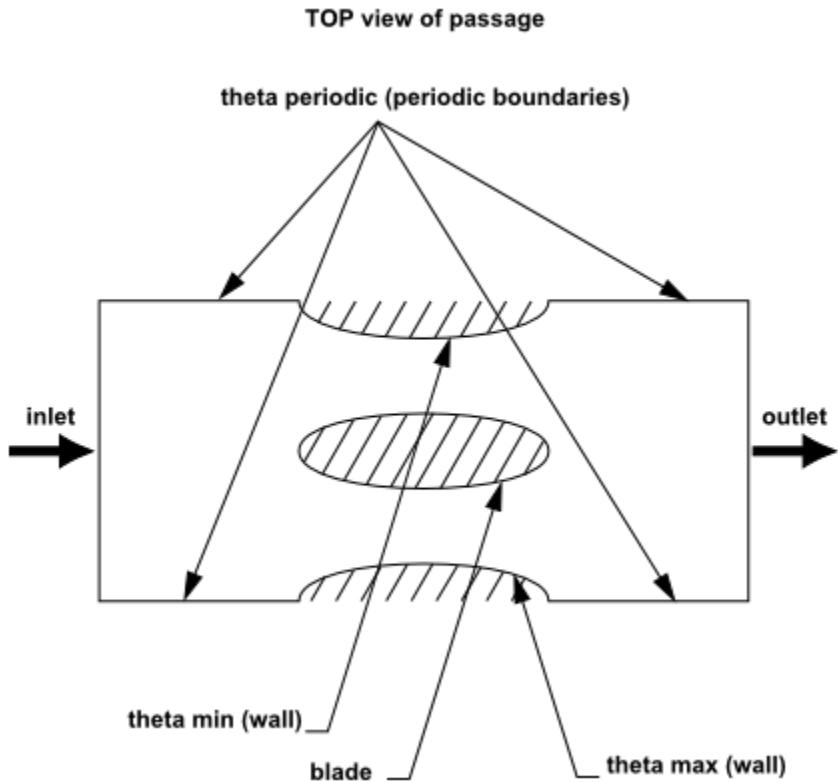

Outlet

is the outlet zone(s) through which the flow exits the passage.

Blade

is the wall zone(s) that defines the blade(s) (if any). Note that these zones cannot be attached to the circumferential boundaries. For this situation, use **Theta Min** and **Theta Max** to define the blade.

Figure 32.86 Turbomachinery Boundary Types

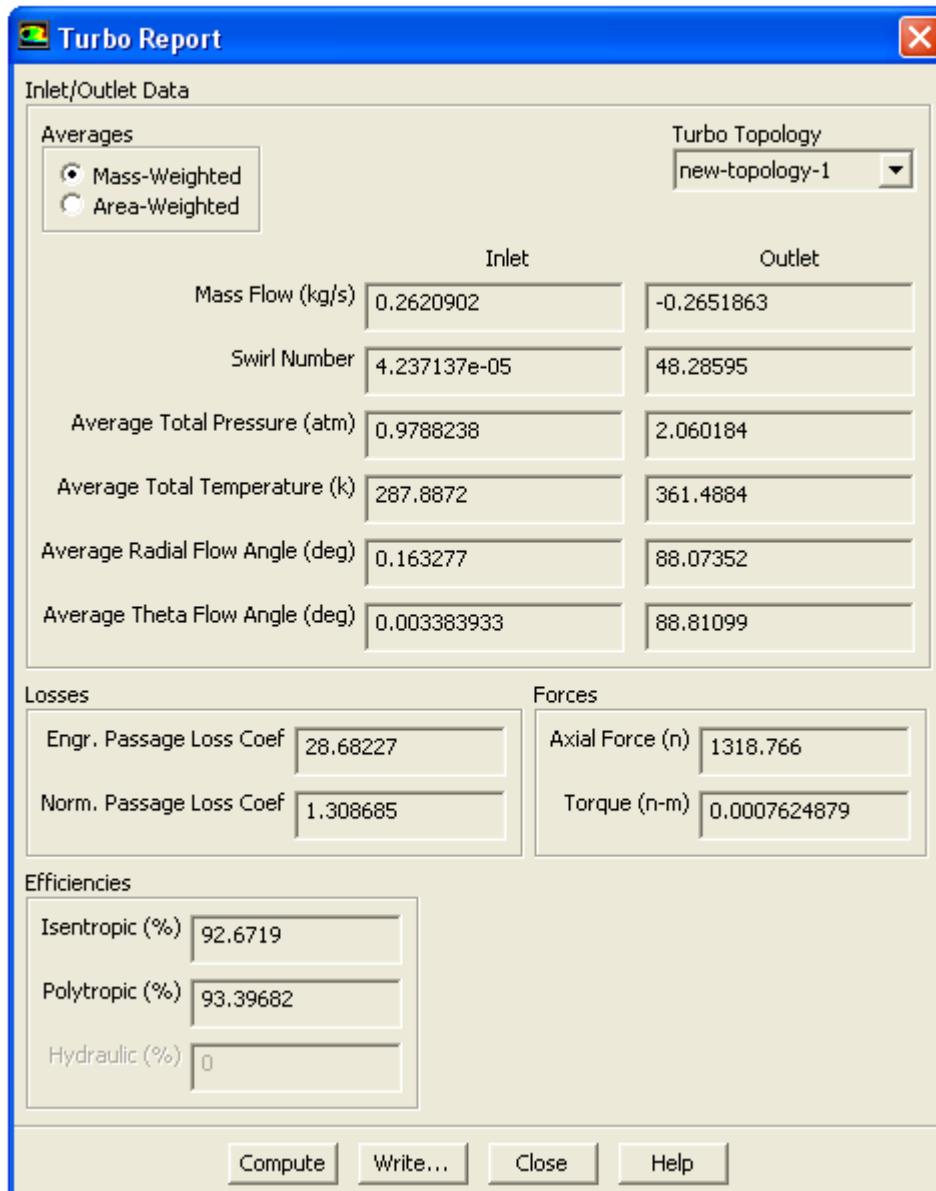

32.10.2. Generating Reports of Turbomachinery Data

Once you have defined your turbomachinery topologies, as described in [Defining the Turbomachinery Topology \(p. 1605\)](#), you can report a number of turbomachinery quantities, including mass flow, swirl number, torque, and efficiencies.

To report turbomachinery quantities in ANSYS FLUENT, you will use the [Turbo Report Dialog Box \(p. 2331\)](#) ([Figure 32.87 \(p. 1609\)](#)).

Turbo → Report...

Figure 32.87 The Turbo Report Dialog Box

The procedure for using this dialog box is as follows:

- Under **Averages**, specify whether you want to report **Mass-Weighted** or **Area-Weighted** averages.
- Under **Turbo Topology**, specify a predefined turbomachinery topology from the drop-down list.
- Click **Compute**. ANSYS FLUENT will compute the turbomachinery quantities as described below, and display their values.
- If you want to save the reported values to a file, click **Write...** and specify a name for the file in [The Select File Dialog Box \(p. 33\)](#).

32.10.2.1. Computing Turbomachinery Quantities

32.10.2.1.1. Mass Flow

The mass flow rate through a surface is defined as follows:

$$\dot{m} = \int_A (\rho \vec{v} \cdot \hat{n}) dA \quad (32-2)$$

where

A = is the area of the inlet or outlet

\vec{v} = the velocity vector

ρ = the fluid density

\hat{n} = a unit vector normal to the surface

32.10.2.1.2. Swirl Number

The swirl number is defined as follows:

$$SW = \frac{\int_S r v_\theta (\vec{v} \cdot \hat{n}) dS}{\bar{r} \int_S v_z (\vec{v} \cdot \hat{n}) dS} \quad (32-3)$$

where

r = the radial coordinate (specifically, the radial distance from the axis of rotation)

v_θ = the tangential velocity

\vec{v} = the velocity vector

\hat{n} = a unit vector normal to the surface,

S = the inlet or outlet

$$\bar{r} = \frac{1}{S} \int_S r dS \quad (32-4)$$

32.10.2.1.3. Average Total Pressure

The area-averaged total pressure is defined as follows:

$$\overline{p}_t = \frac{\int p_t dA}{A} \quad (32-5)$$

where p_t is the total pressure and A is the area of the inlet or outlet.

The mass-averaged total pressure is defined as follows:

$$\overline{p}_t = \frac{\int (\rho p_t |\vec{v} \cdot \hat{n}|) dA}{\int (\rho |\vec{v} \cdot \hat{n}|) dA} \quad (32-6)$$

where,

p_t = the total pressure

A = the area of the inlet or outlet

\vec{v} = the velocity vector

ρ = the fluid density

\hat{n} = a unit vector normal to the surface

32.10.2.1.4. Average Total Temperature

The area-averaged total temperature is defined as follows:

$$\overline{T}_t = \frac{\int T_t dA}{A} \quad (32-7)$$

where T_t is the total temperature and A is the area of the inlet or outlet.

The mass-averaged total temperature is defined as follows:

$$\overline{T}_t = \frac{\int (\rho T_t |\vec{v} \cdot \hat{n}|) dA}{\int (\rho |\vec{v} \cdot \hat{n}|) dA} \quad (32-8)$$

where,

T_t = the total temperature

A = the area of the inlet or outlet

\vec{v} = the velocity vector

ρ = the fluid density

\hat{n} = a unit vector normal to the surface

32.10.2.1.5. Average Flow Angles

The area-averaged flow angles are defined as follows:

$$\bar{\alpha}_r = \tan^{-1} \left(\frac{\int v_\theta dA}{\frac{A}{\int v_z dA}} \right) \quad (32-9)$$

in the radial direction, and

$$\bar{\alpha}_\theta = \tan^{-1} \left(\frac{\int v_r dA}{\frac{A}{\int v_z dA}} \right) \quad (32-10)$$

in the tangential direction, where v_z , v_r , and v_θ represent the axial, radial, and tangential velocities, respectively.

The mass-averaged flow angles are defined as follows:

$$\bar{\alpha}_{r,m} = \tan^{-1} \left(\frac{\int (\rho v_r) dA}{\frac{A}{\int (\rho v_z) dA}} \right) \quad (32-11)$$

in the radial direction, and

$$\bar{\alpha}_{\theta,m} = \tan^{-1} \left(\frac{\int (\rho v_\theta) dA}{\frac{A}{\int (\rho v_z) dA}} \right) \quad (32-12)$$

in the tangential direction.

32.10.2.1.6. Passage Loss Coefficient

The engineering loss coefficient is defined as follows:

$$K_L = \frac{\bar{p}_{t,i} - \bar{p}_{t,o}}{\frac{1}{2}\rho\bar{V}_i^2} \quad (32-13)$$

where,

$\bar{p}_{t,i}$ = the mass-averaged total pressure at the inlet

$\bar{p}_{t,o}$ = the mass-averaged total pressure at the outlet

ρ = the density of the fluid

\bar{V}_i = the mass-averaged velocity magnitude at the inlet

The normalized loss coefficient is defined as follows:

$$K_{L,n} = \frac{\bar{p}_{t,i} - \bar{p}_{t,o}}{\bar{p}_{t,i} - \bar{p}_{s,o}} \quad (32-14)$$

where $\bar{p}_{s,o}$ is the mass-averaged static pressure at the outlet.

32.10.2.1.7. Axial Force

The axial force on the rotating parts is defined as follows:

$$F_a = \left(\int_S (\bar{\tau} \cdot \hat{n}) dS \right) \cdot \hat{a} \quad (32-15)$$

where,

S = the surfaces comprising all rotating parts

$\bar{\tau}$ = the total stress tensor (pressure and viscous stresses)

\hat{n} = a unit vector normal to the surface

\hat{a} = a unit vector parallel to the axis of rotation

32.10.2.1.8. Torque

The torque on the rotating parts is defined as follows:

$$T = \left(\int_S (\vec{r} \times (\bar{\tau} \cdot \hat{n})) dS \right) \cdot \hat{a} \quad (32-16)$$

where,

S = the surfaces comprising all rotating parts

$\bar{\tau}$ = the total stress tensor

\hat{n} = a unit vector normal to the surface

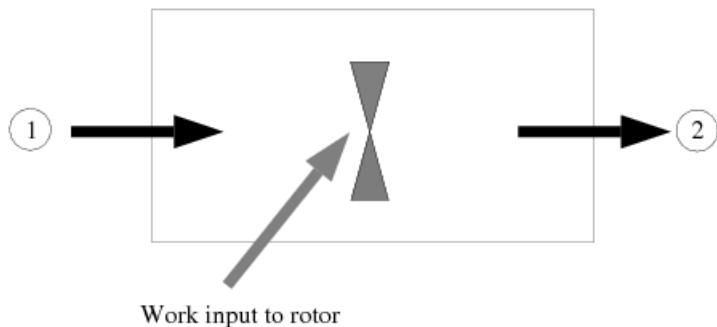

\vec{r} = the position vector

\hat{a} = a unit vector parallel to the axis of rotation

32.10.2.1.9. Efficiencies for Pumps and Compressors

The definitions of the efficiencies for compressible and incompressible flows in pumps and compressors are described in this section. Efficiencies for turbines are described later in this section. Consider a pumping or compression device operating between states 1 and 2 as illustrated in [Figure 32.88 \(p. 1614\)](#). Work input to the device is required to achieve a specified compression of the working fluid.

Figure 32.88 Pump or Compressor

Assuming that the processes are steady state, steady flow, and that the mass flow rates are equal at the inlet and outlet of the device (no film cooling, bleed air removal, and so on), the efficiencies for incompressible and compressible flows are as described in the following subsections.

32.10.2.1.9.1. Incompressible Flows

For devices such as liquid pumps and fans at low speeds, the working fluid can be treated as incompressible. The efficiency of a pumping process with an incompressible working fluid is defined as the ratio of the head rise achieved by the fluid to the power supplied to the rotor/impeller. This can be expressed as follows:

$$\eta = \frac{Q(p_{t2} - p_{t1})}{T\omega} \quad (32-17)$$

where,

Q = volumetric flow rate

p_t = total pressure

T = net torque acting on the rotor/impeller

ω = rotational speed

This definition is sometimes called the "hydraulic efficiency". Often, other efficiencies are included to account for flow leakage (volumetric efficiency) and mechanical losses along the transmission system

between the rotor and the machine providing the power for the rotor/impeller (mechanical efficiency). Incorporating these losses then yields a total efficiency for the system.

32.10.2.1.9.2. Compressible Flows

For gas compressors that operate at high speeds and high pressure ratios, the compressibility of the working fluid must be taken into account. The efficiency of a compression process with a compressible working fluid is defined as the ratio of the work required for an ideal (reversible) compression process to the actual work input. This assumes the compression process occurs between states 1 and 2 *for a given pressure ratio*. In most cases, the pressure ratio is the *total pressure at state 2* divided by the *total pressure at state 1*. If the process is also adiabatic, then the ideal state at 2 is the *isentropic* state.

From the foregoing definition, the efficiency for an adiabatic compression process can be written as

$$\eta_c = \frac{h_{t2,i} - h_{t1}}{h_{t2} - h_{t1}} \quad (32-18)$$

where,

h_{t1} = total enthalpy at 1

h_{t2} = actual total enthalpy at 2

$h_{t2,i}$ = isentropic total enthalpy
at 2

If the specific heat is constant, [Equation 32-18 \(p. 1615\)](#) can also be expressed as

$$\eta_c = \frac{T_{t2,i} - T_{t1}}{T_{t2} - T_{t1}} \quad (32-19)$$

where,

T_{t1} = total temperature at 1

T_{t2} = actual total temperature at 2

$T_{t2,i}$ = isentropic total temperature
at 2

Using the isentropic relation

$$\frac{T_{t2,i}}{T_{t1}} = \left(\frac{p_{t2}}{p_{t1}} \right)^{\frac{\gamma-1}{\gamma}} \quad (32-20)$$

where γ is the ratio of specific heats specified in the [Reference Values Task Page \(p. 2046\)](#).

The efficiency can be written in the compact form

$$\eta_c = \frac{T_{t1} \left[\left(\frac{p_{t2}}{p_{t1}} \right)^{\frac{\gamma-1}{\gamma}} - 1 \right]}{T_{t2} - T_{t1}} \quad (32-21)$$

Note that this definition requires data only for the *actual* states 1 and 2.

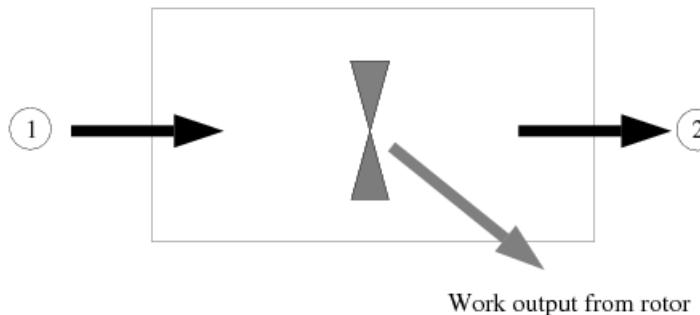

Compressor designers also make use of the polytropic efficiency when comparing one compressor with another. The polytropic efficiency is defined as follows:

$$\eta_{c,p} = \frac{\frac{\gamma-1}{\gamma} \ln \left(\frac{p_{t2}}{p_{t1}} \right)}{\ln \left(\frac{T_{t2}}{T_{t1}} \right)} \quad (32-22)$$

32.10.2.1.10. Efficiencies for Turbines

Consider a turbine operating between states 1 and 2 in *Figure 32.89* (p. 1616). Work is extracted from the working fluid as it expands through the turbine. Assuming that the processes are steady state, steady flow, and that the mass flow rates are equal at the inlet and outlet of the device (no film cooling, bleed air removal, and so on), turbine efficiencies for incompressible and compressible flows are as described below.

Figure 32.89 Turbine

32.10.2.1.10.1. Incompressible Flows

The efficiency of a turbine with an incompressible working fluid is defined as the ratio of the work delivered to the rotor to the energy available from the fluid stream. This ratio can be expressed as follows:

$$\eta = \frac{T\omega}{Q(p_{t1} - p_{t2})} \quad (32-23)$$

where,

Q = volumetric flow rate

p_t = total pressure

T = net torque acting on the rotor/impeller

ω = rotational speed

Note the similarity between this definition and the definition of incompressible compression efficiency ([Equation 32–17 \(p. 1614\)](#)). As with hydraulic pumps and compressors, other efficiencies (for example, volumetric and mechanical efficiencies) can be defined to account for other losses in the system.

32.10.2.1.10.2. Compressible Flows

For high-speed gas turbines operating at large expansion pressure ratios, compressibility must be accounted for. The efficiency of an expansion process with a compressible working fluid is defined as the ratio of the actual work extracted from the fluid to the work extracted from an ideal (reversible) process. This assumes that the expansion process occurs between states 1 and 2 *for a given pressure ratio*. In contrast to the compression process, the pressure ratio for expansion is the *total pressure at state 1* divided by the *total pressure at state 2*. If the process is also adiabatic, then the ideal state at 2 is the *isentropic* state.

From the foregoing definition, the efficiency for an adiabatic expansion process through a turbine can be written as

$$\eta_c = \frac{h_{t1} - h_{t2}}{h_{t1} - h_{t2,i}} \quad (32-24)$$

where

h_{t1} = total enthalpy at 1

h_{t2} = actual total enthalpy at 2

$h_{t2,i}$ = isentropic total enthalpy
at 2

If the specific heat is constant, [Equation 32–24 \(p. 1617\)](#) can also be expressed as

$$\eta_e = \frac{T_{t1} - T_{t2}}{T_{t1} - T_{t2,i}} \quad (32-25)$$

where

T_{t1} = total temperature at 1

T_{t2} = actual total temperature at 2

$T_{t2,i}$ = isentropic total temperature
at 2

Using the isentropic relation

$$\frac{T_{t1}}{T_{t2,i}} = \left(\frac{p_{t1}}{p_{t2}} \right)^{\frac{\gamma-1}{\gamma}} \quad (32-26)$$

the expansion efficiency can be written in the compact form

$$\eta_e = \frac{T_{t1} - T_{t2}}{T_{t1} \left[1 - \left(\frac{p_{t2}}{p_{t1}} \right)^{\frac{\gamma-1}{\gamma}} \right]} \quad (32-27)$$

Note that this definition requires data only for the *actual* states 1 and 2.

As with compressors, one may also define a polytropic efficiency for turbines. The polytropic efficiency is defined as follows:

$$\eta_{e,p} = \frac{\ln \left(\frac{T_{t1}}{T_{t2}} \right)}{\frac{\gamma-1}{\gamma} \ln \left(\frac{p_{t1}}{p_{t2}} \right)} \quad (32-28)$$

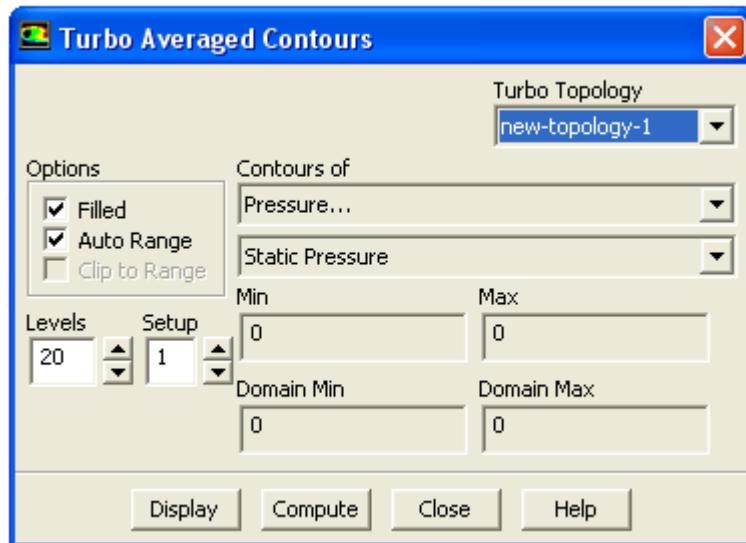

32.10.3. Displaying Turbomachinery Averaged Contours

Turbo averaged contours are generated as projections of the values of a variable averaged in the circumferential direction and visualized on an r - z plane. A sample plot is shown in [Figure 32.91 \(p. 1620\)](#).

32.10.3.1. Steps for Generating Turbomachinery Averaged Contour Plots

You can display contours using the [Turbo Averaged Contours Dialog Box \(p. 2333\)](#) ([Figure 32.90 \(p. 1619\)](#)).

Turbo → Averaged Contours...

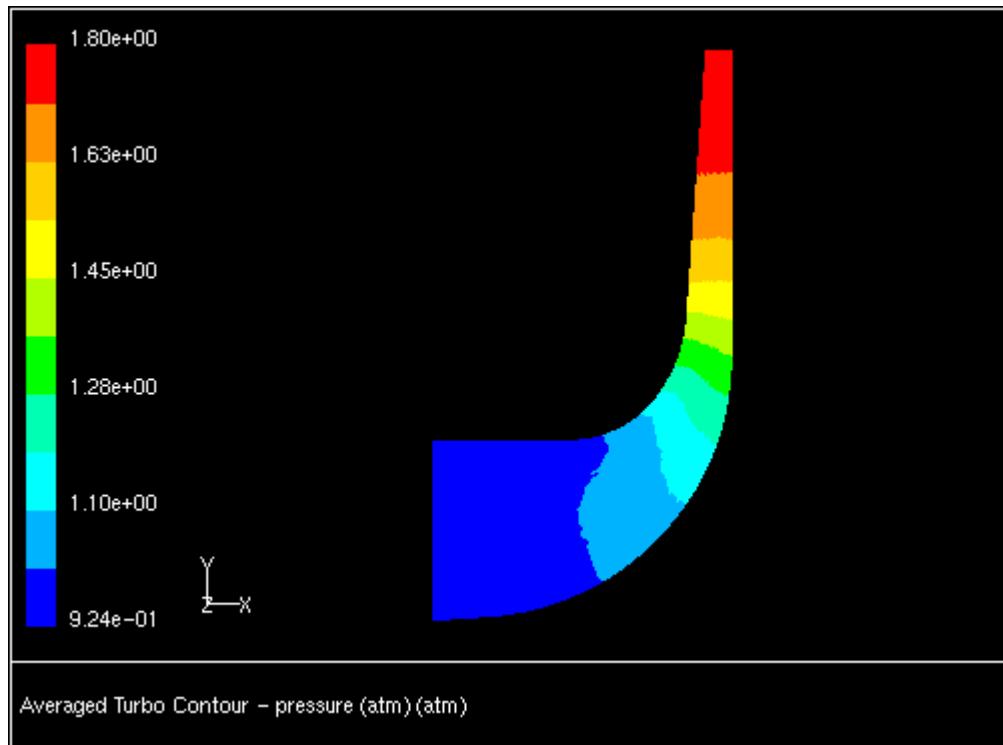

Figure 32.90 The Turbo Averaged Contours Dialog Box

The basic steps for generating a turbo averaged contour plot are as follows:

1. Select **All** or a specific predefined turbomachinery topology from the **Turbo Topology** drop-down list.
2. Select the variable or function to be displayed in the **Contours of** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See *Turbomachinery-Specific Variables* (p. 1623) for a list of turbomachinery-specific variables, and see *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
3. Specify the number of contours in the **Levels** field. The maximum number of levels allowed is 100.
4. Set any of the options described below.
5. Click **Display** to draw the specified contours in the active graphics window.

The resulting display will include the specified number of contours of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

Note that the **Min** and **Max** values displayed in the dialog box are the minimum and maximum averaged values. These limits will in general be different from the global **Domain Min** and **Domain Max**, which are also displayed for your reference (see *Figure 32.90* (p. 1619)).

Figure 32.91 Turbo Averaged Filled Contours of Static Pressure

32.10.3.2. Contour Plot Options

The options mentioned in the procedure above include drawing color-filled contours (instead of line contours), specifying a range of values to be contoured, and storing the contour plot settings. These options are the same as those in the standard *Contours Dialog Box* (p. 2120). See *Contour and Profile Plot Options* (p. 1509) for details about using them.

32.10.4. Displaying Turbomachinery 2D Contours

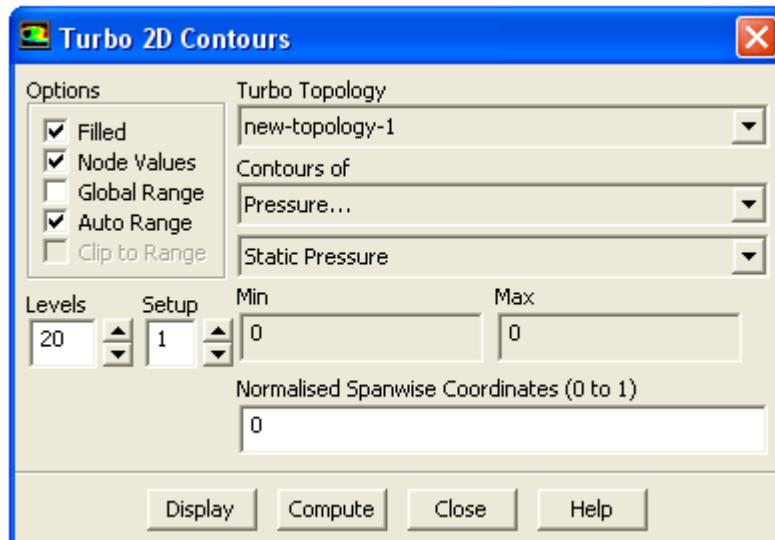

In postprocessing a turbomachinery solution, it is often desirable to display contours on surfaces of constant spanwise coordinate, and then project these contours onto a plane. This permits easier evaluation of the contours, especially for surfaces that are highly three-dimensional.

32.10.4.1. Steps for Generating Turbo 2D Contour Plots

You can display contours using the *Turbo 2D Contours Dialog Box* (p. 2334) (*Figure 32.92* (p. 1621)).

Turbo → 2D Contours...

Figure 32.92 The Turbo 2D Contours Dialog Box

The basic steps for generating a turbo 2D contour plot are as follows:

1. Specify a specific predefined turbomachinery topology using the **Turbo Topology** drop-down list.
2. Enter a value for the **Normalized Spanwise Coordinates (0 to 1)** for the spanwise surface you want to create.

Important

If shroud and hub are the curved surfaces, the iso-surface very close to them may contain void spaces as ANSYS FLUENT displays only a plane cut surface.

3. Select the variable or function to be displayed in the **Contours of** drop-down list.

First select the desired category in the upper list; you may then select a related quantity in the lower list. See *Turbomachinery-Specific Variables* (p. 1623) for a list of turbomachinery-specific variables, and see *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.

4. Specify the number of contours in the **Levels** field. The maximum number of levels allowed is 100.
5. Click **Display** to draw the specified contours in the active graphics window.

The resulting display will include the specified number of contours of the selected variable, with the magnitude on each one determined by equally incrementing between the values shown in the **Min** and **Max** fields.

32.10.4.2. Contour Plot Options

Depending on the type of contour plot you want to display, select appropriate choice under **Options**. These options are the same as those in the standard *Contours Dialog Box* (p. 2120). See *Contour and Profile Plot Options* (p. 1509) for details about using them.

32.10.5. Generating Averaged XY Plots of Turbomachinery Solution Data

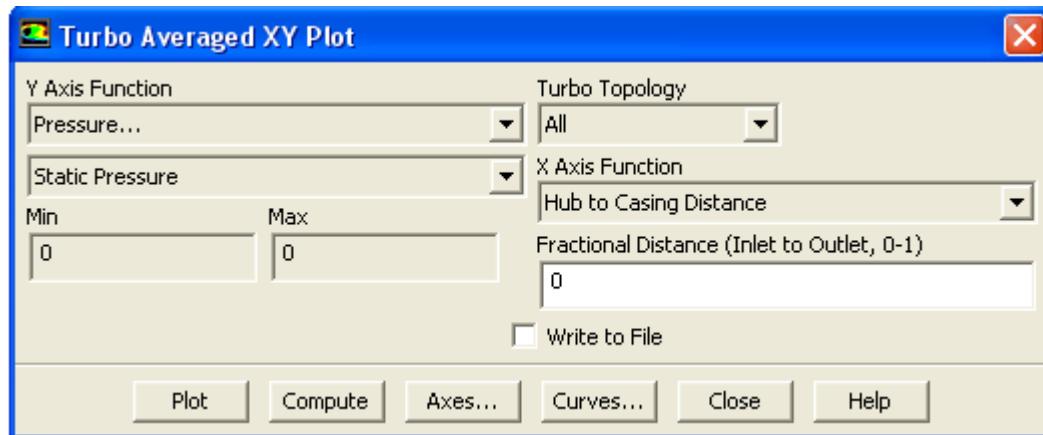

When comparing numerical solutions of turbomachinery problems to experimental data, it is often useful to plot circumferentially averaged quantities in the spanwise and meridional directions. This section describes how to do this in ANSYS FLUENT.

32.10.5.1. Steps for Generating Turbo Averaged XY Plots

To create an XY plot of circumferentially averaged solution data, you will use the *Turbo Averaged XY Plot Dialog Box* (p. 2336) (*Figure 32.93* (p. 1622)).

Turbo → Averaged XY Plot...

Figure 32.93 The Turbo Averaged XY Plot Dialog Box

The procedure for generating a turbo averaged XY plot are as follows:

1. Select the variable or function to be plotted in the **Y Axis Function** drop-down list. First select the desired category in the upper list; you may then select a related quantity in the lower list. (See *Turbomachinery-Specific Variables* (p. 1623) for a list of turbomachinery-specific variables, and see *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
2. Select **All** or a specific predefined turbomachinery topology from the **Turbo Topology** drop-down list.
3. Select the variable or function to be plotted in the **X Axis Function** drop-down list. The choices are **Hub to Casing Distance** and **Meridional Distance**.
4. Specify the desired value in the **Fractional Distance** field. The definition of the fractional distance depends on your selection of **X Axis Function**:
 - If you select **Hub to Casing Distance**, the fractional distance will be **Inlet to Outlet**.
 - If you select **Meridional Distance**, the fractional distance will be **Hub to Casing**.
5. (optional) Modify the attributes of the axes or curves as described in *Modifying Axis Attributes* (p. 1601) and *Modifying Curve Attributes* (p. 1603).
6. Click **Plot** to generate the XY plot in the active graphics window.

Note that you can use any of the mouse buttons to annotate the XY plot (see *Adding Text to the Graphics Window* (p. 1536)).

If you want to write the XY data to a file, follow these steps instead of Step 5 above:

1. Enable the **Write to File** option. The **Plot** button changes to a **Write...** button.
2. Click **Write...**
3. In *The Select File Dialog Box* (p. 33), specify a name for the plot file and save it.

32.10.6. Globally Setting the Turbomachinery Topology

In some cases, that is, iso-surface creation, ANSYS FLUENT enables you to globally set the current turbomachinery topology for your model using the *Turbo Options Dialog Box* (p. 2337) (*Figure 32.94* (p. 1623)).

Turbo → Options...

Figure 32.94 The Turbo Options Dialog Box

To set the current topology, select a topology from the **Current Topology** drop-down list and select **OK**.

32.10.7. Turbomachinery-Specific Variables

The following turbomachinery-specific variables are available in ANSYS FLUENT:

- **Meridional Coordinate**
- **Abs Meridional Coordinate**
- **Spanwise Coordinate**
- **Abs (H-C) Spanwise Coordinate**
- **Abs (C-H) Spanwise Coordinate**
- **Pitchwise Coordinate**
- **Abs Pitchwise Coordinate**

These variables are contained in the **Mesh...** category of the variable selection drop-down list. See *Field Function Definitions* (p. 1653) for their definitions.

32.11. Fast Fourier Transform (FFT) Postprocessing

When trying to interpret time-sequence data from a transient solution, it is often useful to look at the data's spectral (frequency) attributes. For instance, you may wish to determine the major vortex-shedding frequency from the time-history of the drag force on a body recorded during an ANSYS FLUENT simulation. Or, you may want to compute the spectral distribution of static pressure data recorded at a particular location on a body surface. Similarly, you may need to compute the spectral distribution of turbulent kinetic energy using data for fluctuating velocity components. To interpret some of these time dependent

data, you need to perform Fourier transform analysis. In essence, the Fourier transform enables you to take any time dependent data and resolve it into an equivalent summation of sine and cosine waves.

ANSYS FLUENT enables you to analyze your time dependent data using the Fast Fourier Transform (FFT) algorithm. Information on using the FFT algorithm in ANSYS FLUENT is provided in the following sections:

[32.11.1. Limitations of the FFT Algorithm](#)

[32.11.2. Windowing](#)

[32.11.3. Fast Fourier Transform \(FFT\)](#)

[32.11.4. Using the FFT Utility](#)

32.11.1. Limitations of the FFT Algorithm

The following limitations apply to ANSYS FLUENT's FFT module:

- The ANSYS FLUENT FFT module can only read inputs files in the ANSYS FLUENT monitor and x-y file formats.
- The ANSYS FLUENT FFT module assumes that the input data have been sampled at equal intervals and are consecutive (in the order of increasing time).
- The lowest frequency that the FFT module can pick up is given by $1/t$, where t is the total sampling time. If the sampled sequence contains frequencies lower than this, these frequencies will be aliased into higher frequencies.
- The highest frequency that the FFT module can pick up is $1/(2dt)$, where dt is the sampling interval (or time step).

32.11.2. Windowing

The discrete FFT algorithm is based on the assumption that the time-sequence data passed to the FFT corresponds to a single period of a periodically repeating signal. Since, in most situations, the first and the last data points will not coincide, the repeating signal implied in the assumption can often have a large discontinuity. The large discontinuity produces high-frequency components in the resulting Fourier modes, causing an aliasing error. You can condition the input signal before the transform by "windowing" it, in order to avoid this problem.

Suppose that we have N consecutive discrete (time-sequence) data sampled with a constant interval, Δt :

$$\phi_k \equiv \phi(t_k), \quad t_k \equiv k \Delta t, \quad k = 0, 1, 2, \dots, (N-1) \quad (32-29)$$

Windowing is done by multiplying the original input data (ϕ_j) by a window function, W_j :

$$\tilde{\phi}_j = \phi_j W_j \quad j = 0, 1, 2, \dots, (N-1) \quad (32-30)$$

ANSYS FLUENT offers four different window functions:

Hamming's window:

$$W_j = \begin{cases} 0.54 - 0.46 \cos\left(\frac{8\pi j}{N}\right) & j \leq \frac{N}{8}, j \geq \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \quad (32-31)$$

Hanning's window:

$$W_j = \begin{cases} 0.5 \left[1 - \cos\left(\frac{8\pi j}{N}\right) \right] & j \leq \frac{N}{8}, j \geq \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \quad (32-32)$$

Barlett's window:

$$W_j = \begin{cases} \frac{8j}{N} & j \leq \frac{N}{8} \\ 8 \left(1 - \frac{j}{N}\right) & j \geq \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \quad (32-33)$$

Blackman's window:

$$W_j = \begin{cases} 0.42 - 0.5 \cos\left(\frac{8\pi j}{N}\right) + 0.08 \cos\left(\frac{16\pi j}{N}\right) & j \leq \frac{N}{8}, j \geq \frac{7N}{8} \\ 1 & \frac{N}{8} < j < \frac{7N}{8} \end{cases} \quad (32-34)$$

These window functions preserve a large fraction (3/4) of the original data, affecting only 1/4 of the data on both ends.

32.11.3. Fast Fourier Transform (FFT)

The Fourier transform utility in ANSYS FLUENT enables you to compute the Fourier transform of a signal, $\phi(t)$, a real-valued function, from a finite number of its sampled points.

The discrete Fourier transform of ϕ_k is defined by

$$\phi_k = \sum_{n=0}^{N-1} \hat{\phi}_n e^{2\pi i k n / N} \quad k = 0, 1, 2, \dots, (N-1) \quad (32-35)$$

where $\hat{\phi}_n$ are the discrete Fourier coefficients, which can be obtained from where $\hat{\phi}_n$ are the discrete Fourier coefficients, which can be obtained from

$$\hat{\phi}_n = \frac{1}{N} \sum_{k=0}^{N-1} \phi_k e^{-2\pi i k n / N} \quad n = 0, 1, 2, \dots, (N-1) \quad (32-36)$$

Equation 32-35 (p. 1626) and *Equation 32-36 (p. 1626)* form a Fourier transform pair that enables us to determine one from the other.

Note that when we follow the convention of varying n from 0 to $N - 1$ in *Equation 32-35 (p. 1626)* or *Equation 32-36 (p. 1626)* instead of from $-N/2$ to $N/2$, the range of index $1 \leq n \leq N/2 - 1$ corresponds to positive frequencies, and the range of index $N/2 + 1 \leq n \leq N - 1$ corresponds to negative frequencies. $n = 0$ still corresponds to zero frequency.

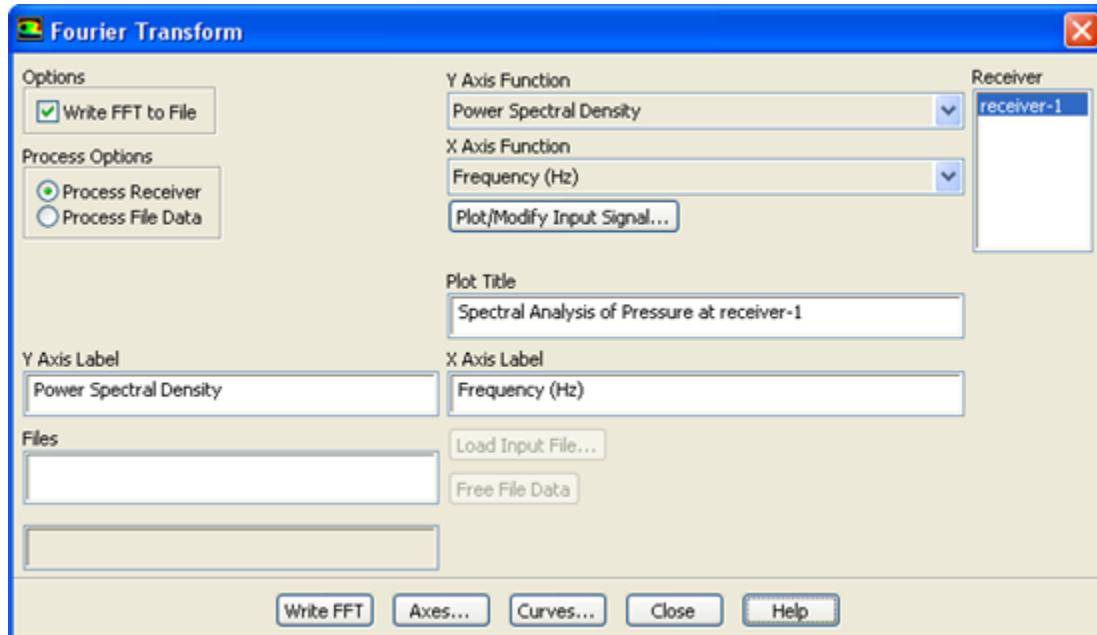

For the actual calculation of the transforms, ANSYS FLUENT adopts the so-called fast Fourier transform (FFT) algorithm which significantly reduces operation counts in comparison to the direct transform. Furthermore, unlike most FFT algorithms in which the number of data should be a power of 2, the FFT utility in ANSYS FLUENT employs a prime-factor algorithm [94] (p. 2372). The number of data points permissible in the prime-factor FFT algorithm is any products of mutually prime factors from the set 2,3,4,5,7,8,9,11,13,16, with a maximum value of $720720 = 5 \times 7 \times 9 \times 11 \times 13 \times 16$. Thus, the prime-factor FFT preserves the original data better than the conventional FFT.

Just prior to computing the transform, ANSYS FLUENT determines the largest permissible number of data points based on the prime factors, discarding the rest of the data.

32.11.4. Using the FFT Utility

The ANSYS FLUENT FFT utility is available through the *Fourier Transform Dialog Box* (p. 2176) (*Figure 32.95 (p. 1627)*).

Plots → FFT → Set Up...

Figure 32.95 The Fourier Transform Dialog Box

32.11.4.1. Loading Data for Spectral Analysis

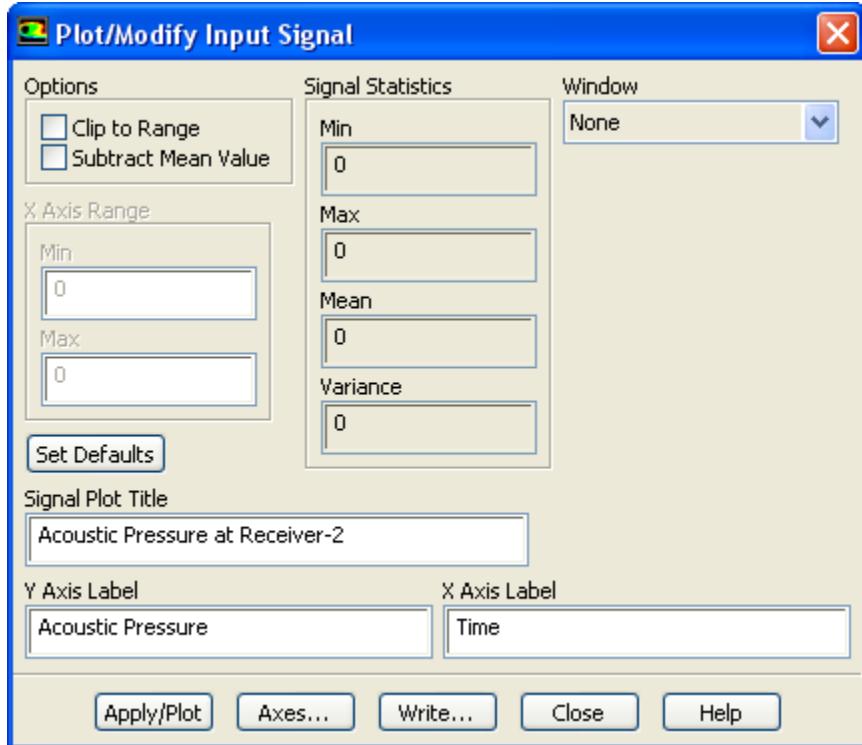

FFT analysis requires an input signal data file consisting of time-sequence data. To load an input signal data file into the *Fourier Transform Dialog Box* (p. 2176), click **Load Input File....** This displays *The Select File Dialog Box* (p. 33) where you can browse through your file directories and locate your data file containing your time-sequence data. To remove a file from the **Files** list, select it and then click **Free File Data**.

If you computed acoustic signals “on the fly”, you have the option of processing signal data from a file or processing receiver data stored in memory. To analyze signal data from an existing input file, select **Process File Data** under **Process Options** and proceed as described above. To analyze receiver data stored in memory, select **Process Receiver** under **Process Options** and select the appropriate receiver in the **Receiver** list.

Click **Plot FFT** to display the spectral analysis data.

32.11.4.2. Customizing the Input

With the input signal data file loaded into the *Fourier Transform Dialog Box* (p. 2176), you may want to customize the input signal data set. You can customize the input signal by clicking the **Plot/Modify Input Signal** button. This displays the *Plot/Modify Input Signal Dialog Box* (p. 2177) (Figure 32.96 (p. 1628)).

Figure 32.96 The Plot/Modify Input Signal Dialog Box

The *Plot/Modify Input Signal Dialog Box* (p. 2177) enables you to analyze a portion of the input signal, view input **Signal Statistics** (**Min**, **Max**, **Mean**, and **Variance**), and set title and label information for the input signal data file.

32.11.4.2.1. Customizing the Input Signal Data Set

By default, the entire data set is analyzed. To analyze a portion of the input signal, enable the **Clip to Range** option and specify the data range by entering **Min** and **Max** values under **X-Axis Range**. To have the *y* axis quantities reduced by the **Mean** value of the relevant signal property, enable the **Subtract Mean Value** option.

The **Set Defaults** button will reset the original values for the **Min** and **Max** fields under **X-Axis Range** and turn off the **Clip to Range** option.

32.11.4.2.2. Viewing Data Statistics

To aid in the signal analysis, whether for the entire input signal or for a certain range of data, the **Signal Statistics** portion of the *Plot/Modify Input Signal Dialog Box* (p. 2177) displays signal information such as minimum, maximum, and average signal values, as well as signal variance.

32.11.4.2.3. Customizing Titles and Labels

You can create a new title or edit the original title for the input signal plot by entering a text string in the **Signal Plot Title** text box. Likewise, you can create a new axis label or edit the original axis label by entering a text string into either the **Y-Axis Label** text box or the **X-Axis Label** text box.

32.11.4.2.4. Applying the Changes in the Input Signal Data

To apply any changes you have made in the [Plot/Modify Input Signal Dialog Box \(p. 2177\)](#) and view a plot of the input signal, click **Apply/Plot**.

32.11.4.3. Customizing the Output

In most practical applications with CFD data, you may want to find out how much power or energy is contained in a certain frequency range, but do not want to distinguish positive and negative frequency. In recognition of this, all the outputs from the FFT module in ANSYS FLUENT pertain to *one-sided spectra* for the range of positive frequency.

The [Fourier Transform Dialog Box \(p. 2176\)](#) ([Figure 32.95 \(p. 1627\)](#)) and [Plot/Modify Input Signal Dialog Box \(p. 2177\)](#) ([Figure 32.96 \(p. 1628\)](#)) enable you to set several different functions for the x and y axes, apply different FFT windowing techniques, and set various output options.

32.11.4.3.1. Specifying a Function for the y Axis

You can choose the y -axis function using the **Y Axis Function** drop-down list. Available options for the y -axis functions are as follows:

Power Spectral Density

is the distribution of signal power in the frequency domain. It has units of the signal magnitude squared (for example, Pa^2) and is defined as

$$\begin{aligned} E(f_0) &= |\hat{\phi}_0|^2 \\ E(f_n) &= 2 |\hat{\phi}_n|^2 \quad n = 1, 2, \dots, N/2 \end{aligned} \tag{32-37}$$

Magnitude

(or amplitude) is the square root of the power spectral density.

$$A(f_n) \equiv \sqrt{E(f_n)} \quad n = 0, 1, 2, \dots, N/2 \tag{32-38}$$

Sound Pressure Level (dB)

is the decibel level. For either general or acoustic data, when the sampled data is pressure (for example, static pressure or sound pressure), you can compute the power in decibel units using

$$L_{sp}(f_n) = 10 \log \left(\frac{p'^2(f_n)}{p_{ref}^2} \right) \quad (dB) \quad (32-39)$$

where $p'^2(f_n)$ is the power spectral density of the pressure fluctuation and p_{ref} is the reference acoustic pressure. See [Enabling the FW-H Acoustics Model \(p. 1058\)](#) for details about specifying this parameter.

Sound Amplitude (dB)

is exactly one-half of the sound pressure level in [Equation 32-39 \(p. 1630\)](#). This quantity is also applicable for acoustics analysis.

$$A_{sp}(f_n) = 10 \log \sqrt{\frac{p'^2(f_n)}{p_{ref}^2}} \quad (dB) \quad (32-40)$$

A-Weighted, Sound Pressure Level (dB A)

is the calculated sound pressure level weighted by the A-scale function to more closely approximate the frequency response of the human ear. A-Weighting is applied for loudness levels below 55 phons (55 dB at 1 kHz) and is the most commonly used weighting function. See [Figure 32.97 \(p. 1630\)](#) for a graphical representation.

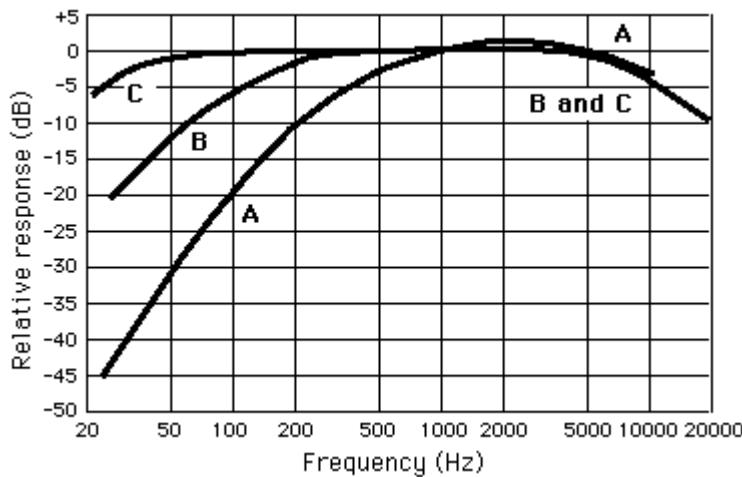

B-Weighted, Sound Pressure Level (dB B)

is the calculated sound pressure level weighted by the B-scale function. B-Weighting is applied to loudness levels between 55 and 85 phons, though it is rarely used.

C-Weighted, Sound Pressure Level (dB C)

is the calculated sound pressure level weighted by the C-scale function. C-Weighting is applied for loudness levels above 85 phons and is commonly used for high-intensity sound such as traffic studies.

Figure 32.97 A-, B-, and C-Weighting Functions

Further graphical customizations for the y axis are available by clicking the **Axes...** button. For more information, see [Modifying Axis Attributes \(p. 1601\)](#).

32.11.4.3.2. Specifying a Function for the x Axis

There are three options for the *x*-axis function you can choose from. They are all related to the discrete frequencies at which the Fourier coefficients are computed. You can apply specific analytic functions for the *x*-axis using the **X Axis Function** drop-down list.

Available options for the *x*-axis functions are:

Frequency (Hz)

is defined as:

$$f_n = \frac{1}{N \Delta t} n \quad n = 0, 1, 2, \dots, N/2 \quad (32-41)$$

where N is the number of data points used in the FFT.

Strouhal Number

is the nondimensionalized version of the frequency defined in [Equation 32-41 \(p. 1631\)](#):

$$St_n \equiv \frac{f_n L_{ref}}{U_{ref}} \quad (32-42)$$

where L_{ref} and U_{ref} are the reference length and velocity scales specified in the [Reference Values Task Page \(p. 2046\)](#).

Fourier Mode

is the index in [Equation 32-35 \(p. 1626\)](#) and/or [Equation 32-36 \(p. 1626\)](#), which represents the n th or k th term in the Fourier transform of the signal.

Octave Band (Hz)

is a range of discrete frequency bands for different octaves within the threshold of hearing. The range of each octave band is double to that of the previous band (see [Table 32.2: Octave Band Frequencies and Weightings \(p. 1631\)](#)).

1/3-Octave Band (Hz)

is a range of discrete frequency bands within the threshold of hearing.

Table 32.2 Octave Band Frequencies and Weightings

Lower Freq. (Hz)	Center Freq. (Hz)	Upper Freq. (Hz)	dB A	dB B	dB C
11	16	22	-56.7	-28.5	-8.5
22	31.5	45	-39.4	-17.1	-3.0
45	63	90	-26.2	-9.3	-0.8
90	125	180	-16.1	-4.2	-0.2
180	250	355	-8.6	-1.3	0.0
355	500	710	-3.2	-0.3	0.0
710	1000	1400	0.0	0.0	0.0

Lower Freq. (Hz)	Center Freq. (Hz)	Upper Freq. (Hz)	dB A	dB B	dB C
1400	2000	2800	1.2	-0.1	-0.2
2800	4000	5600	1.0	-0.7	-0.8
5600	8000	11200	-1.1	-2.9	-3.0
11200	16000	22400	-6.6	-8.4	-8.5

Further graphical customizations for the *x*-axis are available by clicking **Axes....** For more information, see [Modifying Axis Attributes \(p. 1601\)](#).

32.11.4.3.3. Specifying Output Options

You can write out the FFT data directly to a file by choosing the **Write FFT to File** option under **Options** in the [Fourier Transform Dialog Box \(p. 2176\)](#). Once the **Write FFT to File** option is selected, click **Write FFT** to display a file selection dialog box where you can choose a file and/or a location to hold the FFT data.

Further customizations for how the FFT data is displayed are available by clicking **Curves... .** For more information, see [Modifying Curve Attributes \(p. 1603\)](#).

32.11.4.3.4. Specifying a Windowing Technique

You can use the various windowing techniques described in [Windowing \(p. 1624\)](#) by selecting any of the **Window** options in the [Plot/Modify Input Signal Dialog Box \(p. 2177\)](#). By default, **None** is selected so that no windowing technique is applied.

32.11.4.3.5. Specifying Labels and Titles

You can assign a title for your FFT plot using the **Plot Title** text field. You can also assign *y*-axis and *x*-axis labels for your FFT plot using the **Y-Axis Label** and **X-Axis Label** text fields, respectively. By default, ANSYS FLUENT assigns the **Y-Axis Label** and the **X-Axis Label** to the particular selection of **Y-Axis Function** and **X-Axis Function**.

Chapter 33: Reporting Alphanumeric Data

ANSYS FLUENT provides tools for computing and reporting integral quantities at surfaces and boundaries. These tools enable you to find the mass flow rate and heat transfer rate through boundaries, the forces and moments on boundaries, and the area, integral, flow rate, average, and mass average (among other quantities) on a surface or in a volume. In addition, you can print histograms of geometric and solution data, set reference values for the calculation of non-dimensional coefficients, and compute projected surface areas. You can also print or save a summary report of the models, boundary conditions, and solver settings in the current case. These features are described in the following sections.

- 33.1. Reporting Conventions
- 33.2. Creating Output Parameters
- 33.3. Fluxes Through Boundaries
- 33.4. Forces on Boundaries
- 33.5. Projected Surface Area Calculations
- 33.6. Surface Integration
- 33.7. Volume Integration
- 33.8. Histogram Reports
- 33.9. Discrete Phase
- 33.10. S2S Information
- 33.11. Reference Values
- 33.12. Summary Reports of Case Settings
- 33.13. Memory and CPU Usage

Reporting tools for the discrete phase are described in *Postprocessing for the Discrete Phase* (p. 1142).

33.1. Reporting Conventions

For 2D problems, ANSYS FLUENT computes all integral quantities for a unit depth equivalent to 1 meter. This value can be adjusted to match the specific dimension of your application only by manually revising the **Depth** in the *Reference Values Task Page* (p. 2046) (see *Reference Values* (p. 1648)).

Important

The default value of **Depth** will be equivalent to 1 meter, even if the units are changed for **depth** in the *Set Units Dialog Box* (p. 1769) (e.g., if the units for **depth** are changed to cm in the *Set Units Dialog Box* (p. 1769), the value of **Depth** in the *Reference Values Task Page* (p. 2046) will be 100 cm).

For axisymmetric problems, all integral quantities are computed for an angle of 2π radians.

33.2. Creating Output Parameters

You can create output parameters, which allow you to compare reporting values for different cases, or include reporting values in the function minimized by the mesh morpher/optimizer. These are single values generated by the four types of reports, and three monitors:

- Fluxes ([Fluxes Through Boundaries \(p. 1635\)](#))
- Forces ([Forces on Boundaries \(p. 1640\)](#))
- Surface integrals ([Generating a Surface Integral Report \(p. 1644\)](#))
- Volume integrals ([Generating a Volume Integral Report \(p. 1646\)](#))
- Drag ([Monitoring Force and Moment Coefficients \(p. 1390\)](#))
- Lift ([Monitoring Force and Moment Coefficients \(p. 1390\)](#))
- Moments ([Monitoring Force and Moment Coefficients \(p. 1390\)](#))

In the [Reports Task Page \(p. 2183\)](#), click the **Parameters...** button to open the [Parameters Dialog Box \(p. 2198\)](#), where a list of created input parameters will be listed. The list of **Input Parameters** is available after performing the steps outlined in [Defining and Viewing Parameters \(p. 216\)](#). The list of **Output Parameters** is available after clicking the **Save Output Parameters...** button in the **Fluxes, Forces, Surface Integrals, Volume Integrals, Drag Monitor, Lift Monitor, and Moment Monitor** dialog boxes.

You can define the output parameters either through the various reporting and monitor dialog boxes, as described in the sections that follow, or through the **Create** menu. In the **Create** menu, you will find a list of seven items:

- **Fluxes...**
- **Forces...**
- **Surface Integrals...**
- **Volume Integrals...**
- **Drag...**
- **Lift...**
- **Moments...**

Selecting any one of these items will open their respective dialog boxes, where you will define the type of report/monitor you would like to generate. Details on how to generate the various reports/monitors are available in [Fluxes Through Boundaries \(p. 1635\)](#), [Forces on Boundaries \(p. 1640\)](#), [Generating a Surface Integral Report \(p. 1644\)](#), [Generating a Volume Integral Report \(p. 1646\)](#), and [Monitoring Force and Moment Coefficients \(p. 1390\)](#).

Once you have saved your output parameters, you can modify them by selecting the parameter in the **Output Parameters** list and clicking **Edit...**. This will open the report dialog box where you can make your changes.

In addition, you can select any of the following under the **More** menu:

Delete

displays a message in a dialog box, prompting you for a response to confirm the deletion of the output parameter.

Rename

allows you to edit the name of the output parameter.

Print to Console

reports values to the console window. If you select multiple output parameters.

Print All to Console

outputs the values from all output parameters to the console window.

Write...

allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

Write All...

prompts you for a file name and then writes the values for all of the output parameters to a file.

33.3. Fluxes Through Boundaries

This section contains information about generating a flux report. For more background information, see [Fluxes Through Boundaries](#) in the [Theory Guide](#).

For additional information, please see the following sections:

[33.3.1. Generating a Flux Report](#)

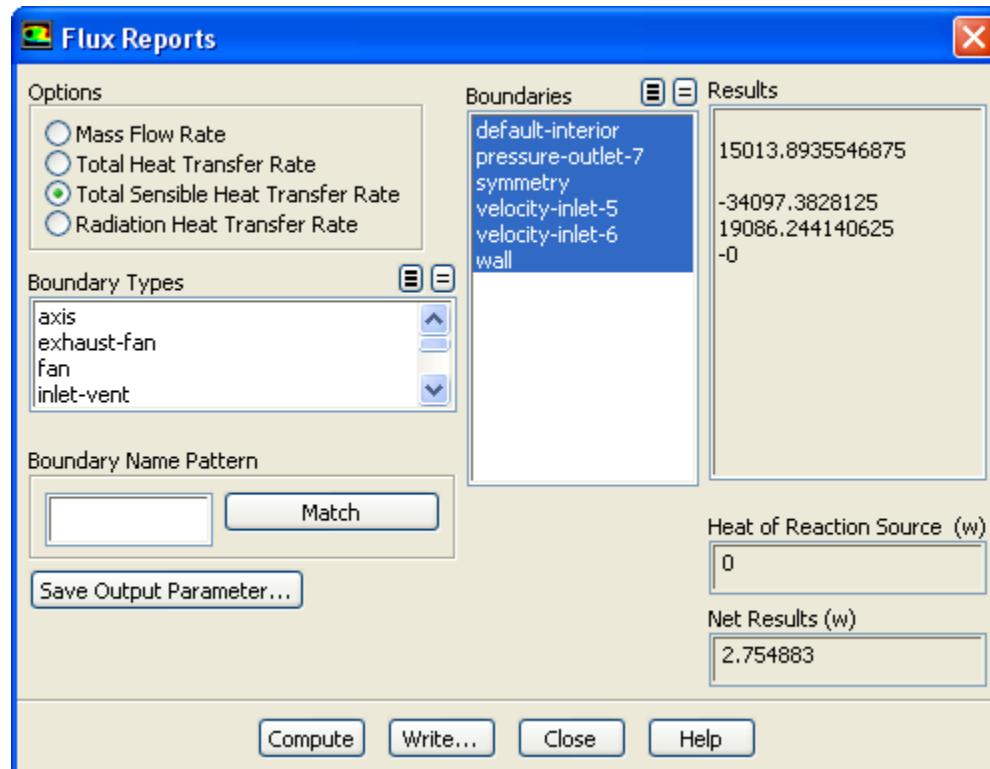

[33.3.2. Flux Reporting for Reacting Flows](#)

33.3.1. Generating a Flux Report

To obtain a report of mass flow rate, total heat transfer rate, total sensible heat transfer rate, or radiation heat transfer rate on selected boundary zones, use the [Flux Reports Dialog Box \(p. 2184\)](#) (*Figure 33.1 (p. 1635)*).

Reports →  Fluxes → Set Up...

Figure 33.1 The Flux Reports Dialog Box

The steps for generating the report are as follows:

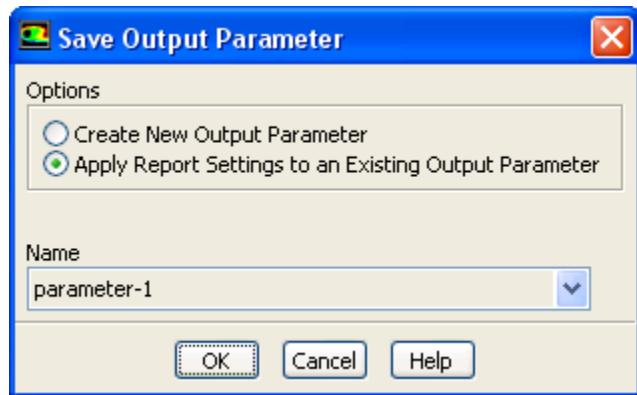

1. Specify which flux computation you are interested in by selecting **Mass Flow Rate**, **Total Heat Transfer Rate**, **Total Sensible Heat Transfer Rate**, or **Radiation Heat Transfer Rate** under **Options**.
2. In the **Boundaries** list, choose the boundary zone(s) on which you want to report fluxes.

If you want to select several boundary zones of the same type, you can select that type in the **Boundary Types** list instead. All of the boundaries of that type will be selected automatically in the **Boundaries** list (or deselected, if they are all already selected).

Another shortcut is to specify a **Boundary Name Pattern** and click **Match** to select boundary zones with names that match the specified pattern. For example, if you specify **wall***, all boundaries whose names begin with **wall** (e.g., **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all boundaries whose names consist of **wall** followed by a single character will be selected (or deselected, if they are all already selected).

3. Click **Save Output Parameter...**. The *Save Output Parameter Dialog Box* (p. 2201) (*Figure 33.2* (p. 1636)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. The default report name format is **report-type-n** (e.g. **flux-1**).

Figure 33.2 The Save Output Parameter Dialog Box

After the output parameter is created, it is listed in the *Parameters Dialog Box* (p. 2198), accessed via the **Parameters...** button in the *Reports Task Page* (p. 2183). You can create any number of output parameters of this report type.

4. Click the **Compute** button to display the results of the selected flux computation for each selected boundary zone. The **Net Results** field will show the summation of the individual zone flux results.

Important

Additional steps must be taken prior to generating a flux report for an interior boundary zone that has the same fluid defined on either side. In such a case, the area vectors of the cell faces associated with the zone may have been automatically defined in an inconsistent manner when the mesh file was read into the solver. Since the flux for each individual cell face is calculated with respect to its area vector, such an inconsistency leads to inaccurate results when the face fluxes are summed to calculate the total flux of the boundary zone.

To ensure accurate flux results for such an interior zone, you must orient the area vectors by changing the definition of the zone **Type** to **wall**. You should then change the **Type** back to **interior** and proceed to generate the flux report.

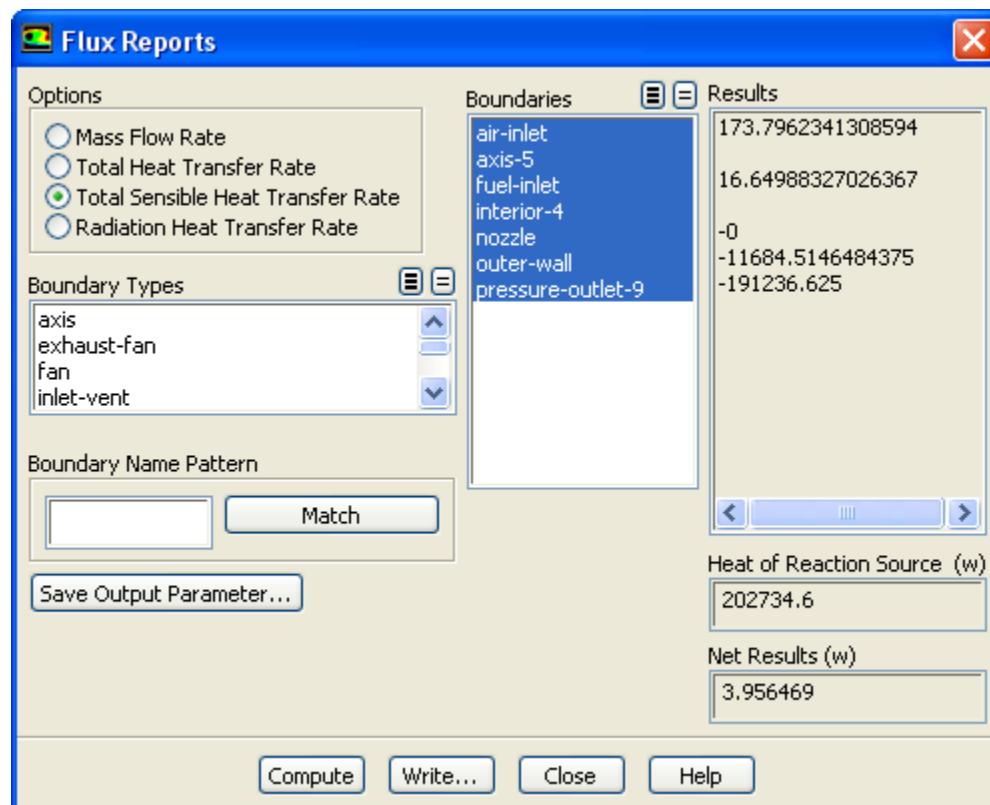

Note that the fluxes are reported exactly as computed by the solver. Therefore, they are inherently more accurate than those computed with the **Flow Rate** option in the *Surface Integrals Dialog Box* (p. 2188) (described in *Surface Integration* (p. 1644)).

33.3.2. Flux Reporting for Reacting Flows

To report heat transfer for reacting flows, one of models in the [Species Model Dialog Box](#) (p. 1814) must be enabled for the **Total Sensible Heat Transfer Rate** option to appear in the [Flux Reports Dialog Box](#) (p. 2184). For reacting flows, ANSYS FLUENT produces two kinds of reports which use a different treatment at the flow boundaries:

- **Total Heat Transfer Rate** reports the total enthalpy flux which consists of the thermal enthalpy, plus the species formation enthalpy when **Volumetric Reactions** are enabled. The heat rate based on this definition is a conserved quantity in reacting flows. See [Heat Transfer Theory](#) in the [Theory Guide](#) for details.
- **Total Sensible Heat Transfer Rate** reports the total energy flux as defined in [Equation 5–2](#) in the [Theory Guide](#). Note that in reacting flows, this is not a conserved quantity and the addition or removal of heat due to the chemical reactions ([Equation 5–10](#) in the [Theory Guide](#)) is reported separately in the **Heat of Reaction Source** field, as shown in [Figure 33.3](#) (p. 1637). If you have more than one reaction defined in your case, the **Heat of Reaction Source** reported is the sum of the heat for all reactions. For exothermic reactions the **Heat of Reaction Source** is reported as a positive quantity, while for endothermic reactions it will be a negative quantity.

Figure 33.3 The Flux Reports Dialog Box

Important

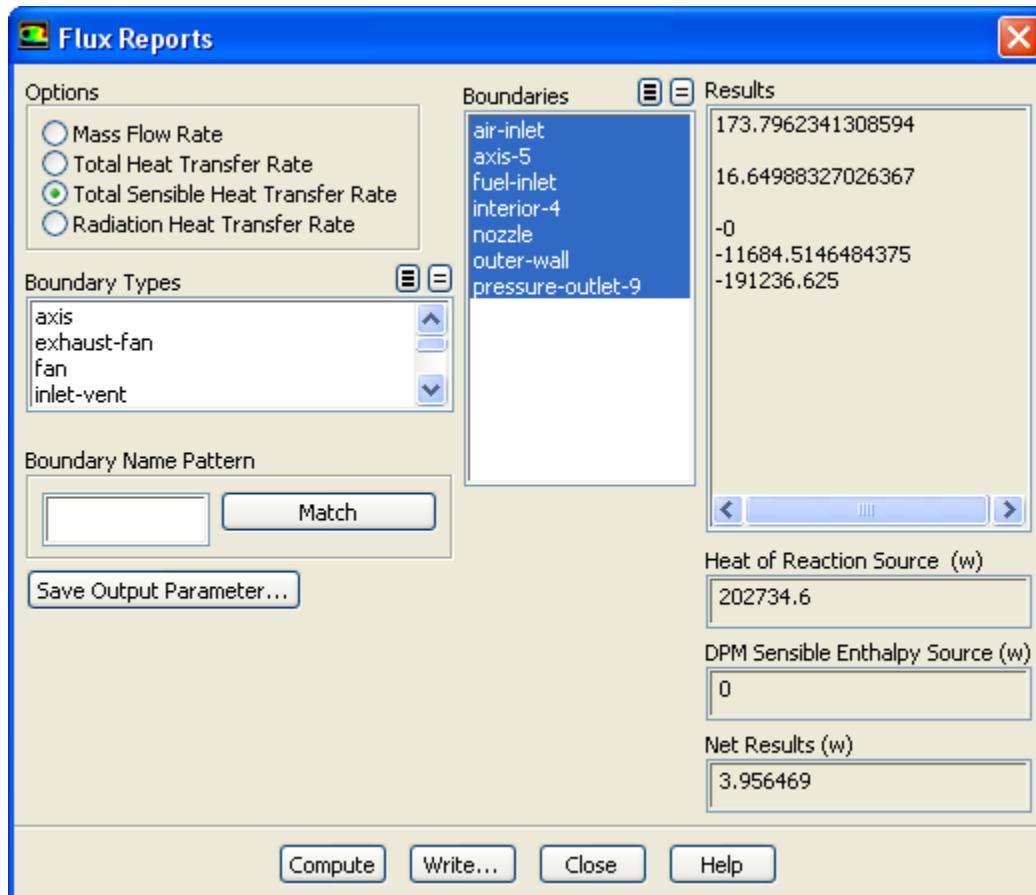

Note that both the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options report a **Net Result**, which may be used as an indication of the energy balance for the case. In general, and if heat sources other than the heat of reaction and DPM are not included in your problem, the **Net Result** reported in both the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options should be a small number for a converged calculation. However, if a reacting case is not well converged for both energy and species transport equations, the **Net Result** reported in the **Total Heat Transfer Rate** and **Total Sensible Heat Transfer Rate** options may differ. In that case, you may consider iterating further to achieve a fully converged solution. In addition, please refer to the sections that follow for special considerations when including particles, multiphase models, or other volumetric energy sources.

Important

Please note that for the non-premixed and partially premixed models the **Heat of Reaction Source** is calculated as the difference of the net **Total Heat Transfer Rate** and the net **Total Sensible Heat Transfer Rate**. The **Heat of Reaction** field function is not available for the non-premixed and partially-premixed models.

33.3.2.1. Flux Reporting with Particles

If you are using the discrete phase model (DPM), the contributions from the particle injections are reported separately and are included in the net mass and heat balance results. Consequently, the **Mass Flow Rate** report includes the **DPM Mass Source**, the **Total Heat Transfer Rate** report includes the **DPM Enthalpy Source**, and the **Total Sensible Heat Transfer Rate** includes the **DPM Sensible Enthalpy Source** ([Figure 33.4](#) (p. 1639)).

Figure 33.4 The Flux Reports Dialog Box with DPM

Important

In the case of reacting flows with the DPM model, the **Heat of Reaction Source** entry reports the heat of all homogeneous reactions in the continuous phase, while the heat released or consumed due to particle reactions (e.g. char combustion) is reported in the **DPM Sensible Enthalpy Source** field.

33.3.2.2. Flux Reporting with Multiphase

If you are using any of the multiphase models, the mass or heat rates can be reported separately for each phase and for the mixture phase. Please note that if your multiphase model includes mass or heat transfer processes between phases, the mass and heat transferred across the phases will be reported as an imbalance in the report of each phase. In order to check the overall balances for the multiphase cases you should select the mixture phase for your report. In that case, the report will include the sum of the fluxes and sources for all phases included in your model.

Finally, if you are solving a multiphase problem that includes chemical reactions, you should be aware of the following conventions when you are requesting a **Total Sensible Heat Transfer Rate** report:

- If you select one of the phases with gas phase chemical reactions, the **Heat of Reaction Source** will only include contributions from reactions in the particular phase.

- When you report the **Total Sensible Heat Transfer Rate** for the mixture phase, the **Heat of Reaction Source** entry will report the sum of the heat of reaction of all gas phase reactions in all phases plus the heat of any heterogeneous reactions that take place.

33.3.2.3. Flux Reporting with Other Volumetric Sources

The reported mass and heat balances address the flow that enters or leaves the domain through boundaries and the contributions from DPM sources; they do not include the contributions from user-defined and other volumetric sources, such as the heat exchanged in the Heat Exchanger Model. For this reason, a mass or heat imbalance may be reported. In that case, and in a converged calculation, the reported imbalance will be equal to the volumetric source.

33.4. Forces on Boundaries

For selected wall zones, you can compute and report the forces along a specified vector, the moments about a specified center and along a specified axis, and the coordinates of the center of pressure. This feature is useful for reporting, for instance, aerodynamic quantities such as lift, drag, and moment coefficients, as well as the center of pressure for an airfoil.

For additional information about forces, moments, and the center of pressure, see [Computing Forces, Moments, and the Center of Pressure](#) in the [Theory Guide](#).

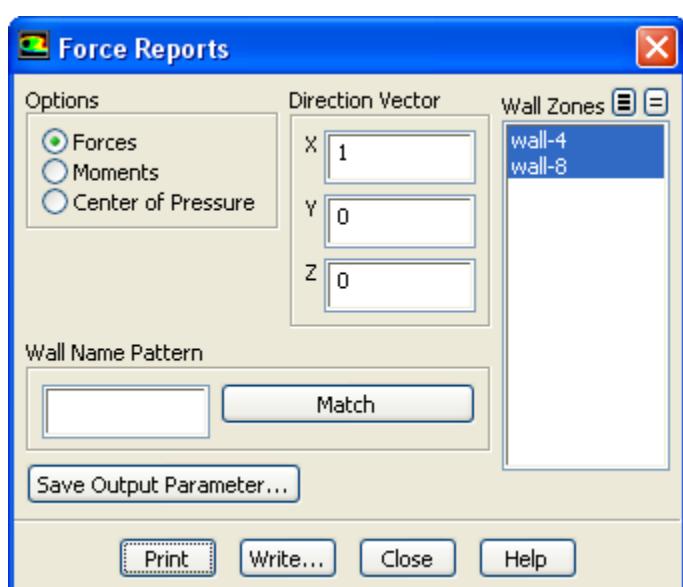

For additional information, please see the following section:

33.4.1. Generating a Force, Moment, or Center of Pressure Report

To obtain a report (for selected wall zones) of forces along a specified vector, moments about a specified center and along a specified axis, or the center of pressure, use the [Force Reports Dialog Box](#) (p. 2186) ([Figure 33.5](#) (p. 1640)).

Reports → Forces → Set Up...

Figure 33.5 The Force Reports Dialog Box

The steps for generating the report are as follows:

1. Specify the type of report in which you are interested by selecting **Forces**, **Moments**, or **Center of Pressure** from the **Options** list.
2. Define the settings associated with report you are generating:
 - a. For a force report, enter the **X**, **Y**, and **Z** components of the **Force Vector** along which the forces will be computed.
 - b. For a moment report, enter the **X**, **Y**, and **Z** coordinates of the **Moment Center** about which the moments will be computed, as well as the **X**, **Y**, and **Z** components of the **Moment Axis** along which the moments will be computed.
 - c. For a center of pressure report, define the line (for 2D geometries) or plane (for 3D geometries) on which you want to calculate the center of pressure. The line or plane must have one of its coordinate values fixed (e.g., a line defined as $y = 10$). Select the axis (**X**, **Y**, or **Z**) in the **Coordinate** group box, and then enter the fixed **Value**. See the example at the end of this section for further details.

Important

If F_x (the x -component of the force) is zero, then either the **Y** or **Z** coordinate can be fixed. If F_y is zero, then either the **X** or **Z** coordinate can be fixed. If F_z is zero, then either the **X** or **Y** coordinate can be fixed.

3. In the **Wall Zones** list, select the wall zone(s) for which you want a report of the forces, moments, or pressure center.

If you have a large number of wall zones, it may be useful to specify a **Wall Name Pattern** and click **Match**. This selects all of the wall zones with names that match the specified pattern. For example, if you specify **out***, all walls whose names begin with **out** (e.g., **outer-wall-top**, **outside-wall**) will be selected automatically. If a wall zone that matches the name pattern is already selected when **Match** is clicked, it will be deselected. If you specify **out?**, all walls whose names consist of **out** followed by a single character will be selected (or deselected, if they are already selected).

4. Click **Save Output Parameter....** The *Save Output Parameter Dialog Box* (p. 2201) (*Figure 33.2* (p. 1636)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. The default report name format is report-type-n (e.g. force-1).

After the output parameter is created, it is listed in the *Parameters Dialog Box* (p. 2198). You can create any number of output parameters of this report type.

5. Click the **Print** button if you want the results displayed in the console window, or click **Write...** to save it to a file.

If you selected **Forces** under **Options**, the pressure force, viscous force (if appropriate), total forces, pressure coefficient, viscous coefficient, and total coefficients for each selected wall zone will be displayed or saved.

If you selected **Moments**, the pressure moments, viscous moments (if appropriate), total moments, pressure coefficient, viscous coefficient and total coefficients for the wall zones about the specified center will be displayed or saved. Additionally, the moments and coefficients in the direction of the specified axis will be displayed or saved. The report will include the values for the individual wall zones, as well as the net values for all of the wall zones combined. See [Computing Forces](#),

Moments, and the Center of Pressure in the [Theory Guide](#) for details about computing forces and moments.

If you selected **Center of Pressure**, then ANSYS FLUENT displays or saves the coordinates about which the moment is zero.

Important

You cannot save your output parameter if **Center of Pressure** is selected.

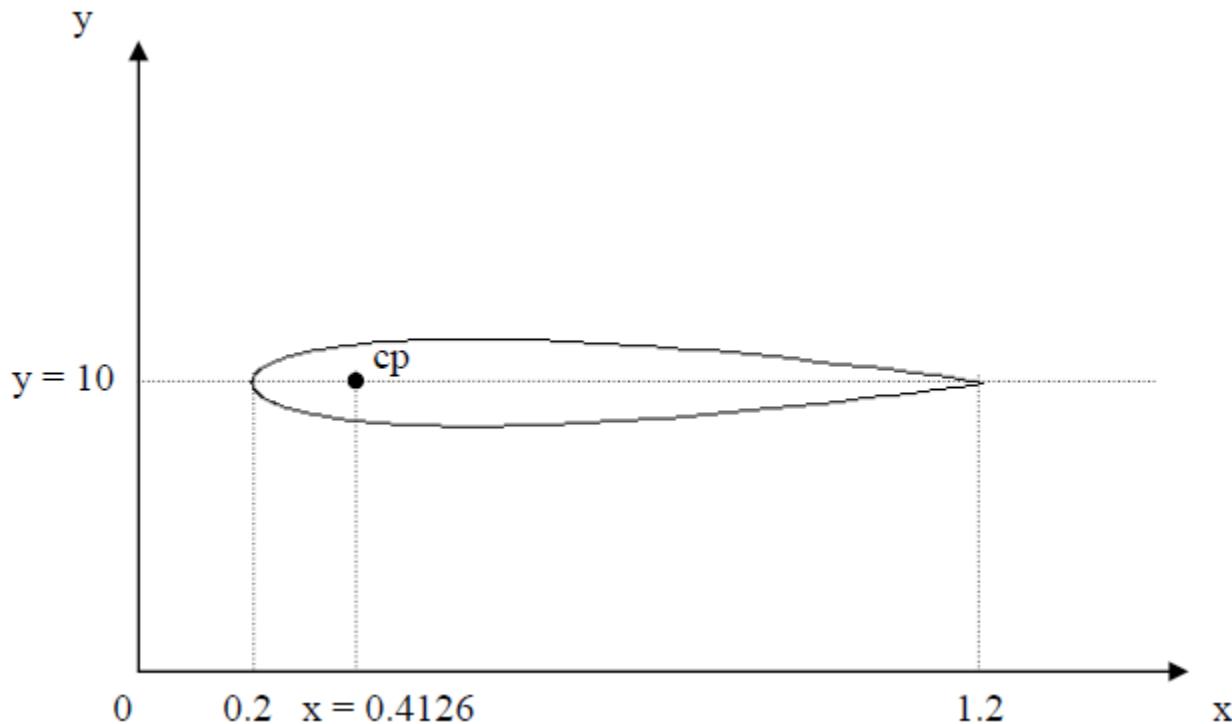

Important

Note that the reported force and moment coefficients are a function of the values entered in the **Reference Values** task page (as described in [Computing Forces, Moments, and the Center of Pressure in the Theory Guide](#)). Therefore, appropriate values must be entered in the **Reference Values** task page to get meaningful results.

33.4.1.1. Example

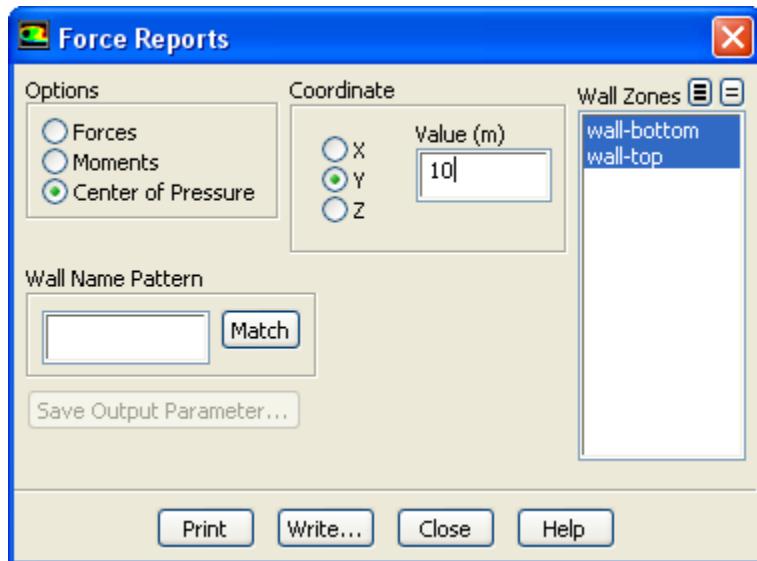

To demonstrate how you would generate and interpret the center of pressure report, consider an airfoil of chord length 1 m (shown in [Figure 33.6 \(p. 1642\)](#)).

Figure 33.6 An Airfoil with its Computed Center of Pressure

Open the **Force Reports** dialog box and perform the steps that follow.

Reports → Forces → Set Up...

Figure 33.7 The Force Reports Dialog Box for a Center of Pressure Report

1. Select **Center of Pressure** from the **Options** list.
2. Define the line on which the center of pressure will be calculated. In this case, the **Y** coordinate for the line has a fixed **Value** of 10.
3. Select the **Wall Zones** that are relevant for the computation.
4. Click **Print** to have the coordinates of the center of pressure displayed in the console window.

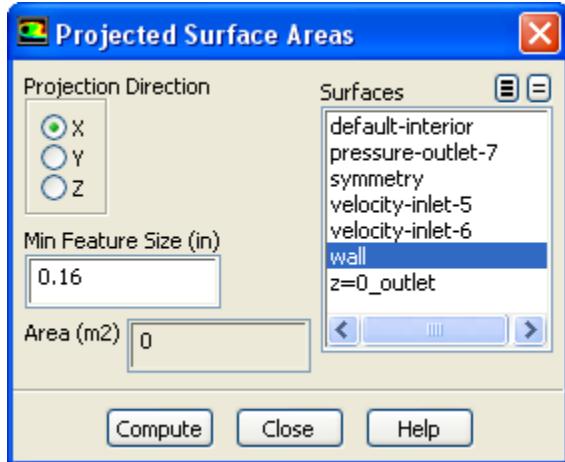

The report generated will be in the following form:

```
Pressure Center Coordinates (in m):
X = 0.41267981
Y = 10
```

33.5. Projected Surface Area Calculations

You can use the *Projected Surface Areas Dialog Box* (p. 2187) (*Figure 33.8* (p. 1644)) to compute an estimated area of the projection of selected surfaces along the x , y , or z axis (i.e., onto the yz , xz , or xy plane).

Reports → **Projected Areas** → **Set Up...**

Figure 33.8 The Projected Surface Areas Dialog Box

The steps for calculating the projected area are as follows:

1. Select the **Projection Direction (X, Y, or Z)**.
2. Choose the surface(s) for which the projected area is to be calculated in the **Surfaces** list.
3. Set the **Min Feature Size** to the length of the smallest feature in the geometry that you want to resolve in the area calculation. (You can just use the default value to start with, if you are not sure of the size of the smallest geometrical feature.)
4. Click on **Compute**. The area will be displayed in the **Area** box and in the console window.
5. To improve the accuracy of the area calculation, reduce the **Min Feature Size** by half and recompute the area. Repeat this step until the computed **Area** stops changing (or you reach memory capacity).

This feature is available only for 3D domains.

33.6. Surface Integration

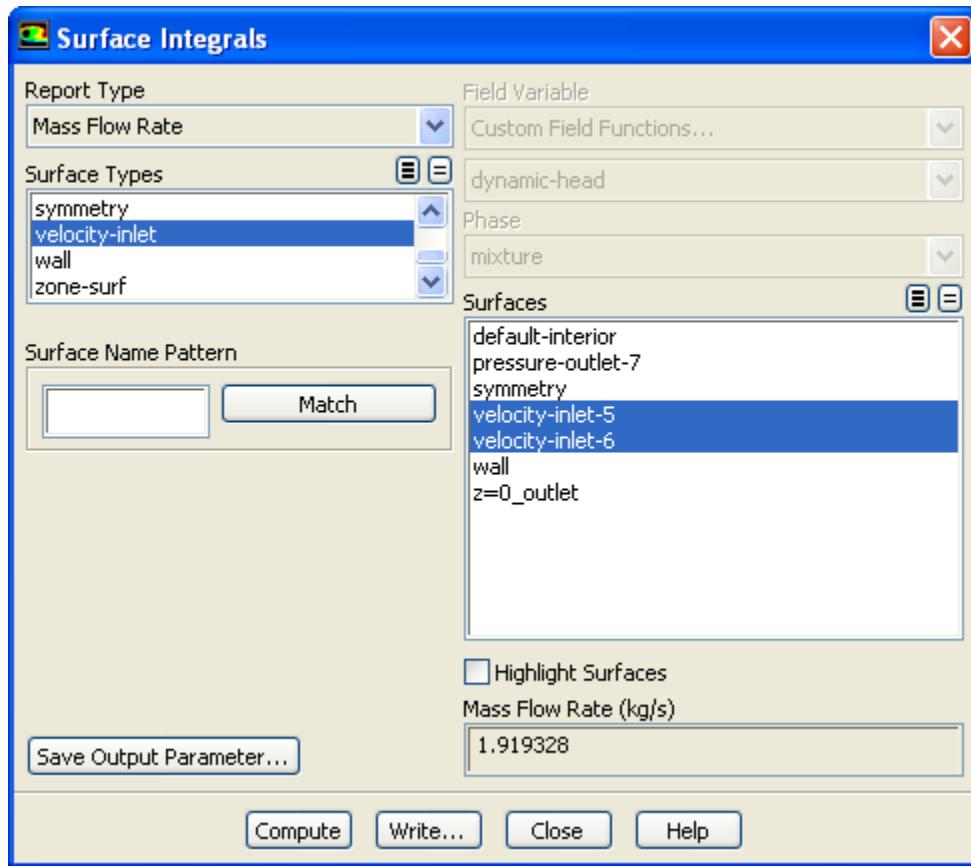

For additional information about surface integrals, see [Computing Surface Integrals](#) in the Theory Guide.

For additional information, please see the following section:

33.6.1. Generating a Surface Integral Report

To obtain a report for selected surfaces of the area, mass flow rate, or volume flow rate, or the integral, flow rate, standard deviation, sum, facet maximum, facet minimum, uniformity index (weighted by mass or area), vertex maximum, vertex minimum, or mass-, area-, facet-, or vertex-averaged quantity of a specified field variable, use the [Surface Integrals Dialog Box \(p. 2188\)](#) ([Figure 33.9 \(p. 1645\)](#)).

Reports → Surface Integrals → Set Up...

Figure 33.9 The Surface Integrals Dialog Box

The steps for generating the report are as follows:

1. Specify which type of report you are interested in by selecting **Area**, **Area-Weighted Average**, **Facet Average**, **Facet Minimum**, **Facet Maximum**, **Flow Rate**, **Integral**, **Mass Flow Rate**, **Mass-Weighted Average**, **Standard Deviation**, **Sum**, **Uniformity Index - Mass Weighted**, **Uniformity Index - Area Weighted**, **Vertex Average**, **Vertex Minimum**, **Vertex Maximum**, or **Volume Flow Rate** in the **Report Type** drop-down list.
2. If you are generating a report of area, mass flow rate, or volume flow rate, skip to the next step. Otherwise, use the **Field Variable** drop-down lists to select the field variable to be used in the surface integrations. First, select the desired category in the upper drop-down list. You can then select a related quantity from the lower list. (See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
3. In the **Surfaces** list, choose the surface(s) on which to perform the surface integration.

If you want to select several surfaces of the same type, you can select that type in the **Surface Types** list instead. All of the surfaces of that type will be selected automatically in the **Surfaces** list (or deselected, if they are all selected already).

Another shortcut is to specify a **Surface Name Pattern** and click **Match** to select surfaces with names that match the specified pattern. For example, if you specify **wall***, all surfaces whose names begin with **wall** (e.g., **wall-1**, **wall-top**) will be selected automatically. If they are all selected already, they will be deselected. If you specify **wall?**, all surfaces whose names consist of **wall** followed by a single character will be selected (or deselected, if they are all selected already).

4. Click **Save Output Parameter....** The *Save Output Parameter Dialog Box* (p. 2201) (*Figure 33.2* (p. 1636)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. The default report name format is report-type-n (e.g. surface-in-integral-1).

After the output parameter is created, it is listed in the *Parameters Dialog Box* (p. 2198). You can create any number of output parameters of this report type.

5. Click on the **Compute** button. Depending on the type of report you have selected, the label for the result will change to **Area**, **Area-Weighted Average**, **Average of Facet Values**, **Minimum of Facet Values**, **Maximum of Facet Values**, **Flow Rate**, **Integral**, **Mass Flow Rate**, **Mass-Weighted Average**, **Standard Deviation**, **Sum of Facet Values**, **Uniformity Index Mass-Wt.**, **Uniformity Index Area-Wt.**, **Average of Surface Vertex Values**, **Minimum of Vertex Values**, **Maximum of Vertex Values**, or **Volumetric Flow Rate** as appropriate. The computed results will also be printed in the ANSYS FLUENT console.
6. To save the computed results to a file, click the **Write...** button and specify the filename in the resulting **Select File** dialog box.

Note the following items:

- Mass averaging “weights” toward regions of higher velocity (i.e., regions where more mass crosses the surface).
- Flow rates reported using the *Surface Integrals Dialog Box* (p. 2188) are not as accurate as those reported with the *Flux Reports Dialog Box* (p. 2184) (described in *Fluxes Through Boundaries* (p. 1635)).
- The facet and vertex average options are recommended for zero-area surfaces.
- The uniformity index represents how a specified field variable varies over a surface, where a value of 1 indicates the highest uniformity. The uniformity index can be weighted by area or mass: the area-weighted uniformity index captures the variation of the quantity (e.g., the species concentration), whereas the mass-weighted uniformity index captures the variation of the flux (e.g., the species flux). See *Computing Surface Integrals* in the *Theory Guide* for the equations used to calculate the uniformity index.

33.7. Volume Integration

For additional information about volume integrals, see *Computing Volume Integrals* in the *Theory Guide*.

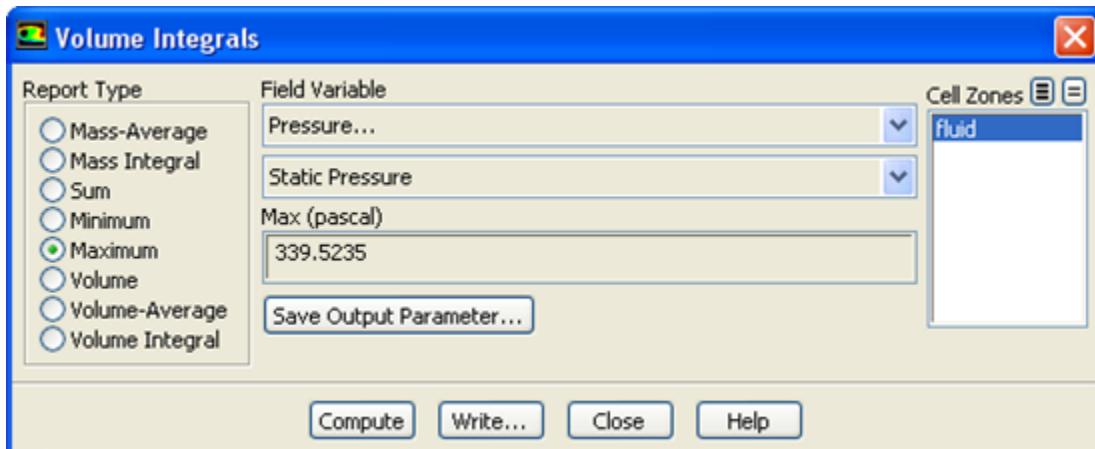

For additional information, please see the following section:

33.7.1. Generating a Volume Integral Report

To obtain a report (of quantities such as the volume, sum, minimum, maximum, volume integral, volume-weighted average, mass-weighted integral, or mass-weighted average) for selected cell zones for a specified field variable, use the *Volume Integrals Dialog Box* (p. 2192) (*Figure 33.10* (p. 1647)).

Reports → **Volume Integrals** → **Set Up...**

Figure 33.10 The Volume Integrals Dialog Box

The steps for generating the report are as follows:

1. Specify which type of report you are interested in by selecting **Volume**, **Sum**, **Max**, **Min**, **Volume Integral**, **Volume-Average**, **Mass Integral**, or **Mass-Average** under **Options**.
2. If you are generating a report of volume, skip to the next step. Otherwise, use the **Field Variable** drop-down lists to select the field variable to be used in the integral, sum, or averaged volume integrations. First, select the desired category in the upper drop-down list. You can then select a related quantity from the lower list. (See *Field Function Definitions* (p. 1653) for an explanation of the variables in the list.)
3. In the **Cell Zones** list, choose the zones on which to compute the volume, sum, max, min, volume integral, volume-weighted average, mass integral, or mass-averaged quantity.
4. Click **Save Output Parameter...**. The *Save Output Parameter Dialog Box* (p. 2201) (Figure 33.2 (p. 1636)) will open where you will specify the name of the newly created output parameter, or overwrite an existing output parameter of the same type. The default report name format is report-type-n (e.g. volume-integral-1).

After the output parameter is created, it is listed in the *Parameters Dialog Box* (p. 2198). You can create any number of output parameters of this report type.

5. Click on the **Compute** button. Depending on the type of report you have selected, the label for the result will change to **Total Volume**, **Sum**, **Max**, **Min**, **Total Volume Integral**, **Volume-Weighted Average**, **Total Mass-Weighted Integral**, or **Mass-Weighted Average**, as appropriate.

The computed results will also be printed in the ANSYS FLUENT console window.

6. To save the computed results to a file, click the **Write...** button and specify the filename in the resulting **Select File** dialog box.

33.8. Histogram Reports

In ANSYS FLUENT, you can print geometric and solution data in the console (text) window in histogram format or plot a histogram in the graphics window. Graphical display of histograms and the procedures for defining a histogram are discussed in *Histograms* (p. 1600).

The number of cells, the range of the selected variable or function, and the percentage of the total number of cells in the interval will be reported, as in the example below:

```
0 cells below 1.195482 (0 %)
2 cells between 1.195482 and 1.196048 (4.166667 %)
```

```
1 cells between 1.196048 and 1.196614 (2.0833333 %)
0 cells between 1.196614 and 1.19718 (0 %)
0 cells between 1.19718 and 1.197746 (0 %)
2 cells between 1.197746 and 1.198312 (4.1666667 %)
1 cells between 1.198312 and 1.198878 (2.0833333 %)
6 cells between 1.198878 and 1.199444 (12.5 %)
9 cells between 1.199444 and 1.20001 (18.75 %)
25 cells between 1.20001 and 1.200576 (52.083333 %)
2 cells between 1.200576 and 1.201142 (4.1666667 %)
0 cells above 1.201142 (0 %)
```

To generate such a printed histogram, use the *Histogram Dialog Box* (p. 2172).

Reports → Histogram → Set Up...

Follow the instructions in *Histograms* (p. 1600) for generating histogram plots, but click on **Print** instead of **Plot** to create the report.

33.9. Discrete Phase

ANSYS FLUENT allows you to write particle states (position, velocity, diameter, temperature, and mass flow rate) to files at various boundaries and planes (lines in 2D) using the *Sample Trajectories Dialog Box* (p. 2193) (*Figure 25.41* (p. 1164)). Information about discrete phase reporting is discussed in detail in *Sampling of Trajectories* (p. 1163), *Histogram Reporting of Samples* (p. 1165), and *Summary Reporting of Current Particles* (p. 1166).

33.10. S2S Information

ANSYS FLUENT allows you to view the values of the view factor and radiation emitted from one zone to another. You will use the *S2S Information Dialog Box* (p. 2317) (*Figure 14.25* (p. 789)) to generate a report of these values. For details on reporting S2S information, refer to *Reporting Radiation in the S2S Model* (p. 788).

33.11. Reference Values

You can control the reference values that are used in the computation of derived physical quantities and non-dimensional coefficients. These reference values are used only for postprocessing.

Some examples of the use of reference values include the following:

- Force coefficients use the reference area, density, and velocity. In addition, the pressure force calculation uses the reference pressure.
- Moment coefficients use the reference length, area, density and velocity. In addition, the pressure force calculation uses the reference pressure.
- Reynolds number uses the reference length, density, and viscosity.
- Pressure and total pressure coefficients use the reference pressure, density, and velocity.
- Entropy uses the reference density, pressure, and temperature.
- Skin friction coefficient uses the reference density and velocity.
- Heat transfer coefficient uses the reference temperature.
- Turbomachinery efficiency calculations use the ratio of specific heats.

For additional information, please see the following sections:

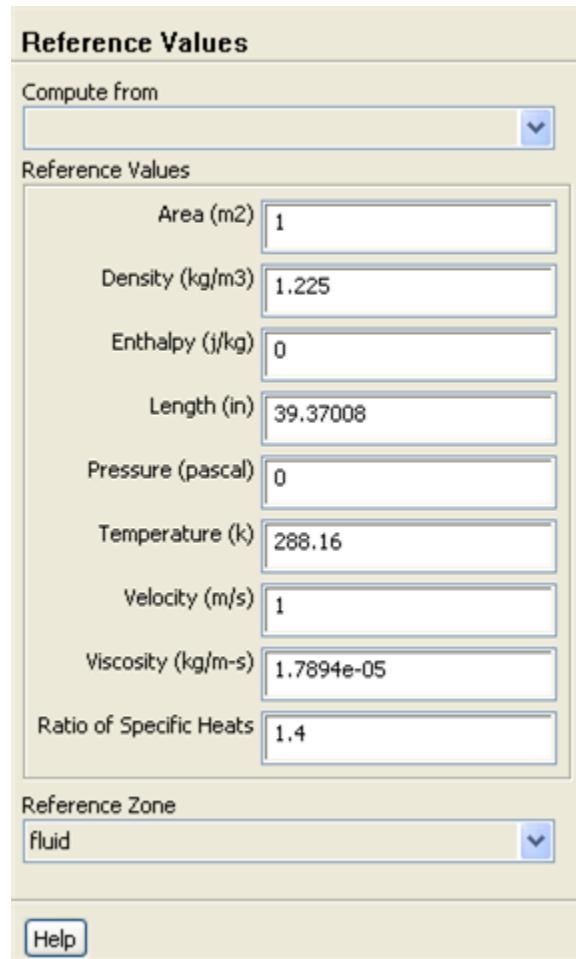

- 33.11.1. Setting Reference Values
- 33.11.2. Setting the Reference Zone

33.11.1. Setting Reference Values

To set the reference quantities used for computing normalized flow-field variables, use the [Reference Values Task Page](#) (p. 2046) (*Figure 33.11* (p. 1649)).

◆ Reference Values

Figure 33.11 The Reference Values Task Page

You can input the reference values manually or compute them based on values of physical quantities at a selected boundary zone. The reference values to be set are **Area**, **Density**, **Enthalpy**, **Length**, **Pressure**, **Temperature**, **Velocity**, dynamic **Viscosity**, and **Ratio Of Specific Heats**.

For 2D problems, an additional quantity, **Depth**, can also be defined. This quantity will be used for reporting fluxes and forces, as well as relevant variables computed using the [Surface Integrals Dialog Box](#) (p. 2188) and the [Volume Integrals Dialog Box](#) (p. 2192) (e.g. **Area**, **Flow Rate**, **Mass Flow Rate**, **Volume**, etc.). You should verify that the value and units of **Depth** corresponds to the depth dimension of your application prior to reporting any of the variables above.

Important

The units for **Depth** are set independently from the units for **Length** in the [Set Units Dialog Box \(p. 1769\)](#).

If you want to compute reference values from the conditions set on a particular boundary zone, select the zone in the **Compute From** drop-down list. Note, however, that depending on the boundary condition used, only some of the reference values may be set. For example, the reference length and area will not be set by computing the reference values from a boundary condition; you will need to set these manually.

To set the values manually, simply enter the value for each under the **Reference Values** heading.

33.11.2. Setting the Reference Zone

If you are solving a flow involving multiple reference frames or sliding meshes, you can plot velocities and other related quantities relative to the motion of a specified “reference zone”. Choose the desired zone in the **Reference Zone** drop-down list. Changing the reference zone allows you to plot velocities (and total pressure, temperature, etc.) relative to the motion of different zones. See [Modeling Flows with Moving Reference Frames \(p. 535\)](#) for details about postprocessing of relative quantities.

33.12. Summary Reports of Case Settings

You may sometimes find it useful to get a report of the current settings in your case. In ANSYS FLUENT, you can list the settings for physical models, boundary conditions, material properties, and solver controls. This report allows you to get an overview of your current problem definition quickly, instead of having to check the settings in each dialog box.

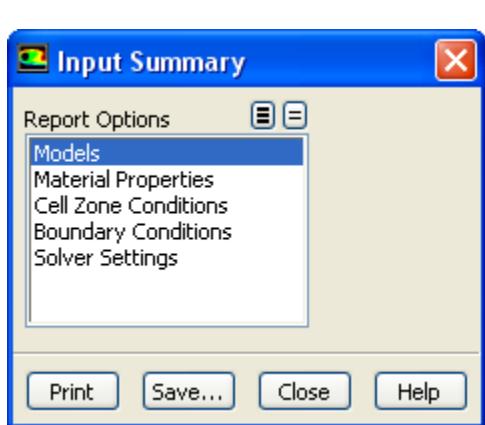

For additional information, please see the following section:

33.12.1. Generating a Summary Report

To generate a summary report you will use the [Input Summary Dialog Box \(p. 2316\) \(Figure 33.12 \(p. 1650\)\)](#).

Report → Input Summary...

Figure 33.12 The Input Summary Dialog Box

The steps are as follows:

1. Select the information you would like to see in the report (**Models**, **Boundary Conditions**, **Solver Controls**, and/or **Material Properties**) in the **Report Options** list.
2. To print the information to the ANSYS FLUENT console window, click on the **Print** button. To save the information to a text file, click on the **Save...** button and specify the filename in the resulting **Select File** dialog box.

33.13. Memory and CPU Usage

There are two types of system reporting, which are accessed using the text interface, that can be performed while running ANSYS FLUENT processes:

- Reporting the status of each of the ANSYS FLUENT processes, including memory and CPU usage (report/system/proc-stats).
- Reporting the status of the machines where ANSYS FLUENT processes have been spawned, including memory and CPU status (report/system/sys-stats).

Important

Note that the report/system/sys-stats text command is only applicable for Windows (ntx86 and win64) and Linux (Inamd64, and Inia64) platforms. Similarly, the report/system/proc-stats text command is only applicable for Windows, and Linux platforms.

The type of information you can expect to see printed to the console when running in parallel, using the report/system/proc-stats text command, is

ID	Mem Usage (MB)				CPU Time Usage (Seconds)		
	Current	Peak	Page Fault	Fault	User	Kernel	Elapsed
host	31.2422	285.242	9.439e+004		34.4531	1.90625	269.593
n0	525.949	743.438	3.933e+005		20.7656	3.70313	264.406
n1	516.063	737.438	3.867e+005		84.2813	166.328	264.437
Total	1073.25	1766.12	8.744e+005		139.5	171.938	-

Under Mem Usage (MB)

Current

is the virtual memory usage at this very moment.

Peak

is the peak virtual memory usage.

Page Fault

is the number of page faults that have occurred.

Under CPU Time Usage (Seconds):

User

is the CPU time used by user processes.

Kernel

is the CPU time used by system kernel.

Elapsed

is the wall clock time elapsed since the process startup.

When using the `report/system/sys-stats` text command, where ANSYS FLUENT processes have been spawned on five machines, the following results are displayed:

Hostname	CPU			System Mem (MB)	
	Number	Clock (MHz)	Load	Total	Available
deva01	2	2211.38	0.2	32205.2	31479
deva03	2	2211.34	0	32205.2	21560.4
deva04	2	2211.34	0	16093.7	12075.8
deva05	2	2211.34	0	16093.7	14624.5
deva06	2	2211.34	0.07	16093.7	12095.4
Total	10	-	-	112691	91835.2

Under CPU

Number

is the number of processors on the machine.

Clock

is the processor speed.

Load

is the work load on the machine.

Under System Mem (MB)

Total

is the total system memory on the machine.

Available

is the available system memory on the machine.

You can use the two commands together to plan ANSYS FLUENT jobs and machines accordingly. It may also be useful to diagnose performance problems.

Chapter 34: Field Function Definitions

You must select flow variables for a number of tasks in ANSYS FLUENT. The values are computed and placed in temporary memory that is allocated for storing the results for each cell. For example, the **Compute** command associated with a dialog box that contains the field variable drop-down list calculates the values of the selected function and places them into temporary storage.

Node, Cell, and Facet Values (p. 1653) and *Velocity Reporting Options* (p. 1655) provide some general information related to the field variables. In *Field Variables Listed by Category* (p. 1656), the variables are listed by category in *Table 34.1:Pressure and Density Categories* (p. 1658) – *Table 34.15:Acoustics Category* (p. 1673). These tables will also indicate when each variable will be available. *Alphabetical Listing of Field Variables and Their Definitions* (p. 1674) contains an alphabetical listing of the variables along with their definitions. All variables appear as they would in the variable selection drop-down lists that are contained in many of the ANSYS FLUENT dialog boxes. *Custom Field Functions* (p. 1708) explains how you can calculate your own field function.

- [34.1. Node, Cell, and Facet Values](#)
- [34.2. Velocity Reporting Options](#)
- [34.3. Field Variables Listed by Category](#)
- [34.4. Alphabetical Listing of Field Variables and Their Definitions](#)
- [34.5. Custom Field Functions](#)

34.1. Node, Cell, and Facet Values

For the following discussion, “surface” refers to a collection of facets, lines or points that are created and manipulated in the **Surface** menu. In most cases, these surfaces are created by computing intersections of constant isovalue with the domain cells or with existing surfaces.

For additional information, please see the following sections:

- [34.1.1. Cell Values](#)
- [34.1.2. Node Values](#)
- [34.1.3. Facet Values](#)

34.1.1. Cell Values

ANSYS FLUENT stores most variables in cells. For postprocessing, the entire region contained within the cell has this value. A surface cell value is the value of the cell that has been intersected by a surface facet or line, or that contains a surface point. Since surface facets and lines are created from the intersection of isovalue and the existing mesh cells, this is a unique definition. Typically, the cell value on a boundary is the value in the cell adjacent to the boundary. For face-only functions like **Wall Shear Stress**, the cell value is the area-weighted average from the face values that define that cell as c0. This value is used for the cell values of postprocessing surfaces. But for boundary faces, the cell value actually displays/uses the exact face value.

34.1.2. Node Values

Node values are explicitly defined or obtained by weighted averaging of the cell data. Various boundary conditions impose values of field variables at the domain boundaries, so mesh node values on these

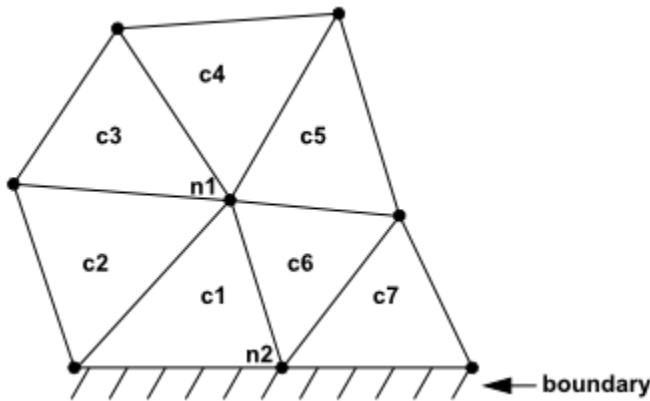

boundary zones are obtained by simple averaging of the adjacent boundary face data. In addition, for several variables (e.g., node coordinates) explicit node values are available at all nodes.

Computation of node values is performed in two steps:

1. Values at all nodes are initialized to the weighted average of the surrounding cell values. The weights are the inverses of the distances between the nodes and the cell centroid.
2. At boundaries, these node values are overwritten with the simple average of the boundary face values. Variables for which explicit node values are available at boundaries are indicated by *bav* in [Table 34.1:Pressure and Density Categories \(p. 1658\)](#) – [Table 34.15:Acoustics Category \(p. 1673\)](#).

For example, in [Figure 34.1 \(p. 1654\)](#), the value at node *n*1 will be computed from the weighted average of the values in the surrounding cells (*c*1–*c*6). The value at node *n*2 will be computed from the simple average of the boundary faces (*bf*1 and *bf*2) if there are explicit boundary values available for the variable in question.

Figure 34.1 Computing Node Values

Important

Note that explicit boundary node values are not available for custom field functions.

34.1.2.1. Vertex Values for Points That are Not Mesh Nodes

The values of the nodes on surfaces are linearly interpolated from the mesh node data. For zone surfaces, the nodes on the surface and the zone correspond; thus, the values are identical. For surfaces that are not zone surfaces (e.g., isosurfaces, plane surfaces, etc.), the node values are interpolated from mesh nodes on the cell faces intersected by the postprocessing surface. For point surfaces, the value is interpolated from all the mesh nodes of the cell containing the point.

34.1.3. Facet Values

Facets can be created on preprocessing surfaces and postprocessing surfaces.

34.1.3.1. Facet Values on Zone Surfaces

The interior facets on a zone surface are associated with two cells (*c*0 and *c*1). The values of a specified variable on such facets are computed as the arithmetic average of the two cell values of the selected variable.

The boundary facet values of a specified field variable on a zone surface are computed from the boundary condition provided by the user.

34.1.3.2. Facet Values on Postprocessing Surfaces

Each facet on a postprocessing surface is associated with a cell. The values of a specified variable on facets are the same as the cell values of the selected variable in the associated cells (this includes iso surfaces, planes, lines, points, rakes, quadric, etc.).

34.2. Velocity Reporting Options

The following methods are available for reporting velocities:

- Cartesian velocities:

These velocities are based on the Cartesian coordinate system used by the geometry. To report Cartesian velocities, select **X Velocity**, **Y Velocity**, or **Z Velocity**. This is the most common type of velocity reported.

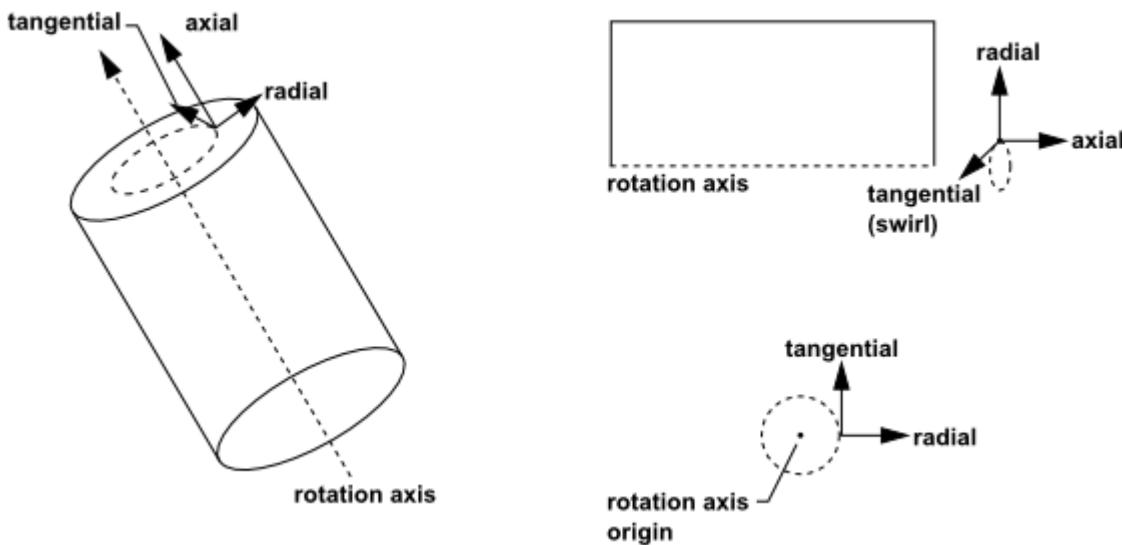

- Cylindrical velocities:

These velocities are the axial, radial, and tangential components based on the following coordinate systems:

- For axisymmetric problems, in which the rotation axis must be the x axis, the x direction is the axial direction and the y direction is the radial direction. (If you model axisymmetric swirl, the swirl direction is the tangential direction.)
- For 2D problems involving a single cell zone, the z direction is the axial direction, and its origin is specified in the [Fluid Dialog Box \(p. 1942\)](#).
- For 3D problems involving a single cell zone, the coordinate system is defined by the rotation axis and origin specified in the [Fluid Dialog Box \(p. 1942\)](#).
- For problems involving multiple zones (e.g., multiple reference frames or sliding meshes), the coordinate system is defined by the rotation axis specified in the [Fluid Dialog Box \(p. 1942\)](#) (or [Solid Dialog Box \(p. 1949\)](#)) for the “reference zone”. The reference zone is chosen in the [Reference Values Task Page \(p. 2046\)](#), as described in [Reference Values \(p. 1648\)](#). Recall that for 2D problems, you will specify only the axis origin; the z direction is always the axial direction.

For all of the above definitions of the cylindrical coordinate system, positive radial velocities point radially out from the rotation axis, positive axial velocities are in the direction of the rotation axis vector, and positive tangential velocities are based on the right-hand rule using the positive rotation axis.

To report cylindrical velocities, select **Axial Velocity**, **Radial Velocity**, etc. [Figure 34.2 \(p. 1656\)](#) illustrates the cylindrical velocities available for different types of domains. For 3D problems, you can report axial, radial, and tangential velocities. For 2D problems, radial and tangential velocities are available. For axisymmetric problems, you can report axial and radial velocities, and, if you are modeling axisymmetric swirl, you can also report the swirl velocity (which is equivalent to the tangential velocity).

Figure 34.2 Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains

- Relative velocities: These velocities are based on the coordinate system and motion of a moving reference frame. They are useful when you are modeling your flow using a moving reference frame, a mixing plane, multiple reference frames, or sliding meshes. (See [Modeling Flows with Moving Reference Frames \(p. 535\)](#) for information about modeling flow in moving zones.) To report relative velocities, select **Relative X Velocity**, **Relative Y Velocity**, **Relative Radial Velocity**, etc. (Note that you can report relative velocities for both Cartesian and cylindrical components.)

If you are using a single moving reference frame, the relative velocity values will be reported with respect to the moving frame. If you are using multiple reference frames, mixing planes, or sliding meshes, you will need to specify the frame to which you want the velocities to be relative by choosing the appropriate cell zone as the **Reference Zone** in the [Reference Values Task Page \(p. 2046\)](#) (see [Reference Values \(p. 1648\)](#)). The axis of rotation for each cell zone is defined in the associated [Fluid Dialog Box \(p. 1942\)](#) or [Solid Dialog Box \(p. 1949\)](#). (See [Specifying the Rotation Axis \(p. 223\)](#) or [Specifying the Rotation Axis \(p. 229\)](#) for details.)

Note that if your problem does not involve any moving zones, relative and absolute velocities will be equivalent.

Note that relative velocities can also be used to compute stagnation quantities (total pressure and total temperature), and that the cylindrical coordinate systems described in the second item above are used for defining the **Axial Coordinate** and **Radial Coordinate** as well.

34.3. Field Variables Listed by Category

In [Table 34.1:Pressure and Density Categories \(p. 1658\)](#) – [Table 34.15:Acoustics Category \(p. 1673\)](#), the following restrictions apply to marked variables:

<i>2d</i>	available only for 2D flows
<i>2da</i>	available only for 2D axisymmetric flows (with or without swirl)
<i>2dasw</i>	available only for 2D axisymmetric swirl flows
<i>3d</i>	available only for 3D flows
<i>ark</i>	available only with the Aungier-Redlich-Kwong real gas model
<i>bns</i>	available only for broadband noise source models

<i>bnd</i>	node values available at boundaries
<i>cpl</i>	available only in the density-based solvers
<i>cv</i>	available only for cell values (Node Values option turned off)
<i>des</i>	available only when the DES turbulence model is used
<i>dil</i>	not available with full multicomponent diffusion
<i>do</i>	available only when the discrete ordinates radiation model is used
<i>dpm</i>	available only for coupled discrete phase calculations
<i>dtrm</i>	available only when the discrete transfer radiation model is used
<i>fwf</i>	available only with the Ffowcs Williams and Hawkings acoustics model
<i>e</i>	available only for energy calculations
<i>edc</i>	available only with the EDC model for turbulence-chemistry interaction
<i>emm</i>	available also when the Eulerian multiphase model is used
<i>ewf</i>	available only with the Eulerian Wall Film model is used
<i>ewt</i>	available only with the enhanced wall treatment
<i>fv</i>	available for face values
<i>gran</i>	available only if a granular phase is present
<i>h2o</i>	available only when the mixture contains water
<i>id</i>	available only when the ideal gas law is enabled for density
<i>ke</i>	available only when one of the k - ϵ turbulence models is used
<i>kklo</i>	available only when the k - kl - ω model is used
<i>kw</i>	available only when one of the k - ω turbulence models is used
<i>les</i>	available only when the LES turbulence model is used
<i>melt</i>	available only when the melting and solidification model is used
<i>mix</i>	available only when the multiphase mixture model is used
<i>mp</i>	available only for multiphase models
<i>nox</i>	available only for NOx calculations
<i>np</i>	not available in parallel solvers
<i>nv</i>	uses explicit node value function
<i>p</i>	available only in parallel solvers
<i>p1</i>	available only when the P-1 radiation model is used
<i>pdf</i>	available only for non-premixed combustion calculations
<i>pmx</i>	available only for premixed combustion calculations
<i>ppmx</i>	available only for partially premixed combustion calculations
<i>r</i>	available only when the Rosseland radiation model is used
<i>rad</i>	available only for radiation heat transfer calculations
<i>rc</i>	available only for finite-rate reactions
<i>rg</i>	available only for the real gas models
<i>rsm</i>	available only when the Reynolds stress turbulence model is used

<i>s2s</i>	available only when the surface-to-surface radiation model is used
<i>sa</i>	available only when the Spalart-Allmaras turbulence model is used
<i>seg</i>	available only in the pressure-based solver
<i>sp</i>	available only for species calculations
<i>sr</i>	available only for surface reactions
<i>sol</i>	available only when the solar model is used
<i>soot</i>	available only for soot calculations
<i>sst</i>	available only when the SST Transition model is used
<i>stat</i>	available only with data sampling for transient statistics
<i>stcm</i>	available only for stiff chemistry calculations
<i>t</i>	available only for turbulent flows
<i>turbo</i>	available only when a turbomachinery topology has been defined
<i>udm</i>	available only when a user-defined memory is used
<i>uds</i>	available only when a user-defined scalar is used
<i>v</i>	available only for viscous flows

34.4. Alphabetical Listing of Field Variables and Their Definitions

Below, the variables listed in [Table 34.1:Pressure and Density Categories](#) (p. 1658) – [Table 34.15:Acoustics Category](#) (p. 1673) are defined. For some variables (such as residuals) a general definition is given under the category name, and variables in the category are not listed individually. When appropriate, the unit quantity is included, as it appears in the **Quantities** list in the [Set Units Dialog Box](#) (p. 1769).

Abs (C-H) Spanwise Coordinate

(in the **Mesh...** category) is the dimensional coordinate in the spanwise direction, from casing to hub. Its unit quantity is **length**.

Abs (H-C) Spanwise Coordinate

(in the **Mesh...** category) is the dimensional coordinate in the spanwise direction, from hub to casing. Its unit quantity is **length**.

Abs Meridional Coordinate

(in the **Mesh...** category) is the dimensional coordinate that follows the flow path from inlet to outlet. Its unit quantity is **length**.

Abs Pitchwise Coordinate

(in the **Mesh...** category) is the dimensional coordinate in the circumferential (pitchwise) direction. Its unit quantity is **angle**.

Absolute Pressure

(in the **Pressure...** category) is equal to the operating pressure plus the gauge pressure. See [Operating Pressure](#) (p. 468) for details. Its unit quantity is **pressure**.

Absorbed Radiation Flux (Band-n)

(in the **Wall Fluxes...** category) is the amount of radiative heat flux absorbed by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Absorbed Visible Solar Flux, Absorbed IR Solar Flux

(in the **Wall Fluxes...** category) is the amount of solar heat flux absorbed by a semi-transparent wall or porous jump boundary for a visible or infrared (IR) radiation.

Absorption Coefficient

(in the **Radiation...** category) is the property of a medium that describes the amount of absorption of thermal radiation per unit path length within the medium. It can be interpreted as the inverse of the mean free path that a photon will travel before being absorbed (if the absorption coefficient does not vary along the path). The unit quantity for **Absorption Coefficient** is **length-inverse**.

Acentric Factor

(in the **Properties...** category) is the mixture acentric factor. This property is available when a composition dependent option is selected for acentric factor in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Acoustic Power

(in the **Acoustics...** category) is the acoustic power per unit volume generated by isotropic turbulence (see [Equation 15–11](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used. Its unit quantity is **power per volume**.

Acoustic Power Level (dB)

(in the **Acoustics...** category) is the acoustic power per unit volume generated by isotropic turbulence and reported in dB (see [Equation 15–14](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Active Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS FLUENT, the partition ID can be used to determine the extent of the various groups of cells. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file. See [Partitioning the Mesh Manually and Balancing the Load \(p. 1736\)](#) for more information.

Adaption...

includes field variables that are commonly used for adapting the mesh. For information about solution adaption, see [Adapting the Mesh \(p. 1441\)](#).

Adaption Function

(in the **Adaption...** category) can be either the **Adaption Space Gradient** or the **Adaption Curvature**, depending on the settings in the [Gradient Adaption Dialog Box \(p. 2277\)](#). For instance, the **Adaption Curvature** is the undivided Laplacian of the values in temporary cell storage. To display contours of the Laplacian of pressure, for example, you first select **Static Pressure**, click the **Compute** (or **Display**) button, select **Adaption Function**, and finally click the **Display** button.

Adaption Iso-Value

(in the **Adaption...** category) is the desired field variable function.

Adaption Space Gradient

(in the **Adaption...** category) is the first derivative of the desired field variable.

$$|e_{i1}| = (A_{cell})^{\frac{r}{2}} |\nabla f| \quad (34-1)$$

Depending on the settings in the [Gradient Adaption Dialog Box \(p. 2277\)](#), this equation will either be scaled or normalized. Recommended for problems with shock waves (i.e., supersonic, inviscid flows). For more information, see [Gradient Adaption Approach](#) in the [Theory Guide](#).

Adaption Curvature

(in the **Adaption...** category) is the second derivative of the desired field variable.

$$|e_{i2}| = (A_{cell})^{\frac{r}{2}} |\nabla^2 f| \quad (34-2)$$

Depending on the settings in the [Gradient Adaption Dialog Box \(p. 2277\)](#), this equation will either be scaled or normalized. Recommended for smooth solutions (i.e., viscous, incompressible flows). For more information, see [Gradient Adaption Approach](#) in the [Theory Guide](#).

Adiabatic Flame Temperature

(in the **Premixed Combustion...** category) is the adiabatic temperature of burnt products in a laminar premixed flame (T_b in [Equation 9–67](#) in the [Theory Guide](#)). Its unit quantity is **temperature**.

Angular Coordinate

(in the **Mesh...** category) is the angle between the radial vector and the position vector. The radial vector is obtained by transforming the default radial vector (y-axis) by the same rotation that was applied to the default axial vector (z-axis). This assumes that, after the transformation, the default axial vector (z-

axis) becomes the reference axis. The angle is positive in the direction of cross-product between reference axis and radial vector.

Abs. Angular Coordinate

(in the **Mesh...** category) is the absolute value of the **Angular Coordinate** defined above.

Axial Coordinate

(in the **Mesh...** category) is the distance from the origin in the axial direction. The axis origin and (in 3D) direction is defined for each cell zone in the [Fluid Dialog Box \(p. 1942\)](#) or [Solid Dialog Box \(p. 1949\)](#). The axial direction for a 2D model is always the z direction, and the axial direction for a 2D axisymmetric model is always the x direction. The unit quantity for **Axial Coordinate** is **length**.

Axial Pull Velocity

(in the **Solidification/Melting...** category) is the axial-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Axial Velocity

(in the **Velocity...** category) is the component of velocity in the axial direction. (See [Velocity Reporting Options \(p. 1655\)](#) for details.) For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. Its unit quantity is **velocity**.

Axial-Wall Shear Stress

(in the **Wall Fluxes...** category) is the axial component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Beam Irradiation Flux (Band-b)

(in the **Wall Fluxes...** category) is specified as an incident heat flux (W/m^2) for each wavelength band.

Boundary Cell Distance

(in the **Adaption...** category) is an integer that indicates the approximate number of cells from a boundary zone.

Boundary Normal Distance

(in the **Adaption...** category) is the distance of the cell centroid from the closest boundary zone.

Boundary Volume Distance

(in the **Adaption...** category) is the cell volume distribution based on the **Boundary Volume, Growth Factor**, and normal distance from the selected **Boundary Zones** defined in the [Boundary Adaption Dialog Box \(p. 2276\)](#). See [Boundary Adaption \(p. 1445\)](#) for details.

Cell Children

(in the **Adaption...** category) is a binary identifier based on whether a cell is the product of a cell subdivision in the hanging-node adaption process (value = 1) or not (value = 0).

Cell Element Type

(in the **Cell Info...** category) is the integer cell element type identification number. Each cell can have one of the following element types:

triangle	1
tetrahedron	2
quadrilateral	3
hexahedron	4
pyramid	5
wedge	6

Cell Equiangle Skew

(in the **Mesh...** category) is a nondimensional parameter calculated using the normalized angle deviation method, and is defined as

$$\max \left[\frac{q_{\max} - q_e}{180 - q_e}, \frac{q_e - q_{\min}}{q_e} \right] \quad (34-3)$$

where

q_{\max} = largest angle in the face or cell

q_{\min} = smallest angle in the face or cell

q_e = angle for an equiangular face or cell (e.g., 60 for a triangle and 90 for a square)

A value of 0 indicates a best case equiangular cell, and a value of 1 indicates a completely degenerate cell. Degenerate cells (slivers) are characterized by nodes that are nearly coplanar (collinear in 2D).

Cell Equiangle Skew applies to all elements.

Cell Equivolume Skew

(in the **Mesh...** category) is a nondimensional parameter calculated using the volume deviation method, and is defined as

$$\frac{(\text{optimal-cell-size}) - (\text{cell-size})}{(\text{optimal-cell-size})} \quad (34-4)$$

where optimal-cell-size is the size of an equilateral cell with the same circumradius. A value of 0 indicates a best case equilateral cell and a value of 1 indicates a completely degenerate cell. Degenerate cells (slivers) are characterized by nodes that are nearly coplanar (collinear in 2D). **Cell Equivolume Skew** applies only to triangular and tetrahedral elements.

Cell Id

(in the **Cell Info...** category) is a unique integer identifier associated with each cell.

Cell Info...

includes quantities that identify the cell and its relationship to other cells.

Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS FLUENT, the partition ID can be used to determine the extent of the various groups of cells.

Cell Refine Level

(in the **Adaption...** category) is an integer that indicates the number of times a cell has been subdivided in the hanging node adaption process, compared with the original mesh. For example, if one quad cell is split into four quads, the **Cell Refine Level** for each of the four new quads will be 1. If the resulting four quads are split again, the **Cell Refine Level** for each of the resulting 16 quads will be 2.

Cell Reynolds Number

(in the **Velocity...** category) is the value of the Reynolds number in a cell. (Reynolds number is a dimensionless parameter that is the ratio of inertia forces to viscous forces.) **Cell Reynolds Number** is defined as

$$Re \equiv \frac{\rho u d}{\mu} \quad (34-5)$$

where ρ is density, u is velocity magnitude, μ is the effective viscosity (laminar plus turbulent), and d is **Cell Volume** $^{1/2}$ for 2D cases and **Cell Volume** $^{1/3}$ in 3D or axisymmetric cases.

Cell Surface Area

(in the **Adaption...** category) is the total surface area of the cell, and is computed by summing the area of the faces that compose the cell.

Cell Volume

(in the **Mesh...** category) is the volume of a cell. In 2D the volume is the area of the cell multiplied by the unit depth. For axisymmetric cases, the cell volume is calculated using a reference depth of 1 radian. The unit quantity of **Cell Volume** is **volume**.

Cell Volume Derivative

(in the **Mesh...** category) is the change of a cell volume overtime.

Cell Volume Error

(in the **Mesh...** category) is the cell volume over the unsteady cell volume.

2D Cell Volume

(in the **Mesh...** category) is the two-dimensional volume of a cell in an axisymmetric computation. For an axisymmetric computation, the 2D cell volume is scaled by the radius. Its unit quantity is **area**.

Cell Volume Change

(in the **Adaption...** category) is the maximum volume ratio of the current cell and its neighbors.

Cell Wall Distance

(in the **Mesh...** category) is the distribution of the normal distance of each cell centroid from the wall boundaries. Its unit quantity is **length**.

Cell Warpage

(in the **Adaption...** category) is the square root of the ratio of the distance between the cell centroid and cell circumcenter and the circumcenter radius:

$$\text{warpage} = \sqrt{\frac{|\vec{r}_{\text{centroid}} - \vec{r}_{\text{circumcenter}}|}{R_{\text{circumcenter}}}} \quad (34-6)$$

Cell Zone Index

(in the **Cell Info...** category) is the integer cell zone identification number. In problems that have more than one cell zone, the cell zone ID can be used to identify the various groups of cells.

Cell Zone Type

(in the **Cell Info...** category) is the integer cell zone type ID. A fluid cell has a type ID of 1, a solid cell has a type ID of 17, and an exterior cell (parallel solver) has a type ID of 21.

Compressibility Factor

(in the **Properties...** category) is the ratio of the ideal gas density of the fluid divided by the real gas fluid density in the in the same flow conditions. Compressibility Factor is defined as

$$Z = \frac{P/RT}{\rho} \quad (34-7)$$

where Z is the compressibility factor, P is the absolute pressure, T is the temperature, and $R = R_u/MW$ (the universal gas constant R_u divided by the molecular weight MW). The compressibility factor is available only with the real gas models.

Contact Resistivity

(in the **Solidification/Melting...** category) is the additional resistance at the wall due to contact resistance. It is equal to $R_c(1 - \beta)/h$, where R_c is the contact resistance, β is the liquid fraction, and h is the cell height of the wall-adjacent cell. The unit quantity for **Contact Resistivity** is **thermal-resistivity**.

Critical Pressure

(in the **Properties...** category) is the mixture critical pressure. This property is available when a composition dependent option is selected for critical pressure in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Critical Specific Volume

(in the **Properties...** category) is the mixture critical specific volume. This property is available when a composition dependent option is selected for critical specific volume in the cases with Aungier-Redlich-Kwong real gas model and species transport.

Critical Strain Rate

(in the **Premixed Combustion...** category) is a parameter that takes into account the stretching and extinction of premixed flames (g_{cr} in [Equation 9-18](#) in the [Theory Guide](#)). Its unit quantity is **time-inverse**.

Critical Temperature

(in the **Properties...** category) is the mixture critical temperature. This property is available when a composition dependent option is selected for critical temperature in the cases with Aungier-Redlich-Kwong real gas model and species transport

Custom Field Functions...

are scalar field functions defined by you. You can create a custom function using the [Custom Field Function Calculator Dialog Box](#) (p. 2264). All defined custom field functions will be listed in the lower drop-down list. See [Custom Field Functions](#) (p. 1708) for details.

Damkohler Number

(in the **Premixed Combustion...** category) is a nondimensional parameter that is defined as the ratio of turbulent to chemical time scales.

Density...

includes variables related to density.

Density

(in the **Density...** category) is the mass per unit volume of the fluid. Plots or reports of **Density** include only fluid cell zones. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. The unit quantity for **Density** is **density**.

Density All

(in the **Density...** category) is the mass per unit volume of the fluid or solid material. Plots or reports of **Density All** include both fluid and solid cell zones. The unit quantity for **Density All** is **density**.

Derivatives...

are the viscous derivatives. For example, **dX-Velocity/dx** is the first derivative of the x component of velocity with respect to the x -coordinate direction. You can compute first derivatives of velocity, angular velocity, and pressure in the pressure-based solver, and first derivatives of velocity, angular velocity, temperature, and species in the density-based solvers.

DES Length Scale

(in the **Turbulence...** category) is defined by [Equation 4–227](#) in the [Theory Guide](#) for the Spalart-Allmaras based DES model and [Equation 4–234](#) in the [Theory Guide](#) for the realizable K-epsilon based DES model.

The DES length scale for the SST K-omega based DES model is defined by $C_{des}\Delta_{max} = \left(\frac{L_t}{F_{DES}} \right)$, where

C_{des} is a calibration constant used in the DES model and has a value of 0.61 and Δ_{max} is the maximum local grid spacing ($\Delta x, \Delta y, \Delta z$).

Diameter

(in the **Properties...** category) is the diameter of particles, droplets, or bubbles of the secondary phase selected in the **Phase** drop-down list. Its unit quantity is **length**.

Diffusion Coef. of Scalar-n

(in the **User Defined Scalars...** category) is the diffusion coefficient for the n th user-defined scalar transport equation. See the UDF manual for details about defining user-defined scalars.

Discrete Phase Model...

includes quantities related to the discrete phase model. See [Modeling Discrete Phase \(p. 1075\)](#) for details about this model.

DPM Absorption Coefficient

(in the **Discrete Phase Model...** category) is the absorption coefficient for discrete-phase calculations that involve radiation (a in [Equation 5–17](#) in the [Theory Guide](#)). Its unit quantity is **length-inverse**.

DPM Accretion

(in the **Discrete Phase Model...** category) is the accretion rate calculated at a wall boundary:

$$R_{accretion} = \sum_{p=1}^N \frac{\dot{m}_p}{A_{face}} \quad (34-8)$$

where \dot{m}_p is the mass flow rate of the particle stream, and A_{face} is the area of the wall face where the particle strikes the boundary. This item will appear only if the optional erosion/accretion model is enabled. See [Monitoring Erosion/Accretion of Particles at Walls \(p. 1085\)](#) for details. The unit quantity for **DPM Accretion** is **mass-flux**.

DPM Burnout

(in the **Discrete Phase Model...** category) is the exchange of mass from the discrete to the continuous phase for the combustion law (Law 5) and is proportional to the solid phase reaction rate. The burnout exchange has units of **mass-flow**.

DPM Concentration

(in the **Discrete Phase Model...** category) is the total concentration of the discrete phase. Its unit quantity is **density**.

DPM Emission

(in the **Discrete Phase Model...** category) is the amount of radiation emitted by a discrete-phase particle per unit volume. Its unit quantity is **heat-generation-rate**.

DPM Enthalpy Source

(in the **Discrete Phase Model...** category) is the exchange of enthalpy (sensible enthalpy plus heat of formation) from the discrete phase to the continuous phase. The exchange is positive when the particles are a source of heat in the continuous phase. The unit quantity for **DPM Enthalpy Source** is **power**.

DPM Erosion

(in the **Discrete Phase Model...** category) is the erosion rate calculated at a wall boundary face:

$$R_{erosion} = \sum_{p=1}^N \frac{\dot{m}_p f(\alpha)}{A_{face}} \quad (34-9)$$

where \dot{m}_p is the mass flow rate of the particle stream, α is the impact angle of the particle path with the wall face, $f(\alpha)$ is the function specified in the [Wall Dialog Box \(p. 2011\)](#), and A_{face} is the area of the wall face where the particle strikes the boundary. This item will appear only if the optional erosion/accretion model is enabled. See [Monitoring Erosion/Accretion of Particles at Walls \(p. 1085\)](#) for details. The unit quantity for **DPM Erosion** is **mass-flux**.

DPM Evaporation/Devolatilization

(in the **Discrete Phase Model...** category) is the exchange of mass, due to droplet-particle evaporation or combusting-particle devolatilization, from the discrete phase to the evaporating or devolatilizing species. If you are not using the non-premixed combustion model, the mass source for each individual species (**DPM species-n Source**, below) is also available; for non-premixed combustion, only this sum is available. The unit quantity for **DPM Evaporation/Devolatilization** is **mass-flow**.

DPM Mass Source

(in the **Discrete Phase Model...** category) is the total exchange of mass from the discrete phase to the continuous phase. The mass exchange is positive when the particles are a source of mass in the continuous phase. If you are not using the non-premixed combustion model, **DPM Mass Source** will be equal to the sum of all species mass sources (**DPM species-n Source**, below); if you are using the non-premixed combustion model, it will be equal to **DPM Burnout** plus **DPM Evaporation/Devolatilization**. The unit quantity for **DPM Mass Source** is **mass-flow**.

DPM Scattering

(in the **Discrete Phase Model...** category) is the scattering coefficient for discrete-phase calculations that involve radiation (σ_s in [Equation 5-17](#) in the [Theory Guide](#)). Its unit quantity is **length-inverse**.

DPM Sensible Enthalpy Source

(in the **Discrete Phase Model...** category) is the exchange of sensible enthalpy from the discrete phase to the continuous phase. The exchange is positive when the particles are a source of heat in the continuous phase. Its unit quantity is **power**.

DPM species-n Source

(in the **Discrete Phase Model...** category) is the exchange of mass, due to droplet-particle evaporation or combusting-particle devolatilization, from the discrete phase to the evaporating or devolatilizing species. (The name of the species will replace **species-n** in **DPM species-n Source**.) These species can be specified in the [Set Injection Properties Dialog Box \(p. 2255\)](#), and their descriptions can be found in [Defining Injection Properties \(p. 1114\)](#). The unit quantity is **mass-flow**. Note that this variable will not be available if you are using the non-premixed combustion model; use **DPM Evaporation/Devolatilization** instead.

DPM Swirl Momentum Source

(in the **Discrete Phase Model...** category) is the exchange of swirl momentum from the discrete phase to the continuous phase. This value is positive when the particles are a source of momentum in the continuous phase. The unit quantity is **force**.

DPM X, Y, Z Momentum Source

(in the **Discrete Phase Model...** category) are the exchange of x -, y -, and z -direction momentum from the discrete phase to the continuous phase. These values are positive when the particles are a source of momentum in the continuous phase. The unit quantity is **force**.

Dynamic Cell Volume Change

(in the **Mesh...** category) is the change of a cell volume.

Dynamic Pressure

(in the **Pressure...** category) is defined as $q \equiv \frac{1}{2}\rho v^2$. Its unit quantity is **pressure**.

Eff Diff Coef of species-n

(in the **Species...** category) is the sum of the laminar and turbulent diffusion coefficients of a species into the mixture:

$$D_{i,m} + \frac{\mu_t}{\rho S c_t} \quad (34-10)$$

(The name of the species will replace **species-n** in **Eff Diff Coef of species-n**.) The unit quantity is **mass-diffusivity**.

Effective Prandtl Number

(in the **Turbulence...** category) is the ratio $\mu_{eff}c_p/k_{eff}$, where μ_{eff} is the effective viscosity, c_p is the specific heat, and k_{eff} is the effective thermal conductivity.

Effective Thermal Conductivity

(in the **Properties...** category) is the sum of the laminar and turbulent thermal conductivities, $k + k_t$, of the fluid. A large thermal conductivity is associated with a good heat conductor and a small thermal conductivity with a poor heat conductor (good insulator). Its unit quantity is **thermal-conductivity**.

Effective Viscosity

(in the **Turbulence...** category) is the sum of the laminar and turbulent viscosities of the fluid. Viscosity, μ , is defined by the ratio of shear stress to the rate of shear. Its unit quantity is **viscosity**.

Enthalpy

(in the **Temperature...** category) is defined differently for compressible and incompressible flows, and depending on the solver and models in use.

For compressible flows,

$$H = \sum_j Y_j H_j \quad (34-11)$$

and for incompressible flows,

$$H = \sum_j Y_j H_j + \frac{p}{\rho} \quad (34-12)$$

where Y_j and H_j are, respectively, the mass fraction and enthalpy of species j . (See **Enthalpy of species-n**, below). For the pressure-based solver, the second term on the right-hand side of [Equation 34-12 \(p. 1682\)](#) is included only if the pressure work term is included in the energy equation (see [Inclusion of Pressure Work and Kinetic Energy Terms](#) in the Theory Guide). For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. For all reacting flow models, the **Enthalpy** plots consist of the thermal (or sensible) plus chemical energy. The unit quantity for **Enthalpy** is **specific-energy**.

In the case of the inert model ([Using the Non-Premixed Model with the Inert Model](#) in the [Theory Guide](#)), the enthalpy in a cell is split into the contributions from the inert and the reacting fractions of the gas phase species in the cell. The cell enthalpy is partitioned as

$$H = \gamma H_{inert} + (1 - \gamma) H_{pdf} \quad (34-13)$$

where γ is the fraction of inert species in the cell. The quantity H_{inert} is the enthalpy of the inert species at the cell temperature, similarly H_{pdf} is the enthalpy of the active species at the cell temperature. It is assumed that the cell temperature is common to both inert and active species, so H_{inert} , H_{pdf} and the cell temperature are chosen so that [Equation 34-13 \(p. 1683\)](#) is satisfied.

Enthalpy of species-n

(in the **Species...** category) is defined differently depending on the solver and models options in use. The quantity:

$$H_j = \int_{T_{ref,j}}^T c_{p,j} dT + h_j^0(T_{ref,j}) \quad (34-14)$$

where $h_j^0(T_{ref,j})$ is the formation enthalpy of species j at the reference temperature $(T_{ref,j})$, is reported only for non-adiabatic PDF cases, or if the density-based solver is selected. The quantity:

$$h_j = \int_{T_{ref}}^T c_{p,j} dT \quad (34-15)$$

where $T_{ref} = 298.15K$, is reported in all other cases. The unit quantity for **Enthalpy of species-n** is **specific-energy**.

Entropy

(in the **Temperature...** category) is a thermodynamic property defined by the equation

$$\Delta S \equiv \int_{rev} \frac{\delta Q}{T} \quad (34-16)$$

$$\Delta S = C_p \ln \left(\frac{T}{T_{ref}} \right) - R \ln \left(\frac{P}{P_{ref}} \right) \quad (34-17)$$

the entropy is computed using the equation

$$\Delta S = C_p \ln \left(\frac{T}{T_{ref}} \right) \quad (34-18)$$

The unit quantity for entropy is **specific-heat**.

Important

Note that for the real gas models the entropy is computed accordingly by the appropriate equation of state formulation.

Existing Value

(in the **Adaption...** category) is the value that presently resides in the temporary space reserved for cell variables (i.e., the last value that you displayed or computed).

External Temperature (Shell)

(in the **Temperature...** category) is the temperature on the external surface of a shell conduction wall (corresponding to the side of the wall surface that is away from the adjacent fluid or solid cell zone). See *Figure 14.4* (p. 749). This option is only available when the domain has at least one external wall with shell conduction enabled. Note that for thin walls with shell conduction, wall thermal boundary conditions are applied on this surface. For external walls that do not have shell conduction enabled or for internal walls, the value reported for **External Temperature (Shell)** will be zero. For information about postprocessing the other surfaces of a shell conduction wall, see **Wall Temperature (Inner Surface)** and **Wall Temperature (Outer Surface)**.

Face Area Magnitude

(in the **Mesh...** category) is the magnitude of the face area vector for noninternal faces (i.e., faces that only have c0 and no c1). The values are stored on the face itself and used when required. This variable is intended only for zone surfaces and not for other surfaces created for postprocessing.

Face Handedness

(in the **Mesh...** category) is a parameter that is equal to one in cells that are adjacent to left-handed faces, and zero elsewhere. It can be used to locate mesh problems.

Film Thickness

(in the **Eulerian Wall Film...** category) is the thickness of the wall film.

Film Mass

(in the **Eulerian Wall Film...** category) is the mass of the wall film.

Film Temperature

(in the **Eulerian Wall Film...** category) is the temperature of the wall film.

Film X-Velocity

(in the **Eulerian Wall Film...** category) is the x-component of the velocity of the wall film.

Film Y-Velocity

(in the **Eulerian Wall Film...** category) is the y-component of the velocity of the wall film.

Film Z-Velocity

(in the **Eulerian Wall Film...** category) is the z-component of the velocity of the wall film.

Film Velocity Magnitude

(in the **Eulerian Wall Film...** category) is the magnitude of the velocity of the wall film.

Film Effective Pressure

(in the **Eulerian Wall Film...** category) is the effective pressure of the wall film.

Film Surface X-Velocity

(in the **Eulerian Wall Film...** category) is the x-component of the surface velocity of the wall film.

Film Surface Y-Velocity

(in the **Eulerian Wall Film...** category) is the y-component of the surface velocity of the wall film.

Film Surface Z-Velocity

(in the **Eulerian Wall Film...** category) is the z-component of the surface velocity of the wall film.

Film Surface Velocity Magnitude

(in the **Eulerian Wall Film...** category) is the magnitude of the surface velocity of the wall film.

Film Surface Temperature

(in the **Eulerian Wall Film...** category) is the surface temperature of the wall film.

Film Courant Number

(in the **Eulerian Wall Film...** category) is the Courant number of the wall film.

Film Weber Number

(in the **Eulerian Wall Film...** category) is the Weber number of the wall film.

Film Stripped Mass Source

(in the **Eulerian Wall Film...** category) is the additional mass source of stripped wall film droplets.

Film Stripped Diam

(in the **Eulerian Wall Film...** category) is the diameter of stripped wall film droplets.

Film DPM Mass Source

(in the **Eulerian Wall Film...** category) is the additional mass of discrete particles being absorbed into the wall film.

Film DPM Energy Source

(in the **Eulerian Wall Film...** category) is the additional energy of discrete particles being absorbed into the wall film.

Film DPM X-Momentum Source

(in the **Eulerian Wall Film...** category) is the x-component of any additional momentum of discrete particles being absorbed into the wall film.

Film DPM Y-Momentum Source

(in the **Eulerian Wall Film...** category) is the y-component of any additional momentum of discrete particles being absorbed into the wall film.

Film DPM Z-Momentum Source

(in the **Eulerian Wall Film...** category) is the z-component of any additional momentum of discrete particles being absorbed into the wall film.

Film X-Momentum Source

(in the **Eulerian Wall Film...** category) is the x-component of any additional momentum being absorbed into the wall film.

Film Y-Momentum Source

(in the **Eulerian Wall Film...** category) is the y-component of any additional momentum being absorbed into the wall film.

Film Shed Mass

(in the **Eulerian Wall Film...** category) is the mass of film shed once film separation occurs.

Fine Scale Mass Fraction of species-n

(in the **Species...** category) is the term Y_i^* in [Equation 7-30](#) in the [Theory Guide](#).

Fine Scale Temperature

(in the **Temperature...** category) is the temperature of the fine scales, which is calculated from the enthalpy when the reaction proceeds over the time scale (τ^* in [Equation 7–29](#) in the [Theory Guide](#)), governed by the Kinetic rates of [Equation 7–8](#) in the [Theory Guide](#). Its unit quantity is **temperature**.

Fine Scale Transfer Rate

(in the **Species...** category) is the transfer rate of the fine scales, which is equal to the inverse of the time scale (τ^* in [Equation 7–29](#) in the [Theory Guide](#)). Its unit quantity is **time-inverse**.

1-Fine Scale Volume Fraction

(in the **Species...** category) is a function of the fine scale volume fraction (ξ^* in [Equation 7–28](#) in the [Theory Guide](#)). The quantity is subtracted from unity to make it easier to interpret.

Fvar Prod

(in the **Pdf...** category) is the production term in the mixture fraction variance equation solved in the non-premixed combustion model (i.e., the last two terms in [Equation 8–5](#) in the [Theory Guide](#)).

Fvar2 Prod

(in the **Pdf...** category) is the production term in the secondary mixture fraction variance equation solved in the non-premixed combustion model. See [Equation 8–5](#) in the [Theory Guide](#).

Gas Constant (R)

(in the **Properties...** category) is the gas constant of the fluid. Its unit quantity is **specific-heat**.

Granular Conductivity

(in the **Properties...** category) is equivalent to the diffusion coefficient in [Equation 17–229](#) in the [Theory Guide](#). For more information, see [Granular Temperature](#) in the [Theory Guide](#). Its unit quantity is kg/m-s.

Granular Pressure...

includes quantities for reporting the solids pressure for each granular phase (p_s in [Equation 17–199](#) in the [Theory Guide](#)). See [Solids Pressure](#) in the [Theory Guide](#) for details. Its unit quantity is **pressure**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Granular Temperature...

includes quantities for reporting the granular temperature for each granular phase (Θ_s in [Equation 17–229](#) in the [Theory Guide](#)). See [Granular Temperature](#) in the [Theory Guide](#) for details. Its unit quantity is m^2/s^2 . For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Mesh...

includes variables related to the mesh.

Mesh X-Velocity, Mesh Y-Velocity, Mesh Z-Velocity

(in the **Velocity...** category) are the vector components of the mesh velocity for moving-mesh problems (rotating or multiple reference frames, mixing planes, or sliding meshes). Its unit quantity is **velocity**.

HCN Density

(in the **NOx...** category) is the mass per unit volume of HCN. The unit quantity is **density**. The **HCN Density** will appear only if you are modeling fuel NOx. See [Fuel NOx Formation](#) in the [Theory Guide](#) for details.

Heat of Heterogeneous Reaction

(in the **Phase Interaction...** category) is the heat added or removed due to heterogeneous chemical reactions. For exothermic reactions the **Heat of Heterogeneous Reaction** is reported as a positive quantity, while for endothermic reactions it will be a negative quantity. If you have more than one heterogeneous reaction defined in your case, the **Heat of Heterogeneous Reaction** reported is the sum of the heat for all heterogeneous reactions. The unit quantity of **Heat of Heterogeneous Reaction** is Watt.

Heat of Reaction

(in the **Reactions...** category) is the heat added or removed due to chemical reactions, as defined in [Equation 5–10](#) in the [Theory Guide](#). For exothermic reactions, the heat of reaction is reported as a positive quantity, while for endothermic reactions it is reported as a negative quantity. If you have more than one reaction defined in your case, the **Heat of Reaction** reported is the sum of the heat for all reactions. The unit of measurement for the heat of reaction is Watts. The **Heat of Reaction** is not available for the non-premixed and partially-premixed models.

Helicity

(in the **Velocity...** category) is defined by the dot product of vorticity and the velocity vector.

$$H = (\nabla \times \vec{V}) \cdot \vec{V} \quad (34-19)$$

Vorticity is a measure of the rotation of a fluid element as it moves in the flow field.

Incident Radiation

(in the **Radiation...** category) is the total radiation energy, G , that arrives at a location per unit time and per unit area:

$$G = \int_{\Omega = 4\pi} Id\Omega \quad (34-20)$$

where I is the radiation intensity and Ω is the solid angle. G is the quantity that the P-1 radiation model computes. For the DO radiation model, the incident radiation is computed over a finite number of discrete solid angles, each associated with a vector direction. The unit quantity for **Incident Radiation** is **heat-flux**.

Incident Radiation (Band n)

(in the **Radiation...** category) is the radiation energy contained in the wavelength band $\Delta\lambda$ for the non-gray P-1 radiation model or the non-gray DO radiation model. Its unit quantity is **heat-flux**.

Intermittency Factor (γ)

(in the **Turbulence...** category) is a measure of the probability that a given point is located inside a turbulent region. Upstream of transition the intermittency is zero. Once the transition occurs, the intermittency is ramped up to one until the fully turbulent boundary layer regime is achieved.

Internal Energy

(in the **Temperature...** category) is the summation of the kinetic and potential energies of the molecules of the substance per unit volume (and excludes chemical and nuclear energies). **Internal Energy** is defined as $e = c_v T$. Its unit quantity is **specific-energy**.

Jet Acoustic Power

(in the **Acoustics...** category) is the acoustic power for turbulent axisymmetric jets (see [Equation 15–15](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Jet Acoustic Power Level (dB)

(in the **Acoustics...** category) is the acoustic power for turbulent axisymmetric jets, reported in dB (see [Equation 15–28](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Kinetic Rate of Reaction-n

(in the **Reactions...** category) is given by the following expression (see [Equation 7–8](#) in the [Theory Guide](#) for definitions of the variables shown here):

$$\hat{R}_r = \Gamma \left(k_f, r \prod_{j=1}^{N_r} [C_{j,r}]^{\eta'_{j,r}} - k_b, r \prod_{j=1}^{N_r} [C_{j,r}]^{\eta''_{j,r}} \right) \quad (34-21)$$

The reported value is independent of any particular species, and has units of $\text{kmol}/\text{m}^3\cdot\text{s}$.

To find the rate of production/destruction for a given species i due to reaction r , multiply the reported reaction rate for reaction r by the term $M_i (\nu''_{i,r} - \nu'_{i,r})$, where M_i is the molecular weight of species i , and $\nu''_{i,r}$ and $\nu'_{i,r}$ are the stoichiometric coefficients of species i in reaction r .

For particle reactions it is the global rate of the particle reaction n expressed in $\text{kmol}/\text{s}/\text{m}^3$. This is computed as

$$\frac{\bar{R}_{j,r}}{M_j V}$$

where $\bar{R}_{j,r}$ is the rate of particle species depletion (or generation) given by [Equation 7-69](#) in the [Theory Guide](#), M_j is the particle species molecular weight, and V is the cell volume.

Lam Diff Coef of species-n

(in the [Species...](#) category) is the laminar diffusion coefficient of a species into the mixture, $D_{i,m}$. Its unit quantity is **mass-diffusivity**.

Laminar Flame Speed

(in the [Premixed Combustion...](#) category) is the propagation speed of laminar premixed flames (U_l in [Equation 9-9](#) in the [Theory Guide](#)). Its unit quantity is **velocity**.

Laminar Kinetic Energy (kl)

(in the [Turbulence...category](#)) is a measure of the "laminar" streamwise fluctuations present in the pre-transitional region of the boundary layer subjected to free-stream turbulence. A transport equation of kl is considered by the k-kl-omega transition model.

LEE Self-Noise X-Source, LEE Self-Noise Y-Source, LEE Self-Noise Z-Source

(in the [Acoustics...](#) category) are the self-noise source terms in the linearized Euler equation for the acoustic velocity component (see [Equation 15-33](#) in the [Theory Guide](#)). They are available only when the **Broadband Noise Sources** acoustics model is being used.

LEE Shear-Noise X-Source, LEE Shear-Noise Y-Source, LEE Shear-Noise Z-Source

(in the [Acoustics...](#) category) are the shear-noise source terms in the linearized Euler equation for the acoustic velocity component (see [Equation 15-33](#) in the [Theory Guide](#)). They are available only when the **Broadband Noise Sources** acoustics model is being used.

LEE Total Noise X-Source, LEE Total Noise Y-Source, LEE Total Noise Z-Source

(in the [Acoustics...](#) category) are the total noise source terms in the linearized Euler equation for the acoustic velocity component (see [Equation 15-33](#) in the [Theory Guide](#)). The total noise source term is the sum of the self-noise and shear-noise source terms. They are available only when the **Broadband Noise Sources** acoustics model is being used.

LES Subgrid Turbulent Viscosity

(in the [Turbulence...](#) category) is the eddy viscosity that is determined by the local algebraic sub-grid scale model in an embedded LES zone, which actually affects the momentum transport equations (see [Embedded Large Eddy Simulation \(ELES\)](#) in the [Theory Guide](#)). Its unit quantity is **viscosity**.

Lilley's Self-Noise Source

(in the **Acoustics...** category) is the self-noise source term in the linearized Lilley's equation (see [Equation 15–37](#) in the [Theory Guide](#)), available only when the **Broadband Noise Sources** acoustics model is being used.

Lilley's Shear-Noise Source

(in the **Acoustics...** category) is the shear-noise source term in the linearized Lilley's equation (see [Equation 15–37](#) in the [Theory Guide](#)), available only when the **Broadband Noise Sources** acoustics model is being used.

Lilley's Total Noise Source

(in the **Acoustics...** category) is the total noise source term in the linearized Lilley's equation (see [Equation 15–37](#) in the [Theory Guide](#)). The total noise source term is the sum of the self-noise and shear-noise source terms, available only when the **Broadband Noise Sources** acoustics model is being used.

Liquid Fraction

(in the **Solidification/Melting...** category) is the liquid fraction β computed by the solidification/melting model:

$$\beta = \frac{\Delta H}{L} = 0 \quad \text{if } T < T_{solidus} \quad (34-22)$$

$$\beta = \frac{\Delta H}{L} = 1 \quad \text{if } T > T_{liquidus} \quad (34-23)$$

$$\beta = \frac{\Delta H}{L} = \frac{T - T_{solidus}}{T_{liquidus} - T_{solidus}} \quad \text{if } T_{solidus} < T < T_{liquidus} \quad (34-24)$$

Mach Number

(in the **Velocity...** category) is the ratio of velocity and speed of sound.

Mark Poor Elements

(in the **Mesh...** category) is a parameter that is equal to one in cells that are identified as invalid or poor, as well as cells that are adjacent to the face of an invalid or poor cell, and zero elsewhere. It can be used to mark and/or display invalid and poor elements.

Mass fraction of HCN, Mass fraction of NH3, Mass fraction of NO, Mass fraction of N2O

(in the **NOx...** category) are the mass of HCN, the mass of NH₃, the mass of NO, and the mass of N₂O per unit mass of the mixture (e.g., kg of HCN in 1 kg of the mixture). The **Mass fraction of HCN** and the **Mass fraction of NH3** will appear only if you are modeling fuel NOx. See [Fuel NOx Formation](#) in the [Theory Guide](#) for details.

Mass fraction of nuclei

(in the **Soot...** category) is the number of particles per unit mass of the mixture (in units of particles $\times 10^{15}$ /kg) The **Mass fraction of nuclei** will appear only if you use the two-step soot model. See [Soot Formation](#) (p. 1040) for details.

Mass fraction of soot

(in the **Soot...** category) is the mass of soot per unit mass of the mixture (e.g., kg of soot in 1 kg of the mixture). See [Soot Formation](#) (p. 1040) for details.

Mass fraction of species-n

(in the **Species...** category) is the mass of a species per unit mass of the mixture (e.g., kg of species in 1 kg of the mixture).

Mean n

(in the **Unsteady Statistics...** category) is the time-averaged value of a solution variable *n* (e.g., **Static Pressure**). See *Postprocessing for Time-Dependent Problems* (p. 1378) for details.

Mean-cff_n

(in the **Unsteady Statistics...** category) is the time-averaged value of a custom field function *cff_n* (e.g., **uns-custom-funtion-0**). See *Postprocessing for Time-Dependent Problems* (p. 1378) for details.

Meridional Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate that follows the flow path from inlet to outlet. Its value varies from 0 to 1.

Mixture Fraction Variance

(in the **Pdf...** category) is the variance of the mixture fraction solved for in the non-premixed combustion model. This is the second conservation equation (along with the mixture fraction equation) that the non-premixed combustion model solves. (See *Definition of the Mixture Fraction* in the **Theory Guide**.)

Modified Turbulent Viscosity

(in the **Turbulence...** category) is the transported quantity $\tilde{\nu}$ that is solved for in the Spalart-Allmaras turbulence model (see *Equation 4-15* in the **Theory Guide**). The turbulent viscosity, μ_t , is computed directly from this quantity using the relationship given by *Equation 4-16* in the **Theory Guide**. Its unit quantity is **viscosity**.

Molar Concentration of species-n

(in the **Species...** category) is the moles per unit volume of a species. Its unit quantity is **concentration**.

Mole fraction of species-n

(in the **Species...** category) is the number of moles of a species in one mole of the mixture.

Mole fraction of HCN, Mole fraction of NH3, Mole fraction of NO, Mole fraction of N2O

(in the **NOx...** category) are the number of moles of HCN, NH₃, NO, and N₂O in one mole of the mixture. The **Mole fraction of HCN** and the **Mole fraction of NH3** will appear only if you are modeling fuel NOx. See *Fuel NOx Formation* in the **Theory Guide** for details.

Mole fraction of soot

(in the **Soot...** category) is the number of moles of soot in one mole of the mixture.

Molecular Prandtl Number

(in the **Properties...** category) is the ratio $c_p \mu_{lam} / k_{lam}$.

Molecular Viscosity

(in the **Properties...** category) is the laminar viscosity of the fluid. Viscosity, μ , is defined by the ratio of shear stress to the rate of shear. Its unit quantity is **viscosity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. For granular phases, this is equivalent to the solids shear viscosity μ_s in *Equation 17-216* in the **Theory Guide**.

Momentum Thickness Re ($Re_{\theta t}$)

(in the **Turbulence...** category) is based on the momentum thickness of the boundary layer. The SST transition model is considering a non local empirical correlation for the value of $Re_{\theta t}$ in the free-stream, based on turbulence intensity, pressure gradient, etc...and a transport equation to allow the free-stream value to diffuse into the boundary layer.

NH3 Density, NO Density, N2O Density

(in the **NOx...** category) are the mass per unit volume of NH₃, NO and N₂O. The unit quantity for each is **density**. The **NH3 Density** will appear only if you are modeling fuel NOx. See [Fuel NOx Formation](#) in the [Theory Guide](#) for details.

NOx...

contains quantities related to the NOx model. See [NOx Formation \(p. 1009\)](#) for details about this model.

Orthogonal Quality

(in the **Mesh...** category) is a measure of the quality of a mesh, and is computed for each cell using the vectors from the cell centroid to each of its faces, the area vectors of the cell's faces, and the vectors from the cell centroid to the centroids of each of the adjacent cells (see [Equation 6-1 \(p. 145\)](#) and [Equation 6-2 \(p. 145\)](#)). The worst cells will have an **Orthogonal Quality** closer to 0, with better cells closer to 1.

Partition Boundary Cell Distance

(in the **Mesh...** category) is the smallest number of cells which must be traversed to reach the nearest partition (interface) boundary.

Partition Neighbors

(in the **Cell Info...** category) is the number of adjacent partitions (i.e., those that share at least one partition boundary face (interface)). It gives a measure of the number of messages that will have to be generated for parallel processing.

Pdf...

contains quantities related to the non-premixed combustion model, which is described in [Modeling Non-Premixed Combustion \(p. 901\)](#).

PDF Table Adiabatic Enthalpy

is the adiabatic enthalpy corresponding to the cell value of mixture fraction. For single mixture fraction cases it is given by the following equation:

$$H_{ad} = H_{fuel}f + H_{oxidizer}(1-f) \quad (34-25)$$

and for cases involving a secondary stream it is given by the following equation:

$$H_{ad} = H_{fuel}f + H_{secondary}f_{sec} + H_{oxidizer}(1-f_{sec}-f) \quad (34-26)$$

where

f = mixture fraction

f_{sec} = secondary mixture fraction

H_{fuel} = total enthalpy of the fuel stream

$H_{secondary}$ = total enthalpy of the secondary stream

$H_{oxidizer}$ = total enthalpy of the oxidizer stream

For adiabatic cases the **PDF Table Adiabatic Enthalpy** is equal to the value of Enthalpy. The unit of measurement is specific-energy.

PDF Table Heat Loss/Gain

is given by the following equation:

$$h_{loss} = (H - H_{min}) / (H_{ad} - H_{min}) - 1 \quad (34-27)$$

if the cell enthalpy is less than the adiabatic enthalpy, and by the following equation:

$$h_{gain} = 1 - (H_{max} - H) / (H_{max} - H_{ad}) \quad (34-28)$$

if the cell enthalpy is higher than adiabatic

where

H = total enthalpy

H_{ad} = the PDF Table Adiabatic Enthalpy

H_{min} = the minimum Enthalpy defined in the PDF table

H_{max} = the maximum Enthalpy defined in the PDF table

The **PDF Table Heat Loss/Gain** is dimensionless and ranges in value from -1, when H is equal to H_{min} , to +1, when H is equal to H_{max} . If H is equal to the adiabatic enthalpy it will be 0.

Phases...

contains quantities for reporting the volume fraction of each phase. See [Modeling Multiphase Flows](#) (p. 1173) for details.

Pitchwise Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate in the circumferential (pitchwise) direction. Its value varies from 0 to 1.

Preconditioning Reference Velocity

(in the **Velocity...** category) is the reference velocity used in the coupled solver's preconditioning algorithm. See [Preconditioning](#) in the [Theory Guide](#) for details.

Premixed Combustion...

contains quantities related to the premixed combustion model, which is described in [Modeling Premixed Combustion](#) (p. 957).

Pressure...

includes quantities related to a normal force per unit area (the impact of the gas molecules on the surfaces of a control volume).

Pressure Coefficient

(in the **Pressure...** category) is a dimensionless parameter defined by the equation

$$C_p = \frac{(p - p_{ref})}{q_{ref}} \quad (34-29)$$

and q_{ref} is the reference dynamic pressure defined by $\frac{1}{2}\rho_{ref}v_{ref}^2$. The reference pressure, density, and velocity are defined in the [Reference Values Task Page](#) (p. 2046).

Product Formation Rate

(in the **Premixed Combustion...** category) is the source term in the progress variable transport equation (S_c in [Equation 9-1](#) in the [Theory Guide](#)). Its unit quantity is **time-inverse**.

Production of k

(in the **Turbulence...** category) is the rate of production of turbulence kinetic energy (times density). Its unit quantity is **turb-kinetic-energy-production**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Progress Variable

(in the **Premixed Combustion...** category) is a normalized mass fraction of the combustion products ($c = 1$) or unburnt mixture products ($c = 0$), as defined by [Equation 9–2](#) in the [Theory Guide](#).

Properties...

includes material property quantities for fluids and solids.

Rate of NO

(in the **NOx...** category) is the overall rate of formation of NO due to all active NO formation pathways (e.g., thermal, prompt, etc.).

Rate of Nuclei

(in the **Soot...** category) is the overall rate of formation of nuclei.

Rate of N2OPath NO

(in the **NOx...** category) is the rate of formation of NO due to the N2O pathway only (only available when N2O pathway is active).

Rate of Prompt NO

(in the **NOx...** category) is the rate of formation of NO due to the prompt pathway only (only available when prompt pathway is active).

Rate of Reburn NO

(in the **NOx...** category) is the rate of formation of NO due to the reburn pathway only (only available when reburn pathway is active).

Rate of SNCR NO

(in the **NOx...** category) is the rate of formation of NO due to the SNCR pathway only (only available when SNCR pathway is active).

Rate of Soot

(in the **Soot...** category) is the overall rate of formation of soot mass.

Rate of Thermal NO

(in the **NOx...** category) is the rate of formation of NO due to the thermal pathway only (only available when thermal pathway is active).

Rate of Fuel NO

(in the **NOx...** category) is the rate of formation of NO due to the fuel pathway only (only available when fuel pathway is active).

Rate of USER NO

(in the **NOx...** category) is the rate of formation of NO due to user defined rates only (only available when UDF rates are added).

Radial Coordinate

(in the **Mesh...** category) is the length of the radius vector in the polar coordinate system. The radius vector is defined by a line segment between the node and the axis of rotation. You can define the rotational axis in the [Fluid Dialog Box](#) (p. 1942). (See also [Velocity Reporting Options](#) (p. 1655).) The unit quantity for **Radial Coordinate** is **length**.

Radial Pull Velocity

(in the **Solidification/Melting...** category) is the radial-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Radial Velocity

(in the **Velocity...** category) is the component of velocity in the radial direction. (See [Velocity Reporting Options \(p. 1655\)](#) for details.) The unit quantity for **Radial Velocity** is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Radial-Wall Shear Stress

(in the **Wall Fluxes...** category) is the radial component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Radiation...

includes quantities related to radiation heat transfer. See [Modeling Radiation \(p. 751\)](#) for details about the radiation models available in ANSYS FLUENT.

Radiation Heat Flux

(in the **Wall Fluxes...** category) is the rate of radiation heat transfer through the control surface. It is calculated by the solver according to the specified radiation model. Heat flux out of the domain is negative, and heat flux into the domain is positive. The unit quantity for **Radiation Heat Flux** is **heat-flux**.

Radiation Temperature

(in the **Radiation...** category) is the quantity θ_R , defined by

$$\theta_R = \left(\frac{G}{4\sigma} \right)^{1/4} \quad (34-30)$$

where G is the **Incident Radiation**. The unit quantity for **Radiation Temperature** is **temperature**.

Rate of Reaction-n

(in the **Reactions...** category) is the effective rate of progress of n th reaction. For the finite-rate model, the value is the same as the **Kinetic Rate of Reaction-n**. For the eddy-dissipation model, the value is equivalent to the **Turbulent Rate of Reaction-n**. For the finite-rate/eddy-dissipation model, it is the lesser of the two.

For particle reactions it is the global rate of the particle reaction n expressed in kmol/s/m³. This is computed as

$$\frac{\bar{R}_{j,r}}{M_j V}$$

where $\bar{R}_{j,r}$ is the rate of particle species depletion (or generation) given by [Equation 7-69](#) in the [Theory Guide](#), M_j is the particle species molecular weight, and V is the cell volume.

Reactions...

includes quantities related to finite-rate reactions. See [Modeling Species Transport and Finite-Rate Chemistry \(p. 855\)](#) for information about modeling finite-rate reactions.

Reduced Temperature

(in the **Properties...** category) is the ratio T/T_c of the fluid temperature T divided by the critical temperature T_c . The reduced temperature T_r is available only with the Angier-Redlich-Kwong real gas model.

Reduced Pressure

(in the **Properties...** category) is the ratio P/P_c of the fluid pressure P divided by the critical pressure P_c . The reduced pressure P_r is available only with the Angier-Redlich-Kwong real gas model.

Reflected Radiation Flux (Band-n)

(in the **Wall Fluxes...** category) is the amount of radiative heat flux reflected by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Reflected Visible Solar Flux, Reflected IR Solar Flux

(in the **Wall Fluxes...** category) is the amount of solar heat flux reflected by a semi-transparent wall or porous jump boundary for a visible or infrared (IR) radiation.

Refractive Index

(in the **Radiation...** category) is a nondimensional parameter defined as the ratio of the speed of light in a vacuum to that in a material. See [Specular Semi-Transparent Walls](#) in the [Theory Guide](#) for details.

Relative Axial Velocity

(in the **Velocity...** category) is the axial-direction component of the velocity relative to the reference frame motion. See [Velocity Reporting Options \(p. 1655\)](#) for details. The unit quantity for **Relative Axial Velocity** is **velocity**.

Relative Humidity

(in the **Species...** category) is the ratio of the partial pressure of the water vapor actually present in an air-water mixture to the saturation pressure of water vapor at the mixture temperature. ANSYS FLUENT computes the saturation pressure, p , from the following equation [69] (p. 2370):

$$\ln \left(\frac{p}{p_c} \right) = \left(\frac{T_c}{T} - 1 \right) \times \sum_{i=1}^8 F_i \left[a \left(T - T_p \right) \right]^{i-1} \quad (34-31)$$

where $p_c = 22.089 \text{ MPa}$

$T_c = 647.286 \text{ K}$

$F_1 = -7.4192420$

$F_2 = 2.9721000 \times 10^{-1}$

$F_3 = -1.1552860 \times 10^{-1}$

$F_4 = 8.6856350 \times 10^{-3}$

$F_5 = 1.0940980 \times 10^{-3}$

$F_6 = -4.3999300 \times 10^{-3}$

$F_7 = 2.5206580 \times 10^{-3}$

$F_8 = -5.2186840 \times 10^{-4}$

$a = 0.01$

$T_p = 338.15 \text{ K}$

Relative Mach Number

(in the **Velocity...** category) is the nondimensional ratio of the relative velocity and speed of sound.

Relative Radial Velocity

(in the **Velocity...** category) is the radial-direction component of the velocity relative to the reference frame motion. (See [Velocity Reporting Options \(p. 1655\)](#) for details.) The unit quantity for **Relative Radial Velocity** is **velocity**.

Relative Swirl Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity relative to the reference frame motion, in an axisymmetric swirling flow. (See *Velocity Reporting Options* (p. 1655) for details.) The unit quantity for **Relative Swirl Velocity** is **velocity**.

Relative Tangential Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity relative to the reference frame motion. (See *Velocity Reporting Options* (p. 1655) for details.) The unit quantity for **Relative Tangential Velocity** is **velocity**.

Relative Total Pressure

(in the **Pressure...** category) is the stagnation pressure computed using relative velocities instead of absolute velocities; i.e., for incompressible flows the dynamic pressure would be computed using the relative velocities. (See *Velocity Reporting Options* (p. 1655) for more information about relative velocities.) The unit quantity for **Relative Total Pressure** is **pressure**.

Relative Total Temperature

(in the **Temperature...** category) is the stagnation temperature computed using relative velocities instead of absolute velocities. (See *Velocity Reporting Options* (p. 1655) for more information about relative velocities.) The unit quantity for **Relative Total Temperature** is **temperature**.

Relative Velocity Angle

(in the **Velocity...** category) is similar to the **Velocity Angle** except that it uses the relative tangential velocity, and is defined as

$$\tan^{-1} \left(-\frac{\text{relative-tangential-velocity}}{\text{axial-velocity}} \right) \quad (34-32)$$

Its unit quantity is **angle**.

Relative Velocity Magnitude

(in the **Velocity...** category) is the magnitude of the relative velocity vector instead of the absolute velocity vector. The relative velocity (\vec{w}) is the difference between the absolute velocity (\vec{v}) and the mesh velocity. For simple rotation, the relative velocity is defined as

$$\vec{w} \equiv \vec{v} - \vec{\Omega} \times \vec{r} \quad (34-33)$$

where $\vec{\Omega}$ is the angular velocity of a moving reference frame about the origin and \vec{r} is the position vector. (See *Velocity Reporting Options* (p. 1655) for details.) The unit quantity for **Relative Velocity Magnitude** is **velocity**.

Relative X Velocity, Relative Y Velocity, Relative Z Velocity

(in the **Velocity...** category) are the x -, y -, and z -direction components of the velocity relative to the reference frame motion. (See *Velocity Reporting Options* (p. 1655) for details.) The unit quantity for these variables is **velocity**.

Residuals...

contains different quantities for the pressure-based and density-based solvers:

In the density-based solvers, this category includes the corrections to the primitive variables pressure, velocity, temperature, and species, as well as the time rate of change of the corrections to these primitive variables for the current iteration (i.e., residuals). Corrections are the changes in the variables between the current and previous iterations and residuals are computed by dividing a cell's correction by its physical time step. The total residual for each variable is the summation of the Euler, viscous,

and dissipation contributions. The dissipation components are the vector components of the flux-like, face-based dissipation operator.

In the pressure-based solver, only the **Mass Imbalance** in each cell is reported (unless you have requested others, as described in [Postprocessing Residual Values \(p. 1388\)](#)). At convergence, this quantity should be small compared to the average mass flow rate.

RMS *n*

(in the **Unsteady Statistics...** category) is the root mean squared value of a solution variable *n* (e.g., **Static Pressure**). See [Postprocessing for Time-Dependent Problems \(p. 1378\)](#) for details.

RMS-*cff_n*

(in the **Unsteady Statistics...** category) is the root mean squared value of a custom field function *cff_n* (e.g., **uns-custom-function-0**). See [Postprocessing for Time-Dependent Problems \(p. 1378\)](#) for details.

Rothalpy

(in the **Temperature...** category) is defined as

$$I = h + \frac{w^2}{2} - \frac{u^2}{2} \quad (34-34)$$

where *h* is the enthalpy, *w* is the relative velocity magnitude, and *u* is the magnitude of the rotational velocity $\vec{u} = \vec{\omega} \times \vec{r}$.

Scalar-*n*

(in the **User Defined Scalars...** category) is the value of the *n*th scalar quantity you have defined as a user-defined scalar. See the UDF manual for more information about user-defined scalars.

Scalar Dissipation

(in the **Pdf...** category) is one of two parameters that describes the species mass fraction and temperature for a laminar flamelet in mixture fraction spaces. It is defined as

$$\chi = 2D|\nabla f|^2 \quad (34-35)$$

where *f* is the mixture fraction and *D* is a representative diffusion coefficient (see [The Flamelet Concept](#) in the [Theory Guide](#) for details). Its unit quantity is **time-inverse**.

Scattering Coefficient

(in the **Radiation...** category) is the property of a medium that describes the amount of scattering of thermal radiation per unit path length for propagation in the medium. It can be interpreted as the inverse of the mean free path that a photon will travel before undergoing scattering (if the scattering coefficient does not vary along the path). The unit quantity for **Scattering Coefficient** is **length-inverse**.

Secondary Mean Mixture Fraction

(in the **Pdf...** category) is the mean ratio of the secondary stream mass fraction to the sum of the fuel, secondary stream, and oxidant mass fractions. It is the secondary-stream conserved scalar that is calculated by the non-premixed combustion model. See [Definition of the Mixture Fraction](#) in the [Theory Guide](#).

Secondary Mixture Fraction Variance

(in the **Pdf...** category) is the variance of the secondary stream mixture fraction that is solved for in the non-premixed combustion model. See [Definition of the Mixture Fraction](#) in the [Theory Guide](#).

Sensible Enthalpy

(in the **Temperature...** category) is available when any of the species models are active and displays only the thermal (sensible) enthalpy.

Skin Friction Coefficient

(in the **Wall Fluxes...** category) is a nondimensional parameter defined as the ratio of the wall shear stress and the reference dynamic pressure

$$C_f \equiv \frac{\tau_w}{\frac{1}{2} \rho_{ref} v_{ref}^2} \quad (34-36)$$

v_{ref} are the reference density and velocity defined in the [Reference Values Task Page \(p. 2046\)](#). For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Solar Heat Flux

(in the **Wall Fluxes...** category) is the rate of solar heat transfer through the control surface. Heat flux out of the domain is negative and heat flux into the domain is positive.

Solidification/Melting...

contains quantities related to solidification and melting.

Soot...

contains quantities related to the **Soot** model, which is described in [Soot Formation \(p. 1040\)](#).

Soot Density

(in the **Soot...** category) is the mass per unit volume of soot. The unit quantity is **density**. See [Fuel NOx Formation](#) in the [Theory Guide](#) for details.

Sound Speed

(in the **Properties...** category) is the acoustic speed. It is computed from $\sqrt{\frac{\gamma p}{\rho}}$. Its unit quantity is **velocity**.

Important

Note that for the real gas models the sound speed is computed accordingly by the appropriate equation of state formulation.

Spanwise Coordinate

(in the **Mesh...** category) is the normalized (dimensionless) coordinate in the spanwise direction, from hub to casing. Its value varies from 0 to 1.

species-n Source Term

(in the **Species...** category) is the source term in each of the species transport equations due to reactions. The unit quantity is always kg/m³-s.

Species...

includes quantities related to species transport and reactions.

Specific Dissipation Rate (Omega)

(in the **Turbulence...** category) is the rate of dissipation of turbulence kinetic energy in unit volume and time. Its unit quantity is **time-inverse**.

Specific Heat (Cp)

(in the **Properties...** category) is the thermodynamic property of specific heat at constant pressure. It is defined as the rate of change of enthalpy with temperature while pressure is held constant. Its unit quantity is **specific-heat**.

Specific Heat Ratio (gamma)

(in the **Properties...** category) is the ratio of specific heat at constant pressure to the specific heat at constant volume.

Spinodal Temperature

(in the **Properties...** category) is the temperature at which the derivative of pressure with respect to volume becomes positive. The **spinodal temperature** defines the point beyond which the equation of state is no longer valid for the gas phase. If the temperature of your case approaches the **spinodal temperature** in some regions, this indicates that the flow conditions in these regions may fall inside the saturation dome. The **spinodal temperature** is available only with the Angier-Redlich-Kwong real gas model.

Stored Cell Partition

(in the **Cell Info...** category) is an integer identifier designating the partition to which a particular cell belongs. In problems in which the mesh is divided into multiple partitions to be solved on multiple processors using the parallel version of ANSYS FLUENT, the partition ID can be used to determine the extent of the various groups of cells. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file. See *Partitioning the Mesh Manually and Balancing the Load (p. 1736)* for more information.

Static Pressure

(in the **Pressure...** category) is the static pressure of the fluid. It is a gauge pressure expressed relative to the prescribed operating pressure. The absolute pressure is the sum of the **Static Pressure** and the operating pressure. Its unit quantity is **pressure**.

Static Temperature

(in the **Temperature...** and **Premixed Combustion...** categories) is the temperature that is measured moving with the fluid. Its unit quantity is **temperature**.

Note that **Static Temperature** will appear in the **Premixed Combustion...** category only for adiabatic premixed combustion calculations. See *Postprocessing for Premixed Combustion Calculations (p. 965)*.

Strain Rate

(in the **Derivatives...** category) relates shear stress to the viscosity. Also called the shear rate ($\dot{\gamma}$ in *Equation 8-29 (p. 432)*), the strain rate is related to the second invariant of the rate-of-deformation tensor \bar{D} . Its unit quantity is **time-inverse**. In 3D Cartesian coordinates, the strain rate, S , is defined as

$$S^2 = \left[\frac{\partial u}{\partial x} \left(\frac{\partial u}{\partial x} + \frac{\partial u}{\partial x} \right) + \frac{\partial u}{\partial y} \left(\frac{\partial u}{\partial y} + \frac{\partial v}{\partial x} \right) + \frac{\partial u}{\partial z} \left(\frac{\partial u}{\partial z} + \frac{\partial w}{\partial x} \right) \right] + \\ \left[\frac{\partial v}{\partial x} \left(\frac{\partial v}{\partial x} + \frac{\partial u}{\partial y} \right) + \frac{\partial v}{\partial y} \left(\frac{\partial v}{\partial y} + \frac{\partial v}{\partial y} \right) + \frac{\partial v}{\partial z} \left(\frac{\partial v}{\partial z} + \frac{\partial w}{\partial y} \right) \right] + \\ \left[\frac{\partial w}{\partial x} \left(\frac{\partial w}{\partial x} + \frac{\partial u}{\partial z} \right) + \frac{\partial w}{\partial y} \left(\frac{\partial w}{\partial y} + \frac{\partial v}{\partial z} \right) + \frac{\partial w}{\partial z} \left(\frac{\partial w}{\partial z} + \frac{\partial w}{\partial z} \right) \right] \quad (34-37)$$

For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Stream Function

(in the **Velocity...** category) is formulated as a relation between the streamlines and the statement of conservation of mass. A streamline is a line that is tangent to the velocity vector of the flowing fluid. For a 2D planar flow, the stream function, ψ , is defined such that

$$\rho u = \frac{\partial \psi}{\partial y} \quad \rho v = - \frac{\partial \psi}{\partial x} \quad (34-38)$$

constant values of stream function defining two streamlines is the mass rate of flow between the streamlines.

The accuracy of the stream function calculation is determined by the text command `/display/set/n-stream-func`.

Stretch Factor

(in the **Premixed Combustion...** category) is a nondimensional parameter that is defined as the probability of unquenched flamelets (G in [Equation 9-15](#) in the [Theory Guide](#)).

Subgrid Dissipation Rate

(in the **Turbulence...** category) is the turbulence dissipation rate of the unresolved eddies, eps_{sgs} , only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$\text{eps}_{sgs} = C_{\text{eps}} * \frac{k_{sgs}^{3/2}}{L_s} \quad (34-39)$$

Its unit quantity is **turbulent-energy-diss-rate**.

Subgrid Dynamic Viscosity Const

(in the **Turbulence...** category) is the Smagorinsky model constant as determined by the dynamic procedure described in [Dynamic Smagorinsky-Lilly Model](#) in the [Theory Guide](#)). Additional information with respect to the Embedded LES (E-LES) model can be found in [Postprocessing for Turbulent Flows](#) (p. 729).

Subgrid Filter Length

(in the **Turbulence...** category) is a mixing length for subgrid scales of the LES turbulence model (defined as L_S in [Equation 4-249](#) in the [Theory Guide](#)).

Subgrid Kinetic Energy

(in the **Turbulence...** category) is the turbulence kinetic energy per unit mass of the unresolved eddies, k_{sgs} , calculated using a transport equation, only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$k_{sgs} = \frac{1}{2} \left(\overline{u_k^2} - \overline{\bar{u}_k^2} \right) \quad (34-40)$$

Additional information with respect to the Embedded LES (E-LES) model can be found in [Postprocessing for Turbulent Flows](#) (p. 729). Its unit quantity is **turbulent-kinetic-energy**.

Subgrid Test-Filter Length

(in the **Turbulence...** category) is the test filter width $\hat{\Delta}$ described in [Dynamic Smagorinsky-Lilly Model](#) in the [Theory Guide](#)). Additional information with respect to the Embedded LES (E-LES) model can be found in [Postprocessing for Turbulent Flows](#) (p. 729).

Subgrid Turbulent Viscosity

(in the **Turbulence...** category) is the turbulent (dynamic) viscosity of the fluid calculated using the LES turbulence model. It expresses the proportionality between the anisotropic part of the subgrid-scale stress tensor and the rate-of-strain tensor. (See [Equation 4–240](#) in the [Theory Guide](#).) Its unit quantity is **viscosity**.

Subgrid Turbulent Viscosity Ratio

(in the **Turbulence...** category) is the ratio of the subgrid turbulent viscosity of the fluid to the laminar viscosity, calculated using the LES turbulence model.

Subtest Kinetic Energy

(in the **Turbulence...** category) is the turbulence kinetic energy of filtered eddies, k_f , only active for the LES and Kinetic Energy Subgrid-Scale Model. It is defined as

$$k_f = L_1 + L_2 + L_3 \quad (34-41)$$

with L_i being the normal components of the Leonard stress.

Its unit quantity is **turbulent-kinetic-energy**

Surface Acoustic Power

(in the **Acoustics...** category) is the **Acoustic Power** per unit area generated by boundary layer turbulence (see [Equation 15–32](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used. Its unit quantity is **power per area**.

Surface Acoustic Power Level (dB)

(in the **Acoustics...** category) is the **Acoustic Power** per unit area generated by boundary layer turbulence, and represented in dB (see [Equation 15–32](#) in the [Theory Guide](#)). It is available only when the **Broadband Noise Sources** acoustics model is being used.

Surface Cluster ID

(in the **Radiation...** category) is used to view the distribution of surface clusters in the domain. Each cluster has a unique integer number (ID) associated with it.

Surface Coverage of species-n

(in the **Species...** category) is the amount of a surface species that is deposited on the substrate at a specific point in time.

Surface Deposition Rate of species-n

(in the **Species...** category) is the amount of a surface species that is deposited on the substrate. Its unit quantity is **mass-flux**.

Surface dpdt RMS

(in the **Acoustics...** category) is the RMS value of the time-derivative of static pressure ($\partial p / \partial t$). It is available when the **Fflowcs-Williams & Hawlings** acoustics model is being used.

Surface Heat Transfer Coef.

(in the **Wall Fluxes...** category), as defined in ANSYS FLUENT, is given by the equation

$$h_{eff} = \frac{q}{T_{wall} - T_{ref}} \quad (34-42)$$

T_{ref} is the reference temperature defined in the [Reference Values Task Page \(p. 2046\)](#). Please note that T_{ref} is a constant value that should be representative of the problem. Its unit quantity is the **heat-transfer coefficient**.

Surface Incident Radiation

(in the **Wall Fluxes...** category) is the net incoming radiation heat flux on a surface. Its unit quantity is **heat-flux**.

Surface Nusselt Number

(in the **Wall Fluxes...** category) is a local nondimensional coefficient of heat transfer defined by the equation

$$Nu = \frac{h_{eff} L_{ref}}{k} \quad (34-43)$$

Surface Stanton Number

(in the **Wall Fluxes...** category) is a nondimensional coefficient of heat transfer defined by the equation

$$St = \frac{h_{eff}}{\rho_{ref} v_{ref} c_p} \quad (34-44)$$

v_{ref} are reference values of density and velocity defined in the [Reference Values Task Page \(p. 2046\)](#), and c_p is the specific heat at constant pressure.

Swirl Pull Velocity

(in the **Solidification/Melting...** category) is the tangential-direction component of the pull velocity for the solid material in a continuous casting process. Its unit quantity is **velocity**.

Swirl Velocity

(in the **Velocity...** category) is the tangential-direction component of the velocity in an axisymmetric swirling flow. See [Velocity Reporting Options \(p. 1655\)](#) for details. The unit quantity for **Swirl Velocity** is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Swirl-Wall Shear Stress

(in the **Wall Fluxes...** category) is the swirl component of the force acting tangential to the surface due to friction. Its unit quantity is **pressure**.

Tangential Velocity

(in the **Velocity...** category) is the velocity component in the tangential direction. (See [Velocity Reporting Options \(p. 1655\)](#) for details.) The unit quantity for **Tangential Velocity** is **velocity**.

Temperature...

indicates the quantities associated with the thermodynamic temperature of a material.

Thermal Conductivity

(in the **Properties...** category) is a parameter (k) that defines the conduction rate through a material via Fourier's law ($q = -k \nabla T$). A large thermal conductivity is associated with a good heat conductor and

a small thermal conductivity with a poor heat conductor (good insulator). Its unit quantity is **thermal-conductivity**.

Thermal Diff Coef of species-n

(in the **Species...** category) is the thermal diffusion coefficient for the *n*th species ($D_{T,i}$ in [Equation 8–58 \(p. 458\)](#), [Equation 8–60 \(p. 458\)](#), and [Equation 8–64 \(p. 460\)](#)). Its unit quantity is **viscosity**.

Time Step

(in the **Residuals...** category) is the local time step of the cell, Δt , at the current iteration level. Its unit quantity is **time**.

Time Step Scale

(in the **Species...** category) is the factor by which the time step is reduced for the stiff chemistry solver (available in the density-based solver only). The time step is scaled down based on an eigenvalue and positivity analysis.

Total Energy

(in the **Temperature...** category) is the total energy per unit mass. Its unit quantity is **specific-energy**.

For all species models, plots of **Total Energy** include the sensible, chemical and kinetic energies. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Enthalpy

(in the **Temperature...** category) is defined as $H + \frac{1}{2}v^2$ where H is the **Enthalpy**, as defined in [Equation 5–7](#) in the [Theory Guide](#), and v is the velocity magnitude. Its unit quantity is **specific-energy**. For all species models, plots of **Total Enthalpy** consist of the sensible, chemical and kinetic energies. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Enthalpy Deviation

(in the **Temperature...** category) is the difference between **Total Enthalpy** and the reference enthalpy, $H + \frac{1}{2}v^2 - H_{ref}$, where H_{ref} is the reference enthalpy defined in the [Reference Values Task Page \(p. 2046\)](#).

However, for non-premixed and partially premixed models, **Total Enthalpy Deviation** is the difference between **Total Enthalpy** and total adiabatic enthalpy (total enthalpy where no heat loss or gain occurs). The unit quantity for **Total Enthalpy Deviation** is **specific-energy**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Total Pressure

(in the **Pressure...** category) is the pressure at the thermodynamic state that would exist if the fluid were brought to zero velocity and zero potential. For compressible flows, the total pressure is computed using isentropic relationships. For constant c_p , this reduces to:

$$p_0 = p \left[1 + \frac{\gamma - 1}{2} M^2 \right]^{\gamma / (\gamma - 1)} \quad (34-45)$$

For incompressible flows (constant density fluid), we use Bernoulli's equation, $p_0 = p + p_{dyn}$, where p_{dyn} is the local dynamic pressure. Its unit quantity is **pressure**.

Important

Note that in the postprocessing, the total pressure is presented as gauge pressure, for compressible and incompressible flows. If the total absolute pressure is needed, then add the value of the reference pressure to the total gauge pressure.

Total Surface Heat Flux

(in the **Wall Fluxes...** category) is the rate of total heat transfer through the control surface. It is calculated by the solver according to the boundary conditions being applied at that surface. By definition, heat flux out of the domain is negative, and heat flux into the domain is positive. The unit quantity for **Total Surface Heat Flux** is **heat-flux**.

Total Temperature

(in the **Temperature...** category) is the temperature at the thermodynamic state that would exist if the fluid were brought to zero velocity. For compressible flows, the total temperature is computed from the total enthalpy using the current c_p method (specified in the *Create/Edit Materials Dialog Box* (p. 1882)). For incompressible flows, the total temperature is equal to the static temperature, unless kinetic energy is explicitly added. The unit quantity for **Total Temperature** is **temperature**.

Transmitted Radiation Flux (Band-n)

(in the **Wall Fluxes...** category) is the amount of radiative heat flux transmitted by a semi-transparent wall for a particular band of radiation. Its unit quantity is **heat-flux**.

Transmitted Visible Solar Flux, Transmitted IR Solar Flux

(in the **Wall Fluxes...** category) is the amount of solar heat flux transmitted by a semi-transparent wall or porous jump boundary for a visible or infrared radiation.

Turbulence...

includes quantities related to turbulence. See *Modeling Turbulence* (p. 683) for information about the turbulence models available in ANSYS FLUENT.

Turbulence Intensity

(in the **Turbulence...** category) is the ratio of the magnitude of the RMS turbulent fluctuations to the reference velocity:

$$I = \frac{\sqrt{\frac{2}{3}k}}{v_{ref}} \quad (34-46)$$

where k is the turbulence kinetic energy and v_{ref} is the reference velocity specified in the *Reference Values Task Page* (p. 2046). The reference value specified should be the mean velocity magnitude for the flow. Note that turbulence intensity can be defined in different ways, so you may want to use a custom field function for its definition. See *Custom Field Functions* (p. 1708) for more information.

Turbulent Dissipation Rate (Epsilon)

(in the **Turbulence...** category) is the turbulent dissipation rate. Its unit quantity is **turbulent-energy-diss-rate**. This quantity is available for the k-epsilon and k-omega based turbulence models, where the epsilon/omega relationship is defined as

$$\varepsilon = 0.09k\omega \quad (34-47)$$

For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Turbulent Flame Speed

(in the **Premixed Combustion...** category) is the turbulent flame speed computed by ANSYS FLUENT using Equation 9–9 in the *Theory Guide*. Its unit quantity is **velocity**.

Turbulent Kinetic Energy (k)

(in the **Turbulence...** category) is the turbulence kinetic energy per unit mass defined as

$$k = \frac{1}{2} \overline{u'_i u'_i} \quad (34-48)$$

Turbulent Rate of Reaction-n

(in the **Reactions...** category) is the rate of progress of the n th reaction computed by [Equation 7-25](#) or [Equation 7-26](#) (in the [Theory Guide](#)). For the “eddy-dissipation” model, the value is the same as the **Rate of Reaction-n**. For the “finite-rate” model, the value is zero.

Turbulent Reynolds Number (Re_y)

(in the **Turbulence...** category) is a nondimensional quantity defined as

$$\frac{\rho d \sqrt{k}}{\mu_{lam}} \quad (34-49)$$

where k is turbulence kinetic energy, d is the distance to the nearest wall, and μ_{lam} is the laminar viscosity.

Turbulent Viscosity

(in the **Turbulence...** category) is the turbulent viscosity of the fluid computed using the turbulence model. Its unit quantity is **viscosity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list. Additional information with respect to the Embedded LES (E-LES) model can be found in [Postprocessing for Turbulent Flows \(p. 729\)](#).

Turbulent Viscosity Ratio

(in the **Turbulence...** category) is the ratio of turbulent viscosity to the laminar viscosity. Additional information with respect to the Embedded LES (E-LES) model can be found in [Postprocessing for Turbulent Flows \(p. 729\)](#).

udm-n

(in the **User Defined Memory...** category) is the value of the quantity in the n th user-defined memory location.

Unburnt Fuel Mass Fraction

(in the **Premixed Combustion...** category) is the mass fraction of unburnt fuel. This function is available only for non-adiabatic models.

Unsteady Statistics...

includes mean and root mean square (RMS) values of solution variables and custom field functions derived from transient flow calculations.

User Defined Memory...

includes quantities that have been allocated to a user-defined memory location. See the separate [UDF Manual](#) for details about user-defined memory.

User-Defined Scalars...

includes quantities related to user-defined scalars. See the separate [UDF Manual](#) for information about using user-defined scalars.

UU Reynolds Stress

(in the **Turbulence...** category) is the $\overline{u'^2}$ stress.

UV Reynolds Stress

(in the **Turbulence...** category) is the $\overline{u'v'}$ stress.

UW Reynolds Stress

(in the **Turbulence...** category) is the $\overline{u'w'}$ stress.

Variance of Species

(in the **NOx...** category) is the variance of the mass fraction of a selected species in the flow field. It is calculated from [Equation 14–113](#) in the [Theory Guide](#).

Variance of Species 1, Variance of Species 2

(in the **NOx...** category) are the variances of the mass fractions of the selected species in the flow field. They are each calculated from [Equation 14–113](#) in the [Theory Guide](#).

Variance of Temperature

(in the **NOx...** category) is the variance of the normalized temperature in the flow field. It is calculated from [Equation 14–113](#) in the [Theory Guide](#).

Velocity...

includes the quantities associated with the rate of change in position with time. The instantaneous velocity of a particle is defined as the first derivative of the position vector with respect to time, $d\vec{r}/dt$, termed the velocity vector, \vec{v} .

Velocity Angle

(in the **Velocity...** category) is defined as follows:

For a 2D model,

$$\tan^{-1} \left(\frac{\text{y-velocity-component}}{\text{x-velocity-component}} \right) \quad (34-50)$$

For a 2D or axisymmetric model,

$$\tan^{-1} \left(\frac{\text{radial-velocity-component}}{\text{axial-velocity-component}} \right) \quad (34-51)$$

For a 3D model,

$$\tan^{-1} \left(\frac{\text{tangential-velocity-component}}{\text{axial-velocity-component}} \right) \quad (34-52)$$

Its unit quantity is **angle**.

Velocity Magnitude

(in the **Velocity...** category) is the speed of the fluid. Its unit quantity is **velocity**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Volume fraction

(in the **Phases...** category) is the volume fraction of the selected phase in the **Phase** drop-down list.

Vorticity Magnitude

(in the **Velocity...** category) is the magnitude of the vorticity vector. Vorticity is a measure of the rotation of a fluid element as it moves in the flow field, and is defined as the curl of the velocity vector:

$$\xi = \nabla \times \vec{V} \quad (34-53)$$

VV Reynolds Stress

(in the **Turbulence...** category) is the $\overline{v'^2}$ stress.

VW Reynolds Stress

(in the **Turbulence...** category) is the $\overline{v'w'}$ stress.

Wall Fluxes...

includes quantities related to forces and heat transfer at wall surfaces.

Wall Func. Heat Tran. Coef.

is defined by the equation

$$h_{eff} = \frac{\rho C_p C_\mu^{1/4} k_p^{1/2}}{T^*} \quad (34-54)$$

where C_p is the specific heat, k_p is the turbulence kinetic energy at point P , and T^* is the dimensionless law-of-the-wall temperature defined in [Equation 4-283](#) in the [Theory Guide](#).

Wall Shear Stress

(in the **Wall Fluxes...** category) is the force acting tangential to the surface due to friction. Its unit quantity is **pressure**. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Wall Temperature (Inner Surface)

(in the **Temperature...** category) is the temperature on the inner surface of a wall. For thin walls without shell conduction, this surface corresponds to the side of the wall surface that is away from the adjacent fluid or solid cell zone (see [Figure 7.35 \(p. 325\)](#)); for thin walls with shell conduction, this surface corresponds to the middle of the cells grown for the wall (see [Figure 14.4 \(p. 749\)](#)). Note that for thin walls without shell conduction, wall thermal boundary conditions are applied on this surface.

Wall Temperature (Outer Surface)

(in the **Temperature...** category) is the temperature on the outer surface of a wall (corresponding to the side of the wall surface that is adjacent to the fluid or solid cell zone). Note that wall thermal boundary conditions are applied on the **Inner Surface**. See [Figure 7.35 \(p. 325\)](#) for thin walls without shell conduction, and see [Figure 14.4 \(p. 749\)](#) for thin walls with shell conduction.

Wall Yplus

(in the **Turbulence...** category) is a nondimensional parameter defined by the equation

$$y^+ = \frac{\rho u_\tau y_P}{\mu} \quad (34-55)$$

where $u_\tau = \sqrt{\tau_w/\rho_w}$ is the friction velocity, y_P is the distance from point P to the wall, ρ is the fluid density, and μ is the fluid viscosity at point P . See [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#) for details. For multiphase models, this value corresponds to the selected phase in the **Phase** drop-down list.

Wall Ystar

(in the **Turbulence...** category) is a nondimensional parameter defined by the equation

$$y^* = \frac{\rho C_\mu^{1/4} k_P^{1/2} y_P}{\mu} \quad (34-56)$$

where k_P is the turbulence kinetic energy at point P , y_P is the distance from point P to the wall, ρ is the fluid density, and μ is the fluid viscosity at point P . See [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#) for details.

WW Reynolds Stress

(in the **Turbulence...** category) is the $\overline{w'^2}$ stress.

X-Coordinate, Y-Coordinate, Z-Coordinate

(in the **Mesh...** category) are the Cartesian coordinates in the x -axis, y -axis, and z -axis directions respectively. The unit quantity for these variables is **length**.

X Face Area, Y Face Area, Z Face Area

(in the **Mesh...** category) are the components of the face area vector for noninternal faces (i.e., faces that only have c0 and no c1). The values are stored on the face itself and used when required. These variables are intended only for zone surfaces and not for other surfaces created for postprocessing.

X Pull Velocity, Y Pull Velocity, Z Pull Velocity

(in the **Solidification/Melting...** category) are the x , y , and z components of the pull velocity for the solid material in a continuous casting process. The unit quantity for each is **velocity**.

X Velocity, Y Velocity, Z Velocity

(in the **Velocity...** category) are the components of the velocity vector in the x -axis, y -axis, and z -axis directions, respectively. The unit quantity for these variables is **velocity**. For multiphase models, these values correspond to the selected phase in the **Phase** drop-down list.

X-Vorticity, Y-Vorticity, Z-Vorticity

(in the **Velocity...** category) are the x , y , and z components of the vorticity vector.

X-Wall Shear Stress, Y-Wall Shear Stress, Z-Wall Shear Stress

(in the **Wall Fluxes...** category) are the x , y , and z components of the force acting tangential to the surface due to friction. The unit quantity for these variables is **pressure**. For multiphase models, these values correspond to the selected phase in the **Phase** drop-down list.

34.5. Custom Field Functions

In addition to the basic field variables provided by ANSYS FLUENT (and described in [Alphabetical Listing of Field Variables and Their Definitions](#) (p. 1674)), you can also define your own field functions to be used in conjunction with any of the commands that use these variables (contour and vector display, XY plots, etc.). This capability is available with the [Custom Field Function Calculator Dialog Box](#) (p. 2264). You can use the default field variables, previously defined calculator functions, and calculator operators to create new functions. (Several sample functions are described in [Sample Custom Field Functions](#) (p. 1712).)

Any field functions that you define will be saved in the case file the next time that you save it. You can also save your custom field functions to a separate file (as described in [Manipulating, Saving, and Loading Custom Field Functions](#) (p. 1711)), so that they can be used with a different case file.

Important

Note that all custom field functions are evaluated and stored in SI units.

Any solver-defined flow variables that you use in your field-function definition will be automatically converted if they are not already in SI units, but you must be careful to enter constants in the appropriate units. Note also that explicit node values are not available for custom field functions; all node values for these functions will be computed by averaging the values in the surrounding cells, as described in [Node Values \(p. 1653\)](#).

Important

When using the parallel version of ANSYS FLUENT, the only packages to which you can export custom field functions are the following:

- ANSYS CFD-Post
- EnSight Case Gold
- Fieldview Unstructured

For further information about exporting files, see [Exporting Solution Data \(p. 86\)](#).

For additional information, please see the following sections:

- 34.5.1. [Creating a Custom Field Function](#)
- 34.5.2. [Manipulating, Saving, and Loading Custom Field Functions](#)
- 34.5.3. [Sample Custom Field Functions](#)

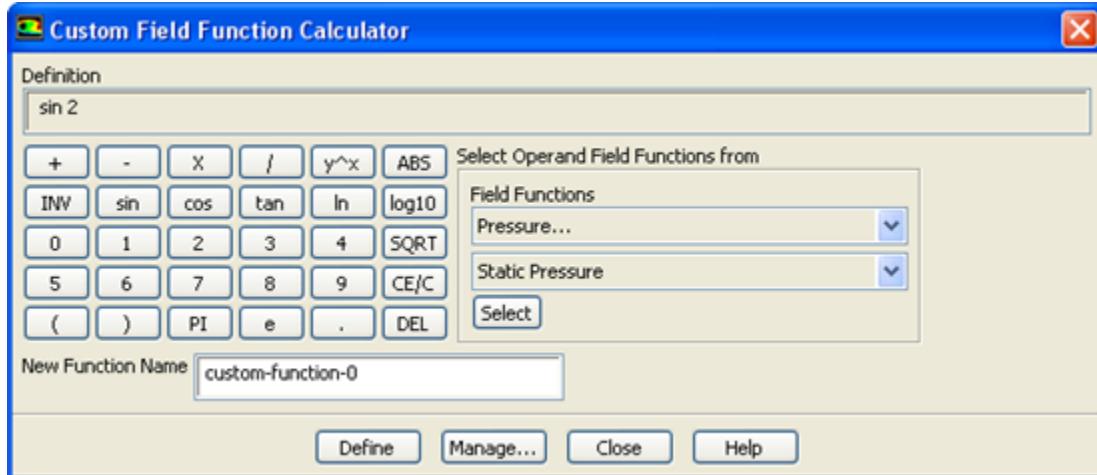

34.5.1. Creating a Custom Field Function

To create your own field function, you will use the [Custom Field Function Calculator Dialog Box \(p. 2264\)](#) ([Figure 34.3 \(p. 1710\)](#)). This dialog box allows you to define field functions based on existing functions, using simple calculator operators. Any functions that you define will be added to the list of default flow variables and other field functions provided by the solver.

Define → Custom Field Functions...

Important

Recall that you must enter all constants in the function definition in SI units.

Figure 34.3 The Custom Field Function Calculator Dialog Box

The steps for creating a custom field function are as follows:

1. Use the calculator buttons and the **Field Functions** list and **Select** button to specify the function definition, as described below. (As you select each item from the **Field Functions** list or click a button in the calculator keypad, its symbol will appear in the **Definition** text entry box. You *cannot* edit the contents of this box directly; if you want to delete part of a function, use the **DEL** button on the keypad.)

Important

The range of integers and real numbers that can be stored is as follows:

$$\begin{aligned} -2147483648 &> \text{integers} < 2147483647 \\ -1.79769e+308 &> \text{real} < 1.79769e+308 \end{aligned}$$

Note that using a number less than 1e-39 may produce inaccurate results, while values less than 1e-45 will produce a result of zero.

2. Specify the name of the function in the **New Function Name** field.

Important

Be sure that you do not specify a name that is already used for a standard field function (e.g., velocity-magnitude); you can see a complete list of the predefined field functions in ANSYS FLUENT by selecting the **display/contours** text command and viewing the available choices for contours of.

3. Click the **Define** button.

When you click **Define**, the solver will create the function and add it to the list of **Custom Field Functions** within the drop-down list of available field functions. The **Define** push button is grayed out after you create a new function or if the **Definition** text entry box is empty.

Should you decide to rename or delete the function after you have completed the definition, you can do so in the *Field Function Definitions Dialog Box* (p. 2265), which you can open by clicking on the **Manage...** push button. See *Manipulating, Saving, and Loading Custom Field Functions* (p. 1711) for details.

34.5.1.1. Using the Calculator Buttons

Your function definition can include many basic calculator operations (e.g., addition, subtraction, multiplication, square root). When you select a calculator button (by clicking on it), the appropriate symbol will appear in the **Definition** text entry box. The meaning of the buttons is straightforward; they are similar to the buttons you would find on any standard calculator. You should, however, note the following:

- The **CE/C** button will clear the entire **Definition** and the **New Function Name**, if you have entered one. The **DEL** button will delete only the last entry in the **Definition** text entry box. You can use **DEL** to delete characters one at a time, starting with the last one entered.
- To obtain the inverse trigonometric functions arcsin, arccos, and arctan, click the **INV** button before selecting **sin**, **cos**, or **tan**.
- The **ABS** button yields the absolute value of the number that follows it. Likewise, the **In** button yields the natural logarithm of the number that follows it, and the **log10** button yields the base 10 logarithm function of the number that follows it.

Important

log10 and **In** will be calculated for values greater than 0. For values less than or equal to 0, the resultant value will be zero.

- The **PI** button represents π and the **e** button represents the base of the natural logarithm system (which is approximately equal to 2.71828).

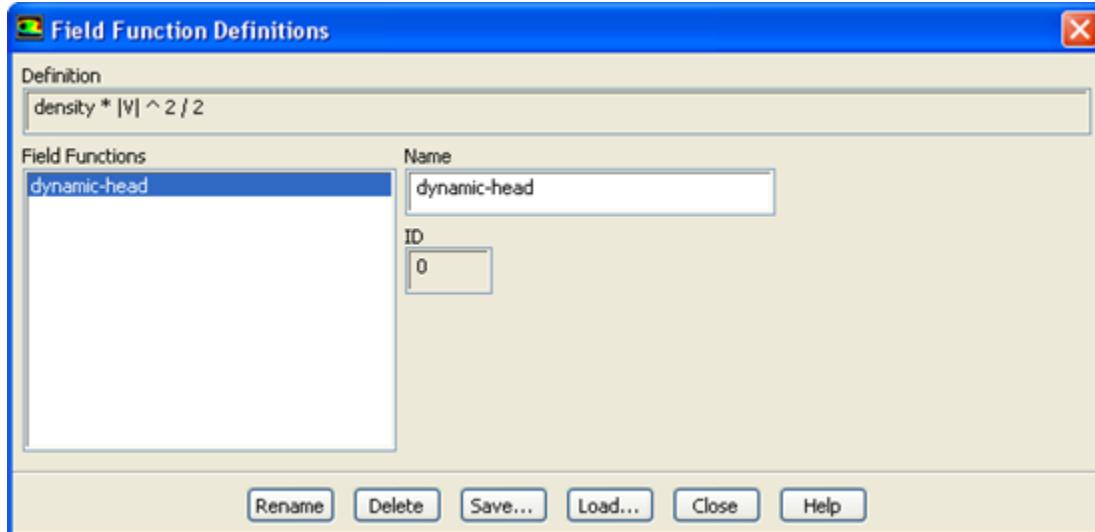

34.5.1.2. Using the Field Functions List

Your function definition can also include any of the field functions defined by the solver (and listed in *Alphabetical Listing of Field Variables and Their Definitions* (p. 1674)) or by you. To include one of these variables/functions in your function definition, select it in the **Field Functions** drop-down list and then click the **Select** button below the list. The symbol for the selected item will appear in the **Definition** text entry box (e.g., **p** will appear if you select **Static Pressure**).

34.5.2. Manipulating, Saving, and Loading Custom Field Functions

Once you have defined your field functions, you can manipulate them using the *Field Function Definitions Dialog Box* (p. 2265) (*Figure 34.4* (p. 1712)). You can display a function definition to be sure that it is correct, delete the function if you decide that it is incorrect and needs to be redefined, or give the function a new name. You can also save custom field functions to a file or read them from a file. The custom field function file allows you to transfer your custom functions between case files.

To open the *Field Function Definitions Dialog Box* (p. 2265), click the **Manage...** button in the *Custom Field Function Calculator Dialog Box* (p. 2264).

Figure 34.4 The Field Function Definitions Dialog Box

The following actions can be performed in the *Field Function Definitions Dialog Box* (p. 2265):

- To check the definition of a function, select it in the **Field Functions** list. Its definition will be displayed in the **Definition** field. This display is for informational purposes only; you cannot edit it. If you want to change a function definition, you must delete the function and define it again in the *Custom Field Function Calculator Dialog Box* (p. 2264).
- To delete a function, select it in the **Field Functions** list and click the **Delete** button.
- To rename a function, select it in the **Field Functions** list, enter a new name in the **Name** field, and click the **Rename** button.

Important

Be sure that you do not specify a name that is already used for a standard field function (e.g., velocity-magnitude); you can see a complete list of the predefined field functions in ANSYS FLUENT by selecting the *display/contours* text command and viewing the available choices for contours of.

- To save all of the functions in the **Field Functions** list to a file, click the **Save...** button and specify the file name in *The Select File Dialog Box* (p. 33).
- To read custom field functions from a file that you saved as described above, click the **Load...** button and specify the file name in the resulting **Select File** dialog box. (Custom field function files are valid Scheme functions, and can also be loaded with the **File/Read/Scheme...** menu item, as described in *Reading Scheme Source Files* (p. 75).)

34.5.3. Sample Custom Field Functions

When you are checking the results of your simulation, you may find it useful to define some of the following field functions:

- To define a function that determines the ratio of static pressure to inlet total pressure, use the relationship

$$R = \frac{p + p_{op}}{p_{to} + p_{op}} \quad (34-57)$$

where p is the static pressure calculated by the solver, p_{to} is the inlet total pressure, and p_{op} is the operating pressure for the problem. Use the solver-defined function **Static Pressure** for p , and the numerical value that you specified for **Gauge Total Pressure** in the *Pressure Inlet Dialog Box* (p. 1994) for p_{to} . Specify the value of the operating pressure to be the value that you set in the *Operating Conditions Dialog Box* (p. 1952). As discussed in *Operating Pressure* (p. 468), all pressures in ANSYS FLUENT are gauge pressures relative to the operating pressure. If the operating pressure is zero, as is generally the case for compressible flow calculations, the expression for the pressure ratio reduces to

$$PR = \frac{p}{p_{to}} \quad (34-58)$$

- To define a function that determines the critical velocity ratio v/a_* , a parameter that is sometimes used in turbomachinery calculations, use the relationship

$$\frac{v}{a_*} = \left[\left(\frac{\gamma + 1}{\gamma - 1} \right) \left(1 - PR^{(\gamma - 1)/\gamma} \right) \right]^{1/2} \quad (34-59)$$

In this relationship, a_* is the critical velocity (i.e., the velocity that would occur for the same stagnation conditions if $M = 1$), γ is the ratio of specific heats, and PR is the pressure ratio defined in *Equation 34-58* (p. 1713) for which you created your own function. For γ , ratio of specific heats, select **Specific Heat Ratio (gamma)** in the **Properties...** category. To include PR , select **Custom Field Functions...** in the first drop-down list under **Field Functions**, and then select from the second list the function name that you assigned PR .

- Suppose you have swirling flow in a pipe, aligned with the z axis, and you want to calculate the flow rate of angular momentum through a cross-sectional plane:

$$\int \rho r v_\theta \vec{v} \cdot d\vec{A} \quad (34-60)$$

You can create a function for the product $r v_\theta$, where r is the **Radial Coordinate** and v_θ is the **Tangential Velocity**. Then use the *Surface Integrals Dialog Box* (p. 2188) to compute the flow rate of this quantity.

Important

The custom field function containing model dependent functions (like temperature when the energy equation is enabled) will be computed only when those models are still active.

Chapter 35: Parallel Processing

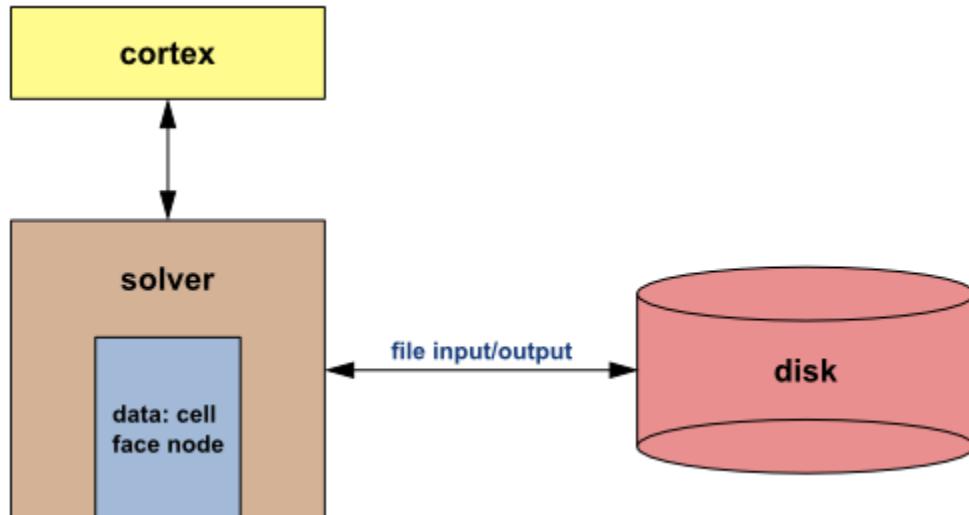

The following sections describe the parallel-processing features of ANSYS FLUENT.

- 35.1. Introduction to Parallel Processing
- 35.2. Starting Parallel ANSYS FLUENT Using FLUENT Launcher
- 35.3. Starting Parallel ANSYS FLUENT on a Windows System
- 35.4. Starting Parallel ANSYS FLUENT on a Linux System
- 35.5. Mesh Partitioning and Load Balancing
- 35.6. Controlling the Threads
- 35.7. Checking Network Connectivity
- 35.8. Checking and Improving Parallel Performance

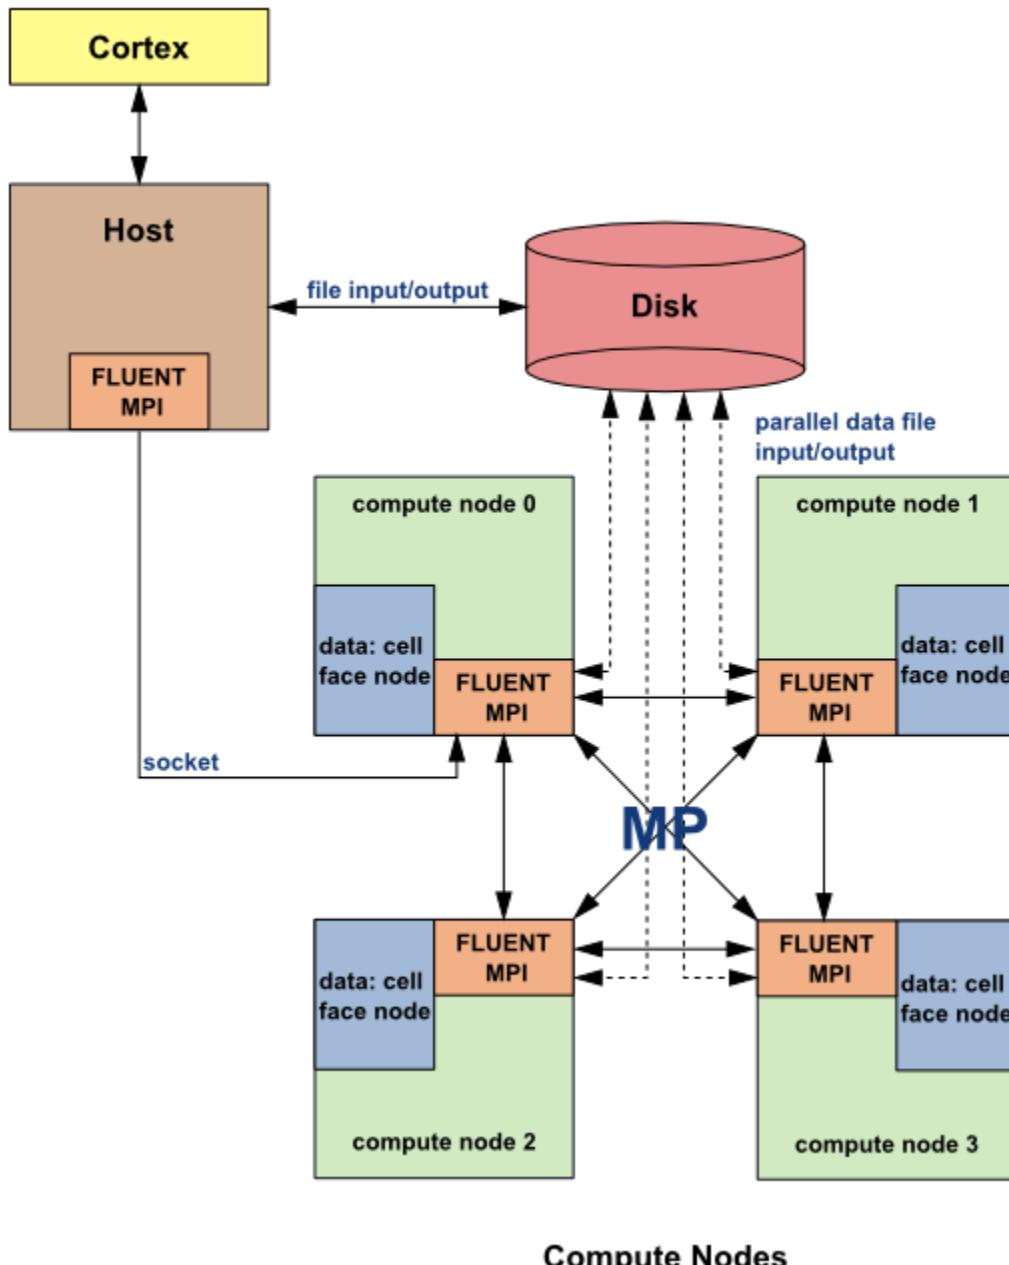

35.1. Introduction to Parallel Processing

The ANSYS FLUENT serial solver manages file input and output, data storage, and flow field calculations using a single solver process on a single computer ([Figure 35.1 \(p. 1715\)](#)).

Figure 35.1 Serial ANSYS FLUENT Architecture

ANSYS FLUENT's parallel solver allows you to compute a solution by using multiple processes that may be executing on the same computer, or on different computers in a network ([Figure 35.2 \(p. 1716\)](#)).

Figure 35.2 Parallel ANSYS FLUENT Architecture

Compute Nodes

Parallel processing in ANSYS FLUENT involves an interaction between ANSYS FLUENT, a host process, and a set of compute-node processes. ANSYS FLUENT interacts with the host process and the collection of compute nodes using a utility called `cortex` that manages ANSYS FLUENT's user interface and basic graphical functions.

Parallel ANSYS FLUENT splits up the mesh and data into multiple partitions, then assigns each mesh partition to a different compute process (or node). The number of partitions is equal to or less than the number of processors (or cores) available on your compute cluster. The compute-node processes can be executed on a massively-parallel computer, a multiple-CPU workstation, or a network cluster of computers.

Generally, as the number of compute nodes increases, turnaround time for solutions will decrease. This is referred to as solver "scalability." However, beyond a certain point, the ratio of network communication

to computation increases, leading to reduced parallel efficiency, so optimal system sizing is important for simulations.

ANSYS FLUENT uses a host process that does not store any mesh or solution data. Instead, the host process only interprets commands from ANSYS FLUENT's graphics-related interface, cortex.

The host distributes those commands to the other compute nodes via a socket interconnect to a single designated compute node called `compute-node-0`. This specialized compute node distributes the host commands to the other compute nodes. Each compute node simultaneously executes the same program on its own data set. Communication from the compute nodes to the host is possible only through `compute-node-0` and only when all compute nodes have synchronized with each other.

Each compute node is virtually connected to every other compute node, and relies on inter-process communication to perform such functions as sending and receiving arrays, synchronizing, and performing global operations (such as summations over all cells). Inter-process communication is managed by a message-passing library. For example, the message-passing library could be a vendor implementation of the Message Passing Interface (MPI) standard, as depicted in [Figure 35.2 \(p. 1716\)](#).

All of the parallel ANSYS FLUENT processes (as well as the serial process) are identified by a unique integer ID. The host collects messages from `compute-node-0` and performs operations (such as printing, displaying messages, and writing to a file) on all of the data, in the same way as the serial solver. You have the option of bypassing the host when inputting or outputting parallel data files, so that the files are passed directly between the compute nodes and the disk in a parallel fashion. This can reduce the time for data file I/O operations. (For details, see [Reading and Writing Parallel Data Files \(p. 70\)](#)).

For additional information, please see the following section:

[35.1.1. Recommended Usage of Parallel ANSYS FLUENT](#)

The recommended procedure for using parallel ANSYS FLUENT is as follows:

1. Start up the parallel solver. For details, see [Starting Parallel ANSYS FLUENT on a Windows System \(p. 1725\)](#) and [Starting Parallel ANSYS FLUENT on a Linux System \(p. 1729\)](#).
2. Read your case file and have ANSYS FLUENT partition the mesh automatically upon loading it.
3. Review the partitions and perform partitioning again, if necessary. See [Checking the Partitions \(p. 1754\)](#) for details on checking your partitions. Note that there are other approaches for partitioning, including manual partitioning in either the serial or the parallel solver. For details, see [Mesh Partitioning and Load Balancing \(p. 1733\)](#).
4. Calculate a solution. See [Checking and Improving Parallel Performance \(p. 1758\)](#) for information on checking and improving the parallel performance.

Note

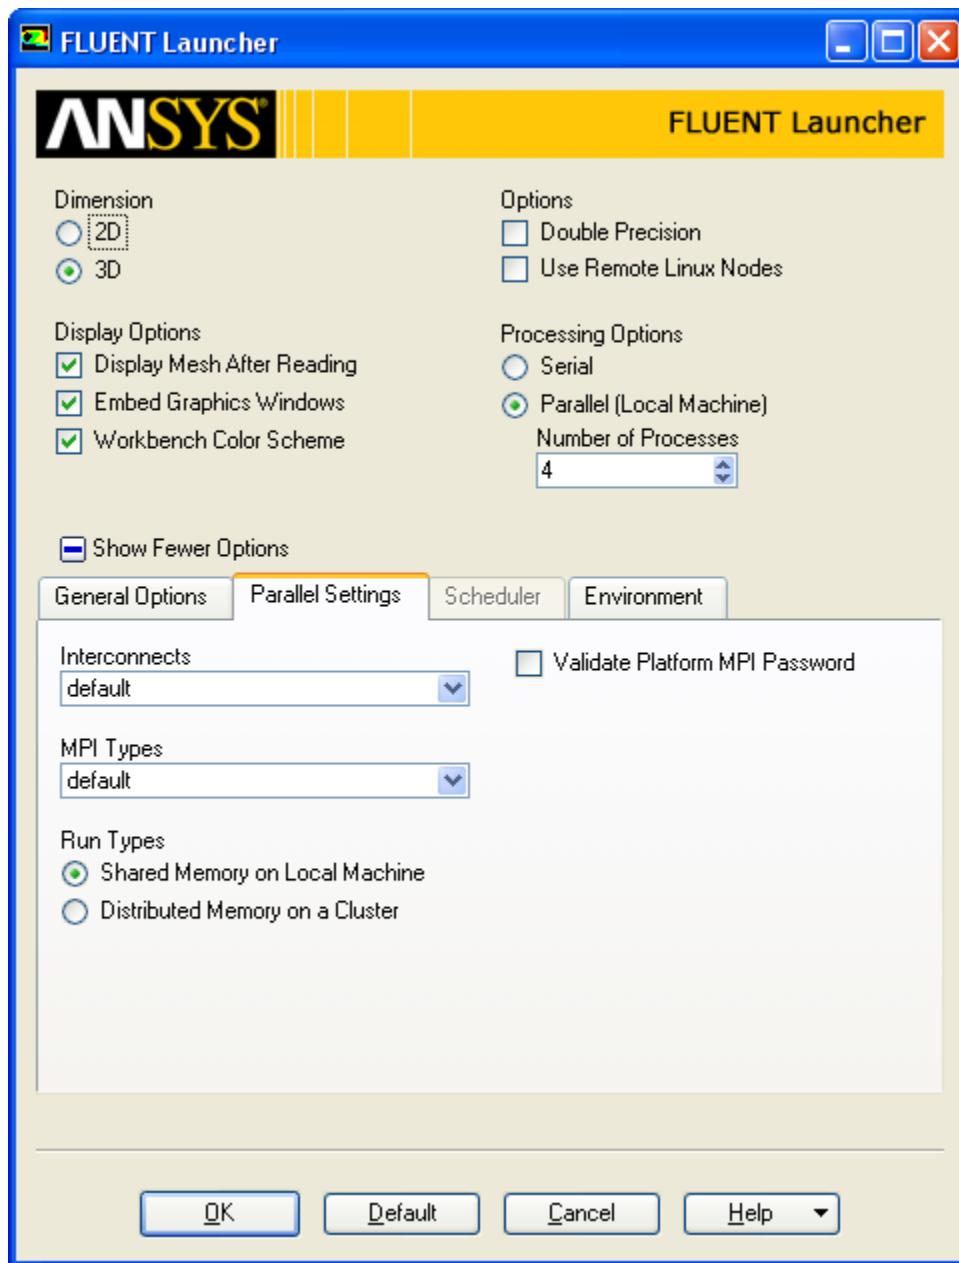

Due to limitations imposed by several MPI implementations, ANSYS FLUENT performance on heterogeneous clusters involving either operating system or processor family differences may not be optimal, and in certain cases cause failures. You are urged to use caution in such parallel operating environments.

35.2. Starting Parallel ANSYS FLUENT Using FLUENT Launcher

Whether you start ANSYS FLUENT either from the Linux or Windows command line with no arguments, from the Windows Programs menu, or from the Windows desktop, FLUENT Launcher will appear. (For details, see [Starting ANSYS FLUENT Using FLUENT Launcher \(p. 1\)](#)), where you can specify the dimensionality of the problem (2D or 3D), as well as other options (e.g., whether you want a single-precision or double-precision calculation).

Parallel calculation options can be set up by selecting **Parallel** under **Processing Options** in FLUENT Launcher. Once you select the **Parallel** option, you can also specify the number of processes using the **Number of Processes** field. Activating the **Parallel** option enables the **Parallel Settings** tab (visible when you select the **Show More Options** button). The **Parallel Settings** tab allows you to specify settings for running ANSYS FLUENT in parallel.

Figure 35.3 The Parallel Settings Tab of FLUENT Launcher

- Specify the interconnect or system in the **Interconnects** drop-down list. The default setting is recommended. For a symmetric multi-processor (SMP) system, the default setting uses shared memory for communication.

If you prefer to select a specific interconnect, you can choose either **ethernet**, **myrinet**, or **infini-band**. For more information about these interconnects, see *Table 35.1: Supported Interconnects for the Windows Platform* (p. 1726), *Table 35.2: Available MPIs for Windows Platforms* (p. 1727), and *Table 35.3: Supported MPIs for Windows Architectures (Per Interconnect)* (p. 1727).

- Specify the type of message passing interface (MPI) you require for the parallel computations in the **MPI Types** field. The list of MPI types varies depending on the selected release and the selected architecture. There are several options, based on the operating system of the parallel cluster. For more information about the available MPI types, see *Table 35.1: Supported Interconnects for the Windows Platform* (p. 1726) - *Table 35.2: Available MPIs for Windows Platforms* (p. 1727).

Important

It is your responsibility to make sure the interconnects and the MPI types are compatible. If incompatible inputs are used, FLUENT Launcher resorts to using the default values.

- (Linux Only) Specify either **RSH** (remote shell client) or **SSH** (secure shell client) under **Remote Spawn Command**. For more information about setting up your remote shell clients and secure shell clients, see *Setting Up Your Remote Shell and Secure Shell Clients* (p. 1732).
- Specify the type of parallel calculation under **Run Types**:
 - Select **Shared Memory on Local Machine** if the parallel calculations are performed by sharing memory allocations on your local machine.
 - Select **Distributed Memory on a Cluster** if the parallel calculations will be distributed among several machines.

You can select **Machine Names** and enter the machine names directly into the text field. Machine names can be separated either by a comma or a space. This is not recommended for a long list of machine names.

Alternatively, you can select **File Containing Machine Names** to specify a hosts file (a file that contains the machine names), or you can use the  button to browse for a hosts file.

To edit an existing hosts file, click the  button.

- Specify if you would like to validate the password for the Platform MPI or not.

Select the **Validate Platform MPI Password** option if you would like to save the required password to use the Platform MPI type.

- For certain platforms, select **Use Job Scheduler** under **Options** if the parallel calculations are to be performed using a designated Job Scheduler. (For details, see *Setting Parallel Scheduler Options in FLUENT Launcher* (p. 1720)). This also enables the **Scheduler** tab of FLUENT Launcher.

For additional information, please see the following sections:

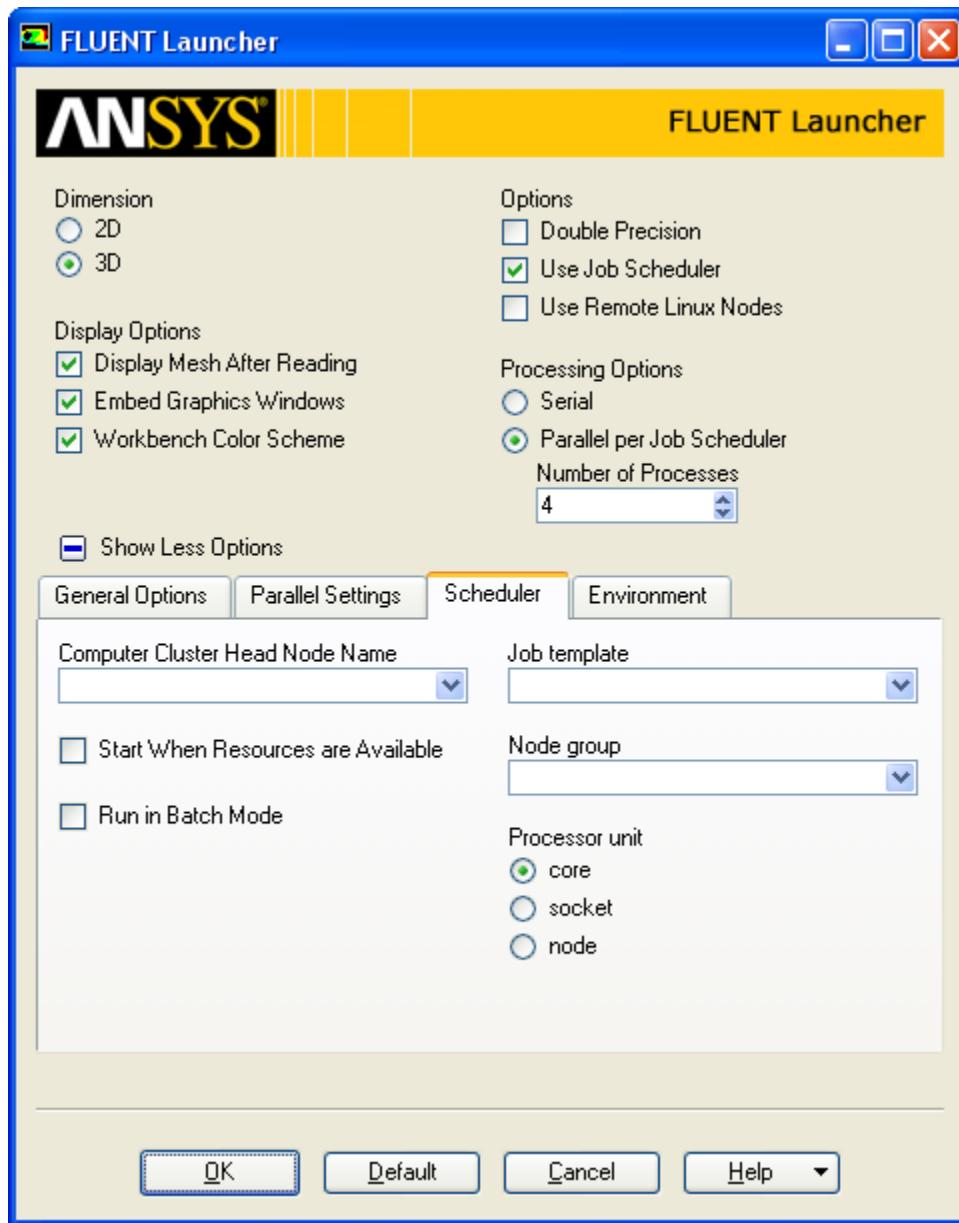

[35.2.1. Setting Parallel Scheduler Options in FLUENT Launcher](#)

[35.2.2. Setting Additional Options When Running on Remote Linux Machines](#)

35.2.1. Setting Parallel Scheduler Options in FLUENT Launcher

Activating the **Use Job Scheduler** option under **Options** in FLUENT Launcher enables the **Scheduler** tab (visible when you select **Show More Options**). The **Scheduler** tab allows you to specify settings for running ANSYS FLUENT with various job schedulers (e.g., the Microsoft Job Scheduler for Windows, or LSF, SGE, and PBS Pro on Linux).

Figure 35.4 The Scheduler Tab of FLUENT Launcher (Windows 64 Version)

For Windows 64-bit, with MSMPI or when the **Use Remote Linux Nodes** option is selected (or for Windows 32-bit, when the **Use Remote Linux Nodes** option is enabled), you can specify that you want to use the Job Scheduler by selecting the **Use Job Scheduler** check box under **Options** in FLUENT Launcher. Once selected, you can then enter a machine name in the **Compute Cluster Head Node Name** text field in the **Scheduler** tab. If you are running ANSYS FLUENT on the head node, then you can keep the field empty. This option translates into the proper parallel command line syntax for using

the Microsoft Job Scheduler (For details, see [Starting Parallel ANSYS FLUENT with the Microsoft Job Scheduler \(p. 1727\)](#)).

If you want ANSYS FLUENT to start after the necessary resources have been allocated by the Scheduler, then select the **Start When Resources are Available** check box.

For Linux, select the **Use Job Scheduler** check box under **Options** to use one of three available job schedulers in the **Scheduler** tab.

- Select the **Use LSF** radio button to use the LSF load management system with or without checkpointing. If you select **Use Checkpointing**, then you can specify a checkpointing directory in the **Checkpointing Directory** field. By default, the current working directory is used. In addition, you can specify a numerical value for the frequency of automatic checkpointing in the **Automatic Checkpoint with Setting of Period** field.

For more information, see [Setting Job Scheduler Options When Running on Remote Linux Machines \(p. 1724\)](#) or [Running FLUENT Under LSF](#).

- Select the **Use SGE** radio button to use the SGE load management system. You can choose to set values for the **SGE qmaster**, as well as the **SGE queue**, or the **SGE pe**. Alternatively, you can select **Use SGE settings** check box and specify the location and name of the SGE configuration file.

For more information, see [Setting Job Scheduler Options When Running on Remote Linux Machines \(p. 1724\)](#) or [Running FLUENT Under SGE](#).

- Select the **Use PBS Pro** radio button to use the PBS Pro load management system. You can choose to set the value for **PBS Submission Host** to specify the PBS Pro submission host name for submitting the job, if the machine you are using to run the launcher cannot submit jobs to PBS Pro.

For more information, see [Setting Job Scheduler Options When Running on Remote Linux Machines \(p. 1724\)](#) or [Running FLUENT Under PBS Professional](#).

For Windows, you also have the ability to run in batch mode (using the **Run in Batch Mode** check box) when you provide a journal file (designated in the **General Options** tab) which exits ANSYS FLUENT at the end of the run.

For machines running the Windows HPC 2008 Server Scheduler, you also have the following options to choose from:

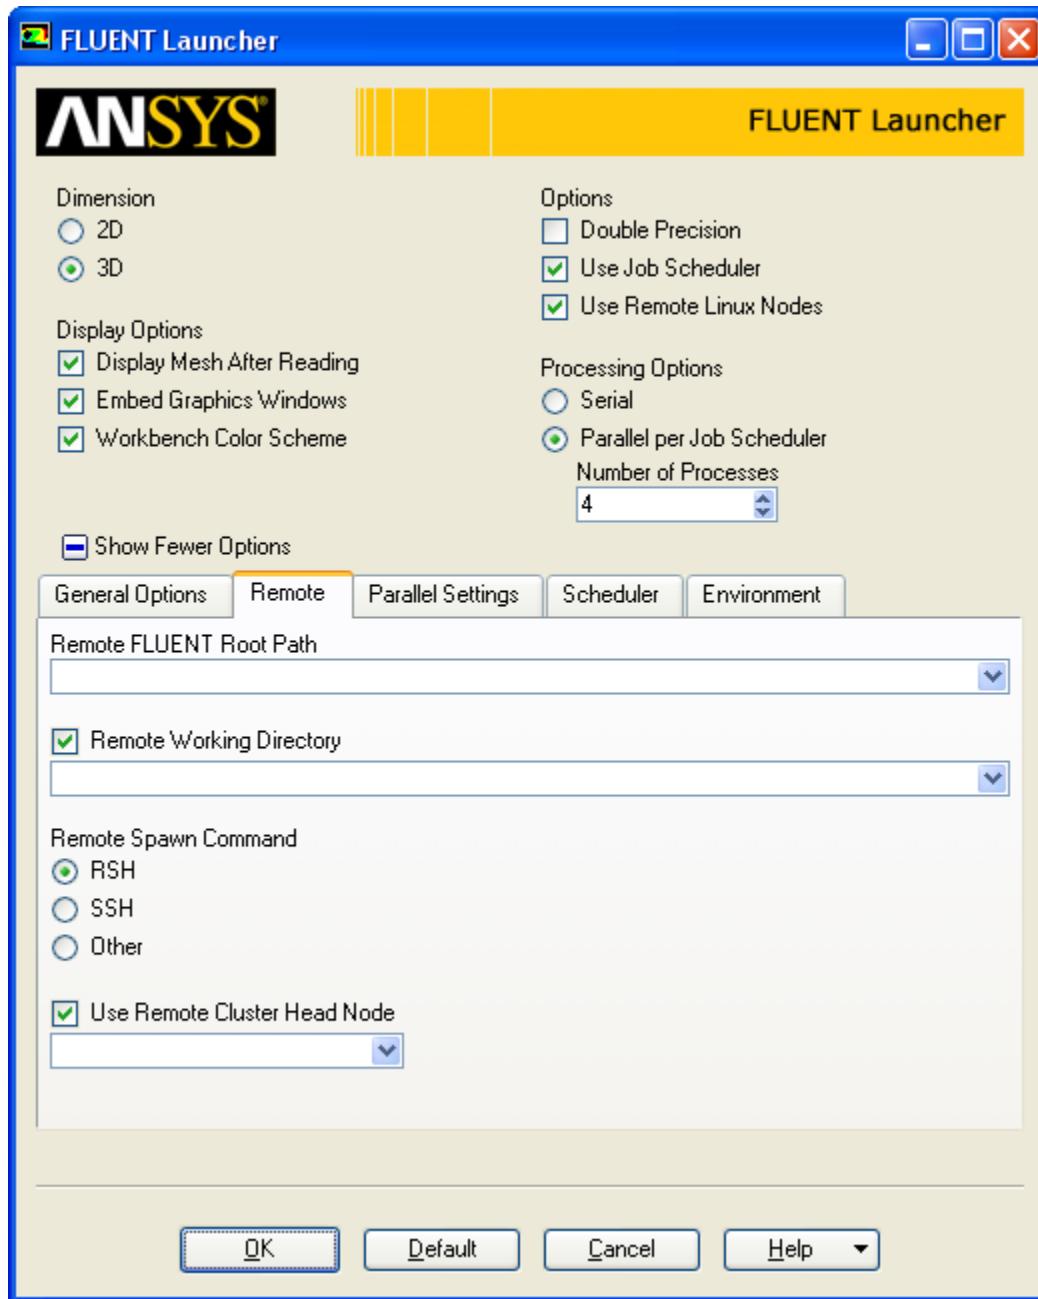

- **Job Template** allows you to create a custom submission policy to define the job parameters for an application. The cluster administrator can use job templates to manage job submission and optimize cluster usage.
- **Node Group** allows you to specify a collection of nodes. Cluster administrators can create groups and assign nodes to one or more groups.
- **Processor Unit** allows you to choose the following:
 - **Core** refers to a single computing unit in a machine. For example, a quad-core processor has 4 cores.
 - **Socket** refers to a set of tightly integrated cores as on a single chip. Machines often have 2 or more sockets, each socket with multiple cores. A dual CPU, hexcore processor, for example, having a total of 12 cores.
 - **Node** refers to a named host, i.e., a single machine used as part of a cluster. Typical clusters range from a few to 10s, 100s or sometimes 1000s of machines.

For more information about running FLUENT jobs using the Windows HPC 2008 Server Scheduler, see the Frequently Asked Questions section of the [Customer Portal](#).

35.2.2. Setting Additional Options When Running on Remote Linux Machines

The **Remote** tab allows you to specify settings for running ANSYS FLUENT parallel simulations on Linux clusters, via the Windows interface.

Figure 35.5 The Remote Tab of FLUENT Launcher

You can run simulations on Linux machines, either in serial or on parallel Linux clusters, via the Windows interface. To access remote 64-bit Linux clusters for your parallel calculation, select the **Parallel (Local Machine)** option under **Processing Options** (For details, see [Setting Parallel Options in FLUENT Launcher \(p. 4\)](#)), then enable **Use Remote Linux Nodes**, which appears under **Options**. The **Remote** tab in

FLUENT Launcher will become available, where you can specify the remote ANSYS FLUENT Linux installation root path in the **Remote FLUENT Root Path** field. The **Remote Working Directory** field allows you to specify a working directory for the remote Linux nodes, other than the default `temp` directory.

Select one of the following **Remote Spawn Commands** to connect to the remote node:

- **RSH** (the default) is used to spawn nodes from the local Windows machine to the Linux head node as well as from the Linux head node to the compute nodes. If you want the Linux cluster to use SSH, then you need to set the `FLUENT_NO_REMOTE_RSH` to 1. You will also need to set up passwordless access.
- **SSH** is used to spawn nodes from the local Windows machine to the Linux head node as well as from the Linux head node to the compute nodes. To use SSH with ANSYS FLUENT, you need to set up passwordless SSH access. If you want the Linux cluster to use RSH, then you need to set the `FLUENT_NO_REMOTE_SSH` to 1. For more information about setting up SSH without a password, see www.debian-administration.org/articles/152.
- **Other** allows you to provide other compatible remote shell commands.

Enable the **Use Remote Cluster Head Node** field and specify the remote node to which ANSYS FLUENT will connect for spawning (e.g., via `rsh` or `ssh`). If this is not provided, then ANSYS FLUENT will try to use the first machine in the machine file. If SGE is chosen as the job scheduler, then the **SGE qmaster** will serve the same purpose. If **PBS Pro** is chosen as the job scheduler, then the host specified here should be the PBS Pro submission host.

In addition to using the settings in the **Remote** tab in FLUENT Launcher, the following command line options are also available when starting ANSYS FLUENT from the command line:

-nodepath=path

is the path on the remote machine where ANSYS FLUENT is installed.

-node0=machine name

is the machine from which to launch other nodes.

-nodehomedir=directory

is the directory that becomes the current working directory for all the nodes. Additionally, this will be used as a scratch area for temporary files that are created on the nodes.

-rsh=remote shell command

is the command that will be used to launch executables remotely. This option defaults to `rsh.exe` but can point to any equivalent program. The form of this command should be that it should not wait for additional inputs such as passwords. For example, if you install SSH, and try to launch in mixed mode using `ssh`, the launch may fail unless you have set up a login for SSH without a password. For more information about setting up SSH without a password, see www.debian-administration.org/articles/152.

As there are known issues with launching ANSYS FLUENT in mixed Windows/Linux mode from cygwin, it is recommended that you use the command prompt (`cmd.exe`).

While ANSYS FLUENT case and data files are read from and written to the Windows machine while running mixed Windows/Linux simulations, parallel data files (`.pdat` files) are written by the nodes and will not be available on the Windows machine. Therefore, the path specified for writing `.pdat` files should be a Linux path (you can set node's home directory if you want to provide relative paths). If you use the graphical user interface to read and/or write `.pdat` files, the directory component of the path is ignored and only the file name is used to read and/or write the `.pdat` file relative to the node's current working directory.

When working with mixed Linux and Windows runs that employ user-defined functions (UDFs), you should keep in mind that the file that you have opened for reading/writing on the host machine will

not be available on remote nodes and vice-versa. You may therefore have to transfer data present on the nodes to the host and write it from host, (or distribute the data from the host to the nodes after reading the data from the host).

35.2.2.1. Setting Job Scheduler Options When Running on Remote Linux Machines

By selecting the **Use Remote Linux Nodes** option and the **Use Job Scheduler** option in FLUENT Launcher, you can set job scheduler options for the remote Linux machines you are accessing for your CFD analysis.

When these options are enabled in FLUENT Launcher, you can use the **Scheduler** tab to set parameters for either **LSF**, **SGE**, or **PBS Pro** job schedulers. You can learn more about each of the schedulers by referring to the Load Management Documentation.

The following list describes the various controls that are available in the **Scheduler** tab:

Use LSF

allows you to use the LSF job scheduler.

LSF queue

allows you to specify a job queue and enter the queue name in the text box.

Use Checkpointing

allows you to use checkpointing with LSF. By default, the checkpointing directory will be the current working directory; however, you have the option of enabling **Checkpointing Directory**.

Checkpointing Directory

allows you to specify a checkpointing directory which is different from the current working directory.

Automatic Checkpoint with Setting of Period

allows you to specify that the checkpointing is done automatically at a set time interval. Enter the period (in minutes) in the text box, otherwise checkpointing will not occur unless you call the bchkpnt command.

Use SGE

allows you to use the SGE job scheduler.

SGE qmaster

is the machine in the SGE job submission host list. SGE will allow the **SGE qmaster** node to summon jobs. By default, **localhost** is specified for **SGE qmaster**. Note that the  button allows you to check the job status.

SGE queue

is the queue where you want to submit your ANSYS FLUENT jobs. Note that you can use the  button to contact the **SGE qmaster** for a list of queues. Leave this field blank if you want to use the default queue.

SGE pe

is the parallel environment where you want to submit your ANSYS FLUENT jobs. The parallel environment must be defined by an administrator. For more information about creating a parallel environment, please refer to the SGE documentation. Leave this field blank if you want to use the default parallel environment.

Use PBS Pro

allows you to use the PBS Pro job scheduler.

Important

While running on remote Linux machines using any one of the Job Scheduler options, if the submitted job is in the job queue because of unavailable requested resources, then the ANSYS FLUENT graphical user interface will remain open until resources are available and the job starts running.

35.3. Starting Parallel ANSYS FLUENT on a Windows System

You can run ANSYS FLUENT on a Windows system using either the graphical user interface (For details, see [Starting Parallel ANSYS FLUENT Using FLUENT Launcher \(p. 1718\)](#)) or command line options (For details, see [Starting Parallel ANSYS FLUENT on a Windows System Using Command Line Options \(p. 1725\)](#)).

Important

See the separate installation instructions for more information about installing parallel ANSYS FLUENT for Windows. The startup instructions below assume that you have properly set up the necessary software, based on the appropriate installation instructions.

Additional information about installation issues can also be found in the Frequently Asked Questions section of the [Customer Portal](#).

For additional information, please see the following section:

[35.3.1. Starting Parallel ANSYS FLUENT on a Windows System Using Command Line Options](#)

35.3.1. Starting Parallel ANSYS FLUENT on a Windows System Using Command Line Options

To start the parallel version of ANSYS FLUENT using command line options, you can use the following syntax in a Command Prompt window:

```
fluent version-tnprocs [-pinterconnect] [-mpi=mpi_type] -cnf=hosts_file
```

where

- *version* must be replaced by the version of ANSYS FLUENT you want to run (2d, 3d, 2ddp, or 3ddp).
- *-pinterconnect* (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See [Table 35.1: Supported Interconnects for the Windows Platform \(p. 1726\)](#), [Table 35.2: Available MPIS for Windows Platforms \(p. 1727\)](#), and [Table 35.3: Supported MPIS for Windows Architectures \(Per Interconnect\) \(p. 1727\)](#) for more information.
- *-mpi=mpi_type* (optional) specifies the MPI implementation. If the option is not specified, the default MPI for the given interconnect (Platform MPI) will be used (the use of the default MPI is recommended). The available MPIS for Windows are shown in [Table 35.2: Available MPIS for Windows Platforms \(p. 1727\)](#).
- *-cnf=hosts_file* specifies the hosts file, which contains a list of the computers on which you want to run the parallel job. If the hosts file is not located in the folder where you are typing the startup command, you will need to supply the full pathname to the file.

You can use a plain text editor such as Notepad to create the hosts file. The only restriction on the filename is that there should be no spaces in it. For example, `hosts.txt` is an acceptable hosts file name, but `my hosts.txt` is not.

Your hosts file (e.g., `hosts.txt`) might contain the following entries:

```
computer1  
computer2
```

Important

The last entry must be followed by a blank line.

If a computer in the network is a multiprocessor, you can list it more than once. For example, if `computer1` has 2 CPUs, then, to take advantage of both CPUs (and similarly for multicore machines), the `hosts.txt` file should list `computer1` twice:

```
computer1  
computer1  
computer2
```

- `-tnprocs` specifies the number of processes to use. When the `-cnf` option is present, the *hosts_file* argument is used to determine which computers to use for the parallel job. For example, if there are 8 computers listed in the hosts file and you want to run a job with 4 processes, set *nprocs* to 4 (i.e., `-t 4`) and ANSYS FLUENT will use the first 4 machines listed in the hosts file. Note that this does not apply to the Compute Cluster Server (CCS).

For example, the full command line to start a 3D parallel job on the first 4 computers listed in a hosts file called `hosts.txt` is as follows:

```
fluent 3d -t4 -cnf=hosts.txt
```

As another example, the full command line to start a 3D symmetrical multiprocessing (SMP) parallel job on 4 computers is as follows:

```
fluent 3d -t4
```

In either case, the default communication library (Platform MPI), and the default interconnect (automatically selected by the MPI used, or ethernet) will be used since these options are not specified.

The first time that you try to run ANSYS FLUENT in parallel, you will be prompted for information about the current Windows account. For more information, see the Platform MPI setup FAQ in the Frequently Asked Questions section of the ANSYS Customer Portal (www.ansys.com/customerportal)..

The supported interconnects for dedicated parallel `ntx86` and `win64` Windows machines, the associated MPIS for them, and the corresponding syntax are listed in *Table 35.1: Supported Interconnects for the Windows Platform* (p. 1726) - *Table 35.3: Supported MPIS for Windows Architectures (Per Interconnect)* (p. 1727).

Table 35.1 Supported Interconnects for the Windows Platform

Platform	Processor	Architecture	Interconnects
Windows	32-bit	ntx86	ethernet (default)

Platform	Processor	Architecture	Interconnects
	64-bit	win64	ethernet (default), infiniband, myrinet

Table 35.2 Available MPIs for Windows Platforms

MPI	Syntax (flag)	Communication Library	Notes
pcmpi	-mpi=pcmpi	Platform MPI	(1), (2)
ms	-mpi=ms	Microsoft MPI	(1)*, (2)
intel	-mpi=intel	Intel MPI	(1), (2)

(1) Used with Shared Memory Machine (SHM) where the memory is shared between the processors on a single machine.

* Ensure that Microsoft MPI is installed on the machine where the shared memory job will be running.

(2) Used with Distributed Memory Machine (DMM) where each processor has its own memory associated with it.

Table 35.3 Supported MPIs for Windows Architectures (Per Interconnect)

Architecture	Ethernet	Myrinet	Infiniband
ntx86	pcmpi (default), intel	-	-
win64	pcmpi (default), intel, ms	ms	ms

35.3.1.1. Starting Parallel ANSYS FLUENT with the Microsoft Job Scheduler

The Microsoft Job Scheduler allows you to manage multiple jobs and tasks, allocate computer resources, send tasks to compute nodes, and monitor jobs, tasks, and compute nodes.

ANSYS FLUENT currently supports Windows XP, Vista, as well as the Windows Server operating systems. The Windows Server operating systems include a compute cluster server (CCS) and a high performance computing server (HPC) that combines the Microsoft MPI type (`msmpi`) with the Microsoft Job Scheduler. ANSYS FLUENT provides a means of using the Microsoft Job Scheduler using the following flag in the parallel command:

`-ccp head-node-name`

where `-ccp` indicates the use of the compute cluster server package, and `head-node-name` indicates the name of the head node of the computer cluster.

For example, if you want to use the Microsoft Job Scheduler to run a 3D model on 2 nodes, the corresponding command syntax would be:

`fluent 3d -t2 -ccp head-node-name`

Important

Both the Platform MPI type (`pcmpi`) and the Intel MPI (`intel`) are not supported with the Microsoft Job Scheduler.

Note

When using Microsoft Job Scheduler, the best interconnect is automatically selected by MS-MPI and the default Ethernet option does not apply.

Though the usage described previously is recommended as an initial starting point for running ANSYS FLUENT with the Microsoft Job Scheduler, there are further options provided to meet your specific needs. ANSYS FLUENT allows you to do any of the following with the Microsoft Job Scheduler:

- Request resources from the Microsoft Job Scheduler first, before you launch ANSYS FLUENT.

This is done by first submitting a job that will run until canceled, as shown in the following example:

```
job new/scheduler:head-node-name /numprocessors:2 /rununtilcanceled:true
```

This example requests a 2-node resource on a cluster named *head-node-name*. You will see that a job is created with the job ID *job-id*:

```
job submit/scheduler:head-node-name /id:job-id
```

Then check if the resources have been allocated:

```
job view job-id /scheduler:head-node-name
```

If the resources are ready, you can start ANSYS FLUENT using the job ID:

```
fluent 3d -t2 -ccp head-node-name -jobid=job-id
```

This job will be reusable until you decide to cancel it, at which point you must enter the following:

```
job cancel job-id /scheduler:head-node-name
```

- Have ANSYS FLUENT submit a CCS job, but delay the launching of ANSYS FLUENT until the actual resources are allocated.

This is done by specifying the job ID as -1, as shown in the following example:

```
fluent 3d -t2 -ccp head-node-name -jobid=-1
```

If you want to stop the job application, click the **Cancel** button. ANSYS FLUENT will prompt you for confirmation, and then clean up the pending job and exit.

- Run your job using XML template files.

This is done by first creating an XML template file, such as shown in the following example:

```
<?xml version="1.0" encoding="utf-8"?>
<Job
  xmlns:m:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xmlns:m:xsd="http://www.w3.org/2001/XMLSchema"
  SoftwareLicense=""
  MaximumNumberOfProcessors="4"
  MinimumNumberOfProcessors="4"
  Runtime="Infinite"
  IsExclusive="true"
  Priority="Normal"
  Name="Name_of_job"
  Project="Fluent runs"
  RunUntilCanceled="false">
  <Tasks xmlns:m="http://www.microsoft.com/ComputeCluster/">
```

```

<Task
  MaximumNumberOfProcessors="4"
  MinimumNumberOfProcessors="4"
  Depend=""
  WorkDirectory="\\file-server\home\user"
  Stdout="fluent-case.%CCP_JOBID%.out"
  Stderr="fluent-case.%CCP_JOBID%.err"
  Name="My Task"
  CommandLine="\\head-node\fluent-sharename\win64\fluent.exe 3d -i bsi.jou -t4"
  IsExclusive="true"
  IsRerunnable="false"
  Runtime="Infinite">
</Task>
</Tasks>
</Job>

```

where fluent-sharename is the name of the shared directory pointing to where ANSYS FLUENT is installed (e.g., C:\Program Files\ANSYS Inc\v140\fluent).

Important

Note that you must create a journal file that exits ANSYS FLUENT at the end of the run, and refer to it using the `-i` flag in your XML template file (`bs1.jou` in the previous example).

After you have saved the file and given it a name (e.g., `job1.xml`), you can submit the job as shown:

```
job submit /jobfile:job1.xml
```

- Run the job in batch mode without displaying the ANSYS FLUENT GUI.

The following is an example of such a batch mode job:

```
job submit /scheduler:head-node-name
/numprocessors:2 /workdir:\\file-server\home\user\
\\head-node\fluent-sharename\ntbin\win64\fluent.exe 3d -t2 -i bs1.jou
```

where fluent-sharename is the name of the shared directory pointing to where ANSYS FLUENT is installed (e.g., C:\Program Files\ANSYS Inc\v140\fluent).

Important

- Note that you must create a journal file that exits ANSYS FLUENT at the end of the run, and refer to it using the `-i` flag in your batch mode job submission (`bs1.jou` in the previous example).
- You can start ANSYS FLUENT jobs from any machine on which is installed either the full CCP or the CCP client tools, but note that all the machines must have the same version installed.

35.4. Starting Parallel ANSYS FLUENT on a Linux System

You can run ANSYS FLUENT on a Linux system using either the graphical user interface (For details, see [Starting Parallel ANSYS FLUENT Using FLUENT Launcher \(p. 1718\)](#)) or command line options (For details, see

Starting Parallel ANSYS FLUENT on a Linux System Using Command Line Options (p. 1730) *Setting Up Your Remote Shell and Secure Shell Clients* (p. 1732)).

For additional information, please see the following sections:

- 35.4.1. Starting Parallel ANSYS FLUENT on a Linux System Using Command Line Options
- 35.4.2. Setting Up Your Remote Shell and Secure Shell Clients

35.4.1. Starting Parallel ANSYS FLUENT on a Linux System Using Command Line Options

To start the parallel version of ANSYS FLUENT using command line options, you can use the following syntax in a command prompt window:

```
fluent version-tnprocs [-pinterconnect] [-mpi=mpi_type] -cnf=hosts_file
```

where

- *version* must be replaced by the version of ANSYS FLUENT you want to run (2d, 3d, 2ddp, or 3ddp).
- *-pinterconnect* (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See *Table 35.4: Supported Interconnects for Linux Platforms (Per Platform)* (p. 1731), *Table 35.5: Available MPIs for Linux Platforms* (p. 1731), and *Table 35.6: Supported MPIs for Linux Architectures (Per Interconnect)* (p. 1731) for more information.
- *-mpi=mpi_type* (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect will be used (the use of the default MPI is recommended). The available MPIs for Linux are shown in *Table 35.5: Available MPIs for Linux Platforms* (p. 1731).
- *-cnf=hosts_file* specifies the hosts file, which contains a list of the computers on which you want to run the parallel job. If the hosts file is not located in the directory where you are typing the startup command, you will need to supply the full pathname to the file.

You can use a plain text editor to create the hosts file. The only restriction on the filename is that there should be no spaces in it. For example, *hosts.txt* is an acceptable hosts file name, but *my hosts.txt* is not.

Your hosts file (e.g., *hosts.txt*) might contain the following entries:

```
computer1  
computer2
```

Important

The last entry must be followed by a blank line.

If a computer in the network is a multiprocessor, you can list it more than once. For example, if *computer1* has 2 CPUs, then, to take advantage of both CPUs, the *hosts.txt* file should list *computer1* twice:

```
computer1  
computer1  
computer2
```

- *-tnprocs* specifies the number of processes to use. When the *-cnf* option is present, the *hosts_file* argument is used to determine which computers to use for the parallel job. For example, if there are

10 computers listed in the hosts file and you want to run a job with 5 processes, set *nprocs* to 5 (i.e., *-t5*) and ANSYS FLUENT will use the first 5 machines listed in the hosts file.

For example, to use the Infiniband interconnect, and to start the 3D solver with 4 compute nodes on the machines defined in the text file called `fluent.hosts`, you can enter the following in the command prompt:

```
fluent 3d -t4 -pinfiniband -cnf=fluent.hosts
```

Note that if the optional `-cnf= hosts_file` is specified, a compute node will be spawned on each machine listed in the file *hosts_file*. (If you enter this optional argument, do not include the square brackets.)

Also, ANSYS FLUENT provides a fault-tolerance feature on Infiniband Linux clusters running OFED. To invoke this feature, use the command line flag `-pinfiniband.ofedft` (or `-pib.ofedft`) which enables transparent port fail-over and high-availability features using Platform MPI. Note that while the simulations proceed more robustly with this option, there may be some degradation in performance.

The supported interconnects for parallel Linux machines are listed below ([Table 35.4: Supported Interconnects for Linux Platforms \(Per Platform\)](#) (p. 1731), [Table 35.5: Available MPIs for Linux Platforms](#) (p. 1731), and [Table 35.6: Supported MPIs for Linux Architectures \(Per Interconnect\)](#) (p. 1731)), along with their associated communication libraries, the corresponding syntax,

Table 35.4 Supported Interconnects for Linux Platforms (Per Platform)

Platform	Processor	Architecture	Interconnects/Systems*
Linux	64-bit	lnamd64	ethernet, infiniband, myrinet
	64-bit Itanium	lnia64	ethernet, infiniband, myrinet, altix

(*) Node processes on the same machine communicate by shared memory. ANSYS FLUENT lets the MPI autoselect the best interconnect available on the system. Users can specify an interconnect to override that selection. Ethernet is the fallback choice.

Table 35.5 Available MPIs for Linux Platforms

MPI	Syntax (flag)	Communication Library	Notes
pcmpi	<code>-mpi=pcmpi</code>	Platform MPI	General purpose for SMPs and clusters
intel	<code>-mpi=intel</code>	Intel MPI	General purpose for SMPs and clusters
sgi	<code>-mpi=sgi</code>	SGI MPI for Altix	Only for SGI Altix systems (SMP); must start ANSYS FLUENT on a system where parallel node processes are to run
openmpi	<code>-mpi=openmpi</code>	Open MPI	Open source MPI-2 implementation. For both SMPs and clusters.

Table 35.6 Supported MPIs for Linux Architectures (Per Interconnect)

Architecture	Ethernet	Myrinet*	Infiniband	Proprietary Systems
lnamd64	pcmpi (default), intel	pcmpi (default), openmpi	pcmpi (default), intel, and openmpi	-
lnia64	pcmpi (default)	pcmpi	pcmpi (default)	sgi [for -paltix]

(*) Both MX and GM Myrinet protocols are supported. ANSYS FLUENT will automatically detect which type is running on the system and will use that particular protocol. You only have to supply the `-pmyrinet` option. If the hardware supports it, the installation and usage of Myrinet MX is recommended (please consult your Myrinet vendor for applicability).

35.4.2. Setting Up Your Remote Shell and Secure Shell Clients

For cluster computing on Linux systems, most parallel versions of ANSYS FLUENT will need the user account set up such that you can connect to all nodes on the cluster (using either the remote shell (`rsh`) client or the secure shell (`ssh`) client) without having to enter a password each time for each machine.

Provided that the appropriate server daemons (either `rshd` or `sshd`) are running, this section briefly describes how you can configure your system in order to use ANSYS FLUENT for parallel computing.

35.4.2.1. Configuring the `rsh` Client

The remote shell client (`rsh`), is widely deployed and used. It is generally easy to configure, and involves adding all the machine names, each on a single line, to the `.rhosts` file in your home directory.

If you refer to the machine you are currently logged on as the ‘client’, and if you refer to the remote machine to which you seek password-less login as the ‘server’, then on the server, you can add the name of your client machine to the `.rhosts` file. The name could be a local name or a fully qualified name with the domain suffix. Similarly, you can add other clients from which you require similar access to this server. These machines are then “trusted” and remote access is allowed without the further need for a password. This setup assumes you have the same user ID on all the machines. Otherwise, each line in the `.rhosts` file would need to contain the machine name as well as the user ID for the client that you want access to. Please refer to your system documentation for further usage options.

Note that for security purposes, the `.rhosts` file must be readable only by the user.

35.4.2.2. Configuring the `ssh` Client

The secure shell client (`ssh`), is a more secure alternative than `rsh` and is also used widely. Depending on the specific protocol and the version deployed, configuration involves a few steps. SSH1 and SSH2 are two current protocols. Open SSH is an open implementation of the SSH2 protocol and is backwards compatible with the SSH1 protocol. To add a client machine, with respect to user configuration, the following steps are involved:

1. Generate a public-private key pair using `ssh-keygen` (or using a graphical user interface client). For example:

```
% ssh-keygen -t dsa
```

where it creates a Digital Signature Authority (DSA) type key pair.

2. Place your public key on the remote host.

- For SSH1, insert the contents of the client (`~/.ssh/identity.pub`) into the server (`~/.ssh/authorized_keys`).
- For SSH2, insert the contents of the client (`~/.ssh/id_dsa.pub`) into the server (`~/.ssh/authorized_keys2`).

The client machine is now added to the access list and you no longer need to type in a password each time. For additional information, consult your system administrator or refer to your system documentation.

35.5. Mesh Partitioning and Load Balancing

Information about mesh partitioning and load balancing is provided in the following sections:

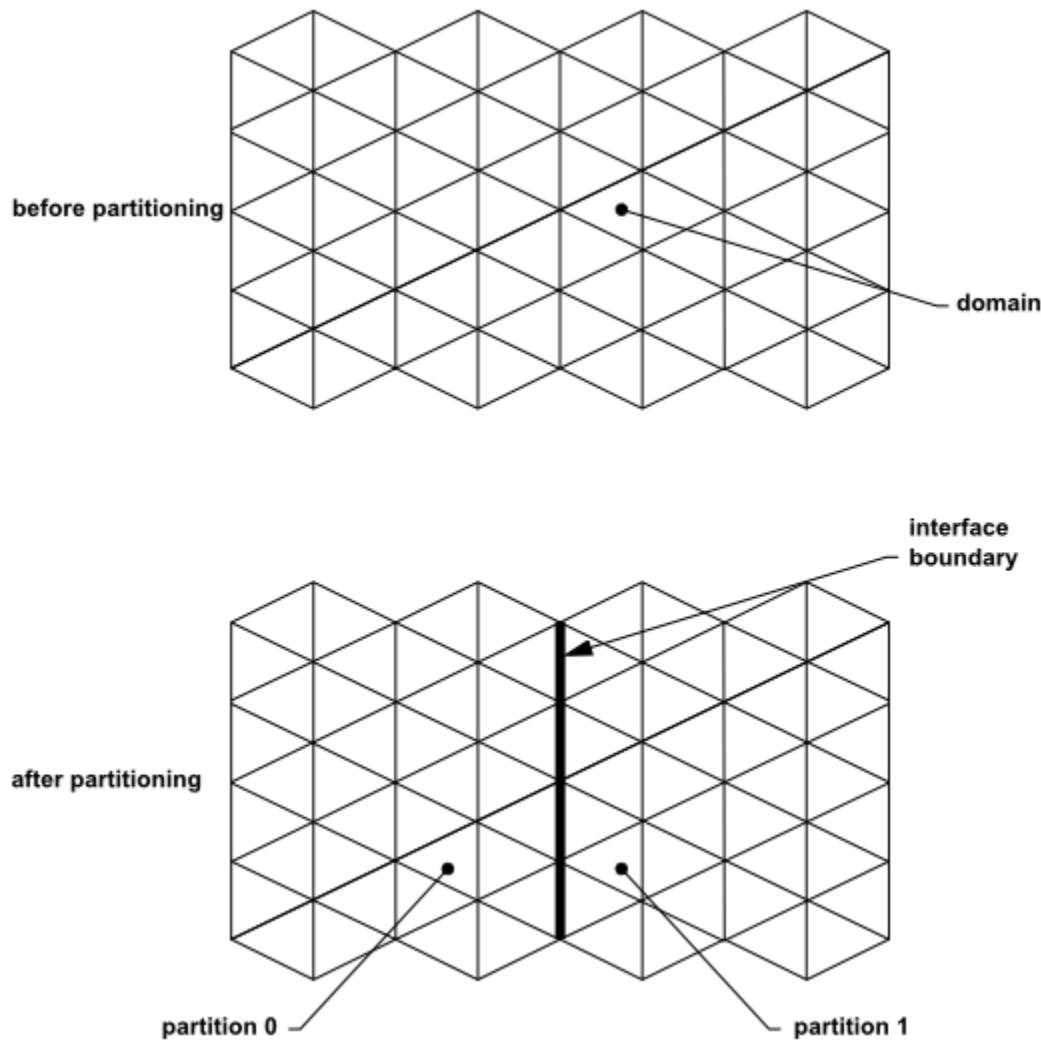

- 35.5.1. Overview of Mesh Partitioning
- 35.5.2. Partitioning the Mesh Automatically
- 35.5.3. Partitioning the Mesh Manually and Balancing the Load
- 35.5.4. Using the Partitioning and Load Balancing Dialog Box
- 35.5.5. Mesh Partitioning Methods
- 35.5.6. Checking the Partitions
- 35.5.7. Load Distribution
- 35.5.8. Troubleshooting

35.5.1. Overview of Mesh Partitioning

When you use the parallel solver in ANSYS FLUENT, you need to partition or subdivide the mesh into groups of cells that can be solved on separate processors (see [Figure 35.6 \(p. 1734\)](#)). You can either use the automatic partitioning algorithms when reading an unpartitioned mesh into the parallel solver (recommended approach, described in [Partitioning the Mesh Automatically \(p. 1734\)](#)), or perform the partitioning yourself in the serial solver or after reading a mesh into the parallel solver (as described in [Partitioning the Mesh Manually and Balancing the Load \(p. 1736\)](#)). In either case, the available partitioning methods are those described in [Mesh Partitioning Methods \(p. 1747\)](#). You can partition the mesh before or after you set up the problem (by defining models, boundary conditions, etc.).

Note that the relative distribution of cells among compute nodes will be maintained during mesh adaption, so manual repartitioning after adaption is not required. For details, see [Load Distribution \(p. 1755\)](#).

If you use the serial solver to set up the problem before partitioning, the machine on which you perform this task must have enough memory to read in the mesh. If your mesh is too large to be read into the serial solver, you can read the unpartitioned mesh directly into the parallel solver (using the memory available in all the defined hosts) and have it automatically partitioned. In this case you will set up the problem after an initial partition has been made. You will then be able to manually repartition the case if necessary. See [Partitioning the Mesh Automatically \(p. 1734\)](#) and [Partitioning the Mesh Manually and Balancing the Load \(p. 1736\)](#) for additional details and limitations, and [Checking the Partitions \(p. 1754\)](#) for details about checking the partitions.

Figure 35.6 Partitioning the Mesh

35.5.2. Partitioning the Mesh Automatically

For automatic mesh partitioning, you can select the partition method and other options for creating the mesh partitions before reading a case file into the parallel version of the solver. For some of the methods, you can perform pretesting to ensure that the best possible partition is performed. See [Mesh Partitioning Methods \(p. 1747\)](#) for information about the partitioning methods available in ANSYS FLUENT.

Note

Architecturally aware partitioning (see [Partitioning \(p. 1736\)](#)) is performed automatically when the case file is read. If the maximum inter-machine communication is reduced by more than 5%, the new partition mapping will be applied, and a message is displayed in the console, for example:

```
inter-node communication reduction by architecture-aware remapping:  
47%
```

While the message indicates actual point-to-point network traffic reduction, solver computational performance improvement may be somewhat less, and depends on the case and the system network configuration.

The procedure for partitioning automatically in the parallel solver is as follows:

1. (optional) Set the partitioning parameters in the **Auto Partition Mesh** dialog box ([Figure 35.7 \(p. 1735\)](#)).

Parallel → Auto Partition...

Figure 35.7 The Auto Partition Mesh Dialog Box

If you are reading in a mesh file or a case file for which no partition information is available, and you keep the **Case File** option turned on, ANSYS FLUENT will partition the mesh using the method displayed in the **Method** drop-down list.

If you want to specify the partitioning method and associated options yourself, the procedure is as follows:

- a. Turn off the **Case File** option. The other options in the dialog box will become available.
- b. Select the partition method in the **Method** drop-down list. The choices are the techniques described in [Partition Methods \(p. 1747\)](#).
- c. You can choose to independently apply partitioning to each cell zone, or you can allow partitions to cross zone boundaries using the **Across Zones** check button. It is recommended that you *not* partition cells zones independently (by turning off the **Across Zones** check button) unless cells in different zones will require significantly different amounts of computation during the solution phase (e.g., if the domain contains both solid and fluid zones).
- d. If you have chosen the **Principal Axes** or **Cartesian Axes** method, you can improve the partitioning by enabling the automatic testing of the different bisection directions before the actual partitioning occurs. To use pretesting, turn on the **Pre-Test** option. Pretesting is described in [Pretesting \(p. 1753\)](#).
- e. Click **OK**.

If you have a case file where you have already partitioned the mesh, and the number of partitions divides evenly into the number of compute nodes, you can keep the default selection of **Case File** in the **Auto Partition Mesh** dialog box. This instructs ANSYS FLUENT to use the partitions in the case file.

2. Read the case file.

File → Read → Case...

35.5.2.1. Reporting During Auto Partitioning

As the mesh is automatically partitioned, some information about the partitioning process will be displayed in the console. If you want additional information, you can display a report from the **Partitioning and Load Balancing** dialog box after the partitioning is completed.

Parallel → Partitioning and Load Balancing...

When you click the **Print Active Partitions** or **Print Stored Partitions** button in the **Partitioning and Load Balancing** dialog box, ANSYS FLUENT will display the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each active or stored partition in the console. In addition, it will display the minimum and maximum cell, face, interface, and face-ratio variations. For details, see [Interpreting Partition Statistics \(p. 1754\)](#). You can examine the partitions graphically by following the directions in [Checking the Partitions \(p. 1754\)](#).

35.5.3. Partitioning the Mesh Manually and Balancing the Load

Automatic partitioning in the parallel solver (described in [Partitioning the Mesh Automatically \(p. 1734\)](#)) is the recommended approach to mesh partitioning, but it is also possible to partition the mesh manually in either the serial solver or the parallel solver. After automatic or manual partitioning, you will be able to inspect the partitions created (for details, see [Checking the Partitions \(p. 1754\)](#)) and optionally repartition the mesh, if necessary. Again, you can do so within the serial or the parallel solver, using the **Partitioning and Load Balancing** dialog box. A partitioned mesh may also be used in the serial solver without any loss in performance.

35.5.3.1. Guidelines for Partitioning the Mesh

The following steps are recommended for partitioning a mesh manually:

1. Partition the mesh using the default method (**Metis**). Generally Metis produces the best quality partitions for most problems and no further user intervention should be necessary.
2. Examine the partition statistics, which are described in [Interpreting Partition Statistics \(p. 1754\)](#). Your aim is to achieve small values of Interface ratio variation and Global interface ratio while maintaining a balanced load (Cell variation). If the statistics are not acceptable, try one of the other partition methods.

Instructions for manual partitioning are provided below.

35.5.4. Using the Partitioning and Load Balancing Dialog Box

35.5.4.1. Partitioning

In order to partition the mesh, you need to select the partition method for creating the mesh partitions, set the number of partitions, select the zones and/or registers, and choose the optimizations to be used. For some methods, you can also perform pretesting to ensure that the best possible partition is per-

formed. Once you have set all the parameters in the **Partitioning and Load Balancing** dialog box to your satisfaction, click the **Partition** button to subdivide the mesh into the selected number of partitions using the prescribed method and optimization(s). For recommended partitioning strategies see *Guidelines for Partitioning the Mesh* (p. 1736).

You can set the relevant inputs in the **Partitioning and Load Balancing** dialog box (*Figure 35.8* (p. 1737) in the parallel solver, or *Figure 35.9* (p. 1738) in the serial solver) in the following manner:

Parallel → Partitioning and Load Balancing...

Figure 35.8 The Partitioning and Load Balancing Dialog Box in the Parallel Solver

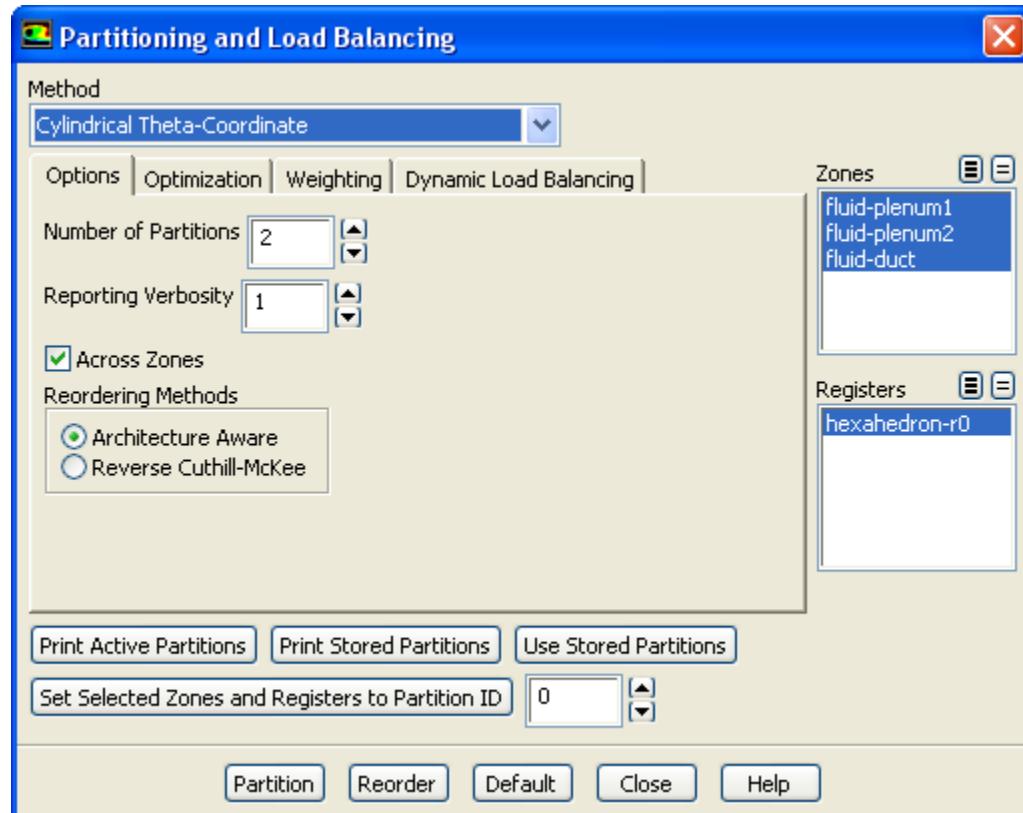

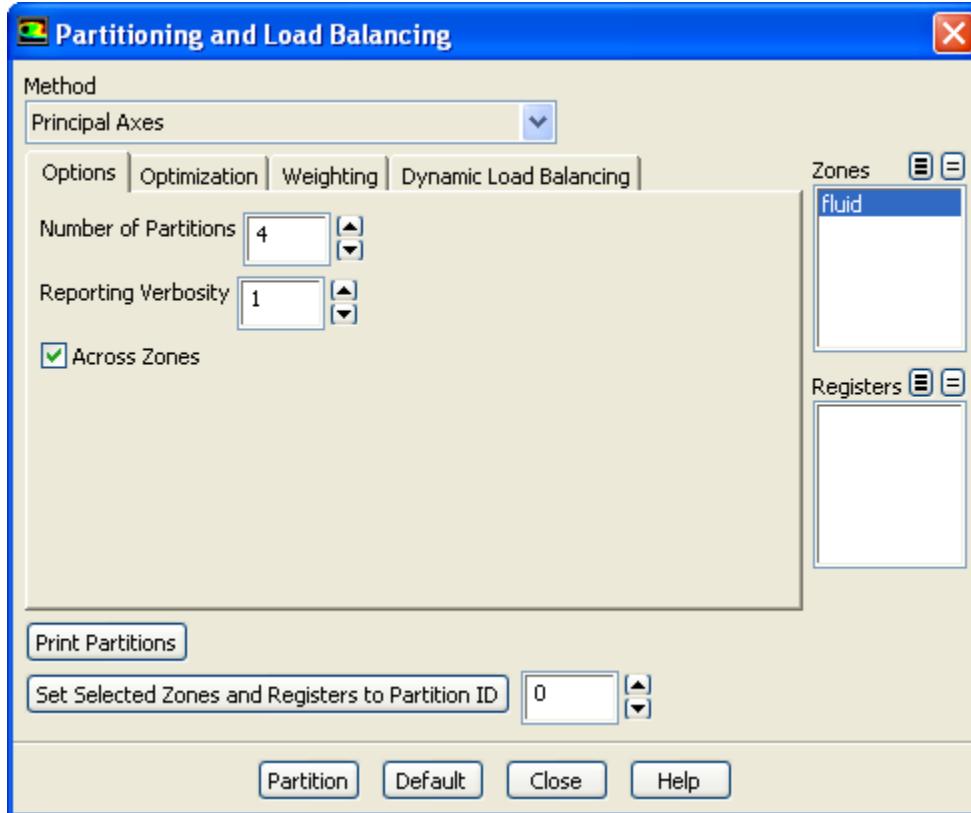

Figure 35.9 The Partitioning and Load Balancing Dialog Box in the Serial Solver

1. Select the **Method** from the drop-down list. The choices are described in [Partition Methods \(p. 1747\)](#).
2. In the **Options** tab
 - a. Set the desired number of mesh partitions in the **Number of Partitions** field. You can use the counter arrows to increase or decrease the value, instead of typing in the box. The number of mesh partitions must be an integer number which is divisible by the number of processors available for parallel computing.
 - b. Set the **Reporting Verbosity**. This allows you to control what is displayed in the console. For details, see [Reporting During Partitioning \(p. 1744\)](#).
 - c. You can choose to independently apply partitioning to each cell zone, or you can allow partitions to cross zone boundaries using the **Across Zones** check button. It is recommended that you *not* partition cell zones independently (by turning off the **Across Zones** check button) unless cells in different zones will require significantly different amounts of computation during the solution phase (e.g., if the domain contains both solid and fluid zones).
 - d. Select the **Reordering Method** for partitions to optimize parallel performance:
 - **Architecture Aware:** This is the default option and it accounts for the system architecture and network topology in remapping the partitions to the processors.
 - **Reverse Cuthill-McKee:** This option minimizes the bandwidth of the compute-node connectivity matrix (the maximum distance between two connected processes) without incorporating the system architecture.

The reordering methods are parallel performance tuning options. After the case is initially partitioned for parallel processing, the partition reordering step will remap the partitions in a more optimal way to improve parallel performance.

Important

The Architecture-aware reordering method is not applicable when only a single machine is used for the simulation.

After initially loading the case into a parallel session, you can click the **Reorder** button to reorder the partitions. The necessary algorithms are executed and ANSYS FLUENT will report if it can find a more optimal mapping for the partitions, as well as the potential improvement in inter-machine communications. If the reported improvement is significant (say, more than 5%), then you can click the **Use Stored Partitions** button to use the new partition mapping. This will generally entail large data transfers amongst all the processes, and another reliable method to activate the new partitions would be to write out a case file and load it back in to a new parallel session. The process is similar to re-partitioning with a new partitioning method, for example. Note that sometimes, depending on the cluster configuration and initial case partitioning, and if the partitions have already been reordered, no improvement is possible, and this will be reported in the console after clicking the **Reorder** button. You can simply continue in this case, and there will be no effect on the simulation. Also, note that partition reordering is specific to the current parallel configuration and should be repeated if the number of machines used changes during subsequent computations.

3. In the **Optimization** tab
 - a. You can activate and control the desired optimization methods (described in [Optimizations \(p. 1752\)](#)). You can activate the **Merge** and **Smooth** schemes by enabling the check button next to each one. For each scheme, you can also set the number of **Iterations**. Each optimization scheme will be applied until appropriate criteria are met, or the maximum number of iterations has been executed. If the **Iterations** counter is set to 0, the optimization scheme will be applied until completion, with no limit on maximum number of iterations.
 - b. Choosing the **Principal Axes** or **Cartesian Axes** method, you can improve the partitioning by enabling the automatic testing of the different bisection directions before the actual partitioning occurs. To use pretesting, enable the **Pre-Test** option. Pretesting is described in [Pretesting \(p. 1753\)](#).
4. In the **Zones** and/or **Registers** lists, select the zone(s) and/or register(s) for which you want to partition. For most cases, you will select all **Zones** (the default) to partition the entire domain. See below for details.
5. You can assign selected **Zones** and/or **Registers** to a specific partition ID by entering a value for the **Set Selected Zones and Registers to Partition ID**. For example, if the **Number** of partitions for your mesh is 2, then you can only use IDs of 0 or 1. If you have three partitions, then you can enter IDs of 0, 1, or 2. This can be useful in situations where the gradient at a region is known to be high. In such cases, you can mark the region or zone and set the marked cells to one of the partition IDs, thus preventing the partition from going through that region. This in turn will facilitate convergence. This is also useful in cases where mesh manipulation tools are not available in parallel. In this case, you can assign the related cells to a particular ID so that the mesh manipulation tools are now functional.

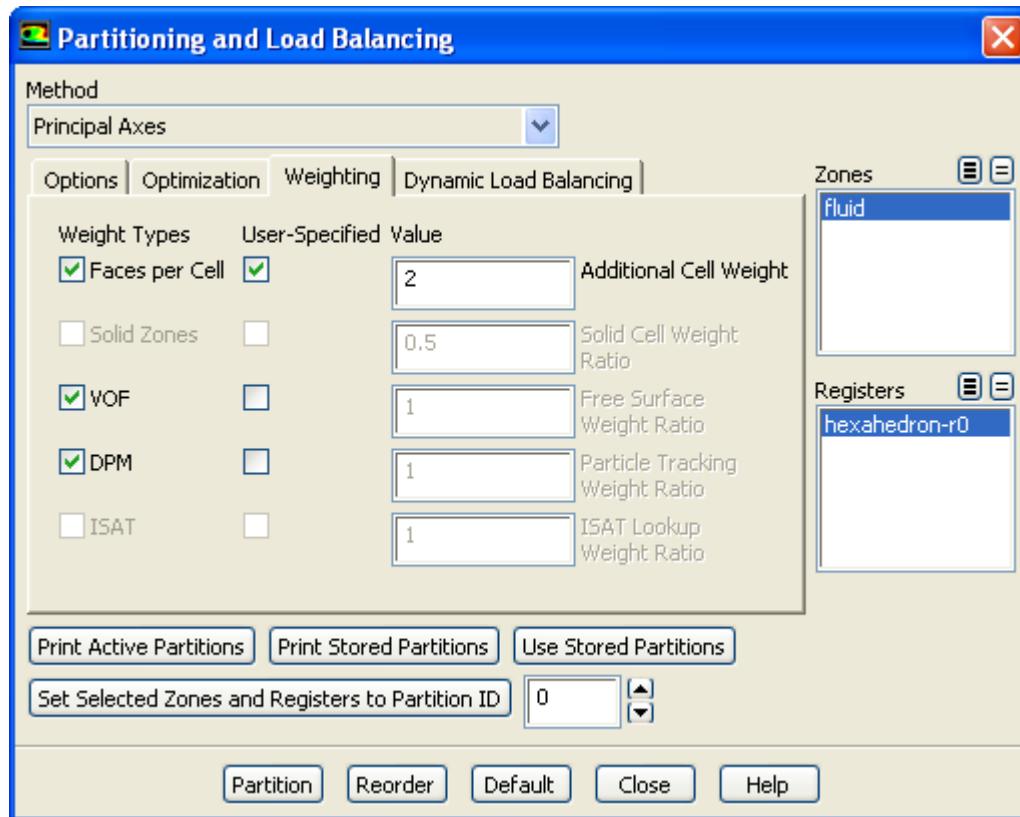

If you are running the parallel solver, and you have marked your region and assigned an ID to the selected **Zones** and/or **Registers**, click the **Use Stored Partitions** button to make the new partitions valid.

Refer to the example described later in this section for a demonstration of how selected registers are assigned to a partition ([Example of Setting Selected Registers to Specified Partition IDs \(p. 1742\)](#)).

6. In the **Weighting** tab ([Figure 35.10 \(p. 1740\)](#)), you can set the appropriate weights, prior to partitioning the mesh, to improve load balancing and overall performance. You can control weights for cells, solid

zones, VOF, and DPM. You can either rely on ANSYS FLUENT timers to set the weight scaling, or you can specify the value by enabling **User-Specified**.

Figure 35.10 The Weighting Tab in the Partitioning and Load Balancing Dialog Box for the Parallel Solver

- Enable **Faces per Cell** so that the partitioning assigns a weight to each cell based on its number of faces. This type of weighting is advantageous when the case has mixed or polyhedral cell zones. If you enable the **User-Specified** check box, the weight assigned to each cell will be the number of faces plus the **Additional Cell Weight** you enter in the number-entry box under **Value**. By default the **Faces per Cell** weighting is enabled with the **Additional Cell Weight** set to **2**.
- Enable **Solid Zones** weighting to allow the partitioning to take solid zones into consideration. By default, ANSYS FLUENT will scale the weight based on the computational time of the solid and fluid zones. If an iteration has not been run, then you may need to specify a value after enabling the user-specified check box. The value you enter is relative to the fluid weight. Typically, it should be less than 1 (e.g., 0 . 0001) so that the calculation will be quicker for the solid zone compared to the fluid zone. Entering a value greater than 1 for the **Solid Zones** means that the calculation will take longer and will be more computationally expensive for the solid zone compared to the fluid zone.

Important

Setting the **Solid Zones** either too high or too low can cause a load imbalance, depending on which equations are being solved. If you are not sure what would be an appropriate value, have ANSYS FLUENT automatically set it for you by making sure that **User-Specified** is disabled.

- c. Enable **VOF** weighting to allow the partitioning to consider the imbalance caused by the free surface reconstruction with the geo-reconstruct scheme. Therefore, it is only available when using the VOF model with geometric reconstruction. You may use the user-specified value before timers are collected, or if you want to specify a value other than timing statistics. The specified value is the VOF proportion of the total computational effort.
- d. Enable **DPM** weighting to set the weight of DPM particles relative to the continuous phase. DPM weights are valid when you have particle tracking in your simulation, where the user-specified value is the DPM proportion of the total computational effort relative to the continuous phase. Note that this is only available when you have injections defined. For details, see [Modeling Discrete Phase \(p. 1075\)](#).

The DPM weight takes into account the distribution of the tracking effort over the partitions and it is available after at least one calculation step with particle tracking. Displaying Particle Tracks does not change the weights. The computational effort is determined by the number of DPM steps performed in each cell. This weight becomes more important when the time for the particle tracking of particles exceeds the time for solving the flow. Enabling this option in the **Weighting** tab activates the counting of the particle steps in the cells. These values are available for contour and vector plots when using the **Discrete Phase Model** and **DPM Steps per Cell** variable. After repartitioning, the DPM weights are reset before the next particle tracking. It is generally preferable to partition along the dominant path of the particles in order to minimize particles crossing partition boundaries and thus reducing associated communication costs. However, partitioning should also consider load balance for the other models, especially the continuous phase, and model weighting provides a means to effectively load balance the overall simulation.

- e. Enable **ISAT** weighting to balance the load during the ISAT table lookup for the stiff-chemistry Laminar, EDC or PDF Transport models. The ISAT algorithm builds an unstructured table in N species dimensions for storage and retrieval of the chemistry mappings. Since chemistry is usually computationally expensive, this storage/retrieval can be very time-consuming (for information about ISAT, refer to [In-Situ Adaptive Tabulation \(ISAT\)](#) in the [Theory Guide](#)). Each parallel node builds its own table, and there is no message passing to tables on other nodes. As some nodes may have more chemical reactions than others (for example one parallel node may contain just air at a constant temperature, in which case the ISAT table will contain only one entry and calculation will be rapid), there may be a load imbalance. The dynamic load balancing algorithm will migrate cells from high computational load nodes to low computational load nodes.

If you decide to specify a value, this user-specified value is the ISAT proportion of the total computational effort.

7. When using the dynamic mesh model in your parallel simulations, the **Partition** dialog box includes an **Auto Repartition** option and a **Repartition Interval** setting. These parallel partitioning options are provided because ANSYS FLUENT migrates cells when local remeshing and smoothing are performed. Therefore, the partition interface becomes very wrinkled and the load balance may deteriorate. By default, the **Auto Repartition** option is selected, where a percentage of interface faces and loads are automatically traced. When this option is selected, ANSYS FLUENT automatically determines the most appropriate repartition interval based on various simulation parameters. Sometimes, using the **Auto Repartition** option provides insufficient results, therefore, the **Repartition Interval** setting can be used. The **Repartition Interval** setting lets you to specify the interval (in time steps or iterations respectively) when a repartition is enforced. When repartitioning is not desired, you can set the **Repartition Interval** to zero.

Important

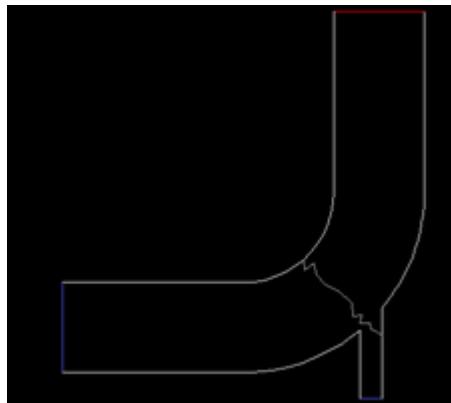

Note that when dynamic meshes and local remeshing is utilized, updated meshes may be slightly different in parallel ANSYS FLUENT (when compared to serial ANSYS FLUENT or when compared to a parallel solution created with a different number of compute nodes), resulting in very small differences in the solutions.

8. Click the **Partition** button to partition the mesh.
9. If you decide that the new partitions are better than the previous ones (if the mesh was already partitioned), click the **Use Stored Partitions** button to make the newly stored cell partitions the active cell partitions. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file.

35.5.4.1.1. Example of Setting Selected Registers to Specified Partition IDs

1. Start ANSYS FLUENT in parallel. The case in this example was partitioned across two nodes.
2. Read in your case.
3. Display the mesh with the **Partitions** option enabled in the **Mesh Display** dialog box ([Figure 35.11 \(p. 1742\)](#)).

Figure 35.11 The Partitioned Mesh

4. Adapt your region and mark your cells. (For details, see [Performing Region Adaption \(p. 1452\)](#)). This creates a register.
5. Open the **Partitioning and Load Balancing** dialog box.
6. Set the **Set Selected Zones and Registers to Partition ID** to 0 and click the corresponding button. This displays the following output in the ANSYS FLUENT console:

```
>> 2 Active Partitions:
-----
Collective Partition Statistics:      Minimum      Maximum      Total
-----
Cell count                      459          459         918
Mean cell count deviation       0.0%        0.0%
Partition boundary cell count    11           11          22
Partition boundary cell count ratio 2.4%        2.4%        2.4%
Face count                      764          1714        2461
Mean face count deviation      -38.3%       38.3%
Partition boundary face count    13           13          17
Partition boundary face count ratio 0.8%        1.7%        0.7%
```

```

Partition neighbor count           1           1
-----
Partition Method                  Metis
Stored Partition Count          2
Done.

```

7. Click the **Use Stored Partitions** button to make the new partitions valid. This migrates the partitions to the compute-nodes. The following output is then displayed in the ANSYS FLUENT console:

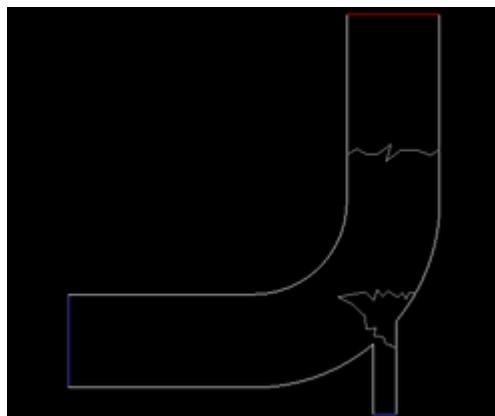

```

Migrating partitions to compute-nodes.
>> 2 Active Partitions:
    P   Cells   I-Cells   Cell Ratio   Faces   I-Faces   Face Ratio   Neighbors
    0     672       24      0.036     2085      29      0.014           1
    1     246       24      0.098      425      29      0.068           1
-----
Collective Partition Statistics:   Minimum   Maximum   Total
-----
Cell count                      246        672        918
Mean cell count deviation      -46.4%     46.4%
Partition boundary cell count   24          24         48
Partition boundary cell count ratio 3.6%      9.8%      5.2%
Face count                      425        2085      2461
Mean face count deviation      -66.1%     66.1%
Partition boundary face count   29          29         49
Partition boundary face count ratio 1.4%      6.8%      2.0%
Partition neighbor count         1           1
-----
Partition Method                  Metis
Stored Partition Count          2
Done.

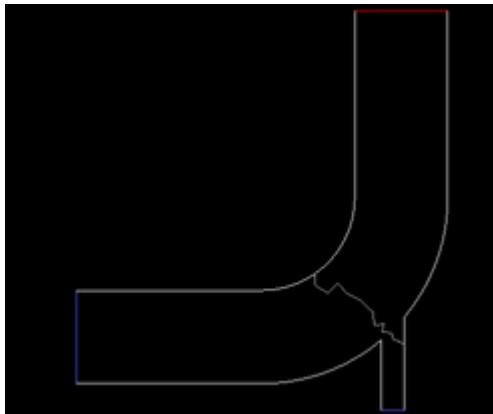

```

8. Display the mesh ([Figure 35.12 \(p. 1743\)](#)).

Figure 35.12 The Partitioned ID Set to Zero

9. This time, set the **Set Selected Zones and Registers to Partition ID** to 1 and click the corresponding button. This displays a report in the ANSYS FLUENT console.
10. Click the **Use Stored Partitions** button to make the new partitions valid and to migrate the partitions to the compute-nodes.
11. Display the mesh ([Figure 35.13 \(p. 1744\)](#)). Notice now that the partition appears in a different location as specified by your partition ID.

Figure 35.13 The Partitioned ID Set to 1**Important**

Although this example demonstrates setting selected registers to specific partition IDs in parallel, it can be similarly applied in serial.

35.5.4.1.2. Partitioning Within Zones or Registers

The ability to restrict partitioning to cell zones or registers gives you the flexibility to apply different partitioning strategies to subregions of a domain. For example, if your geometry consists of a cylindrical plenum connected to a rectangular duct, you may want to partition the plenum using the **Cylindrical Axes** method, and the duct using the **Cartesian Axes** method.

If the plenum and the duct are contained in two different cell zones, you can select one at a time and perform the desired partitioning, as described in [Using the Partitioning and Load Balancing Dialog Box \(p. 1736\)](#). If they are not in two different cell zones, you can create a cell register (basically a list of cells) for each region using the functions that are used to mark cells for adaption. These functions allow you to mark cells based on physical location, cell volume, gradient or isovalue of a particular variable, and other parameters. See [Adapting the Mesh \(p. 1441\)](#) for information about marking cells for adaption. [Manipulating Adaption Registers \(p. 1459\)](#) provides information about manipulating different registers to create new ones. Once you have created a register, you can partition within it as described in [Example of Setting Selected Registers to Specified Partition IDs \(p. 1742\)](#).

Important

Note that partitioning within zones or registers is not available when **Metis** is selected as the partition **Method**.

For dynamic mesh applications, ANSYS FLUENT stores the partition method used to partition the respective zone. Therefore, if repartitioning is done, ANSYS FLUENT uses the same method that was used to partition the mesh.

35.5.4.1.3. Reporting During Partitioning

As the mesh is partitioned, information about the partitioning process will be displayed in the console. By default, the number of partitions created, the time required for the partitioning, and the minimum and maximum cell, face, interface, and face-ratio variations will be displayed. (For details, see [Interpreting Partition Statistics \(p. 1754\)](#).) If you increase the **Reporting Verbosity** to 2 from the default value of 1, the

partition method used, the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each partition will also be displayed in the console. If you decrease the **Reporting Verbosity** to 0, only the number of partitions created and the time required for the partitioning will be reported.

You can request a portion of this report to be displayed again after the partitioning is completed. When you click the **Print Active Partitions** or **Print Stored Partitions** button in the parallel solver, ANSYS FLUENT will display the partition ID, number of cells, faces, and interfaces, and the ratio of interfaces to faces for each active or stored partition in the console. In addition, it will display the minimum and maximum cell, face, interface, and face-ratio variations. In the serial solver, you will obtain the same information about the stored partition when you click **Print Partitions**. For details, see [Interpreting Partition Statistics \(p. 1754\)](#).

Important

Recall that to make the stored cell partitions the active cell partitions you must click the **Use Stored Partitions** button. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file.

35.5.4.1.4. Resetting the Partition Parameters

If you change your mind about your partition parameter settings, you can easily return to the default settings assigned by ANSYS FLUENT by clicking on the **Default** button. When you click the **Default** button, it will become the **Reset** button. The **Reset** button allows you to return to the most recently saved settings (i.e., the values that were set before you clicked on **Default**). After execution, the **Reset** button will become the **Default** button again.

35.5.4.2. Load Balancing

A dynamic load balancing capability is available in ANSYS FLUENT. The principal reason for using parallel processing is to reduce the turnaround time of your simulation, which may be achieved by the following means:

- Faster machines, e.g., faster CPU, memory, cache, and, communication bandwidth between the CPU and memory
- Faster interconnects, e.g., smaller latency and larger bandwidth
- Better Load balancing, e.g., load is evenly distributed and CPUs are not idled during calculation

The first two evolve at the pace of computer technology, which is beyond the scope of this document. The third item is regarding optimization of available computation power. Here we are mainly talking about load balancing on dedicated homogeneous resources, which is often the case nowadays. If you are not using a dedicated homogeneous resource, you may need to account for differences in CPU speeds during partitioning by specifying a load distribution. (For details, see [Load Distribution \(p. 1755\)](#)).

On a dedicated homogeneous system, the key for load balancing is how to evaluate the computational requirement of each cell. By default, ANSYS FLUENT assumes that each cell requires the same computational work, but this is often not the case. For example

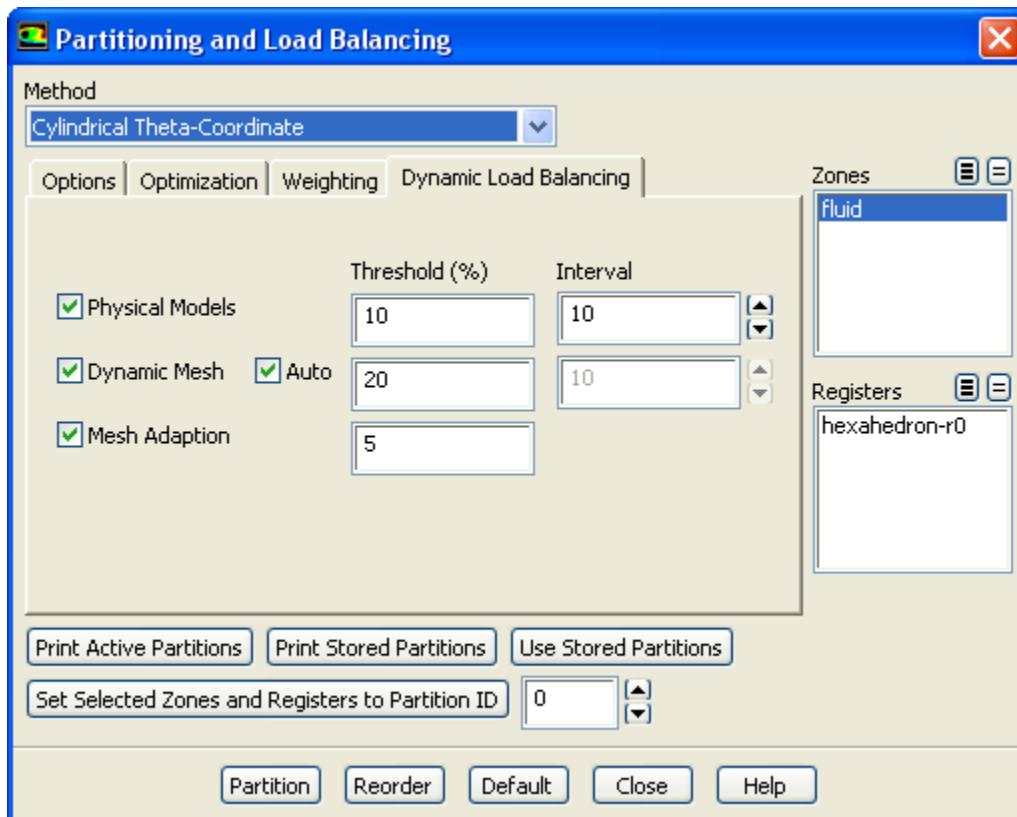

- A hexahedral cell demands more CPU and memory than a tetrahedral cell.
- A cell with particle tracking will use more time than a cell without particle tracking.
- ISAT species model cells may have magnitude differences in time usage.

To balance these differences, ideally, the time used in each cell can be recorded and load balancing can be achieved based on these detailed timing statistics. However, this can be expensive and such low level timings can be unreliable in any case. Instead, we identify features causing computational imbalance and record time usage for these models in aggregate. For a more detailed description of this, please refer to [Partitioning \(p. 1736\)](#) in the discussion of the **Weighting** tab. In addition, the imbalance may happen dynamically during run-time, for example

- The mesh may be changed by adaption or mesh movement.
- In unsteady cases, particle tracking may move from one region to another region.

Dynamic load balancing has been implemented for better scalability of cases with imbalanced physical or geometrical models, thus reducing the simulation time. The implementation considers weights from these models scaled by CPU time usage. Load balancing for DPM, VOF, cell type (number of faces per cell), and solid zones can be performed. In addition, cell weight based load balancing and machine load distribution can also be specified. (For details, see [Load Distribution \(p. 1755\)](#)). ANSYS FLUENT takes the weights from physical models and considers them for partitioning. The weights are assembled based on the time used by each physical model. For dynamic load balancing, the load is checked and balanced based on your specified imbalance threshold. To apply dynamic load balancing on the various models, click the **Dynamic Load Balancing** tab and select the required balancing as follows:

Figure 35.14 The Dynamic Load Balancing Tab

1. Enable **Physical Models** load balancing during iterations so that the load will be evaluated for time usage and weight distribution, based on the **Interval** that you provide. If the imbalance exceeds the specified **Threshold**, then repartitioning will be performed by considering the selected weights. **Physical Models** load balancing will only be available when you have the specific physical models enabled in the case. You will be prompted to enable the weights for those models. When weights for the physical models are all disabled, you will be prompted to disable **Physical Models** load balancing.

2. Enable **Dynamic Mesh** if there is any dynamic mesh movement. Load balancing, based on the number of cells, will be checked and balanced if the imbalance threshold is exceeded. These parallel partitioning options are provided because with mesh motion, when local remeshing and smoothing are performed, the partition interface can become very wrinkled and load balance may deteriorate. By default, the **Auto** option is selected, where a percentage of interface faces and loads are automatically traced. When this option is selected, ANSYS FLUENT automatically determines the most appropriate repartitioning interval based on various simulation parameters. However, sometimes, the frequency of load balancing from the **Auto** option may be inadequate, and then the **Interval** setting can be explicitly set. The **Interval** setting lets you specify the interval (in time steps or iterations, respectively) when load balancing is enforced. When load balancing is not desired, you may disable **Dynamic Mesh** load balancing. Dynamic Mesh load balancing is only available when you have dynamic models enabled in your case.

Important

Note that when dynamic meshes and local remeshing are utilized, updated meshes may be slightly different in parallel ANSYS FLUENT (when compared to serial ANSYS FLUENT or when compared to a parallel solution created with a different number of compute nodes), resulting in very small differences in the solutions.

3. Enable **Mesh Adaption**. Any time mesh adaption occurs, load balancing, based on the number of cells, will be checked and balanced if the imbalance threshold is exceeded. If problems arise in your computations due to adaption, you can disable the load balancing for **Mesh Adaption**.

35.5.5. Mesh Partitioning Methods

Partitioning the mesh for parallel processing has three major goals:

- Create partitions with equal numbers of cells.
- Minimize the number of partition interfaces — i.e., decrease partition boundary surface area.
- Minimize the number of partition neighbors.

Balancing the partitions (equalizing the number of cells) ensures that each processor has an equal load and that the partitions will be ready to communicate at about the same time. Since communication between partitions can be a relatively time-consuming process, minimizing the number of interfaces can reduce the time associated with this data interchange. Minimizing the number of partition neighbors reduces the chances for network and routing contentions. In addition, minimizing partition neighbors is important on machines where the cost of initiating message passing is expensive compared to the cost of sending longer messages. This is especially true for workstations connected in a network.

The partitioning schemes in ANSYS FLUENT use bisection or METIS algorithms to create the partitions, but unlike other schemes which require the number of partitions to be a factor of two, these schemes have no limitations on the number of partitions. You will create as many partitions as there are computing units (cores based on processors and machines) available for your simulation.

35.5.5.1. Partition Methods

The mesh is partitioned using a bisection or METIS algorithm. The selected algorithm is applied to the parent domain, and then recursively applied to the subdomains. For example, to divide the mesh into four partitions with a bisection method, the solver will bisect the entire (parent) domain into two child domains, and then repeat the bisection for each of the child domains, yielding four partitions in total.

To divide the mesh into three partitions with a bisection method, the solver will “bisection” the parent domain to create two partitions—one approximately twice as large as the other—and then bisect the larger child domain again to create three partitions in total. METIS uses graph partitioning techniques that generally provide more optimal partitions than the geometric methods.

The mesh can be partitioned using one of the algorithms listed below. The most efficient choice is problem-dependent, so you can try different methods until you find the one that is best for your problem. See *Guidelines for Partitioning the Mesh* (p. 1736) for recommended partitioning strategies.

Cartesian Axes

bisects the domain based on the Cartesian coordinates of the cells (see *Figure 35.15* (p. 1749)). It bisects the parent domain and all subsequent child subdomains perpendicular to the coordinate direction with the longest extent of the active domain. It is often referred to as coordinate bisection.

Cartesian Strip

uses coordinate bisection but restricts all bisections to the Cartesian direction of longest extent of the parent domain (see *Figure 35.16* (p. 1750)). You can often minimize the number of partition neighbors using this approach.

Cartesian X-, Y-, Z-Coordinate

bisects the domain based on the selected Cartesian coordinate. It bisects the parent domain and all subsequent child subdomains perpendicular to the specified coordinate direction. (See *Figure 35.16* (p. 1750).)

Cartesian R Axes

bisects the domain based on the shortest radial distance from the cell centers to that Cartesian axis (x , y , or z) which produces the smallest interface size. This method is available only in 3D.

Cartesian RX-, RY-, RZ-Coordinate

bisects the domain based on the shortest radial distance from the cell centers to the selected Cartesian axis (x , y , or z). These methods are available only in 3D.

Cylindrical Axes

bisects the domain based on the cylindrical coordinates of the cells. This method is available only in 3D.

Cylindrical R-, Theta-, Z-Coordinate

bisects the domain based on the selected cylindrical coordinate. These methods are available only in 3D.

Metis

uses the METIS software package for partitioning irregular graphs, developed by Karypis and Kumar at the University of Minnesota and the Army HPC Research Center. It uses a multilevel approach in which the vertices and edges on the fine graph are coalesced to form a coarse graph. The coarse graph is partitioned, and then uncoarsened back to the original graph. During coarsening and uncoarsening, algorithms are applied to permit high-quality partitions. Detailed information about METIS can be found in its manual [39] (p. 2369).

Important

If you create non-conformal interfaces, and generate virtual polygonal faces, your METIS partition can cross non-conformal interfaces by using the connectivity of the virtual polygonal faces. This improves load balancing for the parallel solver and minimizes communication by decreasing the number of partition interface cells.

Polar Axes

bisects the domain based on the polar coordinates of the cells (see *Figure 35.19* (p. 1751)). This method is available only in 2D.

Polar R-Coordinate, Polar Theta-Coordinate

bisects the domain based on the selected polar coordinate (see [Figure 35.19 \(p. 1751\)](#)). These methods are available only in 2D.

Principal Axes

bisects the domain based on a coordinate frame aligned with the principal axes of the domain (see [Figure 35.17 \(p. 1750\)](#)). This reduces to Cartesian bisection when the principal axes are aligned with the Cartesian axes. The algorithm is also referred to as moment, inertial, or moment-of-inertia partitioning.

This is the default bisection method in ANSYS FLUENT.

Principal Strip

uses moment bisection but restricts all bisections to the principal axis of longest extent of the parent domain (see [Figure 35.18 \(p. 1751\)](#)). You can often minimize the number of partition neighbors using this approach.

Principal X-, Y-, Z-Coordinate

bisects the domain based on the selected principal coordinate (see [Figure 35.18 \(p. 1751\)](#)).

Spherical Axes

bisects the domain based on the spherical coordinates of the cells. This method is available only in 3D.

Spherical Rho-, Theta-, Phi-Coordinate

bisects the domain based on the selected spherical coordinate. These methods are available only in 3D.

Figure 35.15 Partitions Created with the Cartesian Axes Method

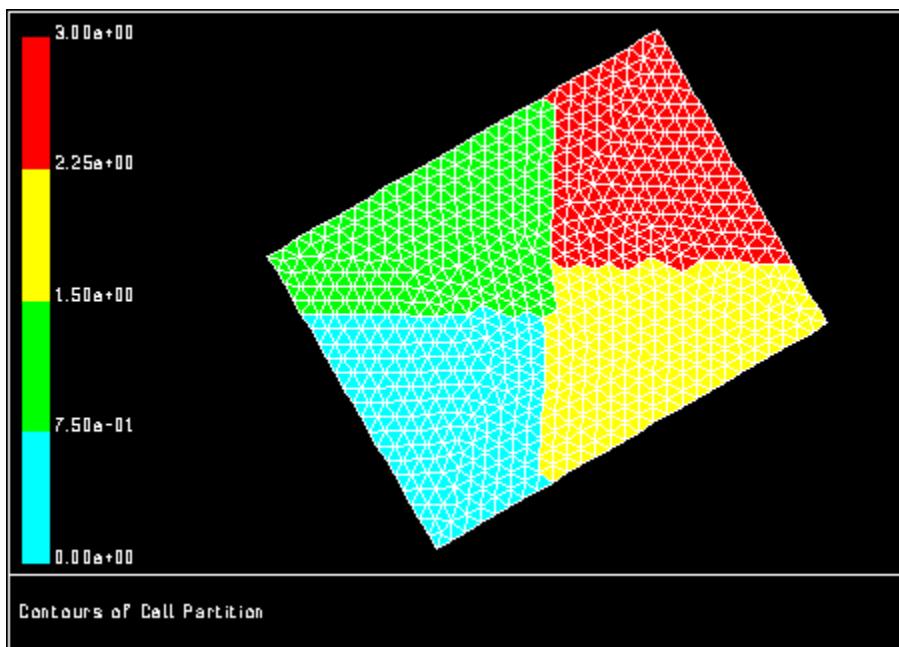

Figure 35.16 Partitions Created with the Cartesian Strip or Cartesian X-Coordinate Method

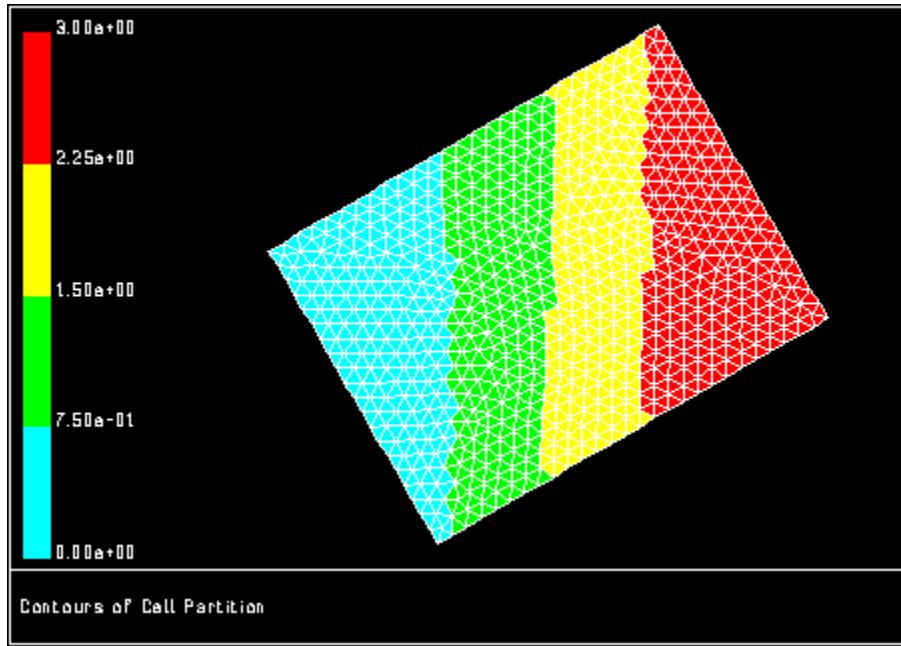

Figure 35.17 Partitions Created with the Principal Axes Method

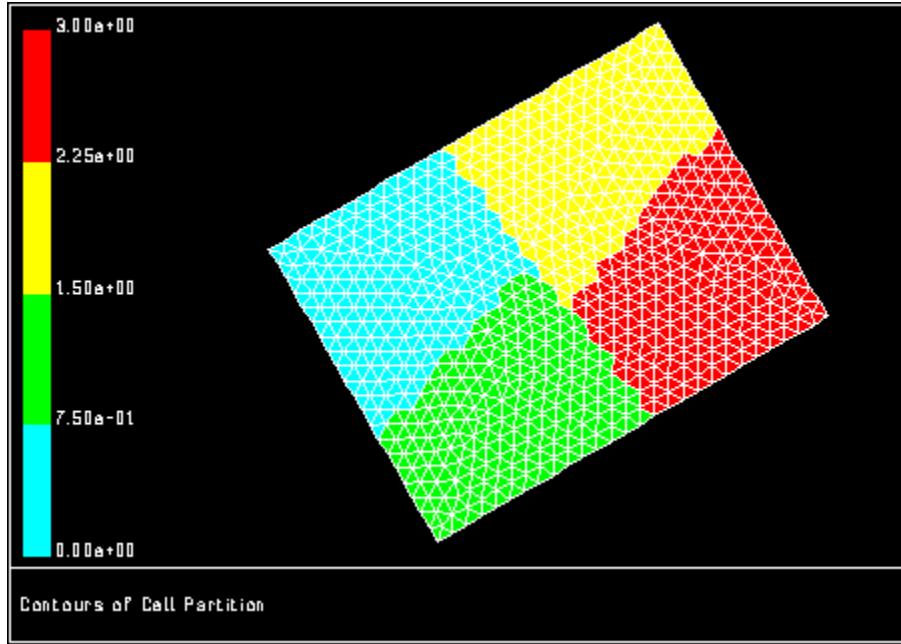

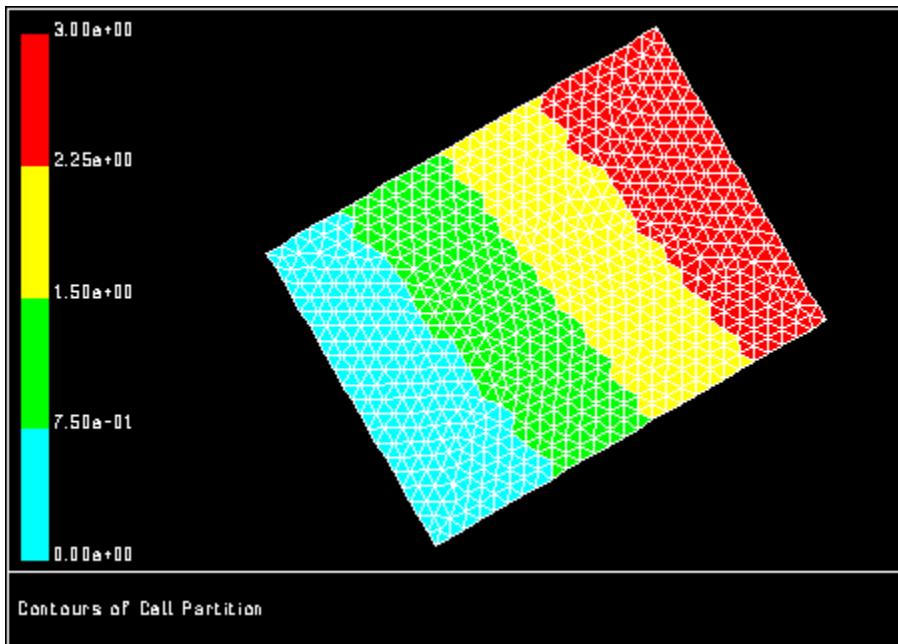

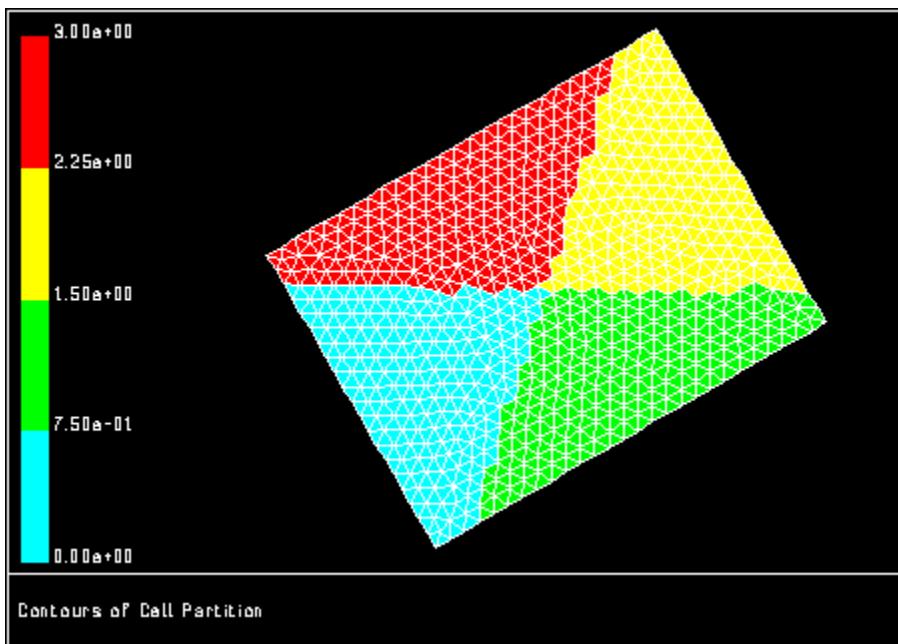

Figure 35.18 Partitions Created with the Principal Strip or Principal X-Coordinate Method**Figure 35.19 Partitions Created with the Polar Axes or Polar Theta-Coordinate Method**

Note

For cases with highly stretched cells, convergence may be difficult to achieve if the partition interface goes through the highly stretched areas. For such cases, cell geometry information is taken into consideration during partitioning with Metis. To assist in cases such as these, use the `parallel/partition/set/stretched-mesh-enhancement` text interface command (serial partition only).

For certain cases, you may want to extrude the partition from specific face zones. Essentially, ANSYS FLUENT will partition the cells attached to the selected face zones first, then extrude the partitions to the other cells. This can be achieved using the `parallel/partition/set/layering` text interface command (serial partition only). The layering method is only intended for meshes with a clear extruding direction, layer by layer in topology.

35.5.5.2. Optimizations

Additional optimizations can be applied to improve the quality of the mesh partitions. The heuristic of bisecting perpendicular to the direction of longest domain extent is not always the best choice for creating the smallest interface boundary. A pre-testing operation, (For details, see [Pretesting \(p. 1753\)](#)) can be applied to automatically choose the best direction before partitioning. In addition, the following iterative optimization schemes exist:

Smooth

attempts to minimize the number of partition interfaces by swapping cells between partitions. The scheme traverses the partition boundary and gives cells to the neighboring partition if the interface boundary surface area is decreased. (See [Figure 35.20 \(p. 1752\)](#).)

Merge

attempts to eliminate orphan clusters from each partition. An orphan cluster is a group of cells with the common feature that each cell within the group has at least one face which coincides with an interface boundary. (See [Figure 35.21 \(p. 1753\)](#).) Orphan clusters can degrade multigrid performance and lead to large communication costs.

Figure 35.20 The Smooth Optimization Scheme

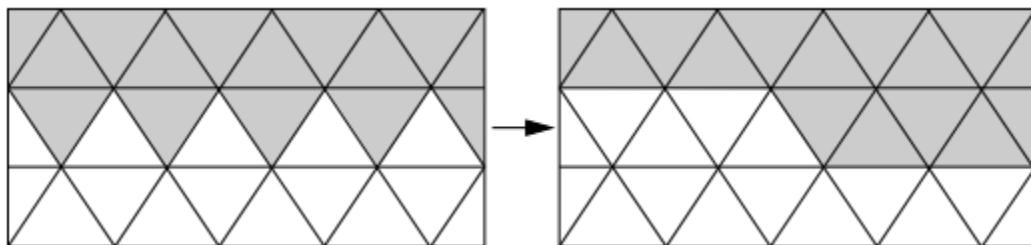

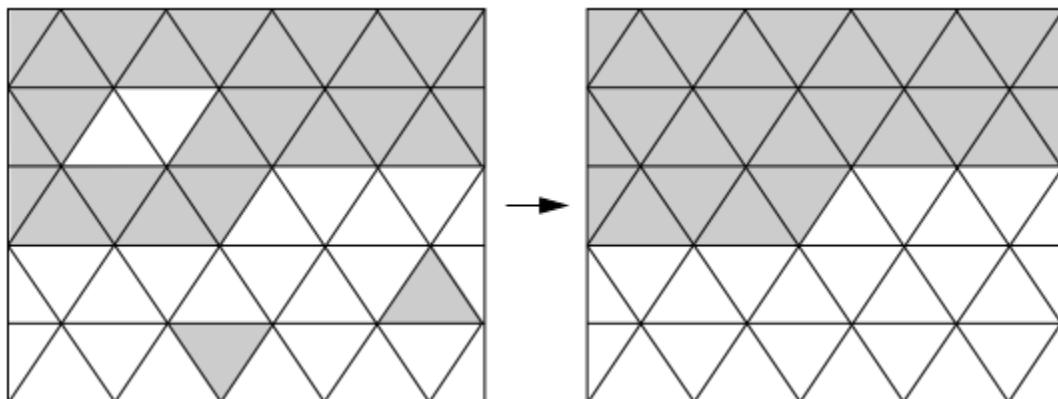

Figure 35.21 The Merge Optimization Scheme

In general, the Smooth and Merge schemes are relatively inexpensive optimization tools.

35.5.5.3. Pretesting

If you choose the **Principal Axes** or **Cartesian Axes** method, you can improve the bisection by testing different directions before performing the actual bisection. If you choose not to use pretesting (the default), ANSYS FLUENT will perform the bisection perpendicular to the direction of longest domain extent.

If pretesting is enabled, it will occur automatically when you click the **Partition** button in the *Partitioning and Load Balancing Dialog Box* (p. 2319), or when you read in the mesh if you are using automatic partitioning. The bisection algorithm will test all coordinate directions and choose the one which yields the fewest partition interfaces for the final bisection.

Note that using pretesting will increase the time required for partitioning. For 2D problems partitioning will take 3 times longer than without pretesting, and for 3D problems it will take 4 times longer.

35.5.5.4. Using the Partition Filter

As noted above, you can use the METIS partitioning method through a filter in addition to within the **Auto Partition Mesh** and **Partitioning and Load Balancing** dialog boxes. To perform METIS partitioning on an unpartitioned mesh, use the **File/Import/Partition/Metis...** menu item.

File → Import → Partition → Metis...

ANSYS FLUENT will use the METIS partitioner to partition the mesh, and then read the partitioned mesh into the solver. The number of partitions will be equal to the number of processes. You can then proceed with the model definition and solution.

Important

Direct import to the parallel solver through the partition filter requires that the host machine has enough memory to run the filter for the specified mesh. If not, you will need to run the filter on a machine that does have enough memory. You can either start the parallel solver on the machine with enough memory and repeat the process described above, or run the filter manually on the new machine and then read the partitioned mesh into the parallel solver on the host machine.

To manually partition a mesh using the partition filter, enter the following command:

```
utility partition input_filename partition_count output_filename
```

where *input_filename* is the filename for the mesh to be partitioned, *partition_count* is the number of partitions desired, and *output_filename* is the filename for the partitioned mesh. You can then read the partitioned mesh into the solver (using the standard **File/Read/Case...** menu item) and proceed with the model definition and solution.

When the **File/Import/Partition/Metis...** menu item is used to import an unpartitioned mesh into the parallel solver, the METIS partitioner partitions the entire mesh. You may also partition each cell zone individually, using the **File/Import/Partition/Metis Zone...** menu item.

File → Import → Partition → Metis Zone...

This method can be useful for balancing the work load. For example, if a case has a fluid zone and a solid zone, the computation in the fluid zone is more expensive than in the solid zone, so partitioning each zone individually will result in a more balanced work load.

35.5.6. Checking the Partitions

After partitioning a mesh, you should check the partition information and examine the partitions graphically.

35.5.6.1. Interpreting Partition Statistics

You can request a report to be displayed after partitioning (either automatic or manual) is completed. In the parallel solver, click the **Print Active Partitions** or **Print Stored Partitions** button in the **Partitioning and Load Balancing** dialog box. In the serial solver, click the **Print Partitions** button.

ANSYS FLUENT distinguishes between two cell partition schemes within a parallel problem: the active cell partition and the stored cell partition. Initially, both are set to the cell partition that was established upon reading the case file. If you re-partition the mesh using the **Partitioning and Load Balancing** dialog box, the new partition will be referred to as the stored cell partition. To make it the active cell partition, you need to click the **Use Stored Partitions** button in the **Partitioning and Load Balancing** dialog box. The active cell partition is used for the current calculation, while the stored cell partition (the last partition performed) is used when you save a case file. This distinction is made mainly to allow you to partition a case on one machine or network of machines and solve it on a different one. Thanks to the two separate partitioning schemes, you could use the parallel solver with a certain number of compute nodes to subdivide a mesh into an arbitrary different number of partitions, suitable for a different parallel machine, save the case file, and then load it into the designated machine.

When you click **Print Partitions** in the serial solver, you will obtain information about the stored partition.

The output generated by the partitioning process includes information about the recursive subdivision and iterative optimization processes. This is followed by information about the final partitioned mesh, including the partition ID, number of cells, number of faces, number of interface faces, ratio of interface faces to faces for each partition, number of neighboring partitions, and cell, face, interface, neighbor, mean cell, face ratio, and global face ratio variations. Global face ratio variations are the minimum and maximum values of the respective quantities in the present partitions. For example, in the sample output below, partitions 0 and 3 have the minimum number of interface faces (10), and partitions 1 and 2 have the maximum number of interface faces (19); hence the variation is 10–19.

Your aim is to achieve small values of Interface ratio variation and Global interface ratio while maintaining a balanced load (Cell variation).

```
>> Partitions:
P    Cells     I-Cells      Cell Ratio      Faces     I-Faces      Face Ratio      Neighbors

Neighbor variation = (1 - 2)

Computing connected regions; type ^C to interrupt.
Connected region count = 4
```

Note that partition IDs correspond directly to compute node IDs when a case file is read into the parallel solver. When the number of partitions in a case file is larger than the number of compute nodes, but is evenly divisible by the number of compute nodes, then the distribution is such that partitions with IDs 0 to ($M - 1$) are mapped onto compute node 0, partitions with IDs M to ($2M - 1$) onto compute node 1, etc., where M is equal to the ratio of the number of partitions to the number of compute nodes.

35.5.6.2. Examining Partitions Graphically

To further aid interpretation of the partition information, you can draw contours of the mesh partitions, as illustrated in

 **Graphics and Animations** →  **Contours** → **Set Up...**

To display the active cell partition or the stored cell partition (which were described above), select **Active Cell Partition** or **Stored Cell Partition** in the **Cell Info...** category of the **Contours Of** drop-down list, and turn off the display of **Node Values**. (For details, see *Displaying Contours and Profiles* (p. 1506) for information about displaying contours.)

Important

If you have not already done so in the setup of your problem, you will need to perform a solution initialization in order to use the **Contours** dialog box.

35.5.7. Load Distribution

If the speeds of the processors that will be used for a parallel calculation differ significantly, you can specify a load distribution for partitioning, using the **load-distribution** text command.

`parallel → partition → set → load-distribution`

For example, if you will be solving on three compute nodes, and one machine is twice as fast as the other two, then you may want to assign twice as many cells to the first machine as to the others (i.e.,

a load vector of (2 1 1)). During subsequent mesh partitioning, partition 0 will end up with twice as many cells as partitions 1 and 2.

For this example, you need to start up ANSYS FLUENT such that compute node 0 is the fast machine, since partition 0, with twice as many cells as the others, will be mapped onto compute node 0. Alternatively, in this situation, you could enable the load balancing feature (described in [Load Balancing \(p. 1745\)](#)) to have ANSYS FLUENT automatically attempt to discern any difference in load among the compute nodes.

35.5.8. Troubleshooting

When running a calculation using parallel ANSYS FLUENT, you may encounter a warning message in the console that reports problems related to the partitioning. The following is an example of such a warning:

```
#AMG# Warning: The global matrix size (1273286) is too large, and may
adversely affect the parallel performance. See the ANSYS FLUENT User's
Guide for information on troubleshooting partitioning issues.
```

The following are possible reasons why the global matrix size is so large, along with recommendations for reducing it:

- The presence of solid zones may cause a partition to have a very small amount of fluid cells. For such cases, it is recommended that you partition the mesh with the **Across Zones** option disabled in the **Partitioning and Load Balancing** dialog box, and then click the **Use Stored Partitions** button.
- A partition may have a small number of cells if you have set up a load distribution for partitioning. Such settings should be disabled, by using the load-distribution text command (described in [Load Distribution \(p. 1755\)](#)) and entering a value of 1 for each of the previously defined partitions.
- Some model settings (e.g., shell conduction) can encapsulate some cells, which may cause difficulties with the coarsening process. To remedy this situation, you can either try a different partitioning method, or you can enable the global coarsening checking criteria with the following rpvar setting:

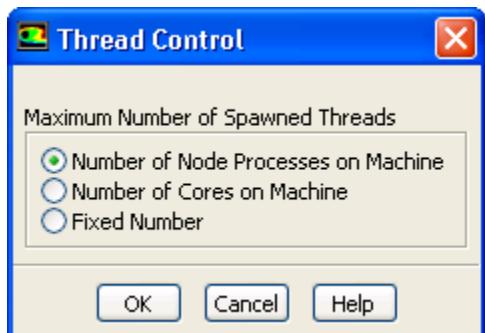

```
(rpsetvar 'amg/parallel/global-check-coarsening? #t )
```

35.6. Controlling the Threads

You can control the maximum number of threads on each machine by using the **Thread Control** dialog box ([Figure 35.23 \(p. 1757\)](#)).

Parallel → Thread Control...

Figure 35.22 The Thread Control Dialog Box

You have the following options when using the **Thread Control** dialog box:

- **Number of Node Processes on Machine**

This is the default option. When this option is chosen, the maximum number of threads on each machine is equal to the number of ANSYS FLUENT node processes on each machine.

- **Number of Cores on Machine**

When this option is chosen, the maximum number of threads on each machine is equal to the number of cores on the machine. ANSYS FLUENT obtains the number of cores from the OS. This may be applicable when the multi-threaded part of the calculation is dominating the computation time, and the continuous phase calculation is relatively small, and you want to take full advantage of the computation resources. For example, if you have a very small case with regard to the number of cells, but a large number of particles to be tracked, you may want to spawn one ANSYS FLUENT node process on each machine, but use the maximum number of cores in order to get a good overall performance.

- **Fixed Number**

When this option is chosen, you may input the maximum number of threads that can be spawned on each machine in the number-entry box below **Fixed Number**. This may only be applicable when you want to have fine control of the number of threads on each machine; it is not recommended in general.

35.7. Checking Network Connectivity

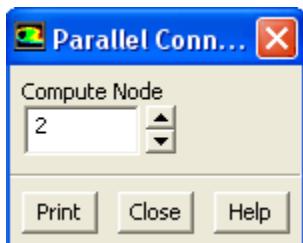

For any compute node, you can print network connectivity information that includes the hostname, architecture, process ID, and ID of the selected compute node and all machines connected to it. The ID of the selected compute node is marked with an asterisk.

The ID for the ANSYS FLUENT host process is always `host`. The compute nodes are numbered sequentially starting from `node-0`. All compute nodes are completely connected. In addition, compute node 0 is connected to the host process.

To obtain connectivity information for a compute node, you can use the *Parallel Connectivity Dialog Box* (p. 2329) (*Figure 35.23* (p. 1757)).

Parallel → **Network** → **Show Connectivity...**

Figure 35.23 The Parallel Connectivity Dialog Box

Indicate the compute node ID for which connectivity information is desired in the **Compute Node** field, and then click the **Print** button. Sample output for compute node 0 is shown below:

ID	Comm.	Hostname	O.S.	PID	Mach ID	HW ID	Name
----	-------	----------	------	-----	---------	-------	------

host	pcmpi	balin	Linux-32	17272	0	7	Fluent Host
n3	pcmpi	balin	Linux-32	17307	1	10	Fluent Node
n2	pcmpi	filio	Linux-32	17306	0	-1	Fluent Node
n1	pcmpi	bofur	Linux-32	17305	0	1	Fluent Node
n0*	pcmpi	balin	Linux-32	17273	2	11	Fluent Node

O . S is the architecture, Comm . is the communication library (i.e., MPI type), PID is the process ID number, Mach ID is the compute node ID, and HW ID is an identifier specific to the interconnect used.

35.8. Checking and Improving Parallel Performance

To determine how well the parallel solver is working, you can measure computation and communication times, and the overall parallel efficiency, using the performance meter. You can also control the amount of communication between compute nodes in order to optimize the parallel solver, and take advantage of the automatic load balancing feature of ANSYS FLUENT.

Information about checking and improving parallel performance is provided in the following sections:

35.8.1. Checking Parallel Performance

35.8.2. Optimizing the Parallel Solver

35.8.1. Checking Parallel Performance

The performance meter allows you to report the wall clock time elapsed during a computation, as well as message-passing statistics. Since the performance meter is always activated, you can access the statistics by displaying them after the computation is completed. To view the current statistics, use the **Parallel/Timer/Usage** menu item.

Parallel → Timer → Usage

Performance statistics will be displayed in the console.

To clear the performance meter so that you can eliminate past statistics from the future report, use the **Parallel/Timer/Reset** menu item.

Parallel → Timer → Reset

The following example demonstrates how the current parallel statistics are displayed in the console:

```
Performance Timer for 1 iterations on 4 compute nodes
Average wall-clock time per iteration:          4.901 sec
Global reductions per iteration:                 408 ops
Global reductions time per iteration:           0.000 sec (0.0%)
Message count per iteration:                    801 messages
Data transfer per iteration:                   9.585 MB
LE solves per iteration:                      12 solves
LE wall-clock time per iteration:            2.445 sec (49.9%)
LE global solves per iteration:              27 solves
LE global wall-clock time per iteration:    0.246 sec (5.0%)
AMG cycles per iteration:                     64 cycles
Relaxation sweeps per iteration:             4160 sweeps
Relaxation exchanges per iteration:          920 exchanges

Total wall-clock time:                        4.901 sec
Total CPU time:                            17.030 sec
```

A description of the parallel statistics is as follows:

- Average wall-clock time per iteration describes the average real (wall clock) time per iteration.

- Global reductions per iteration describes the number of global reduction operations (such as variable summations over all processes). This requires communication among all processes.

A global reduction is a collective operation over all processes for the given job that reduces a vector quantity (the length given by the number of processes or nodes) to a scalar quantity (e.g., taking the sum or maximum of a particular quantity). The number of global reductions cannot be calculated from any other readily known quantities. The number is generally dependent on the algorithm being used and the problem being solved.

- Global reductions time per iteration describes the time per iteration for the global reduction operations.
- Message count per iteration describes the number of messages sent between all processes per iteration. This is important with regard to communication latency, especially on high-latency interconnects.

A message is defined as a single point-to-point, send-and-receive operation between any two processes. This excludes global, collective operations such as global reductions. In terms of domain decomposition, a message is passed from the process governing one subdomain to a process governing another (usually adjacent) subdomain.

The message count per iteration is usually dependent on the algorithm being used and the problem being solved. The message count and the number of messages that are reported are totals for all processors.

The message count provides some insight into the impact of communication latency on parallel performance. A higher message count indicates that the parallel performance may be more adversely affected if a high-latency interconnect is being used. Ethernet has a higher latency than Myrinet or Infiniband. Thus, a high message count will more adversely affect performance with Ethernet than with Infiniband.

To check the latency of the overall cluster interconnect, refer to [Checking Latency and Bandwidth \(p. 1760\)](#).

- Data transfer per iteration describes the amount of data communicated between processors per iteration. This is important with respect to interconnect bandwidth.

Data transfer per iteration is usually dependent on the algorithm being used and the problem being solved. This number generally increases with increases in problem size, number of partitions, and physics complexity.

The data transfer per iteration may provide some insight into the impact of communication bandwidth (speed) on parallel performance. The precise impact is often difficult to quantify because it is dependent on many things including: ratio of data transfer to calculations, and ratio of communication bandwidth to CPU speed. The unit of data transfer is a byte.

To check the bandwidth of the overall cluster interconnect, refer to [Checking Latency and Bandwidth \(p. 1760\)](#).

- LE solves per iteration describes the number of linear systems being solved per iteration. This number is dependent on the physics (non-reacting versus reacting flow) and the algorithms (pressure-based versus density-based solver), but is independent of mesh size. For the pressure-based solver, this is usually the number of transport equations being solved (mass, momentum, energy, etc.).
- LE wall-clock time per iteration describes the time (wall-clock) spent doing linear equation solvers (i.e., multigrid).

- LE global solves per iteration describes the number of solutions on the coarse level of the AMG solver where the entire linear system has been pushed to a single processor (n0). The system is pushed to a single processor to reduce the computation time during the solution on that level. Scaling generally is not adversely affected because the number of unknowns is small on the coarser levels.
- LE global wall-clock time per iteration describes the time (wall-clock) per iteration for the linear equation global solutions.
- AMG cycles per iteration describes the average number of multigrid cycles (V, W, flexible, etc.) per iteration.
- Relaxation sweeps per iteration describes the number of relaxation sweeps (or iterative solutions) on all levels for all equations per iteration. A relaxation sweep is usually one iteration of Gauss-Siedel or ILU.
- Relaxation exchanges per iteration describes the number of solution communications between processors during the relaxation process in AMG. This number may be less than the number of sweeps because of shifting the linear system on coarser levels to a single node/process.
- Time-step updates per iteration describes the number of sub-iterations on the time step per iteration.
- Time-step wall-clock time per iteration describes the time per sub-iteration.
- Total wall-clock time describes the total wall-clock time.
- Total CPU time describes the total CPU time used by all processes. This does not include any wait time for load imbalances or for communications (other than packing and unpacking local buffers).

The most relevant quantity is the Total wall clock time. This quantity can be used to gauge the parallel performance (speedup and efficiency) by comparing this quantity to that from the serial analysis (the command line should contain -t1 in order to obtain the statistics from a serial analysis). In lieu of a serial analysis, an approximation of parallel speedup may be found in the ratio of Total CPU time to Total wall clock time.

35.8.1.1. Checking Latency and Bandwidth

You can check the latency and bandwidth of the overall cluster interconnect, to help identify any issues affecting ANSYS FLUENT scalability, by using the **Parallel/Network>Show Latency...** and **Parallel/Network>Show Bandwidth...** menu items.

Parallel → Network → Show Latency...

Depending on the number of machines and processors being used, a table containing information about the communication speed for each node will be displayed in the console. The table will also summarize the minimum and maximum latency between two nodes.

Consider the following example when checking for latency:

```
Latency (usec) with 1000 samples [1.83128 sec]
-----
ID      n0      n1      n2      n3      n4      n5
-----
n0          48.0    48.2    48.2    48.3    *50
n1    48.0          48.2    48.3    48.3    *48
n2    48.2    48.2          48.8    49.1    *53
n3    48.2    48.3    *49          48.6    48.5
n4    48.3    48.3    49.1    48.6          *50
n5    49.7    48.5    *53    48.5    49.7
-----
Min: 47.9956 [n0<-->n1]
```

```
Max: 52.6836 [n5<-->n2]
-----
```

Important

In the above table, (*) is the maximum value in that row. The smaller the latency, the better.

Six processors (n0 to n5) are spawned. The latency between n0 and n1 is 48.0 μs . Similarly, the latency between n1 and n2 is 48.2 μs . The minimum latency occurs between n0 and n1 and the maximum latency occurs between n2 and n5, as noted in the table. Checking the latency is particularly useful when you are not seeing expected speedup on a cluster.

Parallel → Network → Show Bandwidth...

In addition to checking for latency, you can check your bandwidth. A table containing information about the amount of data communicated within one second between two nodes is displayed in the console. The table will also summarize the minimum and maximum bandwidth between two nodes.

Consider the following example when checking for bandwidth:

```
Bandwidth (MB/s) with 5 messages of size 4MB [4.36388 sec]
-----
ID      n0      n1      n2      n3      n4      n5
-----
n0      111.8    *55    111.8    97.5    101.3
n1      111.8        69.2    98.7    111.7    *51
n2      54.7     69.2        72.9    104.8    *45
n3      111.8    98.7     72.9        64.0    *45
n4      97.6     111.7    104.8    *64        76.9
n5      101.2    50.9     45.5    *45        76.9
-----
Min: 45.1039 [n5<-->n3]
Max: 111.847 [n0<-->n3]
```

Important

In the above table, (*) is the minimum value in that row. The larger the bandwidth, the better.

The bandwidth between n0 and n1 is 111.8 MB/s. Similarly, the bandwidth between n1 and n2 is 69.2 MB/s. The minimum amount of bandwidth occurs between n3 and n5 and the maximum occurs between n0 and n3, as noted in the table. Checking the bandwidth is particularly useful when you cannot see good scalability with relatively large cases.

35.8.2. Optimizing the Parallel Solver

35.8.2.1. Increasing the Report Interval

In ANSYS FLUENT, you can reduce communication and improve parallel performance by increasing the report interval for residual printing/plotting or other solution monitoring reports. You can modify the value for **Reporting Interval** in the *Run Calculation Task Page* (p. 2107).

 **Run Calculation → Calculate...**

Important

Note that you will be unable to interrupt iterations until the end of each report interval.

Chapter 36: Task Page Reference Guide

This reference guide provides information about the task pages in FLUENT.

- 36.1. Problem Setup Task Page
- 36.2. General Task Page
- 36.3. Models Task Page
- 36.4. Materials Task Page
- 36.5. Phases Task Page
- 36.6. Cell Zone Conditions Task Page
- 36.7. Boundary Conditions Task Page
- 36.8. Mesh Interfaces Task Page
- 36.9. Dynamic Mesh Task Page
- 36.10. Reference Values Task Page
- 36.11. Solution Task Page
- 36.12. Solution Methods Task Page
- 36.13. Solution Controls Task Page
- 36.14. Monitors Task Page
- 36.15. Solution Initialization Task Page
- 36.16. Calculation Activities Task Page
- 36.17. Run Calculation Task Page
- 36.18. Results Task Page
- 36.19. Graphics and Animations Task Page
- 36.20. Plots Task Page
- 36.21. Reports Task Page

36.1. Problem Setup Task Page

The **Problem Setup** task page introduces you to the main tasks involved in setting up your CFD simulation using ANSYS FLUENT.

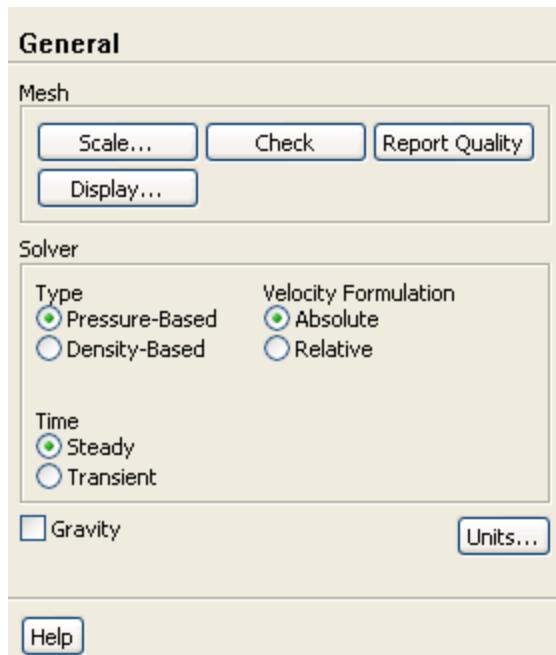

Problem Setup

The task pages accessed under Problem Setup allow you to perform the most common problem setup tasks. Additional problem setup tasks can be accessed through the main menu bar above.

Help

36.2. General Task Page

The **General** task page allows you to set various generic problem settings, such as those related to the mesh or the solver.

Controls

Mesh

contains controls relating to mesh settings.

Scale...

opens the [Scale Mesh Dialog Box \(p. 1766\)](#).

Check

verifies the validity of the mesh. The check provides volume statistics, mesh topology and periodic boundary information, verification of simplex counters, and verification of node position with reference to the x axis for axisymmetric cases. See [Checking the Mesh \(p. 173\)](#) for details.

It is recommended that you check the mesh right after reading it into the solver, in order to detect any mesh trouble before you get started with the problem setup.

Report Quality

displays various quantities related to the quality of the mesh in the console, such as Minimum Orthogonal Quality and Maximum Aspect Ratio. See [Mesh Quality \(p. 145\)](#) for details.

Display...

opens the [Mesh Display Dialog Box \(p. 1767\)](#).

Solver

contains controls relating to solver settings.

Type

contains the solution methods available for computing a solution for your model. See [Using the Solver \(p. 1311\)](#) for details.

Pressure-Based

enables the pressure-based Navier-Stokes solution algorithm (the default).

Density-Based

enables the density-based Navier-Stokes coupled solution algorithm.

Velocity Formulation

specifies the velocity formulation to be used in the calculation. See [Choosing the Relative or Absolute Velocity Formulation \(p. 541\)](#) for details.

Absolute

enables the use of the absolute velocity formulation. This is the default setting.

Relative

enables the use of the relative velocity formulation. This option is available only with the **Pressure-Based** solver.

Time

contains options related to time dependence.

Steady

specifies that a steady flow is being solved.

Transient

enables a time-dependent solution. See [Performing Time-Dependent Calculations \(p. 1365\)](#) for details.

2D Space

contains options available only when solving two-dimensional problems.

Planar

indicates that the problem is two-dimensional. (This option is available only when you start the 2D version of the solver.)

Axisymmetric

indicates that the domain is axisymmetric about the x axis. When **Axisymmetric** is enabled, the 2D axisymmetric form of the governing equations is solved instead of the 2D Cartesian form.

(This option is available only when you start the 2D version of the solver.) Be sure to change the zone type of the axis of rotation to **axis**, using the [Boundary Conditions Task Page \(p. 1958\)](#), as described in [Changing Cell and Boundary Zone Types \(p. 213\)](#).

Axisymmetric Swirl

specifies that the swirl component (circumferential component) of velocity is to be included in your axisymmetric model. You should select this option if you are solving swirling flow in an axisymmetric geometry (see [Swirling and Rotating Flows \(p. 519\)](#) for more information).

Gravity

enables the specification of gravity.

Gravitational Acceleration

sets the x , y , and z components of the gravitational acceleration vector. (The z component is available only in 3D solvers.) See [Natural Convection and Buoyancy-Driven Flows \(p. 743\)](#) for details about buoyancy-driven flows. This option appears only when **Gravity** is enabled.

Units...

opens the [Set Units Dialog Box \(p. 1769\)](#).

For additional information, please see the following sections:

[36.2.1. Scale Mesh Dialog Box](#)

[36.2.2. Mesh Display Dialog Box](#)

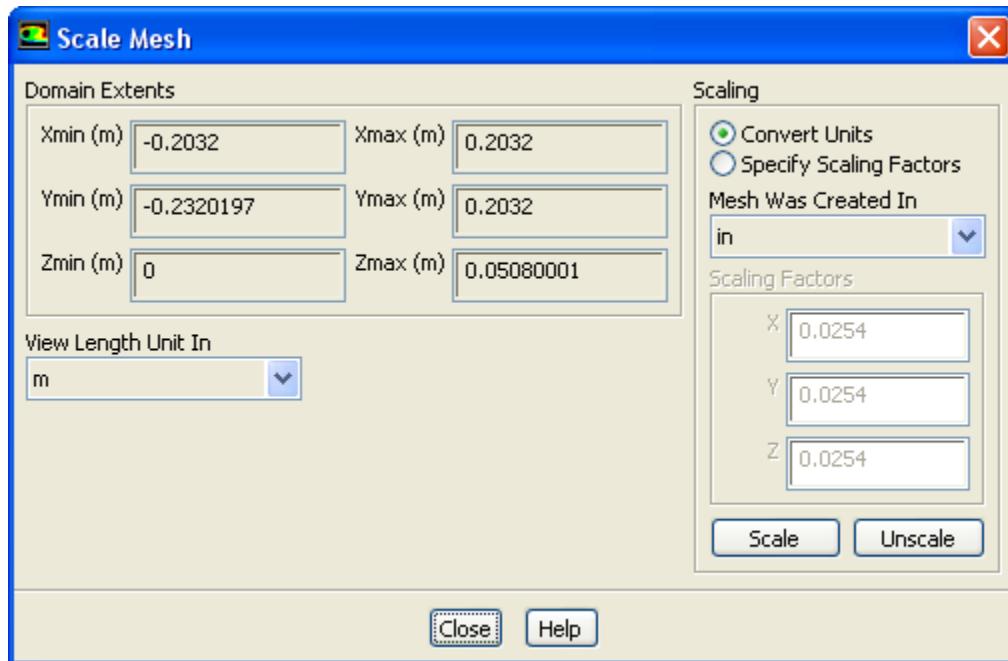

[36.2.3. Set Units Dialog Box](#)

[36.2.4. Define Unit Dialog Box](#)

[36.2.5. Mesh Colors Dialog Box](#)

36.2.1. Scale Mesh Dialog Box

The **Scale Mesh** dialog box allows you to convert the mesh from various units of measurement to SI or to apply custom scale factors to the individual coordinates of the mesh. See [Scaling the Mesh \(p. 205\)](#) for details.

Controls

Domain Extents

displays the Cartesian coordinate extremes of the nodes in the mesh. (These values are not editable; they are purely informational.)

Xmin, Ymin, Zmin

shows the minimum values of Cartesian coordinates in the mesh.

Xmax, Ymax, Zmax

shows the maximum values of Cartesian coordinates in the mesh.

Scaling

contains controls for converting units and setting the scale factors automatically.

Convert Units

allows you to use the conversion factors provided by ANSYS FLUENT. Then indicate the units used when creating the mesh by selecting the appropriate abbreviation for meters, centimeters, millimeters, inches, or feet from the **Mesh Was Created In** drop-down list. The **Scaling Factors** will automatically be set to the correct values (e.g., 0.0254 meters/inch).

Specify Scaling Factors

allows you to manually specify a scale factor in each of the Cartesian coordinate directions.

Mesh Was Created In

contains a list of common units of length. The **Scaling Factors** will automatically be set based on your selection. The units include common SI and British units such as centimeters (cm), millimeters (mm), inches (in), and feet (ft).

Scaling Factors

contains the factors applied to the mesh in each of the Cartesian coordinate directions. You can enter values manually, or use the **Mesh Was Created In** list to set scale factors automatically.

X

is the scale factor in the *x* direction.

Y

is the scale factor in the *y* direction.

Z

is the scale factor in the *z* direction (appears only in 3D).

Scale

multiples each of the node coordinates by the specified scale factors.

Unscale

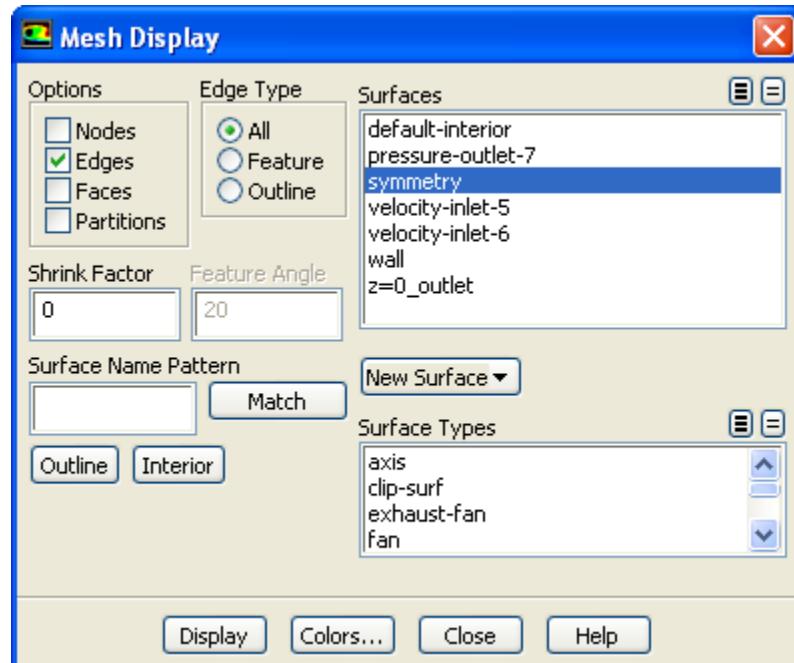

divides each of the node coordinates by the specified scale factors.

View Length Unit In

contains a list of common units of length. The **Domain Extents** will automatically be set based on your selection. The units include common SI and British units such as centimeters (cm), millimeters (mm), inches (in), and feet (ft). The units of length in the *Set Units Dialog Box* (p. 1769) will change each time you change your selection in the **View Length Unit In** drop-down list.

36.2.2. Mesh Display Dialog Box

The **Mesh Display** dialog box controls the display of zone, surface, and partition boundary meshes. See *Displaying the Mesh* (p. 1500) for details about the items below.

Controls

Options

contains the rendering options described below. To see the effects of your selection you must click the **Display** button.

Nodes

enables the display of nodes on the selected surfaces.

Edges

enables the display of mesh edges on the selected surfaces.

Faces

enables the display of mesh faces (filled meshes) on the selected surfaces.

Partitions

enables the display of partition boundaries.

Shrink Factor

specifies the amount to shrink faces and cells. See [Shrinking Faces and Cells in the Display \(p. 1505\)](#) for details.

Edge Type

controls the display of edges. (These items will not appear if the **Edges** option is turned off.)

All

enables the display of all mesh edges.

Feature

enables feature lines in an outline display. See [Adding Features to an Outline Display \(p. 1504\)](#) for details.

Outline

enables the display of the mesh outline.

Feature Angle

controls the amount of detail added to a feature outline display. See [Adding Features to an Outline Display \(p. 1504\)](#) for details. (This item will be available only if the **Feature** edge type is enabled.)

Surface Name Pattern

specifies the pattern to look for in the names of surfaces. Type the pattern in the text field and click **Match** to select (or deselect) the zones in the **Surfaces** list with names that match the specified pattern. See [Generating Mesh or Outline Plots \(p. 1501\)](#) for information about matching additional characters using * and ?.

Surfaces

contains a list from which you can select the surfaces for which the mesh is to be drawn.

New Surface

is a drop-down list button that contains a list of surface options:

Point

opens the [Point Surface Dialog Box \(p. 2078\)](#).

Line/Rake

opens the [Line/Rake Surface Dialog Box \(p. 2079\)](#).

Plane

opens the [Plane Surface Dialog Box \(p. 2080\)](#).

Quadric

opens the [Quadric Surface Dialog Box \(p. 2082\)](#).

Iso-Surface

opens the [Iso-Surface Dialog Box \(p. 2084\)](#).

Iso-Clip

opens the [Iso-Clip Dialog Box \(p. 2086\)](#).

Surface Types

contains a selectable list of types of surfaces. If you select (or deselect) an item in this list, all surfaces of that type will be selected (or deselected) automatically in the **Surfaces** list.

Outline

selects all “outline” boundaries in the **Surfaces** list. If all outline boundaries are already selected, it deselects them.

Interior

selects all “interior” surfaces in the **Surfaces** list. If all interior surfaces are already selected, it deselects them.

Display

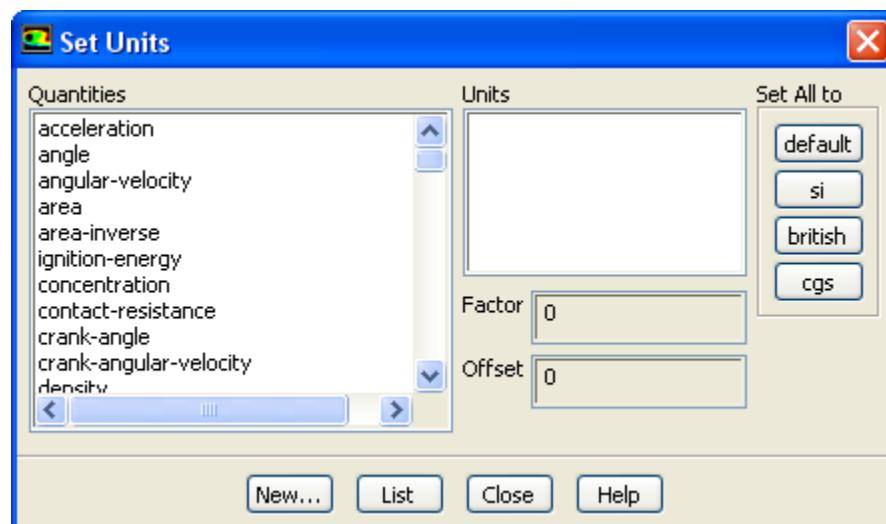

displays the defined mesh plot.

Colors...

opens the *Mesh Colors Dialog Box* (p. 1770).

36.2.3. Set Units Dialog Box

The **Set Units** dialog box allows you to set the units system for any quantity used in ANSYS FLUENT. All quantities may be set to a standard system, such as SI or British, or the units of individual quantities may be set. See *Unit Systems* (p. 125) for details about the items below.

**Controls****Quantities**

displays the list of all quantities used by ANSYS FLUENT for input and output.

Units

lists the units appropriate for the currently selected quantity. Selecting an item in the **Units** list causes that unit to be used for the currently selected quantity.

Factor

displays the conversion factor from the currently selected units to SI.

Offset

displays the conversion offset from the currently selected units to SI.

Set All to

contains standard sets of units that are applied to all quantities when selected.

default

is similar to **si**, but uses degrees instead of radians for angles.

si

selects the System International (SI) standard for all units.

british

selects the English Engineering standard for all units.

cgs

selects the CGS (centimeter-gram-second) standard for all units

New...

opens the [Define Unit Dialog Box \(p. 1770\)](#), in which you can specify a customized unit for a particular quantity.

List

displays the current units for all quantities in the console.

36.2.4. Define Unit Dialog Box

The **Define Unit** dialog box allows you to customize the units for a particular quantity. It is opened from the [Set Units Dialog Box \(p. 1769\)](#). For details about using this dialog box, see [Defining a New Unit \(p. 127\)](#).

**Controls****Quantity**

shows the name of the quantity for which you are defining a new unit. (You cannot edit this field; the quantity is selected in the [Set Units Dialog Box \(p. 1769\)](#).)

Unit

sets the name for the new unit.

Factor

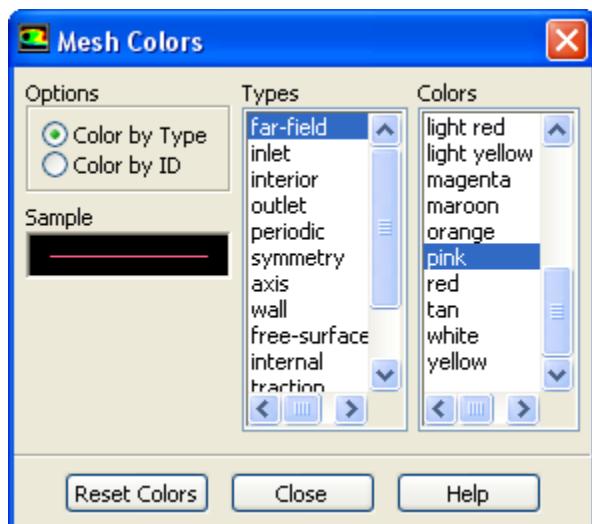

sets the conversion factor from the currently selected units to SI.

Offset

sets the conversion offset from the currently selected units to SI.

36.2.5. Mesh Colors Dialog Box

The **Mesh Colors** dialog box allows you to control the colors that are used to draw meshes. It is opened from the [Mesh Display Dialog Box \(p. 1767\)](#). See [Modifying the Mesh Colors \(p. 1503\)](#) for details about the items below.

Controls

Options

contains options to select the method by which to set the colors.

Color by Type

sets the color based on the type of zone.

Color by ID

sets the color by ID.

Types

contains a selectable list of zone types. You can select the zone type for which you want to set the color.

Colors

contains a list from which you can select a color for the selected type.

Sample

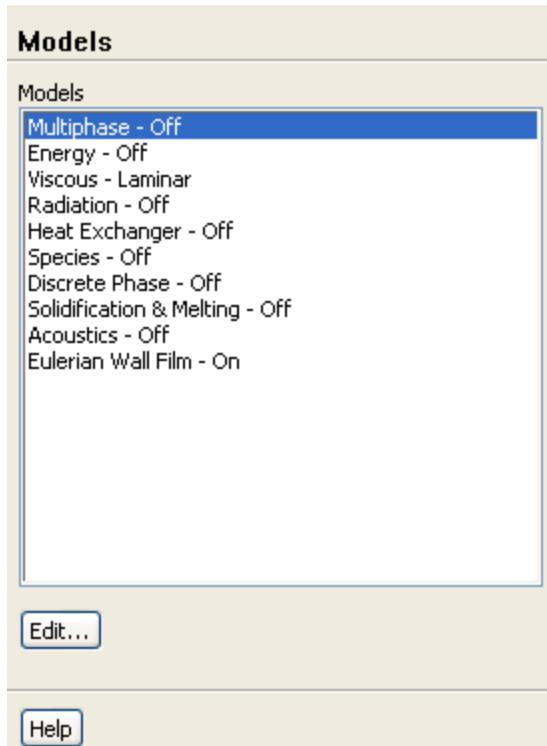

displays a sample of the currently selected color.

Reset Colors

resets the mesh colors to the default selections.

36.3. Models Task Page

The **Models** task page allows you to set various generic model settings.

Controls

Models

contains a listing of the various models available in ANSYS FLUENT.

You can double-click an item in the **Models** list to open the corresponding dialog box, or you can select the item in the list and click the **Edit...** button.

Multiphase

- selecting this item and clicking the **Edit...** button opens the *Multiphase Model Dialog Box* (p. 1774).

Energy

- selecting this item and clicking the **Edit...** button opens the *Energy Dialog Box* (p. 1778).

Viscous

- selecting this item and clicking the **Edit...** button opens the *Viscous Model Dialog Box* (p. 1778).

Radiation

- selecting this item and clicking the **Edit...** button opens the *Radiation Model Dialog Box* (p. 1790).

Heat Exchanger

- selecting this item and clicking the **Edit...** button opens the *Heat Exchanger Model Dialog Box* (p. 1799).

Species

- selecting this item and clicking the **Edit...** button opens the *Species Model Dialog Box* (p. 1814).

The following models are made available, depending on your setup of the **Species** dialog box.

- **Spark Ignition** - selecting this item and clicking the **Edit...** button opens the *Spark Ignition Dialog Box* (p. 1833). Note that spark ignition is only available for transient calculations.
- **Autoignition** - selecting this item and clicking the **Edit...** button opens the *Autoignition Model Dialog Box* (p. 1836). Note that autoignition is only available for transient calculations.

- **Inert** - selecting this item and clicking the **Edit...** button opens the *Inert Dialog Box* (p. 1838). Note that the inert model is only available when the non-premixed or partially premixed model is selected in the **Species Model** dialog box, or when a PDF file is read.
- **NOx** - selecting this item and clicking the **Edit...** button opens the *NOx Model Dialog Box* (p. 1839). Note that the NOx model is not compatible with premixed combustion.
- **SOx** - selecting this item and clicking the **Edit...** button opens the *SOx Model Dialog Box* (p. 1846). Note that the SOx model is not compatible with premixed combustion.
- **Soot** - selecting this item and clicking the **Edit...** button opens the *Soot Model Dialog Box* (p. 1850). Note that none of the soot models are compatible with premixed combustion.
- **Decoupled Detailed Chemistry** - selecting this item and clicking the **Edit...** button opens the *Decoupled Detailed Chemistry Dialog Box* (p. 1856).
- **Reacting Channel Model** - selecting this item and clicking the **Edit...** button opens the *Reacting Channel Model Dialog Box* (p. 1857).

Discrete Phase

- selecting this item and clicking the **Edit...** button opens the *Discrete Phase Model Dialog Box* (p. 1859).

Solidification & Melting

- selecting this item and clicking the **Edit...** button opens the *Solidification and Melting Dialog Box* (p. 1869).

Acoustics

- selecting this item and clicking the **Edit...** button opens the *Acoustics Model Dialog Box* (p. 1871).

Eulerian Wall Film

- selecting this item and clicking the **Edit...** button opens the *Eulerian Wall Film Dialog Box* (p. 1876).

Edit...

displays the dialog box corresponding to the selected item in the **Models** list.

36.3.1. Multiphase Model Dialog Box

The **Multiphase Model** dialog box allows you to set parameters for modeling multiphase flow. See [Enabling the Multiphase Model \(p. 1175\)](#) – [Including Cavitation Effects \(p. 1239\)](#) for details.

Controls

Model

allows you to select one of four multiphase models.

Off

disables the calculation of multiphase flow.

Volume of Fluid

enables the VOF model described in [Volume of Fluid \(VOF\) Model Theory](#) in the [Theory Guide](#). See [Setting Up the VOF Model \(p. 1203\)](#) for details about using the model. This is available only with the pressure-based solver.

Mixture

enables the mixture model described in [Mixture Model Theory](#) in the [Theory Guide](#). See [Setting Up the Mixture Model \(p. 1230\)](#) for details about using the model. This is available only with the pressure-based solver.

Eulerian

enables the Eulerian model described in [Eulerian Model Theory](#) in the [Theory Guide](#). See [Setting Up the Eulerian Model \(p. 1240\)](#) for details about using the model. This is available only with the pressure-based solver.

Wet Steam

enables the wet steam model described in [Wet Steam Model Theory](#) in the Theory Guide. See [Setting Up the Wet Steam Model \(p. 1267\)](#) for details about using the model. This is available only with the density-based solver.

Number of Eulerian Phases

allows you to specify the number of phases for the multiphase calculation. You can specify up to 20 phases.

Coupled Level Set + VOF

allows you to apply an interface tracking method that couples the level set method with the VOF formulation.

Volume Fraction Parameters

contains parameters related to the VOF and Eulerian model. This section of the dialog box will appear only when **Volume of Fluid** or **Eulerian** is the selected **Model**.

Scheme

allows you to select the desired interface-tracking scheme.

Explicit

enables the Euler explicit scheme, described in [The Explicit Scheme](#) in the Theory Guide. See [Choosing a Volume Fraction Formulation \(p. 1177\)](#) for more information.

Implicit

enables the implicit scheme, described in [The Implicit Scheme](#) in the Theory Guide. See [Choosing a Volume Fraction Formulation \(p. 1177\)](#) for more information.

Volume Fraction Cutoff

specifies a cutoff limit for the volume fraction values. The value that you provide is used as the lower cutoff for the volume fraction. All volume fraction values in the domain below this cutoff value are set to zero. The upper cutoff is calculated as (1.0 - lower cutoff). All volume fraction values above the upper cutoff value are set to 1.0. The default value is 1e-6.

Important

The **Volume Fraction Cutoff** value can be specified when using the VOF model, or when using the Eulerian Multiphase model with the **Explicit** scheme.

Courant Number

specifies the maximum Courant number allowed near the free surface. This item will not appear if the **Implicit Scheme** is selected. See [Setting Time-Dependent Parameters for the VOF Model \(p. 1228\)](#) for details.

Open Channel Flow

enables the model to study the effects of open channel flow. See [Open Channel Flow](#) in the Theory Guide and [Modeling Open Channel Flows \(p. 1204\)](#) for details.

Open Channel Wave BC

enables the model to set specific parameters for a particular boundary for open channel wave boundaries. See [Backflow Volume Fraction Specification](#) in the Theory Guide and [Modeling Open Channel Wave Boundary Conditions \(p. 1210\)](#) for details.

Zonal Discretization

allows you to set the value of the slope limiter. You can select either diffused or sharp interface behavior in different cell zones. This option is available if the **Volume of Fluid** model is used, or if the **Eulerian** model with the **Multi-Fluid VOF Model** option is enabled.

Mixture Parameters

contains options related to the **Mixture** model.

Slip Velocity

enables/disables the calculation of slip velocities for the secondary phases as described in [Relative \(Slip\) Velocity and the Drift Velocity](#) in the [Theory Guide](#). See also [Solving a Homogeneous Multiphase Flow](#) (p. 1179).

Eulerian Parameters

contains options related to the **Eulerian** model.

Dense Discrete Phase Model

allows you to include the Dense Discrete Phase model (see [Including the Dense Discrete Phase Model](#) (p. 1254) for details). Enabling this model automatically enables the DPM model.

Multi-Fluid VOF Model

allows you to include the multi-fluid VOF model (see [Including the Multi-Fluid VOF Model](#) (p. 1266) for details). The multi-fluid VOF model allows the modeling of interface sharpening schemes and free surface flow.

Boiling Model

allows you to include the Boiling model (see [Including the Boiling Model](#) (p. 1258) for details).

Boiling Model Options

allows you to select the type of boiling model to apply to your case.

RPI Boiling Model

is where the total heat flux from the wall to the liquid is partitioned into three components, namely the convective heat flux, the quenching heat flux, and the evaporative heat flux.

Details about this model can be found in [RPI Model](#) in the [Theory Guide](#).

Non-equilibrium Boiling

is a modification to the RPI model in order to model different boiling regimes like DNB and critical heat flux. Details about this model can be found in [Non-equilibrium Subcooled Boiling](#) in the [Theory Guide](#).

Critical Heat Flux

is where the critical heat flux condition is characterized by a sharp reduction of local heat transfer coefficients and the excursion of wall surface temperatures. Details about this model can be found in [Critical Heat Flux](#) in the [Theory Guide](#).

Number of Discrete Phase

allows you to specify the number of discrete phases when the **Dense Discrete Phase Model** option is enabled.

Body Force Formulation

contains an additional option for body force calculations.

Implicit Body Force

enables the implicit body force treatment described in [Including Body Forces](#) (p. 1180).

Note

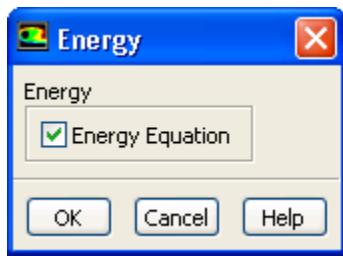

If you want ANSYS FLUENT to solve the volume fraction equation(s) at every iteration within a time step, use the text command:

define → models → multiphase →

and select vof as the model. When prompted to solve vof every iteration?, enter yes.

36.3.2. Energy Dialog Box

The **Energy** dialog box allows you to set parameters related to energy or heat transfer in your model.

**Controls****Energy**

contains inputs related to the modeling of energy.

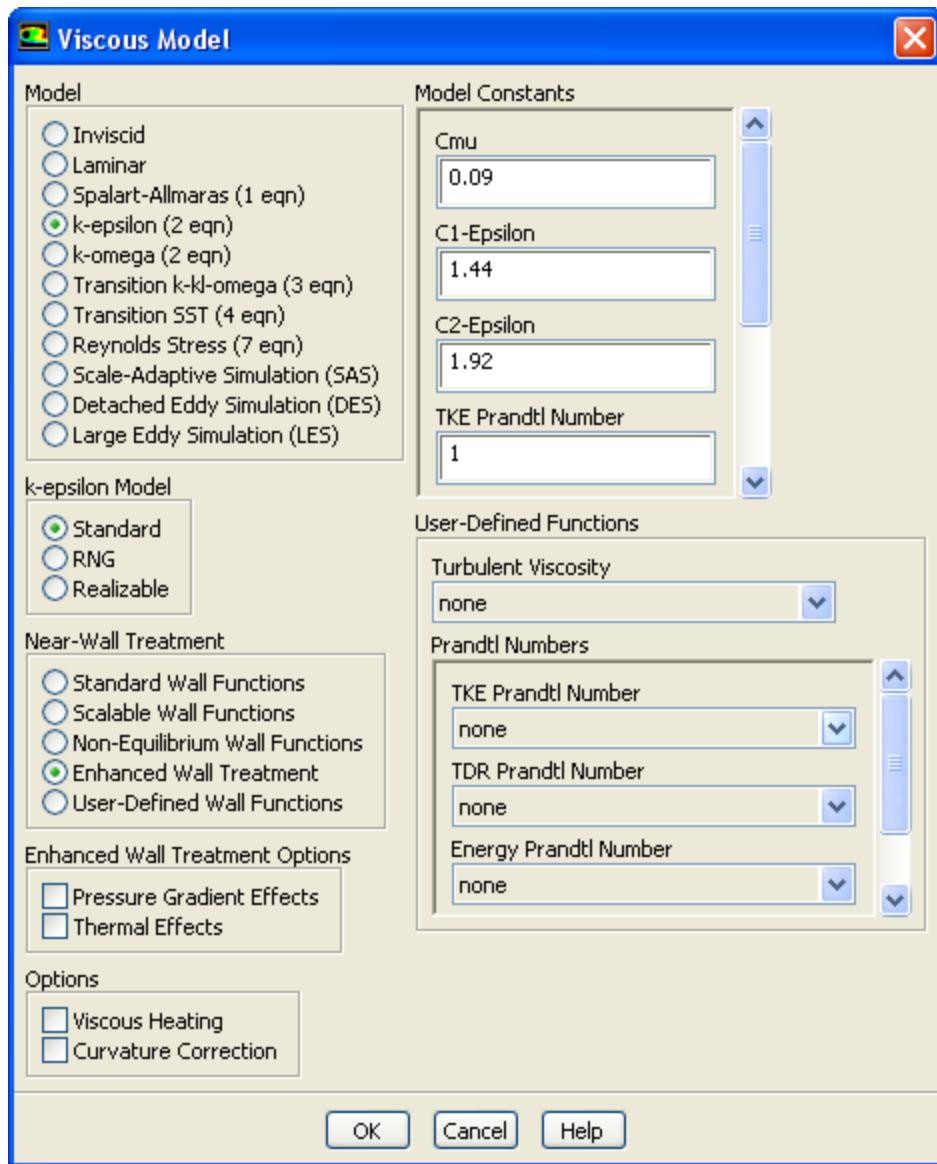

Energy Equation

enables/disables the calculation of energy in the model.

36.3.3. Viscous Model Dialog Box

The **Viscous Model** dialog box allows you to set parameters for inviscid, laminar, and turbulent flow.

See [Steps in Using a Turbulence Model \(p. 696\)](#) for details about using this dialog box to set up a turbulent flow calculation.

Controls

Model

contains options for specifying the viscous model.

Inviscid

specifies inviscid flow.

Laminar

specifies laminar flow.

Spalart-Allmaras

specifies turbulent flow to be calculated using the Spalart-Allmaras model. (See [Spalart-Allmaras Model](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Spalart-Allmaras Model](#) (p. 698) for details about using this model.)

k-epsilon

specifies turbulent flow to be calculated using one of three $k-\varepsilon$ models. (See [Standard, RNG, and Realizable k- \$\varepsilon\$ Models](#) in the [Theory Guide](#) for background about this model. See [Setting Up the k- \$\varepsilon\$ Model](#) (p. 699) for details about using this model.)

k-omega

specifies turbulent flow to be calculated using one of two k - ω models. (See [Standard and SST k- \$\omega\$ Models](#) in the [Theory Guide](#) for background about these models. See [Setting Up the k- \$\omega\$ Model](#) (p. 702) for details about using this model.)

Transition k-kl-omega

specifies turbulent flow to be calculated using the Transition k - kl - ω model. (See [k- kl- \$\omega\$ Transition Model](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Transition k- kl- \$\omega\$ Model](#) (p. 704) for details about using this model.)

Transition SST

specifies turbulent flow to be calculated using the Transition SST model. (See [Transition SST Model](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Transition SST Model](#) (p. 704) for details about using this model.)

Reynolds Stress

specifies turbulent flow to be calculated using the RSM. (See [Reynolds Stress Model \(RSM\)](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Reynolds Stress Model](#) (p. 705) for details about using this model.)

Scale-Adaptive Simulation

specifies turbulent flow to be unsteady. (See [Scale-Adaptive Simulation \(SAS\) Model](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Scale-Adaptive Simulation \(SAS\) Model](#) (p. 708) for details about using this model.)

Detached Eddy Simulation

specifies turbulent flow to be calculated using the DES. (See [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Detached Eddy Simulation Model](#) (p. 709) for details about using this model.)

Large Eddy Simulation

(3D only) specifies turbulent flow to be calculated using the LES model. (See [Large Eddy Simulation \(LES\) Model](#) in the [Theory Guide](#) for background about this model. See [Setting Up the Large Eddy Simulation Model](#) (p. 712) for details about using this model.)

Spalart-Allmaras Production

contains options for the Spalart-Allmaras model. This portion of the dialog box will appear only if **Spalart-Allmaras** is selected as the **Model**.

Vorticity-Based

selects the vorticity-based calculation of the deformation tensor S (see [Equation 4–22](#) in the [Theory Guide](#)).

Strain/Vorticity-Based

selects the strain/vorticity-based calculation of the deformation tensor S (see [Equation 4–24](#) in the [Theory Guide](#)).

k-epsilon Model

contains options for specifying which of the k - ε models is to be used. This portion of the dialog box will appear only if **k-epsilon** is selected as the **Model**.

Standard

selects the standard k - ε model, described in [Standard k- \$\varepsilon\$ Model](#) in the [Theory Guide](#) and [Setting Up the k- \$\varepsilon\$ Model](#) (p. 699).

RNG

selects the RNG k - ε model, described in [RNG k- \$\varepsilon\$ Model](#) in the [Theory Guide](#) and [Setting Up the k- \$\varepsilon\$ Model](#) (p. 699).

Realizable

selects the realizable k - ε model, described in [Realizable \$k\$ - \$\varepsilon\$ Model](#) in the [Theory Guide](#) and [Setting Up the \$k\$ - \$\varepsilon\$ Model](#) (p. 699).

RNG Options

specifies parameters that affect the solution of problems solved with the RNG k - ε model. This portion of the dialog box will appear only if **RNG** is selected as the **k-epsilon Model**.

Differential Viscosity Model

specifies whether or not the low-Reynolds-number RNG modifications to turbulent viscosity should be included. By default, this option is turned off. It is likely to have an effect only when the near-wall regions in the domain are well resolved in terms of mesh density. See [Differential Viscosity Modification](#) (p. 718) for details.

Swirl Dominated Flow

specifies whether or not the RNG modification to turbulent viscosity for swirling flows should be included. This option is available only in 3D and 2D axisymmetric swirl solvers, and it can yield improved predictions when solving flows with significant swirl. See [Swirl Modification](#) (p. 718) for details.

k-omega Model

contains options for specifying which of the k - ω models is to be used. This portion of the dialog box will appear only if **k-omega** is selected as the **Model**.

Standard

selects the standard k - ω model, described in [Standard \$k\$ - \$\omega\$ Model](#) in the [Theory Guide](#) and [Setting Up the \$k\$ - \$\omega\$ Model](#) (p. 702).

SST

selects the shear-stress transport (SST) k - ε model, described in [Shear-Stress Transport \(SST\) \$k\$ - \$\varepsilon\$ Model](#) in the [Theory Guide](#) and [Setting Up the \$k\$ - \$\omega\$ Model](#) (p. 702).

k-omega Options

specifies parameters that affect the solution of problems solved with the k - ω models. This portion of the dialog box will appear only if **k-omega** is selected as the **Model**.

Low-Re Corrections

specifies whether corrections that improve the accuracy in predicting low Reynolds number flows should be included. This option is available only for the standard k - ω model. See [Low-Re Corrections](#) (p. 718) for details.

Shear Flow Corrections

specifies whether corrections that improve the accuracy in predicting free shear flows should be included. This option is available only for the standard k - ω model. See [Shear Flow Corrections](#) (p. 718) for details.

Turbulence Damping

is required for the accurate modeling of the interfacial area. This option is available for the standard and SST k - ω model. The VOF and Mixture models and also the Eulerian multiphase model with the **Multi-Fluid VOF Model** must be selected when using this option. Enter the desired **Damping Factor**, which by default is set to 10. See [Turbulence Damping](#) (p. 719) for details.

Transition SST Options

allows you to include the **Roughness Correlation** of rough walls as described in [Transition SST](#) and [Rough Walls](#) in the [Theory Guide](#).

Roughness Correlation

when enabled allows you to specify the **Geometric Roughness Height** as a constant value.

Reynolds-Stress Model

specifies the various Reynolds stress models (RSM).

Linear Pressure-Strain

enables the linear pressure-strain model. See [Linear Pressure-Strain Model](#) in the [Theory Guide](#) for details.

Quadratic Pressure-Strain

enables the quadratic pressure-strain model for superior performance in a range of basic shear flows, including plane strain, rotating plane shear, and axisymmetric expansion/contraction. See [Quadratic Pressure-Strain Model](#) in the [Theory Guide](#) for details. Note that this option cannot be used with the **Wall Reflection Effects** option or the **Enhanced Wall Treatment**.

Stress-Omega

enables a stress-transport model that is based on the omega equations and LRR model [102] (p. 2372). This model is ideal for modeling flows over curved surfaces and swirling flows. See [Low-Re Stress-Omega Model](#) in the [Theory Guide](#) for details.

Reynolds-Stress Options

specifies parameters that affect the solution of problems solved with the Reynolds stress model. This portion of the dialog box will appear only if **Reynolds Stress** is selected as the **Model**.

Wall BC from k Equation

enables the explicit setting of boundary conditions for the Reynolds stresses near the walls, using the values computed with [Equation 4-215](#) in the [Theory Guide](#). See [Solving the k Equation to Obtain Wall Boundary Conditions](#) (p. 719) for details. This option is on by default.

Wall Reflection Effects

enables the calculation of the component of the pressure strain term responsible for the redistribution of normal stresses near the wall. See [Including the Wall Reflection Term](#) (p. 719) for details. Note that this option is not available if you have enabled the **Quadratic Pressure-Strain Model**.

RANS Model

contains options for the subgrid-scale model used by the **Detached Eddy Simulation Model**. This portion of the dialog box will appear only if **Detached Eddy Simulation Model** is selected as the **Model**.

Spalart-Allmaras

enables the Spalart-Allmaras RANS model. See [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#) for details.

Realizable k-epsilon

enables the Realizable k - ε RANS model. See [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#) for details.

SST k-omega

enables the SST k - ω RANS Model. See [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#) for details.

DES Options

contain the option to include a delayed Detached Eddy Simulation.

Delayed DES

is useful for RANS meshes with high aspect ratios in the boundary layer. This option preserves the RANS model throughout the boundary layer. (See [Delayed Detached Eddy Simulation \(DDES\)](#) (p. 718) for details.)

Subgrid-Scale Model

contains options for the subgrid-scale model used by the LES model. This portion of the dialog box will appear only if **Large Eddy Simulation** is selected as the **Model**.

Smagorinsky-Lilly

selects the Smagorinsky-Lilly subgrid-scale model described in [Subgrid-Scale Models in the Theory Guide](#).

WALE

selects the Wall-Adapting local Eddy-Viscosity model described in [Wall-Adapting Local Eddy-Viscosity \(WALE\) Model](#) in the [Theory Guide](#).

WMLES

selects the Algebraic Wall-Modeled LES model described in [Algebraic Wall-Modeled LES Model \(WMLES\)](#) in the [Theory Guide](#).

Kinetic-Energy Transport

selects the dynamic kinetic energy subgrid-scale model described in [Dynamic Kinetic Energy Subgrid-Scale Model](#) in the [Theory Guide](#).

LES Model Options

contains options for the Large Eddy Simulation model. This portion of the dialog box will appear only if **Large Eddy Simulation** is selected as the **Model**.

Dynamic Stress

enables the dynamic stress model. It is available when the LES option **Smagorinsky-Lilly** is enabled.

Dynamic Energy Flux

enables the dynamic energy flux model. It is available when the LES option **Kinetic-Energy Transport** is enabled.

Dynamic Scalar Flux

enables the dynamic computation of turbulent Sc (σ_t in [Equation 8–5](#) in the [Theory Guide](#)). See [Definition of the Mixture Fraction](#) in the [Theory Guide](#) for details.

Near-Wall Treatment

specifies the near-wall treatment to be used for modeling turbulence. See [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#) for details about the available methods. This portion of the dialog box will appear if **k-epsilon** or **Reynolds Stress** is selected as the **Model**.

Standard Wall Functions

enables the use of standard wall functions (described in [Standard Wall Functions](#) in the [Theory Guide](#)).

Scalable Wall Functions

enables the use of scalable wall functions (described in [Scalable Wall Functions](#) in the [Theory Guide](#)).

Non-Equilibrium Wall Functions

enables the use of non-equilibrium wall functions (described in [Non-Equilibrium Wall Functions](#) in the [Theory Guide](#)).

Enhanced Wall Treatment

enables the use of the enhanced wall treatment (described in [Enhanced Wall Treatment \$\varepsilon\$ -Equation \(EWT- \$\varepsilon\$ \)](#) in the [Theory Guide](#)). Note that this option will not appear if you have enabled the **Quadratic Pressure-Strain Model** under **Reynolds-Stress Options**.

User-Defined Wall Functions

enables you to hook a user-defined function, used to define the **Law of the Wall**. See [User-Defined Wall Functions](#) in the [Theory Guide](#) for more information.

Enhanced Wall Treatment Options

allows you to include pressure gradient or thermal effects in the calculation. See [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#).

Pressure Gradient Effects

enables the effect of pressure gradient.

Thermal Effects

enables thermal effects in the calculation. This option appears only if the energy equation is enabled.

Options

contains general options for viscous modeling.

Viscous Heating

(if enabled) includes the viscous dissipation terms in the energy equation. This option is recommended when you are solving a compressible flow. Note that this option is always turned on when one of the density-based solvers is used; you will not be able to turn it off.

Low-Pressure Boundary Slip

includes slip boundary conditions for velocity and temperature for modeling fluid flow at very low pressures as in semiconductor fabrication devices. See [Slip Boundary Formulation for Low-Pressure Gas Systems](#) in the [Theory Guide](#). This option is available only for laminar flows.

Full Buoyancy Effects

enables the inclusion of buoyancy effects on ε . See [Including Turbulence Generation Due to Buoyancy](#) (p. 717) for details. This option will appear if **k-epsilon** or **Reynolds Stress** is selected as the **Model** and a non-zero gravitational acceleration has been specified in the [Operating Conditions Dialog Box](#) (p. 1952).

Curvature Correction

when enabled, modifies the turbulence production term to sensitize the standard eddy-viscosity models to the effects of streamline curvature and system rotation. This is available for the **Spalart-Allmaras**, **k-epsilon**, **k-omega**, **Transition SST**, **Scale-Adaptive Simulation**, and **Detached Eddy Simulation** with the **SST k-omega** model.

Turbulent Drift Force

includes the effect of drift velocity. See [Modeling Turbulence](#) (p. 1250). Note that this option is only available if either the **Eulerian** multiphase model is selected, or the **Mixture** model with **Slip Velocity** is enabled in the **Multiphase Model** dialog box.

Turbulence Multiphase Model

contains options for multiphase turbulence models. This portion of the dialog box will appear if **Eulerian** is selected as the **Model** in the [Multiphase Model Dialog Box](#) (p. 1774).

Mixture

specifies the (default) mixture turbulence model.

Dispersed

specifies the dispersed turbulence model.

Per Phase

specifies the calculation of a set of turbulence equations for each phase.

See [Turbulence Models](#) in the [Theory Guide](#) for details about the available multiphase turbulence models.

Model Constants

contains constants used in the equations for turbulence. See [Spalart-Allmaras Model](#), [Standard k- \$\varepsilon\$ Model](#), [RNG k- \$\varepsilon\$ Model](#), [k- kl- \$\omega\$ Transition Model](#), [Transition SST Model](#), [Realizable k- \$\varepsilon\$ Model](#), [Reynolds Stress Model \(RSM\)](#), [Standard k- \$\omega\$ Model](#), [Shear-Stress Transport \(SST\) k- \$\omega\$ Model](#), and [Large Eddy Simulation \(LES\) Model](#) in the [Theory Guide](#) for details about these constants.

Cb1

(only for the Spalart-Allmaras model) is the constant C_{b1} in [Equation 4-19](#) in the [Theory Guide](#).

Cb2

(only for the Spalart-Allmaras model) is the constant C_{b2} in [Equation 4-15](#) in the [Theory Guide](#).

Cv1

(only for the Spalart-Allmaras model) is the constant C_{v1} in [Equation 4–17](#) in the [Theory Guide](#).

Cw2

(only for the Spalart-Allmaras model) is the constant C_{w2} in [Equation 4–28](#) in the [Theory Guide](#).

Cw3

(only for the Spalart-Allmaras model) is the constant C_{w3} in [Equation 4–27](#) in the [Theory Guide](#).

Cprod

(only for the Spalart-Allmaras model when the **Strain/Vorticity-Based Production** option is used) is the constant C_{prod} in [Equation 4–24](#) in the [Theory Guide](#).

Cmu

(only for the standard or RNG k - ε model, the RSM, or the k - kL - ω Transition model) is the constant C_μ that is used to compute μ_t .

C1-Epsilon

(only for the standard or RNG k - ε model or the RSM) is the constant $C_{1\varepsilon}$ used in the transport equation for ε .

C2-Epsilon

(only for the standard, RNG, or realizable k - ε model or the RSM) is the constant $C_{2\varepsilon}$ used in the transport equation for ε .

C3-Epsilon

(only for the dispersed or per-phase k - ε multiphase models) is the constant $C_{3\varepsilon}$ in [Equation 17–266](#) in the [Theory Guide](#).

C-lambda

(only for the k - kL - ω Transition model) is the constant C_λ in the definition of the effective length,

CR

(only for the k - kL - ω Transition model) is the constant C_R used in the definition of R , where R represents the averaged effect of the breakdown of streamwise fluctuations into turbulence during bypass transition

ANAT

(only for the k - kL - ω Transition model) is the constant A_{NAT}

ATS

(only for the k - kL - ω Transition model) is the constant A_{TS}

CNAT, crit

(only for the k - kL - ω Transition model) is the constant $C_{NAT,crit}$

CTS, crit

(only for the k - kL - ω Transition model) is the constant $C_{TS,crit}$

CRNAT

(only for the k - kL - ω Transition model) is the constant $C_{R,NAT}$

Anu

(only for the k - kL - ω Transition model) is the constant A_v

CINT

(only for the k - kL - ω Transition model) is the constant C_{INT}

Cw1

(only for the k - kl - ω Transition model) is the constant $C_{\omega 1}$

Cw3

(only for the k - kl - ω Transition model) is the constant $C_{\omega 3}$

Calpha-teta

(only for the k - kl - ω Transition model) is the constant $C_{\alpha,\theta}$

Ctaul

(only for the k - kl - ω Transition model) is the constant $C_{\tau,1}$

SDR Prandtl Number

(only for the k - kl - ω Transition model) is the effective “Prandtl” number for the transport of the specific dissipation rate, σ_{ω} .

Ca1

(only for the Transition SST model)

Ca2

(only for the Transition SST model)

Ce1

(only for the Transition SST model)

Ce2

(only for the Transition SST model)

C_theta

(only for the Transition SST model)

C_s1

(only for the Transition SST model)

Intermit. Prandtl #)

(only for the Transition SST model)

Re_theta. Prandtl #)

(only for the Transition SST model)

Swirl Factor

sets the value of α_s in [Equation 4–40](#) in the [Theory Guide](#). This item appears for the RNG k - ε model when the **Swirl Dominated Flow** option is turned on.

Alpha*_inf

(only for the standard or SST k - ω model, and the Transition SST model) is the constant α_{∞}^* in [Equation 4–68](#) in the [Theory Guide](#).

Alpha_inf

(only for the standard or SST k - ω model, and the Transition SST model) is the constant α_{∞} in [Equation 4–76](#) in the [Theory Guide](#).

Alpha_0

(only for the standard or SST k - ω model with the **Transitional Flows** option enabled) is the constant α_0 in [Equation 4–76](#) in the [Theory Guide](#).

Beta*_inf

(only for the standard or SST k - ω model, and the Transition SST model) is the constant β_{∞}^* in [Equation 4–81](#) in the [Theory Guide](#).

Beta_i

(only for the standard $k-\omega$ model) is the constant β_i in [Equation 4–89](#) in the [Theory Guide](#).

R_beta

(only for the standard or SST $k-\omega$ model) is the constant R_β in [Equation 4–81](#) in the [Theory Guide](#).

R_k

(only for the standard or SST $k-\omega$ model with the **Transitional Flows** option enabled) is the constant R_k in [Equation 4–68](#) in the [Theory Guide](#).

R_w

(only for the standard or SST $k-\omega$ model with the **Transitional Flows** option enabled) is the constant R_w in [Equation 4–76](#) in the [Theory Guide](#).

Zeta*

(only for the standard or SST $k-\omega$ model) is the constant ζ^* in [Equation 4–80](#) in the [Theory Guide](#).

Mt0

(only for the standard or SST $k-\omega$ model) is the constant M_{t0} in [Equation 4–90](#) in the [Theory Guide](#).

a1

(only for the SST $k-\omega$ model, and the Transition SST model) is the constant a_1 in [Equation 4–98](#) in the [Theory Guide](#).

Beta_i (Inner)

(only for the SST $k-\omega$ model, and the Transition SST model) is the constant $\beta_{i,1}$ in [Model Constants](#) in the [Theory Guide](#).

Beta_i (Outer)

(only for the SST $k-\omega$ model, and the Transition SST model) is the constant $\beta_{i,2}$ in [Model Constants](#) in the [Theory Guide](#).

Cs

(only for LES) is the Smagorinsky constant C_s in [Equation 4–249](#) in the [Theory Guide](#).

C1-PS

(only for RSM) is the constant C_1 in [Equation 4–186](#) in the [Theory Guide](#).

C2-PS

(only for RSM) is the constant C_2 in [Equation 4–187](#) in the [Theory Guide](#).

C1'-PS

(only for RSM) is the constant C'_1 in [Equation 4–188](#) in the [Theory Guide](#).

C2'-PS

(only for RSM) is the constant C'_2 in [Equation 4–188](#) in the [Theory Guide](#).

C1-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_l in [Equation 4–197](#) in the [Theory Guide](#).

C1'-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C'_1 in [Equation 4–197](#) in the [Theory Guide](#).

C2-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_2 in [Equation 4-197](#) in the [Theory Guide](#).

C3-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_3 in [Equation 4-197](#) in the [Theory Guide](#).

C3'-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_3^* in [Equation 4-197](#) in the [Theory Guide](#).

C4-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_4 in [Equation 4-197](#) in the [Theory Guide](#).

C5-SSG-PS

(only for RSM with the **Quadratic Pressure-Strain Model**) is the constant C_5 in [Equation 4-197](#) in the [Theory Guide](#).

Prandtl Number

(only for the Spalart-Allmaras model) is the constant σ_v in [Equation 4-15](#) in the [Theory Guide](#).

TKE Prandtl Number

(only for the standard or realizable k - ε model, the standard or SST k - ω model, the k - kl - ω Transition model, or the RSM) is the effective “Prandtl” number for transport of turbulence kinetic energy σ_k . This effective Prandtl number defines the ratio of the momentum diffusivity to the diffusivity of turbulence kinetic energy via turbulent transport.

TKE (Inner) Prandtl #

(only for the SST k - ω model, and the Transition SST model) is the effective “Prandtl” number for the transport of turbulence kinetic energy, $\sigma_{k,1}$, inside the near-wall region. See [Modeling the Effective Diffusivity](#) in the [Theory Guide](#) for details.

TKE (Outer) Prandtl #

(only for the SST k - ω model, and the Transition SST model) is the effective “Prandtl” number for the transport of turbulence kinetic energy, $\sigma_{k,2}$, outside the near-wall region. See [Modeling the Effective Diffusivity](#) in the [Theory Guide](#) for details.

TDR Prandtl Number

is the effective “Prandtl” number for transport of the turbulent dissipation rate, σ_ε , for the standard or realizable k - ε model or the RSM. This effective Prandtl number defines the ratio of the momentum diffusivity to the diffusivity of turbulence dissipation via turbulent transport.

For the standard k - ω model, the **TDR Prandtl Number** is the effective “Prandtl” number for the transport of the specific dissipation rate, σ_ω .

SDR (Inner) Prandtl #

(only for the SST k - ω model, and the Transition SST model) is the effective “Prandtl” number for the transport of the specific dissipation rate, $\sigma_{\omega,1}$, inside the near-wall region. See [Modeling the Effective Diffusivity](#) in the [Theory Guide](#) for details.

SDR (Outer) Prandtl #

(only for the SST k - ω model, and the Transition SST model) is the effective “Prandtl” number for the transport of the specific dissipation rate, $\sigma_{\omega,2}$, outside the near-wall region. See [Modeling the Effective Diffusivity](#) in the [Theory Guide](#) for details.

Dispersion Prandtl Number

(only for the k - ε multiphase models) is the effective “Prandtl” number for the dispersed phase, σ_{pq} . See [Turbulence Models](#) in the [Theory Guide](#) for details.

Energy Prandtl Number

(for any turbulence model except the RNG k - ε model) is the turbulent Prandtl number for energy, Pr_t , in [Equation 4-205](#) in the [Theory Guide](#). (This item will not appear for premixed or partially premixed combustion models.)

Wall Prandtl Number

(for all turbulence models) is the turbulent Prandtl number at the wall, Pr_t in [Equation 4-283](#) in the [Theory Guide](#). (This item will not appear for adiabatic premixed combustion or partially premixed combustion models.)

Turbulent Schmidt Number

(for turbulent species transport calculations using any turbulence model except the RNG k - ε model) is the turbulent Schmidt number, Sc_t , in [Equation 7-3](#) in the [Theory Guide](#).

PDF Schmidt Number

(for non-premixed or partially premixed combustion calculations using any turbulence model) is the model constant σ_t in [Equation 8-5](#) in the [Theory Guide](#).

User-Defined Transition Correlations

(only for the Transition SST model) allows you to select the user-defined correlations for **F_length**, **Re_thetaac**, **Re_thetat**.

User-Defined Functions

allows you to select the user-defined functions for various constants.

Turbulent Viscosity

appears for Spalart Allmaras, k - ε and k - ω models. You can select the user-defined functions for turbulent viscosity in the drop-down list.

Prandtl Numbers

contains a list of relevant Prandtl numbers for which you can select user-defined functions.

TKE Prandtl Number

allows you to select a user-defined function to define the TKE Prandtl number for the standard and realizable k - ε models and the standard k - ω model.

TDR Prandtl Number

allows to select a user-defined function to define the TDR Prandtl number for the standard and realizable k - ε models.

Energy Prandtl Number

allows you to select a user-defined function to define the Energy Prandtl number for the standard and realizable k - ε models and the standard k - ω model when energy is enabled.

Wall Prandtl Number

allows you to select a user-defined function to define the Wall Prandtl number for the standard and realizable k - ε models and the standard k - ω model when energy is enabled.

SDR Prandtl Number

allows you to select a user-defined function to define the SDR Prandtl number for the standard k - ω model.

Subgrid-Scale Turbulent Viscosity

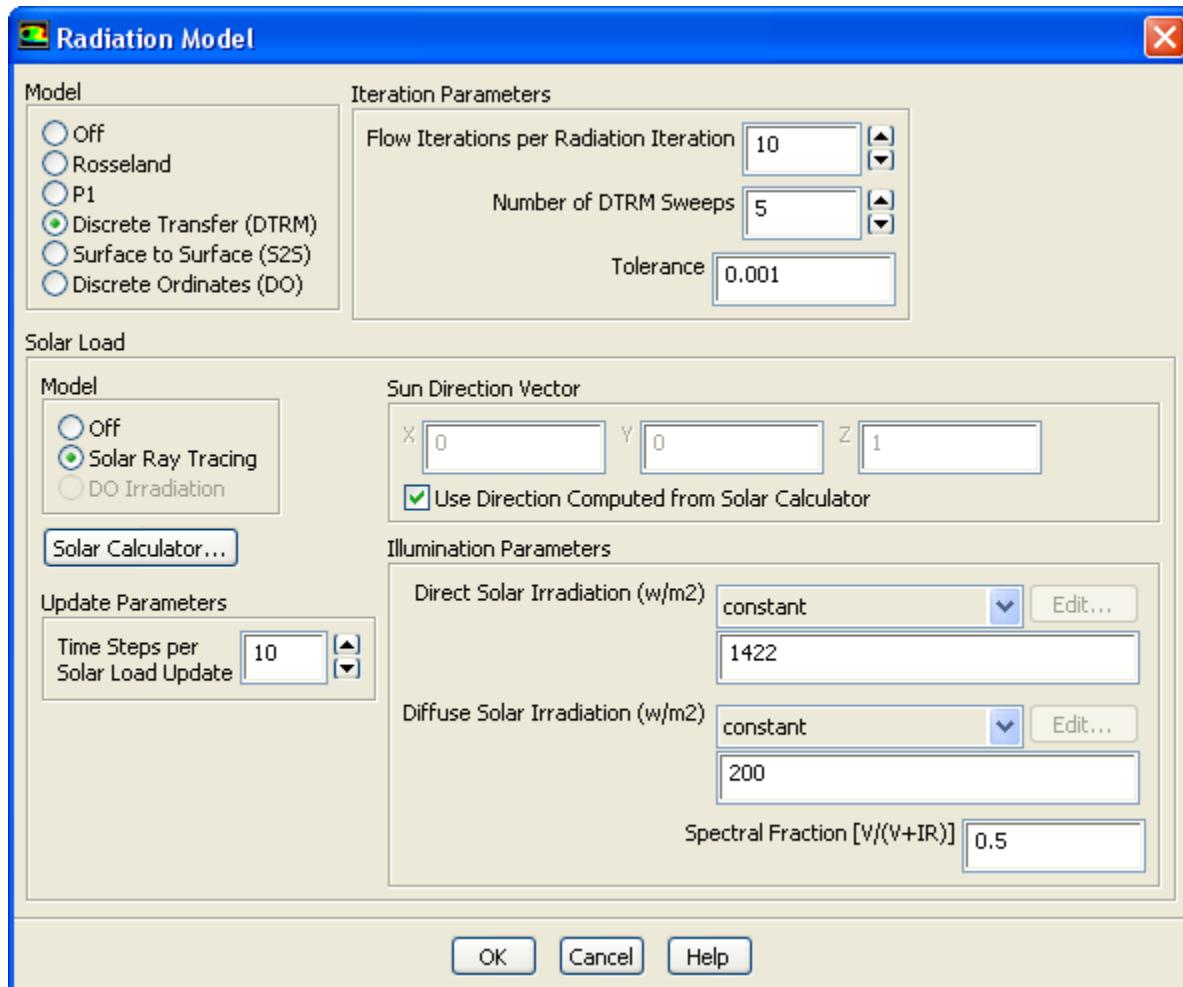

allows you to select a user-defined function for the subgrid-scale turbulent viscosity for the LES model.

Shielding Functions

allows you to select the shielding functions (**SST F1 Function**, **SST F2 Function**, **DDES**, and **IDDES**) for the SST Detached Eddy Simulation Model (see *Shielding Functions for the SST Detached Eddy Simulation Model* (p. 721) for details).

36.3.4. Radiation Model Dialog Box

The **Radiation Model** dialog box allows you to select a model for radiation heat transfer and set the associated parameters. See *Using the Radiation Models* (p. 752) – *Defining Non-Gray Radiation for the DO Model* (p. 769) for details about the items below.

**Controls****Model**

indicates which model, if any, is used to calculate radiation heat transfer. See *Modeling Radiation* (p. 751) for details about modeling radiation heat transfer.

Off

disables the calculation of radiation heat transfer.

Rosseland

enables the Rosseland radiation model.

P1

enables the P-1 radiation model.

Discrete Transfer (DTRM)

enables the discrete transfer radiation model (DTRM).

Surface to Surface (S2S)

enables the surface-to-surface (S2S) radiation model.

Discrete Ordinates (DO)

enables the discrete ordinates (DO) radiation model.

DO/Energy Coupling

allows you to couple the energy and DO intensity equations at each cell, solving them simultaneously.

See [Defining Non-Gray Radiation for the DO Model \(p. 769\)](#) for details.

Iteration Parameters

contains parameters related to the DTRM, S2S and the DO models. This portion of the dialog box will appear only if **Discrete Transfer (DTRM)**, **Surface to Surface (S2S)**, or **Discrete Ordinates (DO)** is selected as the **Model**.

Flow Iterations per Radiation Iteration

controls the frequency with which the radiation terms are updated as the solution proceeds. It is set to 10 by default. This implies that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence. This appears for the **Discrete Transfer (DTRM)** and **Discrete Ordinates (DO)** models.

Number of DTRM Sweeps

controls the number of DTRM passes.

Tolerance

allows you to control the accuracy during each iteration.

Energy Iterations per Radiation Iteration

controls the frequency with which the radiation terms are updated as the continuous phase solution proceeds. The **Energy Iterations per Radiation Iteration** parameter is set to 10 by default. This implies that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence.

Maximum Number of Radiation Iterations

controls the maximum number of iterations of the radiation calculation during each global iteration. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

This item appears only when **Discrete Transfer** or **Surface to Surface** is selected as the **Model**.

Residual Convergence Criteria

determines when the radiation intensity update is converged. It is defined as the maximum normalized change in the surface intensity from one radiation iteration to the next (see [Equation 14-8 \(p. 785\)](#)).

This item appears only when **Discrete Transfer** or **Surface to Surface** is selected as the **Model**.

View Factors and Clustering

contains parameters related to the S2S model. This portion of the dialog box will appear only if **Surface to Surface** is selected as the **Model**. See [Setting Up the S2S Model \(p. 757\)](#) for more information about the use of these parameters.

Settings...

opens the [View Factors and Clustering Dialog Box \(p. 1793\)](#), in which you can set parameters related to surface clusters and view factors.

Compute/Write/Read...

allows you to compute the view factors, write the computed view factors to a file, and read the file into ANSYS FLUENT. When you click **Compute/Write/Read...**, the [The Select File Dialog Box \(p. 33\)](#) will open so that you can specify a name for the file where ANSYS FLUENT should save the view factors after computing them.

Read Existing File...

opens the [The Select File Dialog Box \(p. 33\)](#), in which you can specify the file from which ANSYS FLUENT should read view factors.

Angular Discretization

contains parameters for angular discretization and pixelation for the DO model. This portion of the dialog box will appear only if **Discrete Ordinates** is selected as the **Model**. See [Setting Up the DO Model \(p. 768\)](#) for more information about the use of these parameters.

Theta Divisions, Phi Divisions

define the number of control angles used to discretize each octant of the angular space (see [Figure 5.3: "Angular Coordinate System" in the Theory Guide](#)).

Theta Pixels, Phi Pixels

are used to control the pixelation that accounts for any control volume overhang (see [Figure 5.7: "Pixelation of Control Angle" in the Theory Guide](#) and the figures and discussion preceding it).

Non-Gray Model

contains parameters related to the non-gray P-1 model or non-gray DO model. This portion of the dialog box will appear only if **P1** or **Discrete Ordinates** is selected as the **Model**. See [Setting Up the P-1 Model with Non-Gray Radiation \(p. 753\)](#) or [Defining Non-Gray Radiation for the DO Model \(p. 769\)](#) for more information about the use of these parameters.

Number of Bands

specifies the number of bands for the non-gray radiation.

Wavelength Intervals (n=1)

contains inputs that define each wavelength band. (It appears only when the **Number of Bands** is non-zero.) For each band, you can specify a **Name**, as well as the **Start** and **End** wavelength of the band in μm . Note that the wavelength bands are specified for vacuum ($n = 1$). ANSYS FLUENT will automatically account for the refractive index in setting band limits for media with n different from unity.

Solar Load

contains parameters related to solar load model that can be used to calculate radiation effects from the sun's rays that enter a computational domain. It is available only for the 3D version of ANSYS FLUENT. See [Solar Load Model \(p. 789\)](#) for more information about the use of these parameters.

Model

indicates which model is used to calculate radiation effects.

Off

disables the calculation of solar radiations.

Solar Ray Tracing

enables the solar ray tracing algorithm

DO Irradiation

enables the DO irradiation option. Select **Discrete Ordinates** under **Model** before selecting this option.

Solar Calculator

opens the *Solar Calculator Dialog Box* (p. 1798).

Sun Direction Vector

contains the components of sun direction vector.

X, Y, Z

are the components of the sun direction vector.

Use Direction Computed from Solar Calculator

enables the use of direction vector computed from the solar calculator.

Illumination Parameters

contains illumination options.

Direct Solar Irradiation

is the amount of energy per unit area due to direct solar irradiation.

Diffuse Solar Irradiation

is the amount of energy per unit area due to diffuse solar irradiation.

Spectral Fraction

is the fraction of incident solar radiation in the visible part of the solar radiation spectrum. The spectral fraction is not used for DO irradiation since the DO implementation is intended only for a single band. This parameter is available only for **Solar Ray Tracing**.

Update Parameters

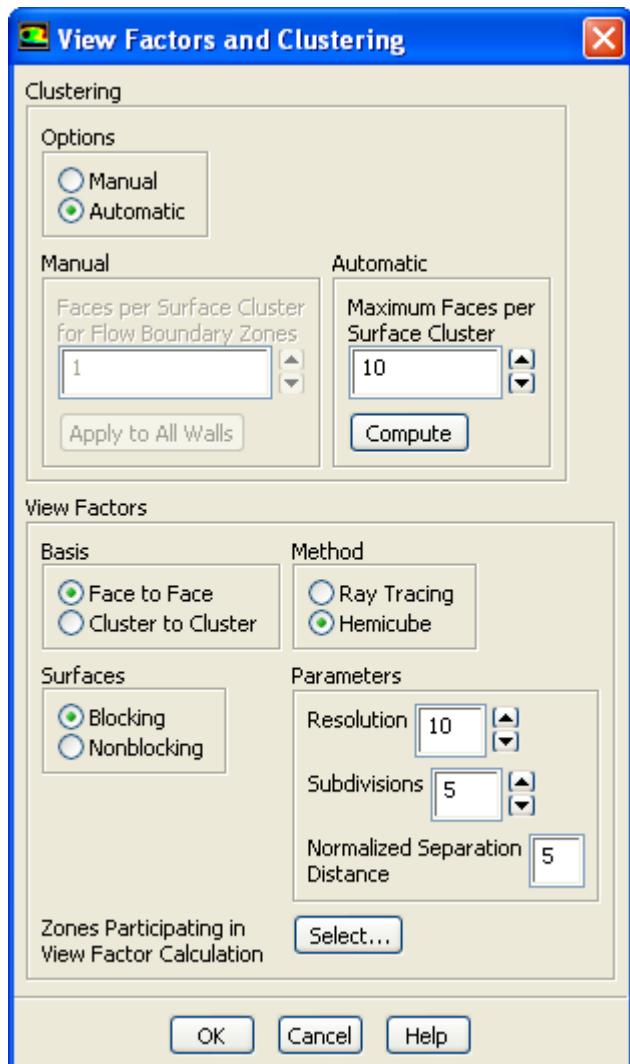

contains update parameters for transient simulations.

Time Steps per Solar Load Update

specifies the number of time steps that will direct the ANSYS FLUENT solver to update the solar load data for the specified flow-time intervals in the unsteady solution process.

36.3.5. View Factors and Clustering Dialog Box

The **View Factors and Clustering** dialog box allows you to set parameters related to surface clusters and view factors for the surface-to-surface radiation model. See *Setting Up the S2S Model* (p. 757) for information about using this dialog box.

Controls

Clustering

contains the methods and settings for creating surface clusters. See *Forming Surface Clusters (p. 759)* for information about surface cluster settings.

Options

gives you a choice of forming clusters either manually or automatically.

Manual

allows you to form clusters manually.

Automatic

allows ANSYS FLUENT to form the cluster automatically.

Manual

(available only when the **Manual** option is enabled) allows you to set the faces per surface cluster (FPSC) value for walls and inlet and outlet boundaries.

Faces per Surface Cluster for Flow Boundary Zones

specifies the number of faces in each surface cluster for inlet and outlet boundaries (i.e., exhaust fan, inlet vent, intake fan, outlet vent, mass-flow inlet, pressure far-field, pressure inlet, pressure outlet, outflow, and velocity inlet boundaries). This FPSC value can also be applied to all walls

that are adjacent to fluid zones by clicking the **Apply to All Walls** button. The default is set to 1. See [Clustering](#) in the [Theory Guide](#) for details about clustering.

Apply to All Walls

applies the value specified in the **Faces per Surface Cluster for Flow Boundary Zones** field to all walls that are adjacent to fluid zones.

Automatic

(available only when the **Automatic** option is enabled) allows you to assign different faces per surface cluster (FPSC) values to the walls automatically, based on the distance of the walls from and the FPSC values of the walls that are defined as critical.

Maximum Faces per Surface Cluster

specifies the maximum number of faces per surface cluster automatically assigned to non-critical wall zones adjacent to fluid zones. The default is set to 10.

Compute

results in ANSYS FLUENT automatically calculating and updating the face per surface cluster values in the boundary conditions dialog box for non-critical wall zones adjacent to fluid zones, without computing the clusters.

View Factors

contains settings for computing the view factors. See [Setting Up the View Factor Calculation \(p. 761\)](#) for information about view factor calculation settings.

Basis

specifies how surfaces are defined for the calculation of view factors. See [Selecting the Basis for Computing View Factors \(p. 761\)](#) for more information.

Face to Face

specifies that the surfaces used to calculate the view factors are the boundary faces.

Cluster to Cluster

specifies that the surfaces used to calculate the view factors are the clusters defined by the settings in the **Clustering** group box. The cluster to cluster basis is only available for 3D cases.

Surfaces

specifies the geometric orientation of surface pairs with respect to each other when using the hemicube method.

Blocking

specifies that the view factor calculation accounts for surfaces that block the views between the surfaces under consideration.

Nonblocking

specifies that the view factor calculation does not account for surfaces that block the views between the surfaces under consideration.

Method

specifies the method for computing the view factors. See [Selecting the Method for Computing View Factors \(p. 762\)](#) for information about choosing a method.

Hemicube

specifies the use of the hemicube method for computing the view factors. The hemicube method is available only for 3D and axisymmetric cases.

Ray Tracing

specifies the use of the ray tracing method for computing the view factors. For 2D cases, the number of rays used with this method is two times the value set for **Resolution** in the **Parameters** group box; for 3D cases, the number of rays is three times the square of the **Resolution** value.

The ray tracing method should not be used when any of the zones are defined as periodic.
The ray tracing method is only available with the face to face basis.

Parameters

contains settings related to the hemicube and ray tracing methods for computing the view factors. All of these inputs are available when **Hemicube** is selected under **Method**, whereas only **Resolution** is available when **Ray Tracing** is selected. See *Selecting the Method for Computing View Factors* (p. 762) for information about setting the method parameters.

Resolution

specifies the resolution of the hemicube. The default value is set to 10. You can increase the value to reduce aliasing effects that can lead to overestimated or underestimated view factors.

Subdivisions

specifies the number of subfaces into which each face is divided. The default value is set to 5. This parameter is only available when the hemicube method is used in conjunction with the face to face basis.

Normalized Separation Distance

specifies the ratio of the minimum face separation to the effective diameter of the face. The default value is set to 5. This parameter is only available for the hemicube method.

Zones Participating in View Factor Calculation

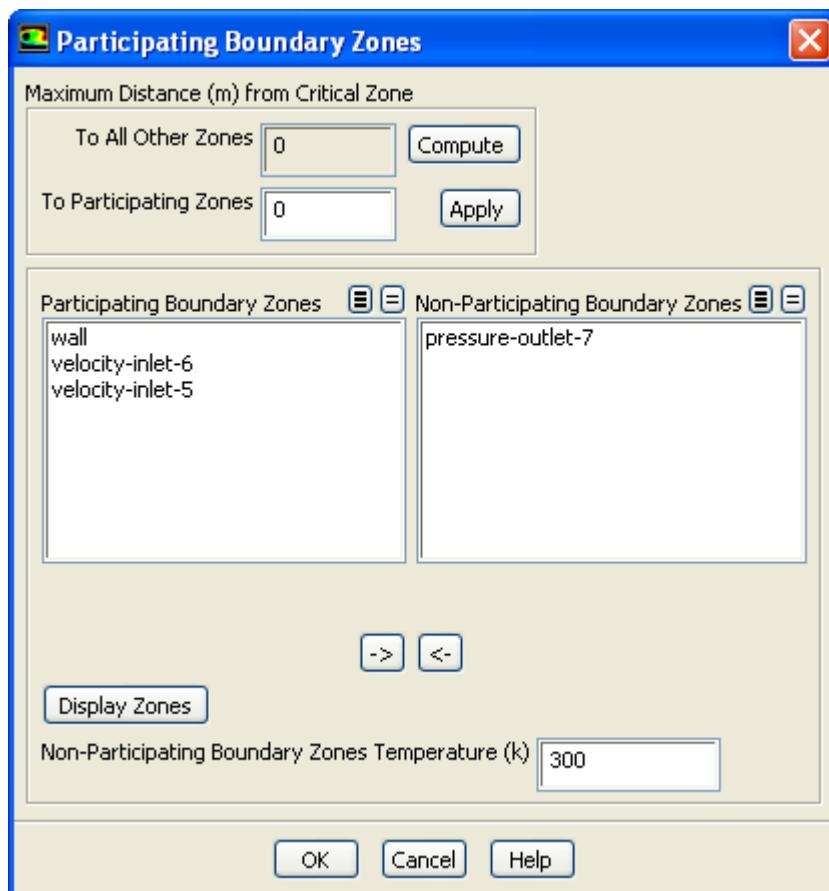

allows you to define which boundary zones participate in the view factor calculation. See *Specifying Boundary Zone Participation* (p. 763) for more information.

Select...

opens the *Participating Boundary Zones Dialog Box* (p. 1796), where you can define which boundary zones participate in the view factor calculation.

36.3.6. Participating Boundary Zones Dialog Box

The **Participating Boundary Zones** dialog box allows you to define which boundary zones participate in the view factor calculation, to display zones in the graphics window, and set the temperature of zones that do not participate in the view factor calculation. See *Specifying Boundary Zone Participation* (p. 763) for details. This dialog box opens when you click on the **Select...** button next to the **Zones Participating in View Factor Calculation** label in the **View Factors and Clustering** dialog box.

Controls

Maximum Distance from Critical Zone

allows you to view the maximum distance between critical zones and other zones, and set all boundary zones that are located beyond a certain distance from a critical zone as not participating in the view factor calculation.

To All Other Zones

displays the maximum of the distances between the centroids of critical and all other wall, inlet, and exit zones when the **Compute** button is clicked. This field is not editable. This is only available when using the **Automatic** option for clustering.

Compute

calculates the distances between the centroids of critical zones and all the other wall, inlet, and exit zones and displays the maximum value in the **To All Other Zones** field and the **To Participating Zones** text-entry box. It requires the definition of the critical zone.

To Participating Zones

displays the maximum of the distances between the centroids of critical and all other wall, inlet, and exit zones when the **Compute** button is clicked. Unlike the **To All Other Zones** field, you can edit this text-entry box. You can specify the maximum distance allowed between the centroids of critical zones and all other wall, inlet, or exit zones that participate in the view factor calculation; when you click the **Apply** button, all of the zones will be marked as either participating or not participating, according to the distance criteria you specified. Note that this field is only available when using the **Automatic** option for clustering.

Apply

marks all of the wall, inlet, and exit zones as either participating or not participating in the view factor calculation, depending on whether the distance from their centroid to the centroid of a critical

zone is equal to or less than value entered for **To Participating Zones**. The **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists will be updated accordingly.

Participating Boundary Zones

shows all the zones that are participating in the view factor calculation. You can select a zone and click the arrow button that points to the left to move the zone to the **Non-Participating Boundary Zones** list.

Non-Participating Boundary Zones

shows all the zones that are not participating in the view factor calculation. You can select a zone and click the arrow button that points to the right to move the zone to the **Participating Boundary Zones** list.

Display Zones

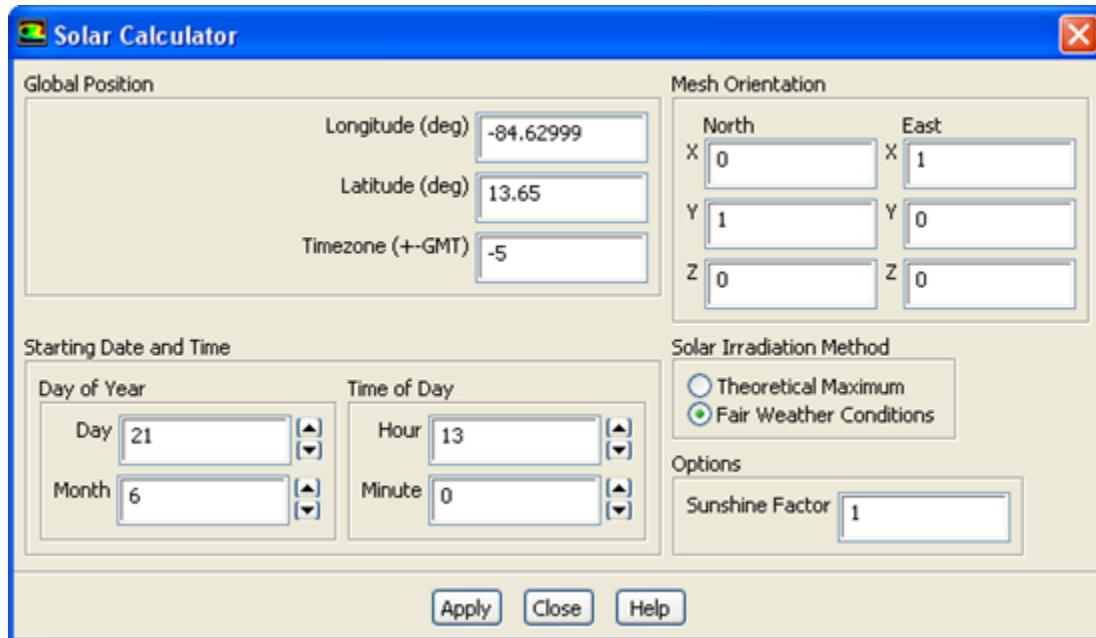

displays any zones selected in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists in the graphics window.

Non-Participating Boundary Zones Temperature

allows you to specify the temperature of the zones that do not participate in the view factor calculation.

36.3.7. Solar Calculator Dialog Box

The **Solar Calculator** dialog box allows you to set parameters related to the calculation of solar load models. See [Solar Load Model \(p. 789\)](#) for details. This dialog box opens when you click on the **Solar Calculator...** button in the **Radiation Model** dialog box.

Controls

Global Position

contains the parameters to define the position of solar radiation.

Longitude

specifies the longitude of the desired location in degrees. Values may range from –180 to 180, where negative values indicate the Western hemisphere and positive values indicate the Eastern hemisphere.

Latitude

specifies the latitude of the desired location in degrees. Values may range from -90 (South pole) to 90 (North pole) with 0 defined as the equator.

Timezone

specifies the local time zone of the desired location in hours relative to Greenwich Mean Time (+-GMT). This integer value can range from 12 to -12 .

Starting Date and Time

contains parameters to specify date and time.

Day of Year

contains parameters to specify day and month.

Time of Day

contains parameters to specify hour and minutes.

Mesh Orientation

specifies the orientation as the vectors for North and East in the CFD grid system of coordinates.

Solar Irradiation Method

contains parameters to choose the solar irradiation method.

Theoretical Maximum

enables theoretically maximum solar irradiation method.

Fair Weather Conditions

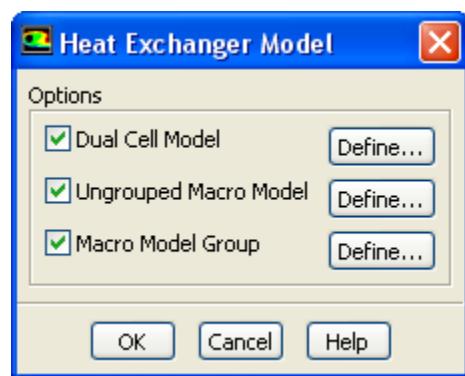

enables fair weather condition solar irradiation method.

Sunshine Factor

is a linear reduction factor for the computed incident load that allows for cloud cover to be accounted for, if appropriate.

36.3.8. Heat Exchanger Model Dialog Box

The **Heat Exchanger Model** dialog box allows you to define a heat exchanger as part of your model. See *[Modeling Heat Exchangers](#)* (p. 819) for details about using the items below.

**Controls****Options**

contains options related to the heat exchanger model. See *[Choosing a Heat Exchanger Model](#)* (p. 820) for details about the differences between the models associated with these options.

Dual Cell Model

allows you to enable or disable the Dual Cell heat exchanger model. When this option is enabled, the corresponding **Define...** button opens the *[Dual Cell Heat Exchanger Dialog Box](#)* (p. 1800).

Ungrouped Macro Model

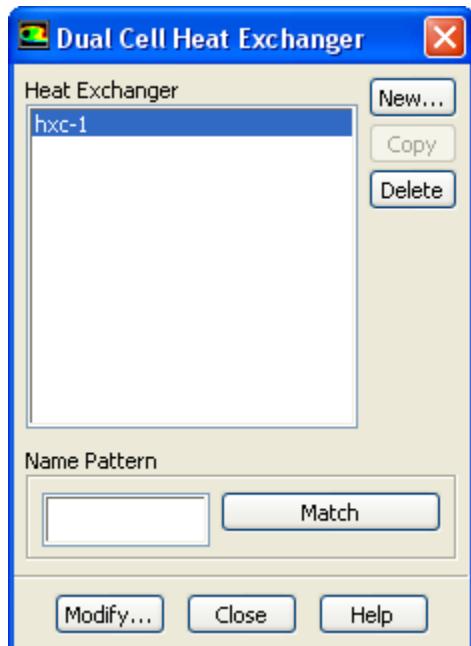

allows you to enable or disable the Ungrouped Macro heat exchanger model. When this option is enabled, the corresponding **Define...** button opens the *Ungrouped Macro Heat Exchanger Dialog Box* (p. 1805).

Macro Model Group

allows you to enable or disable the Macro heat exchanger group model. When this option is enabled, the corresponding **Define...** button opens the *Macro Heat Exchanger Group Dialog Box* (p. 1810).

36.3.9. Dual Cell Heat Exchanger Dialog Box

The **Dual Cell Heat Exchanger** dialog box allows you to use the NTU method for heat transfer calculations. This model allows the solution of auxiliary flow on a separate mesh (other than the primary fluid mesh). See *Using the Dual Cell Heat Exchanger Model* (p. 822) for information about using this dialog box.

**Controls****Heat Exchanger**

contains a list of predefined heat exchangers.

New...

opens the *Set Dual Cell Heat Exchanger Dialog Box* (p. 1801).

Copy

opens the *Copy From Dialog Box* (p. 1805), which allows you to copy the currently selected heat exchanger.

Delete

removes the currently selected heat exchanger.

Name Pattern

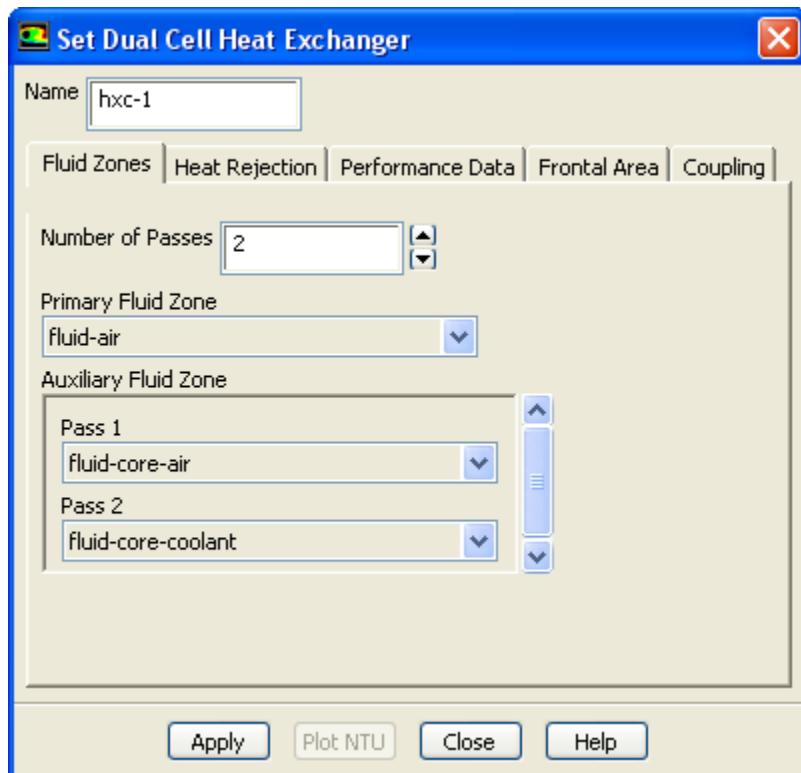

specifies the pattern to look for in the names of heat exchangers. Type the pattern in the text field and click **Match** to select (or deselect) the listing in the **Heat Exchanger** list with names that match the specified pattern.

Modify...

opens the *Set Dual Cell Heat Exchanger Dialog Box* (p. 1801).

36.3.10. Set Dual Cell Heat Exchanger Dialog Box

The **Set Dual Cell Heat Exchanger** dialog box allows you to define the heat exchanger parameters. See *Using the Dual Cell Heat Exchanger Model* (p. 822) for details about using this dialog box.

Controls

Name

allows you to specify a name for the dual cell heat exchanger.

Fluid Zones

allows you to specify the fluid zone parameters for the heat exchanger.

Number of Passes

specifies the number of passes for the heat exchanger.

Primary Fluid Zone

allows you to specify the fluid of the primary fluid zone for the heat exchanger.

Auxiliary Fluid Zone

allows you to specify the fluid for the auxiliary fluid zone, per pass.

Important

The selected zones must be overlapping in physical space.

Heat Rejection

contains parameters specific to the rejection of heat in the heat exchanger.

Options

allows you to specify how the heat rejection in the heat exchanger is computed.

Fixed Heat Rejection

allows you to specify heat rejection parameters.

Fixed Inlet Temperature

allows you use total heat rejection as the desired output.

Heat Rejection Targeted

allows you to specify the heat rejection desired from the heat exchanger (available only when the **Fixed Heat Rejection** option is enabled).

Inlet Zone for Temperature Updates

allows ANSYS FLUENT to change the temperature of the specified inlet zone in order to match the targeted heat rejection (available only when the **Fixed Heat Rejection** option is enabled).

Temperature Update Under-Relaxation

controls convergence (available only when the **Fixed Heat Rejection** option is enabled).

Iteration Interval Between Temperature Updates

controls divergence (available only when the **Fixed Heat Rejection** option is enabled).

Performance Data

contains parameters for specifying the heat exchanger's performance data.

Options

allows you to choose between using raw performance data or NTU performance data.

Raw Data

allows you to specify raw performance data for the heat exchanger.

NTU Data

allows you to specify NTU performance data for the heat exchanger.

Heat Exchanger Performance Data

contains parameters concerning the heat exchanger's performance data.

NTU Table

opens the [NTU Table Dialog Box \(p. 1804\)](#) (available only when the **NTU Data** option is enabled).

Heat Transfer Table

opens the [Heat Transfer Data Table Dialog Box \(p. 1803\)](#) (available only when the **Raw Data** option is enabled).

Effectiveness-NTU Relation

computes the NTU values from the heat transfer data. Choose **cross-flow-unmixed**, **parallel-flow**, or **counter-flow**, all of which are described in [NTU Relations](#) (available only when the **Raw Data** option is enabled).

Reference Inlet Temperature

allows you to specify the inlet reference temperature for the primary and the auxiliary fluids. (available only when the **Raw Data** option is enabled).

Frontal Area

allows you to specify the frontal area for the heat exchanger.

Primary Fluid

allows you to specify a value for the **Core Frontal Area** for the primary fluid, or to compute the value from a surface zone using the **Compute From** drop-down list.

Auxiliary Fluid

allows you to specify a value for the **Core Frontal Area** for the auxiliary fluid, or to compute the value from a surface zone using the **Compute From** drop-down list.

Coupling

specifies parameters when you want to couple the heat exchanger passes.

Temperature

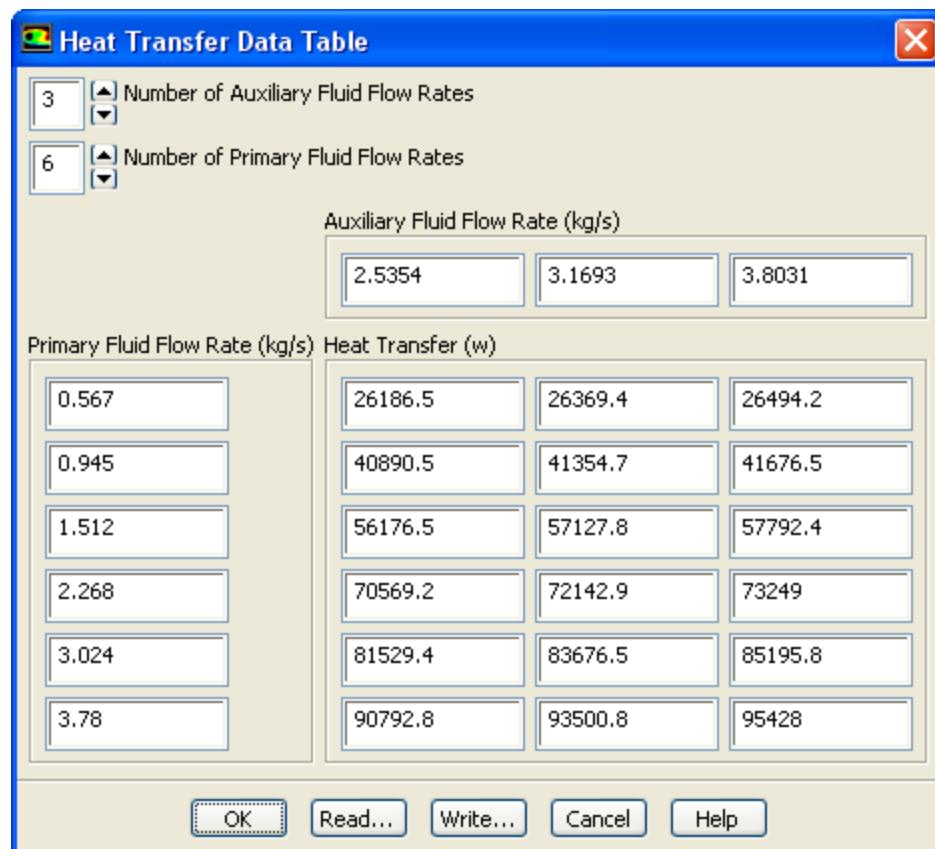

specifies, by default, the mass-weighted average for the temperature of the outlet of Pass 1 to the inlet of Pass 2. Similarly, the mass-weighted-average temperature of the outlet of Pass 2 will be applied at the inlet zone of Pass 3, and so on. (available only when multiple passes are specified in the **Fluid Zones** tab).

Plot NTU

plots the performance data curve for the selected heat exchanger. The performance data is supplied through the **Performance Data** tab.

36.3.11. Heat Transfer Data Table Dialog Box

The **Heat Transfer Data Table** dialog box contains information on the number of fluid flow rates and heat transfer data for the primary and auxiliary fluids. See *Using the Ungrouped Macro Heat Exchanger Model* (p. 831) for details about using this dialog box.

**Controls****Number of Auxiliary Fluid Flow Rates**

sets the number of auxiliary fluid flow rates.

Number of Primary Fluid Flow Rates

sets the number of primary fluid flow rates.

Auxiliary Fluid Flow Rate

sets fluid flow rates for the auxiliary fluid.

Primary Fluid Flow Rate

sets fluid flow rates for the primary fluid.

Heat Transfer

sets the heat transfer for the corresponding primary and auxiliary fluid flow rates.

Read...

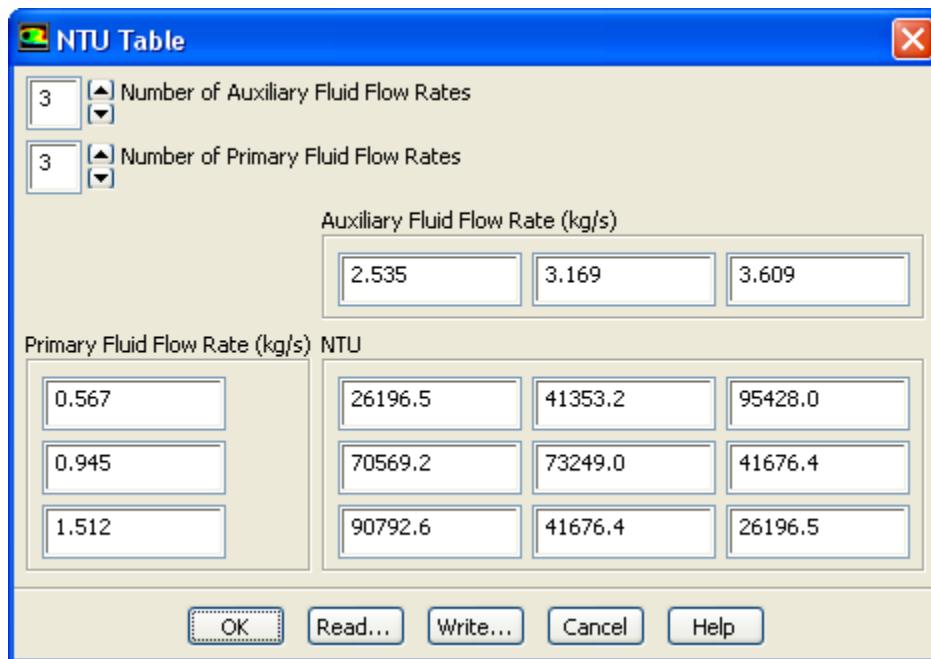

allows you to read in a file containing heat transfer data.

Write...

allows you to write a file containing heat transfer data.

36.3.12. NTU Table Dialog Box

The **NTU Table** dialog box contains information on the number of fluid flow rates and NTU data for the primary and auxiliary fluids. See [Using the Ungrouped Macro Heat Exchanger Model \(p. 831\)](#) for details about using this dialog box.

**Controls****Number of Auxiliary Fluid Flow Rates**

sets the number of auxiliary fluid flow rates.

Number of Primary Fluid Flow Rates

sets the number of primary fluid flow rates.

Auxiliary Fluid Flow Rate

sets fluid flow rates for the auxiliary fluid.

Primary Fluid Flow Rate

sets fluid flow rates for the primary fluid.

NTU

sets the NTU values for the corresponding primary and auxiliary fluid flow rates.

Read...

allows you to read in a file containing NTU data.

Write...

allows you to write a file containing NTU data.

36.3.13. Copy From Dialog Box

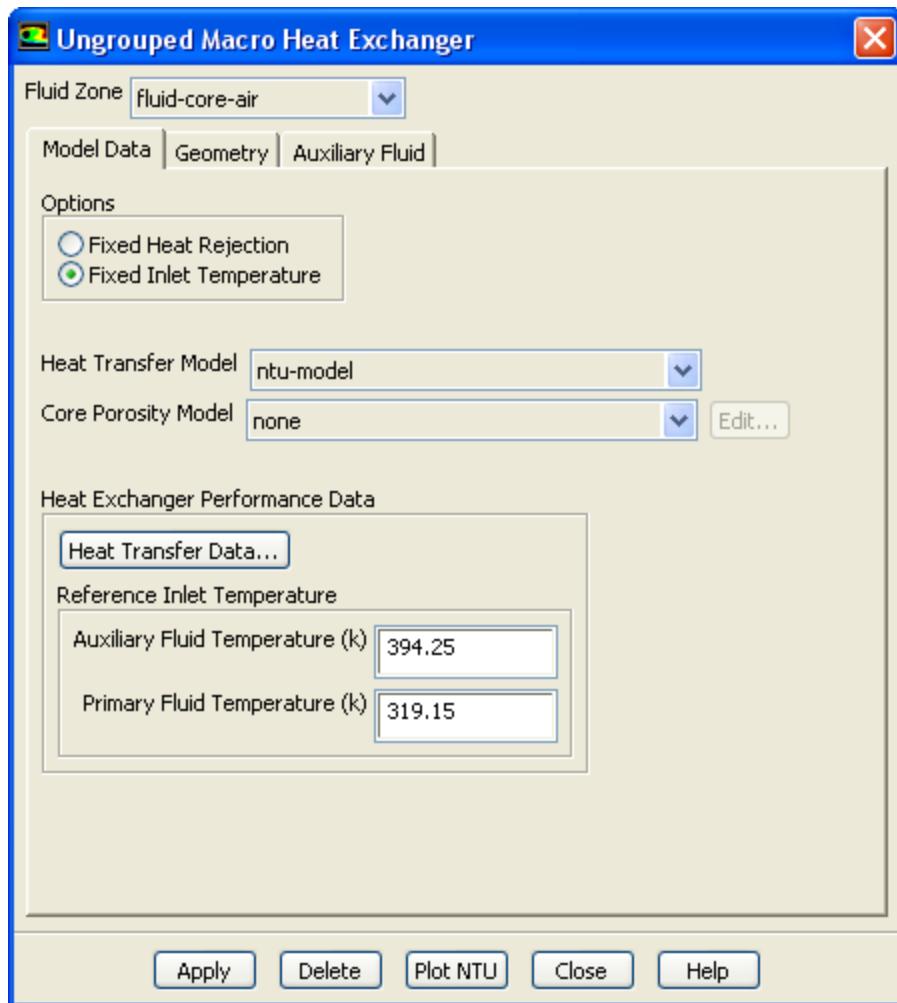

The **Copy From** dialog box allows you to copy the setup of one heat exchanger to another.

**Controls****Existing Heat Exchangers**

contains a list of heat exchangers, from which you can copy the settings from one heat exchanger to another.

36.3.14. Ungrouped Macro Heat Exchanger Dialog Box

The **Ungrouped Macro Heat Exchanger** dialog box allows you to set up the ungrouped macro heat exchanger model. See [Using the Ungrouped Macro Heat Exchanger Model \(p. 831\)](#) for details about using this dialog box.

Controls

Fluid Zone

specifies the zone that represents the heat exchanger.

Model Data

contains the parameters related to the heat exchanger model.

Options

allows you to choose one of the following settings:

Fixed Heat Rejection

specifies that ANSYS FLUENT should compute the auxiliary fluid inlet temperature for a specified heat rejection.

Fixed Inlet Temperature

specifies that ANSYS FLUENT should compute the total heat rejection of the core for a given inlet auxiliary temperature.

Heat Transfer Model

allows you to specify either the **ntu-model** or the **simple-effectiveness-model** for heat transfer.

See [Choosing a Heat Exchanger Model \(p. 820\)](#) for information on the differences between these models.

Core Porosity Model

contains a drop-down list of all available core porosity models.

Edit...

opens the [Core Porosity Model Dialog Box \(p. 1809\)](#).

Heat Exchanger Performance Data

contains the parameters for heat transfer.

Heat Transfer Data...

opens the [Heat Transfer Data Table Dialog Box \(p. 1803\)](#). This item will appear for the NTU model only.

Auxiliary Fluid Temperature

specifies the auxiliary fluid temperature. This item will appear only for the NTU model.

Primary Fluid Temperature

specifies the gas stream temperature. This item will appear only for the NTU model.

Velocity Effectiveness Curve...

opens the [Velocity Effectiveness Curve Dialog Box \(p. 1808\)](#) in which you can define the effectiveness of the heat exchanger core (ε in [Equation 6–11 in the Theory Guide](#)). This item will appear for simple effectiveness model only.

Geometry

contains parameters to define the macro grid.

Width

sets the width of the heat exchanger core. The **Width** is measured in the pass-to-pass direction.

Height

sets the height of the heat exchanger core. The **Height** is measured in the auxiliary fluid inlet direction.

Depth

sets the depth of the heat exchanger core.

Number of Passes

specifies the number of passes for the macro grid. (See [Figure 15.17 \(p. 837\)](#).)

Number of Rows/Pass, Number of Columns/Pass

specify the number of macro rows and columns per pass in the macro grid. (See [Figure 15.17 \(p. 837\)](#).)

View Passes

displays the macro grid. (This button becomes available after you click **Apply**.) The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n - 1$ is blue.

Draw Mesh

toggles between displaying and not displaying the mesh when the macro mesh is displayed (using the **View Passes** button). The [Mesh Display Dialog Box \(p. 1767\)](#) opens when **Draw Mesh** is selected.

Update from Plane Tool

updates the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** from the plane tool orientation. The **Width**, **Height**, and **Depth** will also be updated. See [Using the Plane Tool \(p. 1485\)](#) for information about using the plane tool.

Auxiliary Fluid Inlet Direction (height)

specifies the direction in which the auxiliary fluid enters the heat exchanger. See [Figure 15.17 \(p. 837\)](#).

Pass-to-Pass Direction (width)

specifies the direction in which the auxiliary fluid moves at the end of each pass through the heat exchanger. See [Figure 15.17 \(p. 837\)](#).

Auxiliary Fluid

contains the option to specify the auxiliary fluid properties.

Auxiliary Fluid Properties Method

contains options for specifying auxiliary fluid properties.

constant-specific-heat

allows you to specify a constant value for the auxiliary fluid specific heat.

user-defined-enthalpy

allows you to specify a user-defined function for the auxiliary fluid enthalpy.

Auxiliary Fluid Specific Heat

specifies the value of $c_{p,auxiliary}$ in [Equation 6–17](#) in the [Theory Guide](#). This value is specified only if **constant-specific-heat** is selected.

Auxiliary Fluid Enthalpy UDF

allows you to specify a UDF for the auxiliary fluid enthalpy (see [Equation 6–17](#) in the [Theory Guide](#)). This option is available only when **user-defined-enthalpy** is selected.

Auxiliary Fluid Flow Rate

sets the flow rate of the auxiliary fluid (\dot{m} in [Equation 6–16](#) in the [Theory Guide](#)).

Heat Rejection

sets the total heat rejection (q_{total} in [Equation 6–15](#) in the [Theory Guide](#)). This value is specified only if **Fixed Heat Rejection** is selected.

Initial Temperature

sets an initial guess for the inlet temperature (T_{in} in [Equation 6–11](#) and [Equation 6–16](#) in the [Theory Guide](#)). This value is specified only if **Fixed Heat Rejection** is selected.

Inlet Temperature

sets the auxiliary fluid initial temperature (T_{in} in [Equation 6–11](#) and [Equation 6–16](#) in the [Theory Guide](#)). This value is specified only if **Fixed Inlet Temperature** is selected in the **Model Data** tab.

Inlet Pressure

sets the auxiliary fluid inlet pressure. This value is specified only if **user-defined-enthalpy** is selected.

Inlet Quality

specifies the value of x in [Equation 6–20](#) in the [Theory Guide](#). This value is specified only if **user-defined-enthalpy** is selected.

Pressure Drop

specifies the value of p_{in} in [Equation 6–21](#) in the [Theory Guide](#). This value is specified only if **user-defined-enthalpy** is selected.

Apply

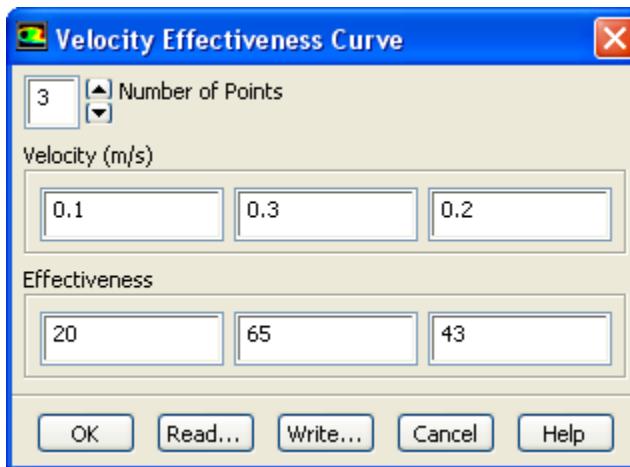

saves all the settings for the heat exchanger specified in the **Fluid Zone** list.

Delete

deletes the heat exchanger specified in the **Fluid Zone** list.

36.3.15. Velocity Effectiveness Curve Dialog Box

The **Velocity Effectiveness Curve** dialog box allows you to define effectiveness curve. It is opened by clicking **Velocity Effectiveness Curve...** in the [Ungrouped Macro Heat Exchanger Dialog Box](#) (p. 1805).

Controls

Number of Points

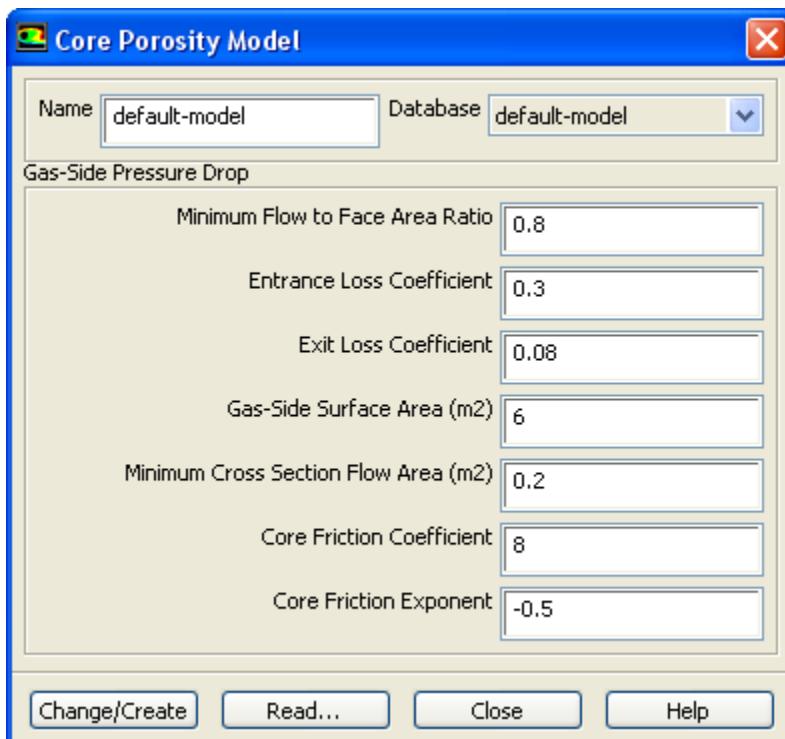

specifies the number of data pairs in the effectiveness profile. The default value of 1 indicates a constant effectiveness.

Velocity, Effectiveness

specify the data pairs for the effectiveness profile. These items are available only if the simple effective model has been selected.

36.3.16. Core Porosity Model Dialog Box

The **Core Porosity Model** dialog box allows you to modify or define a heat exchanger core model. This dialog box opens when you click **Edit...** in the *Ungrouped Macro Heat Exchanger Dialog Box* (p. 1805).

Controls

Name

specifies the name of a new heat exchanger core model.

Database

contains a drop-down list of all heat exchanger core models that are currently available.

Gas-Side Pressure Drop

contains parameters that define the air-side pressure drop.

Minimum Flow to Face Area Ratio

sets the value of σ in [Equation 6–2](#) in the [Theory Guide](#).

Entrance Loss Coefficient

sets the value of K_c in [Equation 6–2](#) in the [Theory Guide](#).

Exit Loss Coefficient

sets the value of K_e in [Equation 6–2](#) in the [Theory Guide](#).

Gas Side Surface Area

sets the value of A in [Equation 6–2](#) in the [Theory Guide](#).

Minimum Cross Section Flow Area

sets the value of A_c in [Equation 6–2](#) in the [Theory Guide](#).

Core Friction Coefficient

sets the value of a in [Equation 6–3](#) in the [Theory Guide](#).

Core Friction Exponent

sets the value of b in [Equation 6–3](#) in the [Theory Guide](#).

Change/Create

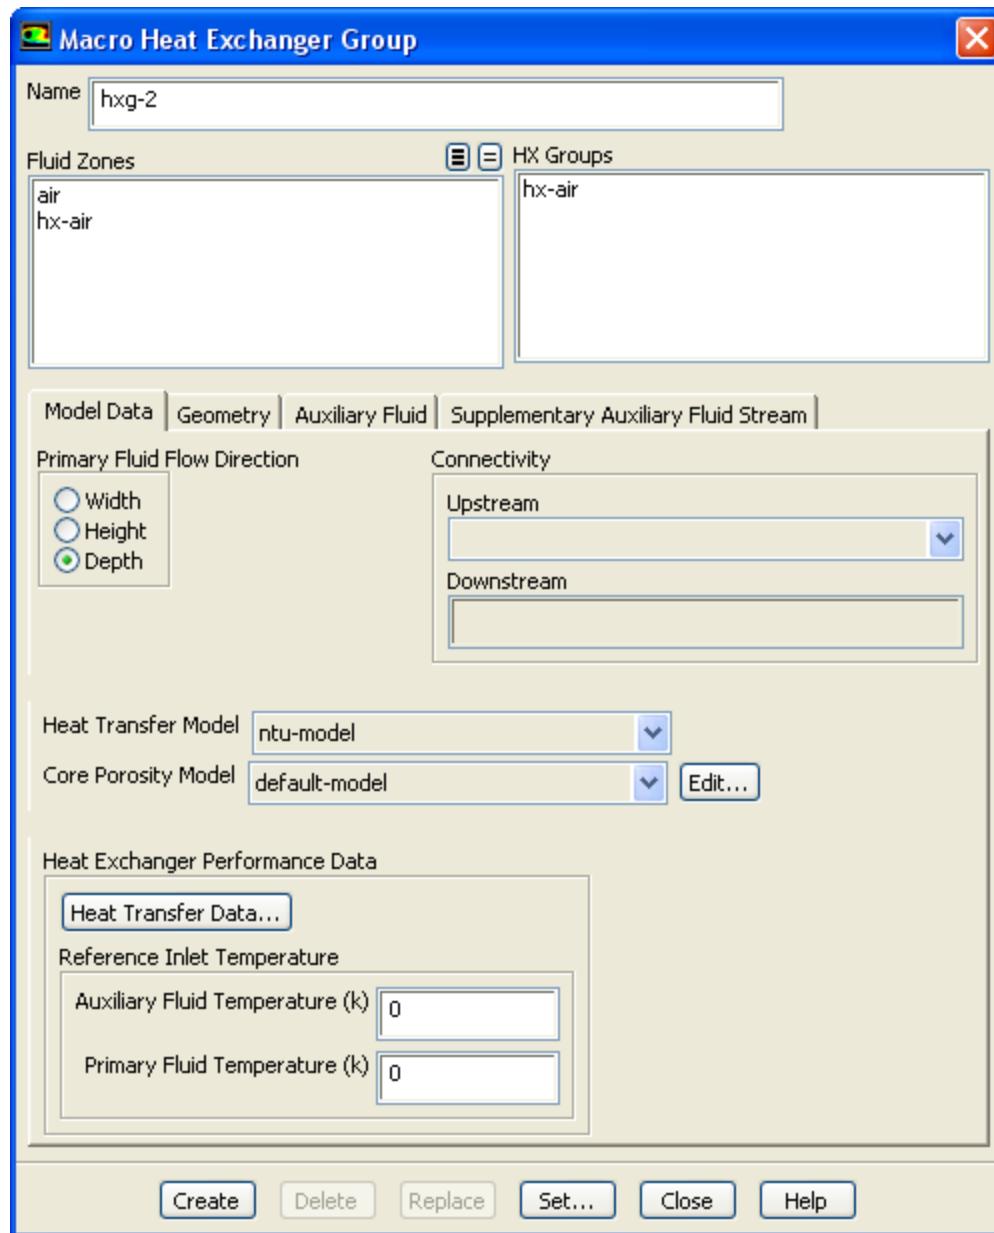

saves the settings in the dialog box and adds the new model to the **Database** list.

Read...

opens the [The Select File Dialog Box](#) (p. 33), in which you can select an external file containing a pre-defined heat exchanger core model.

36.3.17. Macro Heat Exchanger Group Dialog Box

The **Macro Heat Exchanger Group** dialog box allows you to modify or define a heat exchanger core group.

Controls

Name

specifies the name of a new heat exchanger group.

Fluid Zones

contains a list of all the fluid zones.

HX Groups

contains list of the heat exchanger groups.

Model Data

contains all the parameters to be specified for the model.

Primary Fluid Flow Direction

gives you a choice of gas flow direction.

Width, Height, Depth

specifies the width, height and the depth of the gas flow direction.

Connectivity

allows you to define the upstream and downstream connections.

Upstream

specifies the upstream heat exchanger group.

Downstream

specifies the downstream heat exchanger group.

Heat Transfer Model

allows you to select either the **simple-effectiveness-model** or the **ntu-model**. See *Choosing a Heat Exchanger Model* (p. 820) for information on the differences between these models.

Core Porosity Model

specifies whether default values are chosen for the core porosity model.

Edit...

opens the *Core Porosity Model Dialog Box* (p. 1809) for the definition of a new core porosity model.

Heat Exchanger Performance Data

contains the parameters for heat transfer.

Heat Transfer Data...

opens the *Heat Transfer Data Table Dialog Box* (p. 1803). This dialog box allows you to define the heat transfer for different primary and auxiliary fluid flow rates. This item will appear for the NTU model only.

Velocity Effectiveness Curve...

opens the *Velocity Effectiveness Curve Dialog Box* (p. 1808) in which you can define the effectiveness of the heat exchanger core (ε in [Equation 6–11](#) in the [Theory Guide](#)). This item will appear for simple effectiveness model only.

Auxiliary Fluid Temperature

specifies the auxiliary fluid temperature. This item will appear for the NTU model only.

Primary Fluid Temperature

specifies the gas stream fluid temperature. This item will appear for the NTU model only.

Geometry

contains parameters to define the macro grid.

Width, Height, Depth

specifies the width, height and the depth of the heat exchanger.

Number of Passes

specifies the number of passes.

Number of Rows/Pass

specifies the number of rows per pass.

Number of Columns/Pass

specifies the number of columns per pass.

View Passes

displays the macro grid. (This button becomes available after you click **Set**.) The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n - 1$ is blue.

Draw Mesh

toggles between displaying and not displaying the mesh when the macro mesh is displayed (using the **View Passes** button). The *Mesh Display Dialog Box* (p. 1767) opens when **Draw Mesh** is selected.

Update from Plane Tool

updates the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** from the plane tool orientation. The **Width**, **Height**, and **Depth** will also be updated. See [Using the Plane Tool \(p. 1485\)](#) for information about using the plane tool.

Auxiliary Fluid Inlet Direction

specifies the direction in which the auxiliary fluid enters the heat exchanger. See [Figure 15.17 \(p. 837\)](#).

Pass-to-Pass Direction

specifies the direction in which the auxiliary fluid moves at the end of each pass through the heat exchanger. See [Figure 15.17 \(p. 837\)](#).

Auxiliary Fluid

contains inputs to specify the properties of the auxiliary fluid.

Properties Method

specifies the method to specify the auxiliary fluid properties. You can choose from **constant-specific-heat** and **user-defined-enthalpy**.

Specific Heat

sets the specific heat of the auxiliary fluid (c_p in [Equation 6–16](#) you choose **constant-specific-heat**).

Enthalpy UDF

sets the enthalpy as defined by the UDF selected from the drop-down list.

Auxiliary Fluid Flow Rate

sets the flow rate of the auxiliary fluid (\dot{m} in [Equation 6–16](#) in the [Theory Guide](#)).

Initial Temperature

sets an initial guess for the inlet temperature (T_{in} in [Equation 6–11](#) and [Equation 6–16](#) in the [Theory Guide](#)). This value is specified only if **Fixed Heat Rejection** is selected.

Inlet Pressure

sets the auxiliary fluid inlet pressure. This value is specified only if **user-defined-enthalpy** is selected.

Inlet Quality

specifies the value of x in [Equation 6–20](#) in the [Theory Guide](#).

Pressure Drop

specifies the value of p_{in} in [Equation 6–21](#) in the [Theory Guide](#). This value is specified only if **user-defined-enthalpy** is selected.

Supplementary Auxiliary Fluid Stream

specifies properties of the supplementary auxiliary stream.

Supplementary Mass Flow Rate

specifies the supplementary fluid flow rate as **constant**, **polynomial** or **piecewise-linear**.

Supplementary Flow Temperature

specifies the supplementary fluid temperature as **constant**, **polynomial** or **piecewise-linear**.

Supplementary Flow Quality

specifies the supplementary fluid quality.

Create

saves all the settings in the dialog box.

Delete

deletes the group that is selected in the **HX Groups** list.

Replace

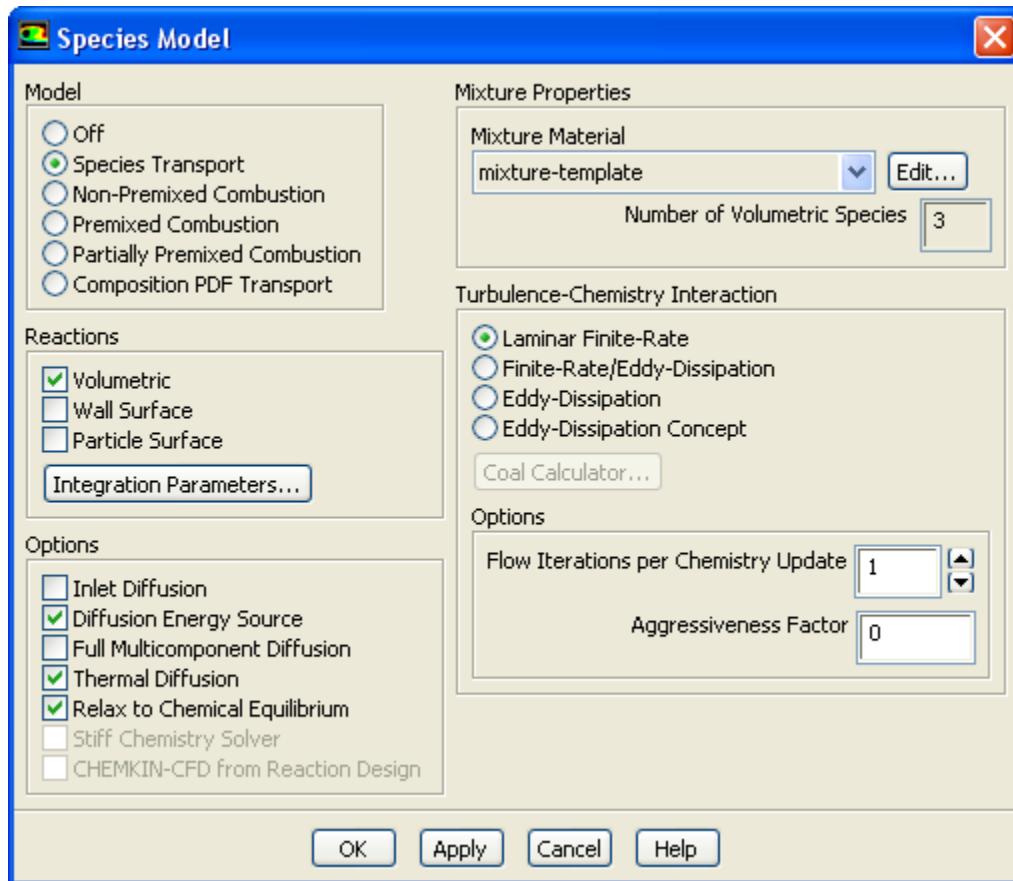

changes the parameters of the already existing group that is selected in the **HX Groups** list.

Set...

opens the *Ungrouped Macro Heat Exchanger Dialog Box* (p. 1805), in which you can define a new heat exchanger core model or read one from an external file.

36.3.18. Species Model Dialog Box

The **Species Model** dialog box allows you to set parameters related to the calculation of species transport and combustion. See *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857), *User Inputs for Wall Surface Reactions* (p. 886), *User Inputs for Particle Surface Reactions* (p. 892), *Using the Premixed Combustion Model* (p. 958), *Using the Partially Premixed Combustion Model* (p. 969), and *Steps for Using the Composition PDF Transport Model* (p. 975) for details about the items below.

Controls

Model

indicates which model, if any, is used to calculate species transport/combustion.

Off

disables species calculations.

Species Transport

enables the calculation of multi-species transport (either non-reacting or reacting, depending on the selection for **Reactions**). See *Modeling Species Transport and Finite-Rate Chemistry* (p. 855) for details.

Non-Premixed Combustion

enables the calculation of turbulent reacting flow using the non-premixed combustion model. See *Modeling Non-Premixed Combustion* (p. 901) for details. This option is available only for turbulent flows using the pressure-based solver.

Premixed Combustion

enables the premixed turbulent combustion model. See [Modeling Premixed Combustion \(p. 957\)](#) for details. This option is available only for turbulent flows using the pressure-based solver.

Partially Premixed Combustion

enables the partially premixed turbulent combustion model. See [Modeling Partially Premixed Combustion \(p. 969\)](#) for details. This option is available only for turbulent flows using the pressure-based solver.

Composition PDF Transport

enables the composition PDF transport model. See [Modeling a Composition PDF Transport Problem \(p. 975\)](#) for details. This option is available only for turbulent flows using the pressure-based solver.

Reactions

contains options related to the modeling of reacting flow. (This section of the dialog box appears only when **Species Transport** or **Composition PDF Transport** is the specified **Model**.)

Volumetric

enables the calculation of reacting flow using the finite-rate formulation. See [Volumetric Reactions \(p. 855\)](#) for details.

Wall Surface

enables the calculation of wall surface reactions. See [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#) for details. This item will appear only if **Volumetric** is enabled.

Particle Surface

enables the calculation of particle surface reactions. See [Particle Surface Reactions \(p. 892\)](#) for details. This item will appear only if **Volumetric** is enabled.

Integration Parameters...

is a command button that opens the [Integration Parameters Dialog Box \(p. 1828\)](#). This button appears for the species transport model, when **Volumetric** is enabled under **Reactions** and **Stiff Chemistry Solver** is enabled under **Options** or when **Eddy-Dissipation Concept** is enabled under **Turbulence-Chemistry Interaction**.

Wall Surface Reaction Options

contains additional options for wall surface reactions. This portion of the dialog box appears only if **Wall Surface** is enabled under **Reactions**.

Heat of Surface Reactions

(if enabled) includes the heat release due to surface reactions in the energy equation. You must remember to set appropriate formation enthalpies (standard state enthalpies) if you enable this option.

Mass Deposition Source

(if enabled) includes the effect of surface mass transfer in the continuity equation.

Aggressiveness Factor

is a numerical factor which controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 (the default) is the most robust, but results in the slowest convergence.

Options

contains additional options for the **Species Transport** model and for the **Composition PDF Transport**. (This section will not appear in the dialog box for the other models.)

Inlet Diffusion

includes the diffusion flux of species at inlet.

Diffusion Energy Source

(if enabled) includes the effect of enthalpy transport due to species diffusion in the energy equation.

Full Multicomponent Diffusion

enables the full multicomponent diffusion model. See [Full Multicomponent Diffusion \(p. 459\)](#) for details.

Thermal Diffusion

enables the thermal diffusion model. See [Thermal Diffusion Coefficients \(p. 461\)](#) for details.

Relax to Chemical Equilibrium

enables the calculation of the characteristic time for the turbulence-chemistry interaction models. See [The Relaxation to Chemical Equilibrium Model](#) for details.

Stiff Chemistry Solver

enables the calculations for modeling stiff laminar flames. See [Solution of Stiff Laminar Chemistry Systems \(p. 880\)](#) for details.

Liquid Micro-Mixing

is used to model liquid reactions. When the **Liquid Micro-Mixing** model is invoked, ANSYS FLUENT uses the **volume-weighted-mixing-law** formula to calculate the density.

CHEMKIN-CFD From Reaction Design

enables the use of reaction rates-of-production from Reaction Design's CHEMKIN module, coupled to ANSYS FLUENT's ISAT algorithm.

Thickened Flame Model

enables the modeling of laminar flames. This application is typically used as an LES combustion model for turbulent premixed and partially-premixed flames.

Include Temperature Fluctuations

enables the calculation of the multi-mode energy equation. This option is available when the composition PDF transport model is selected.

Mixture Properties

contains controls and information about the mixture being modeled. This section of the dialog box will not appear if **Premixed Combustion** is the selected under **Model**.

Mixture Material

contains a drop-down list of available mixture materials. When you first enable the **Species Transport** model, you can choose from all of the mixture materials defined in the database, or you can choose a "template" and define your own material. (Click **View...** to open the [FLUENT Database Materials Dialog Box \(p. 1890\)](#) and check the properties of the mixture material selected in the list.) See [Enabling Species Transport and Reactions and Choosing the Mixture Material \(p. 857\)](#) for details.

When you use the **Non-Premixed Combustion** or **Partially Premixed Combustion** model, this list will be inactive. The mixture material for a non-premixed or partially premixed combustion calculation will be determined from the content of the PDF file generated in ANSYS FLUENT using the **PDF Options** parameters.

Number of Volumetric Species

displays the number of gas-phase species in the selected **Mixture Material**. This is an informational display only; you cannot edit this value.

Number of Solid Species

displays the number of solid species defined in the selected **Mixture Material**. This is an informational display only; you cannot edit this value. (This list will appear only for **Species Transport** models involving **Wall Surface** reactions.)

Number of Site Species

displays the number of site species defined in the selected **Mixture Material**. This is an informational display only; you cannot edit this value. (This list will appear only for **Species Transport** models involving **Wall Surface** reactions.)

Turbulence-Chemistry Interaction

indicates which model is to be used for turbulence-chemistry interaction when the **Species Transport** model with **Volumetric** reactions is used.

Laminar Finite-Rate

computes only the Arrhenius rate (see [Equation 7–8](#) in the [Theory Guide](#)) and neglects turbulence-chemistry interaction.

Finite-Rate/Eddy-Dissipation

(for turbulent flows) computes both the Arrhenius rate and the mixing rate and uses the smaller of the two.

Eddy-Dissipation

(for turbulent flows) computes only the mixing rate (see [Equation 7–25](#) and [Equation 7–26](#) in the [Theory Guide](#)).

Eddy-Dissipation Concept

(for turbulent flows) models turbulence-chemistry interaction with detailed chemical mechanisms (see [Equation 7–25](#) and [Equation 7–26](#) in the [Theory Guide](#)).

Coal Calculator...

opens the [Coal Calculator Dialog Box \(p. 1826\)](#).

Options

contains parameters related to the Laminar Finite-Rate or the Eddy-Dissipation Concept model. This section of the dialog box will appear when **Laminar Finite-Rate** or the **Eddy-Dissipation Concept** is selected for **Turbulence-Chemistry Interaction**.

Flow Iterations Per Chemistry Update

specifies how often ANSYS FLUENT will update the chemistry during the calculation. Increasing the number can reduce the computational expense of the chemistry calculations.

Aggressiveness Factor

is a numerical factor which controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 (the default) is the most robust, but results in the slowest convergence.

Volume Fraction Constant

specifies the value of C_ζ in [Equation 7–28](#) in the [Theory Guide](#).

Time Scale Constant

specifies the value of C_τ in [Equation 7–29](#) in the [Theory Guide](#).

Number of Grid Points in Flame

by default are 8 grid points.

PDF Options

contains options related for the non-premixed combustion model. (This section will appear only if **Non-Premixed Combustion** or **Partially-Premixed Combustion** is the selected **Model**.)

Inlet Diffusion

includes the diffusion flux of species at inlet.

Compressibility Effects

can be enabled to account for cases where substantial pressure changes occur in time and/or space when modeling a non-adiabatic system. See [Specifying the Operating Pressure for the System \(p. 907\)](#) for details.

Liquid Micro-Mixing

is used to model liquid reactions. When the **Liquid Micro-Mixing** model is invoked, ANSYS FLUENT uses the **volume-weighted-mixing-law** formula to calculate the density.

Chemistry

tab contains the parameters to define problems using the chemistry model. See [Setting Up the Equilibrium Chemistry Model \(p. 905\)](#) for details.

State Relation**Equilibrium**

enables the equilibrium chemistry model. See [Setting Up the Equilibrium Chemistry Model \(p. 905\)](#) for details.

Steady Flamelet

enables the steady laminar flamelet model. See [The Laminar Flamelet Models Theory](#) in the [Theory Guide](#) for details.

Unsteady Flamelet

enables the Eulerian unsteady laminar flamelet model.

Diesel Unsteady Flamelet

enables the diesel unsteady laminar flamelet model. See [Using the Diesel Unsteady Laminar Flamelet Model \(p. 913\)](#) for details.

Energy Treatment**Adiabatic**

enables adiabatic modeling options for the problem.

Non-Adiabatic

enables nonadiabatic modeling options for the problem. See [Non-Adiabatic Extensions of the Non-Premixed Model](#) in the [Theory Guide](#) for details.

Coal Calculator

opens the [Coal Calculator Dialog Box \(p. 1826\)](#).

Stream Options

contains the parameters for the equilibrium chemistry model or the steady laminar flamelet model.

Secondary Stream

includes the secondary inlet stream in the model.

Empirical Fuel Stream

enables parameters to define fuel stream empirically. This option is available only with the full equilibrium chemistry model.

Empirical Secondary Stream

enables parameters to define secondary stream empirically. This option is available only with the full equilibrium chemistry model.

Model Settings

contains a list of parameter settings.

Operating Pressure

specifies the system operating pressure used to calculate the density using the ideal gas law. See [Specifying the Operating Pressure for the System \(p. 907\)](#) for details.

Fuel Stream Rich Flammability Limit

specifies the rich flammability limit for fuel stream when the equilibrium chemistry option is used. You will not set these if you have used the empirical definition option for fuel composition. See [Enabling the Rich Flammability Limit \(RFL\) Option \(p. 909\)](#) for details.

Secondary Stream Flammability Limit

specifies the rich flammability limit for secondary stream when the equilibrium chemistry option is used. You will not set these if you have used the empirical definition option for fuel composition. See [Enabling the Rich Flammability Limit \(RFL\) Option \(p. 909\)](#) for details.

Empirical Fuel Lower Calorific Value

specifies the lower calorific value of fuel stream.

Empirical Fuel Specific Heat

specifies the specific heat value of fuel stream.

Empirical Fuel Molecular Weight

specifies the molecular weight of the fuel stream.

Empirical Secondary Lower Calorific Value

specifies the lower calorific value of secondary stream.

Empirical Secondary Specific Heat

specifies the specific heat value of secondary stream.

Empirical Secondary Molecular Weight

specifies the molecular weight of the secondary stream.

Options

contains options related to the steady flamelet model.

Create Flamelet

enables the **Import CHEMKIN Mechanism...** button that opens the [CHEMKIN Mechanism Import Dialog Box \(p. 2213\)](#) where you can import the **CHEMKIN** mechanism and thermodynamic data, to create a flamelet file. This option is available for the steady flamelet model. See [Setting Up the Steady and Unsteady Laminar Flamelet Models \(p. 909\)](#) for details.

Import Flamelet

enables the **Import Flamelet File...** button that opens the [The Select File Dialog Box \(p. 33\)](#) where you can select the existing flamelet in ANSYS FLUENT. You can also set the file type parameters to import the existing flamelet in ANSYS FLUENT. See [Setting Up the Steady and Unsteady Laminar Flamelet Models \(p. 909\)](#) for details. This option is available for the steady flamelet model.

File Type

contains the toggle buttons for two flamelet file types.

Standard

enables the import of an ASCII format standard flamelet file.

Oppdif

enables the import of a binary format OPPDIF flamelet file.

CFX-RIF

enables the import of an ASCII format CFX-RIF flamelet file.

Mixture Fraction Method

contains the three methods of computing the mixture fraction profile along the laminar flamelet.

Drake

calculates the mixture fraction using carbon and hydrogen elements.

Bilger

calculates the mixture fraction using hydrocarbon formula.

Nitrogen

calculates the mixture fraction in terms of nitrogen species.

Oppdif Flamelet Type

gives you have a choice of importing **Single** or **Multiple** OPPDIF files.

Flamelet Property File Name

opens the [The Select File Dialog Box \(p. 33\)](#) in which you can save the existing flamelet in ANSYS FLUENT to use when running an existing case.

Thermodynamic Database File Name

specifies a path for the thermodynamic database file to be read.

Boundary

tab contains the list of boundary species and related parameters. This is available only for equilibrium chemistry model. See [Defining the Stream Compositions \(p. 913\)](#) for details.

Species

contains the list of the species used in the problem.

Fuel

specifies the fuel species.

Oxid

specifies the oxidizing species.

Second

specifies the secondary species.

Boundary Species

allows to specify the species you want to add or remove from the model. You can type the species chemical formula in the text box below it.

Add

adds the species in the model.

Remove

removes the species from the model.

List Available Species

prints a list of all species in the thermodynamic database file (thermo.db) in the console window.

Temperature

specifies the temperature of different streams that you have defined.

Fuel

is the temperature of the fuel inlet in the model.

Oxid

is the temperature of the oxidizer inlet in the model.

Second

is the temperature of the secondary stream inlet in the model.

Specify Species in

allows to define the unit of species concentration.

Mass Fraction

allows to specify the species in terms of mass fraction.

Mole Fraction

allows to specify the species in terms of mole fraction.

Control

tab contains the parameters for exclusion and inclusion of equilibrium species. This is available only for equilibrium chemistry model. See [Forcing the Exclusion and Inclusion of Equilibrium Species \(p. 924\)](#) for details.

Species Excluded from Equilibrium

lists the species excluded from equilibrium calculation.

Species

lists the slow-forming species that are zeroed in the initial flamelet profile.

Add

allows to add equilibrium species.

Remove

allows to remove equilibrium species.

List Available Species

prints a list of all species in the thermodynamic database file in the console window.

Flamelet Controls

allows you to adjust the controls for the flamelet solution. Note that the **Create Flamelet** option in the **Chemistry** tab must be selected for the **Steady Flamelet** model for these controls to be available.

Initial Fourier Number

sets the first time step for the solution.

Fourier Number Multiplier

increases the time step at subsequent times. Every time step after the first is multiplied by this value.

Relative Error Tolerance and Absolute Error Tolerance

specifies the local error controls during numerical integration.

Flamelet Convergence Tolerance

specifies the maximum absolute change in species fraction or temperature at any discrete mixture-fraction.

Maximum Integration Time

specifies the maximum total elapsed time for flamelet calculation. ANSYS FLUENT will stop the flamelet calculation after the total elapsed time has exceeded this value.

Flamelet

tab allows you to adjust the controls for the flamelet solution. See [Defining the Flamelet Controls \(p. 925\)](#) for details.

Flamelet Parameters

consist of the controls for the flamelet solution.

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f = 0$) and the fuel ($f = 1$).

Maximum Number of Flamelets

specifies the maximum number of laminar flamelet profiles to be calculated.

Initial Scalar Dissipation

is the scalar dissipation of the first flamelet in the library.

Scalar Dissipation Step

specifies the interval between scalar dissipation values (in s^{-1}) for which multiple flamelets will be calculated.

Unsteady Flamelet Parameters

consist of the controls for the unsteady flamelet solution.

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f = 0$) and the fuel ($f = 1$).

Mixture Fraction Lower Limit for Initial Probability

is the limit at which the unsteady flamelet model temporally convects and diffuses a marker probability equation through a steady-state ANSYS FLUENT flow-field.

Maximum Scalar Dissipation

is where flamelets extinguish at large scalar dissipation (mixing) rates.

Courant Number

is the number at which ANSYS FLUENT automatically selects the time step for the probability equation based on this convective Courant number.

Calculate Flamelets

begins the laminar flamelet calculation.

Display Flamelets...

opens the [Flamelet 3D Surfaces Dialog Box \(p. 1830\)](#) from which you can display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation.

Initialize Unsteady Flamelet Probability

initializes the unsteady flamelet and its probability marker equation.

Display Unsteady Flamelet...

opens the [Flamelet 2D Curves Dialog Box \(p. 1832\)](#) from which you can display 2D plots of the different variables.

Table

tab contains parameters to create the look-up table. See [Calculating the Look-Up Tables \(p. 933\)](#) for details of the items listed below.

Table Parameters

consist of the controls for the lookup table.

Number of Mean Mixture Fraction Points

is the number of discrete values of \bar{f} at which the look-up tables will be computed.

Number of Secondary Mixture Fraction Points

is the number of discrete values of p_{sec} at which the look-up tables will be computed. This option is available only when a secondary stream has been defined.

Number of Mixture Fraction Variance Points

is the number of discrete values of $\overline{f^2}$ at which the look-up tables will be computed. This option is available only when no secondary stream has been defined.

Maximum Number of Species

is the maximum number of species that will be included in the look-up tables.

Number of Mean Enthalpy Points

is the number of discrete values of enthalpy at which the three-dimensional look-up tables will be computed. This input is required only if you are modeling a non-adiabatic system.

Minimum Temperature

is used to determine the lowest temperature for which the look-up tables are generated (see [Figure 8.10: "Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems"](#) in the [Theory Guide](#)). This option is available only if you are modeling a non-adiabatic system.

Include Equilibrium Flamelet

specifies that an equilibrium flamelet (i.e., $\chi = 0$) will be generated in ANSYS FLUENT and appended to the flamelet library before the PDF table is calculated. This option is available only when you are generating more than one laminar flamelet.

Calculate PDF Table

generates the look-up table.

Display PDF Table

opens the [PDF Table Dialog Box](#) (p. 2303) where you can display 2D plots and 3D surfaces showing the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy.

Premixed

tab contains parameters needed to modify the piecewise-linear points. See [Modifying the Unburnt Mixture Property Polynomials](#) (p. 972) for the details.

Partially Premixed Mixture Properties

contains the list of properties that you can modify. **Edit...** opens the [Quadratic Mixture Fraction](#) dialog box where you can modify the values of the polynomial coefficients.

For each polynomial function of \bar{f} under **Partially Premixed Mixture Properties** you can click **Edit...** and specify values for **Coefficient 1**, **Coefficient 2**, **Coefficient 3**, and **Coefficient 4** in the appropriate [Quadratic of Mixture Fraction](#) dialog box.

Non-Adiabatic Laminar Flame Speed

when enabled includes the non-adiabatic effects on the laminar flame speed by tabulating the laminar speeds in the PDF table. See [Laminar Flame Speed](#) in the [Theory Guide](#).

Recalculate Properties

will calculate the partially premixed properties.

Premixed Combustion Model Options

contains options for the premixed combustion model. (This section will appear only if **Premixed Combustion** is the selected **Model**.)

Adiabatic

enables the adiabatic premixed combustion model, which calculates temperature using [Equation 9–64](#) in the [Theory Guide](#).

Non-Adiabatic

enables the non-adiabatic premixed combustion model, which calculates temperature using [Equation 9–65](#) in the [Theory Guide](#).

Premixed Model

contains options for choosing a premixed model.

C Equation

allows you to choose the C equation as described in [C-Equation Model Theory](#).

Extended Coherent Flamelet Model

allows you to choose the Extended Coherent Flamelet model as described in [Extended Coherent Flamelet Model Theory](#).

G Equation

allows you to choose the G equation as described in [G-Equation Model Theory](#).

Turbulent Flame Speed Model

contains the **Flame Speed Model** drop-down list, which allows you to choose between the **zimont** or the **peters** model constants for the Zimont premixed combustion model. (This section will appear only if **Premixed Combustion** or **Partially Premixed Combustion** is the selected **Model** and if the **C Equation** or **G Equation** premixed model is chosen.)

Turbulent Length Scale Constant

specifies the value of C_D in [Equation 9–11](#) in the Theory Guide.

Turbulent Flame Speed Constant

specifies the value of A in [Equation 9–9](#) in the Theory Guide.

Stretch Factor Coefficient

specifies the value of μ_{str} in [Equation 9–16](#) in the Theory Guide.

Turbulent Schmidt Number

specifies the value of Sc_t in [Equation 9–1](#) in the Theory Guide.

Wall Damping Coefficient

specifies the value of α_w in [Equation 9–19](#).

Ewald Corrector

is enabled by default and described in [Peters Flame Speed Model](#).

G Equation Settings

allows you to select either the **transport equation** or **algebraic** option for the calculation of the flame distance variance. Consult [Peters Flame Speed Model](#) in the Theory guide for the variance transport and algebraic equation expressions ([Equation 9–6](#) and [Equation 9–7](#)).

Flame Curvature Source

includes the curvature source term in the G-Equation, which is the last term in [Equation 9–4](#).

Extended Coherent Flamelet Model Constants

contains model constants for the Extended Coherent Flame Model. (This section will appear only if **Premixed Combustion** or **Partially Premixed Combustion** is the selected **Model** and if the **Extended Coherent Flame Model** flame speed model is chosen.) See [Modifying the Constants for the ECFM Flame Speed Closure](#) (p. 964) for details.

ITNFS Treatment

contains a drop-down list of the available ITNFS treatments: **constant-delta**, **meneveau**, **blint**, **poinsot**, and **constant**.

ITNFS Flame Thickness

sets the flame thickness ([Equation 9–28](#) in the Theory Guide).

Turbulent Schmidt Number

set the turbulent Schmidt number (Sc_t).

Wall Flux Coefficient

set the wall flux coefficient.

PDF Transport Options

contains options for the Composition PDF Transport combustion model. (This section will appear only if **Composition PDF Transport** is the selected **Model**.)

Lagrangian

solves the composition PDF transport equation by stochastically tracking Lagrangian particles through the domain.

Eulerian

assumes a shape for the PDF, allowing Eulerian transport equations to be derived.

Mixing

tab contains the mixing models.

Mixing Model

contains options to specify the method for modeling molecular diffusion. (This section will appear only if **Composition PDF Transport** is the selected **Model**.) See [Particle Mixing](#) in the [Theory Guide](#) for details.

Modified Curl

enables the modified curl model for molecular diffusion.

IEM

enables the IEM model for molecular diffusion.

EMST

enables the EMST mixing model for molecular diffusion.

Mixing Constant

specifies the value of the mixing constant C_ϕ in [Equation 11–6](#) and [Equation 11–8](#) in the [Theory Guide](#).

Boundary

tab allows you to define the fuel and oxidizer compositions. This is only available if you select **Eulerian** as the **PDF Transport Option**.

Species

consists of the fuel species and the oxidizer.

Fuel

is the mole or mass fraction of the fuel stream. The sum of mass or mole fractions of all species in the fuel stream should be 1.

Oxidizer

is the mole or mass fraction of the oxidizer stream. The sum of mass or mole fractions of all species in the fuel oxidizer stream should be 1.

Specify Species in

specifies the species as a **Mass Fraction** or **Mole Fraction**.

Control

tab contains Lagrangian PDF transport parameters.

PDF Transport Parameters

allows you to set the **Particles Per Cell**.

Particles Per Cell

sets the number of PDF particles per cell. Higher values of this parameter will reduce statistical error, but increase computational time.

Local Time Stepping

toggles the calculation of local time steps. If this option is disabled, then you will need to specify the **Time Step** directly (see [Equation 11–4](#) in the [Theory Guide](#)). This option is available for steady-state simulations.

Convection #

specifies the particle convection number (see Δt_{conv} in Equation 11–4 in the Theory Guide).

Diffusion #

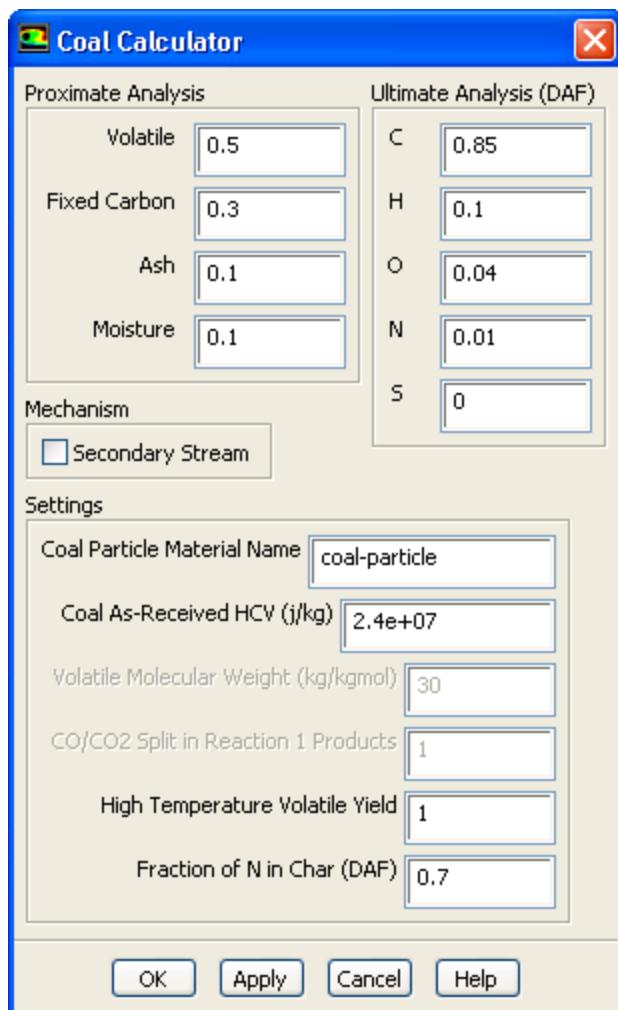

specifies the particle diffusion number (see Δt_{diff} in Equation 11–4 in the Theory Guide).

Mixing #

specifies the particle mixing number (see Δt_{mix} in Equation 11–4 in the Theory Guide).

36.3.19. Coal Calculator Dialog Box

The **Coal Calculator** dialog box automates the calculations described in *Additional Coal Modeling Inputs in ANSYS FLUENT* (p. 921).

**Proximate Analysis**

is the mass fraction of **Volatile**, **Fixed Carbon**, **Ash**, and **Moisture** in the coal.

Volatile

is the fraction of the volatile component.

Fixed Carbon

is calculated as one minus the sum of the actual **Volatile**, **Ash**, and **Moisture** fractions.

Ash

is the fraction of ash.

Moisture

is the moisture fraction in the coal.

Ultimate Analysis (DAF)

is the mass fraction of atomic **C, H, O, N** and optionally **S**, in the Dry-Ash-Free (DAF) coal.

Mechanism

allows you to set the mechanisms.

Secondary Stream

when enabled, allows you to set the two mixture fraction model with the primary stream representing char as $C < s >$, and an empirical secondary stream representing the volatiles. This is available when using the non-premixed combustion model.

One-step Reaction

is defined in *Equation 16–6 (p. 877)*.

Two-step Reaction

involves oxidation of volatiles to CO in the first reaction and oxidation of CO to CO_2 in the second reaction, as described in *Equation 16–7 (p. 877)*.

Include SO₂

when enabled, allows you to input the atomic mass fraction of sulphur, **S**, which appears under **Ultimate Analysis**.

Options**Wet Combustion**

when enabled will activate the DPM **Wet Combustion** option by default in all injections created after the **OK** button is clicked in the **Coal Calculator** dialog box.

Settings

is where you will specify the values used in the calculation.

Coal Particle Material Name

is the name of the DPM combusting particle material. The default name is *coal-particle*.

Coal As-Received HCV

is the higher caloric value of the coal.

Volatile Molecular Weight

is the molecular weight of pure volatiles.

CO/CO₂ Split in Reaction 1 Products

can be used to specify the molar fraction of CO to CO_2 in the first reaction of *Equation 16–7 (p. 877)*. The default value of 1 implies that all carbon is reacted to CO , with no CO_2 produced.

High Temperature Volatile Yield

is where the enhanced devolatilization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction.

Fraction of N in Char (DAF)

is used in calculating the split of atomic nitrogen for the Fuel NOx model.

Coal Dry Density

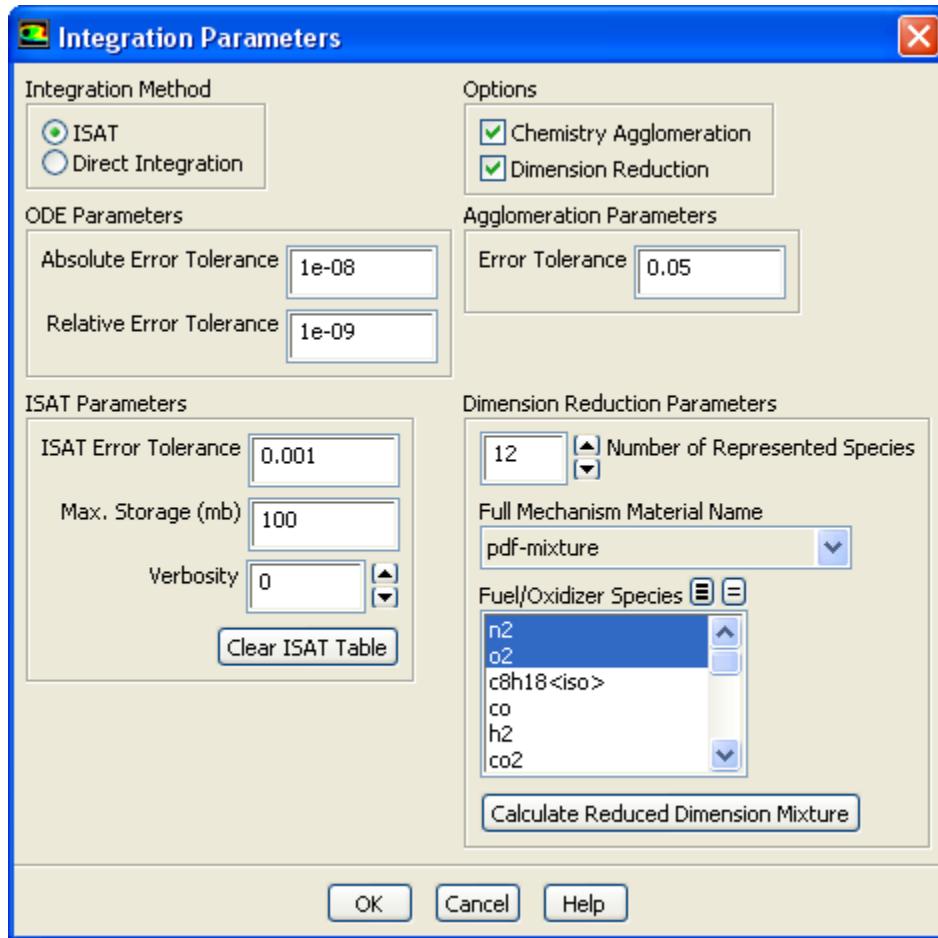

is used to calculate the **Volume Fraction** of liquid-water for the **Wet Combustion** option in the **Injections** dialog box.

Gas Phase Reaction

lists the reaction based on your entries for the proximate and ultimate analyses.

36.3.20. Integration Parameters Dialog Box

The **Integration Parameters** dialog box allows you to set the parameters for the integration of the chemical source term S in Equation 11–10 in the Theory Guide. See [Using ISAT \(p. 988\)](#) for details.

Integration Method

contains options to choose the method for integration.

ISAT

enables the ISAT option and expands the dialog box to include inputs for ISAT parameters.

Direct Integration

enables the direct integration method to integrate the chemical source term in the calculation.

ODE Parameters

contains options to specify the error tolerances.

Absolute Error Tolerance

specifies the absolute error tolerance.

Relative Error Tolerance

specifies the relative error tolerance.

ISAT parameters

contains inputs required for ISAT integration method.

ISAT Error Tolerance

controls the numerical error in ISAT liner interpolation. Decrease this value to get accurate minor species and pollutant predictions.

Max. Storage

is the maximum RAM used by the ISAT table, and has a default value is 100 MB.

Verbosity

specifies the level of detail at which you can monitor the ISAT performance.

Clear ISAT Table

purges the ISAT table.

Options

contains options to choose the method for chemistry acceleration.

Chemistry Agglomeration

when enabled, provides additional run-time improvement, with a corresponding decrease in accuracy.

Dimension Reduction

is a chemistry acceleration method in addition to ISAT storage-retrieval and Cell Agglomeration, providing faster chemistry calculations with a corresponding loss of accuracy.

Agglomeration Parameters

allows you to specify the **Error Tolerance**. This determines the size of the clusters and by default the value is 0.05

Dimension Reduction Parameters

contains settings to accelerate the chemistry.

Number of Represented Species

must be greater than 10 and less than the number of species in the full mechanism. The **Number of Represented Species** must also be less than 50 minus the number of unrepresented elements (the number of chemical elements in the unrepresented species).

Full Mechanism Material Name

is typically the name of the CHEMKIN mechanism that you imported.

Fuel/Oxidizer Species

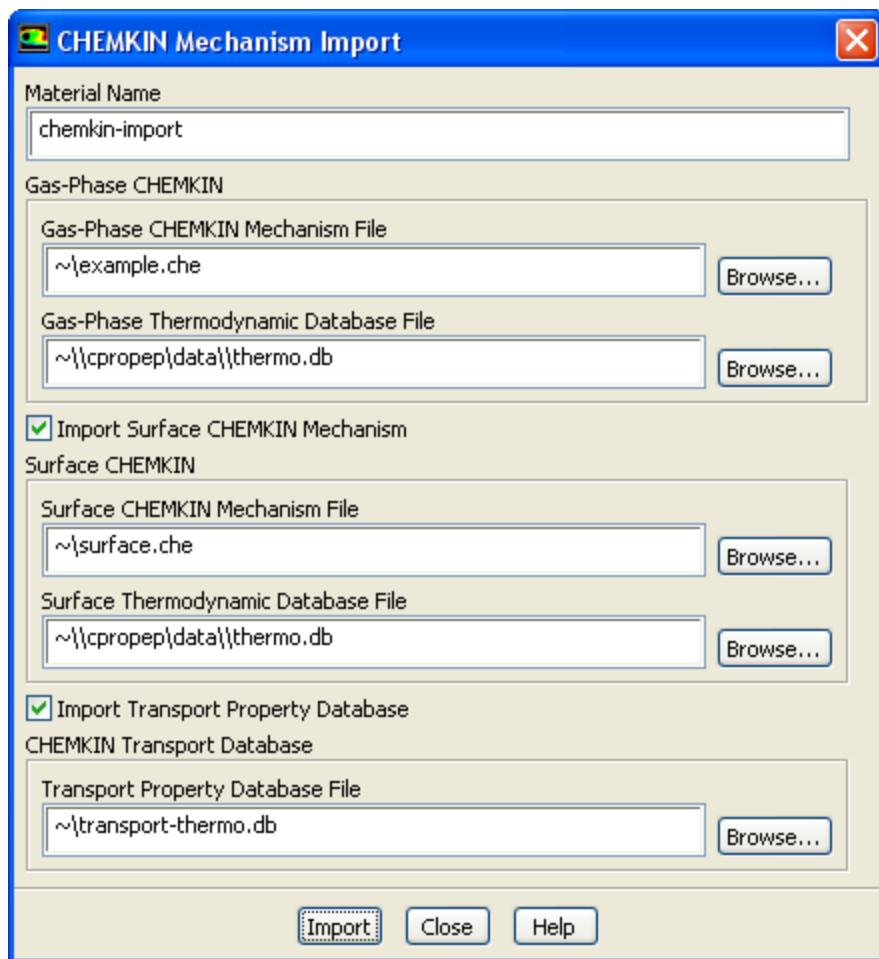

is where the boundary and initial fuel and oxidizer, as well as product species, are set as represented species.

Create Reduced Dimension Mixture

creates a new mixture material called `reduced-dimension-mixture`, which contains the represented species as well as proxy 'species' for the unrepresented elements.

36.3.21. Chemkin Mechanism Import Dialog Box

The **Chemkin Mechanism Import** dialog box allows you to read the chemical kinetic mechanism and thermodynamic data. See [Setting Up the Steady and Unsteady Laminar Flamelet Models \(p. 909\)](#) for details on the items listed below.

Gas-Phase CHEMKIN

contains parameters to import the gas phase chemkin mechanism.

Gas-Phase CHEMKIN Mechanism File

specifies the path of the Chemkin file to be read.

Gas-Phase Thermodynamic Database File

specifies the location of the thermodynamic database.

Import Surface Chemkin Mechanism

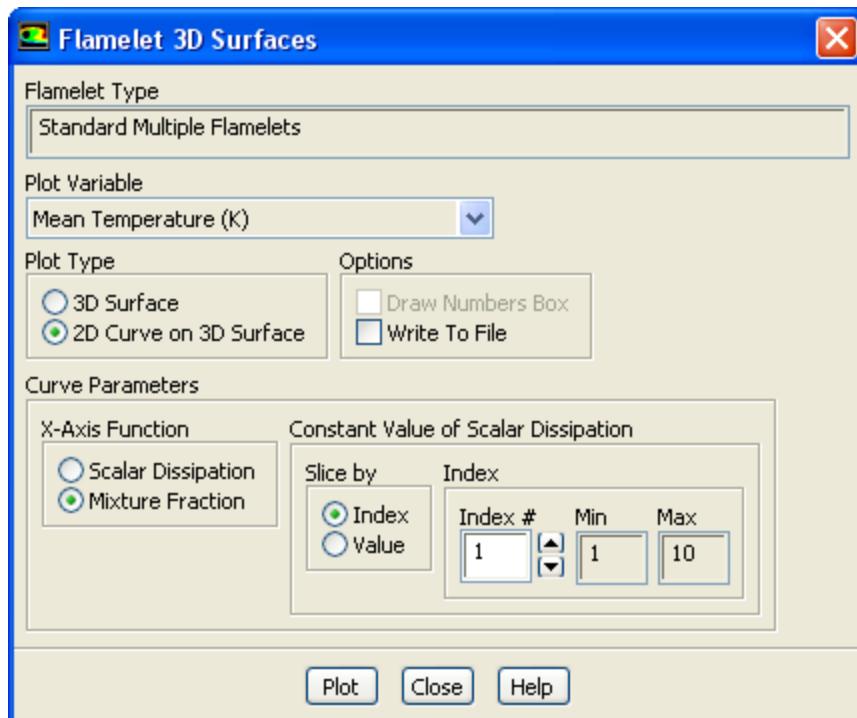

enables parameters to import the surface chemkin mechanism.

Import Transport Property Databases

(optional) allows to import transport properties.

36.3.22. Flamelet 3D Surfaces Dialog Box

The **Flamelet 3D Surfaces** dialog box allows you to display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation. See [Postprocessing the Flamelet Data \(p. 931\)](#) for details.

Flamelet Type

indicates the type of flamelets whose surfaces will be displayed.

Plot Variable

enables you to choose temperature or species fraction as the variable to be plotted.

Plot Type

consists of options for plot type.

3D Surface

enables plotting on 3D surfaces.

2D curve on 3D surface

enables plotting of a 2D curve on a 3D surface.

Options

consists of the following parameters:

Draw Numbers Box

enables the display of a wireframe box with the numerical limits in each coordinate direction.

Write To File

enables saving the plot data to a file.

Curve Parameters

consists of controls related to plot display.

X-Axis Function

consists of the function against which the plot variable will be displayed.

Scalar Dissipation

enables display of plot variable against the scalar dissipation function.

Mixture Fraction

enables display of plot variable against the mixture fraction.

Constant Value of Scalar Dissipation

consists of the controls to specify the type of discretization (i.e., how the flamelet data will be sliced) for the variable that is being held constant.

Slice by

consists of the controls to specify discretization.

Index

enables you to specify discretization index of the variable that is being held constant.

Value

enables you to specify the numerical value of the variable that is being held constant.

Index

consists of the controls that are displayed when you enable **Index** under **Slice by**.

Index #

displays the index number.

Min

displays the minimum of the range of integer values that you are allowed to choose from.

Max

displays the maximum of the range of integer values that you are allowed to choose from.

Value

consists of the controls that are displayed when you enable **Value** under **Slice by**.

Value

enables you to enter the numerical value of the variable that is being held constant.

Min

displays the minimum of the range of integer values that you are allowed to choose from.

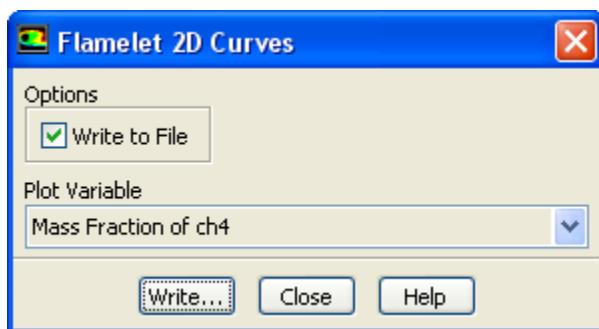

Max

displays the maximum of the range of integer values that you are allowed to choose from.

36.3.23. Flamelet 2D Curves Dialog Box

The **Flamelet 2D Curves** dialog box allows you to display or write 2D curves of the unsteady flamelet.

See [Postprocessing the Flamelet Data \(p. 931\)](#) for details.

**Options**

gives you the option to plot or **Write to File** 2D curves.

Plot Variable

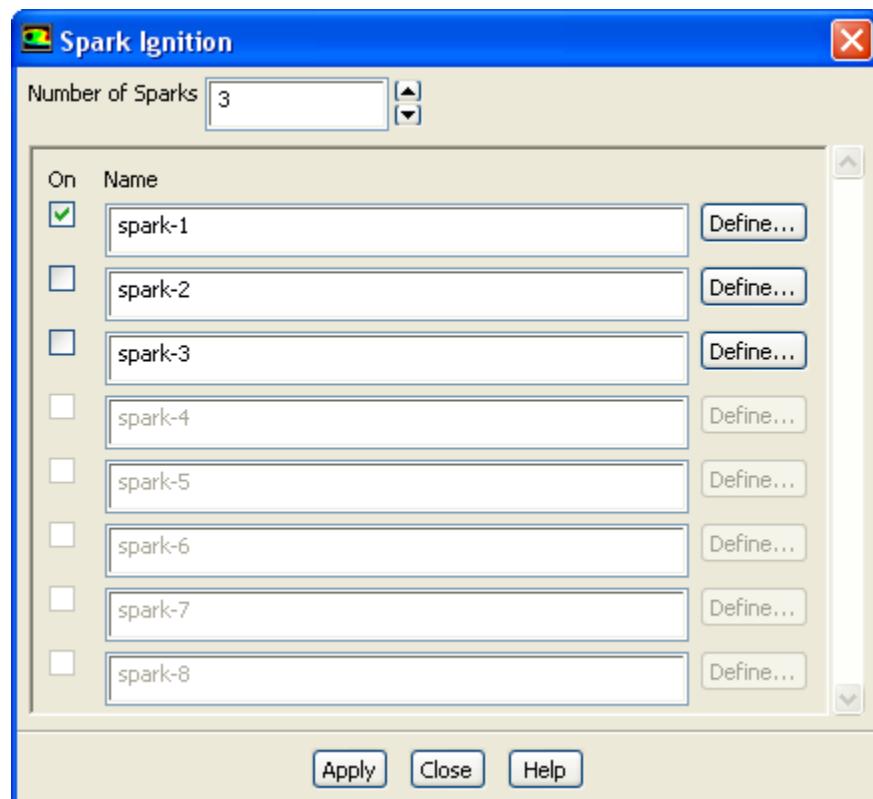

consists of a drop-down list of variables that you can plot or write.

Plot

is available by default. When the **Write to File** option is enabled the **Plot** button changes to a **Write....**

36.3.24. Spark Ignition Dialog Box

The **Spark Ignition** dialog box allows you to define multiple sparks (see [Spark Model \(p. 995\)](#) for details).

Controls

Number of Sparks

is the quantity of sparks you would like to include in your simulation. You can define up to 16 sparks.

On

if enabled, activates those sparks that will be included in the simulation.

Name

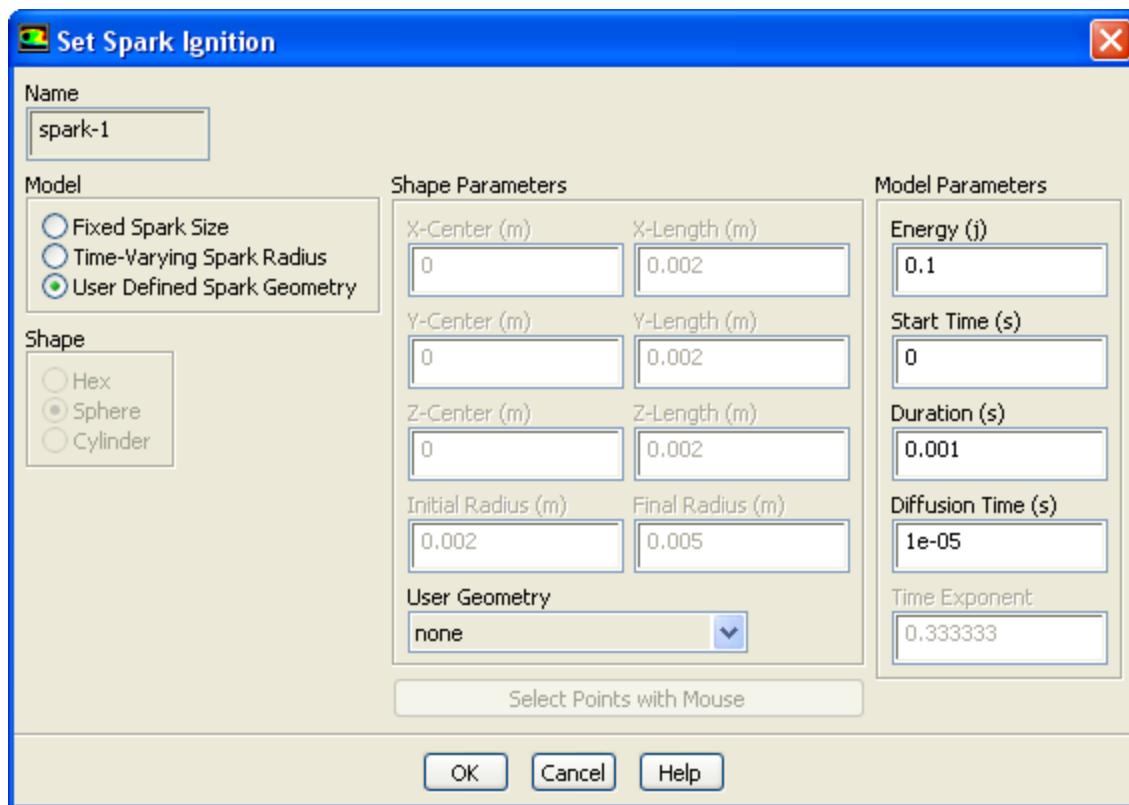

is the name of the spark. You can specify a name, or use the default name.

Define...

opens the [Set Spark Ignition Dialog Box \(p. 1833\)](#).

36.3.25. Set Spark Ignition Dialog Box

The **Set Spark Ignition** dialog box allows you to set the parameters related to the spark ignition model (see [Spark Model \(p. 995\)](#) for details).

Controls

Name

displays the name of the spark being defined.

Model

contains the available spark ignition models.

Fixed Spark Size

enables the spark ignition calculations using the fixed spark size model.

Time-Varying Spark Radius

enables the spark ignition calculations using the time varying spark radius.

User Defined Spark Geometry

allows you to hook a user-defined function to define custom spark kernel volume shapes.

Shape

contains the different shapes of the spark. This option is available only for **Fixed Spark Size** model

Hex

enables hex shape spark.

Sphere

enables spherical shape spark.

Cylinder

enables cylindrical shape spark.

ECFM Spark Model

contains model variants used to define the value of the flame surface density. These models appear only when the **Extended Coherent Flamelet Model** ([Setting Up the Extended Coherent Flame Model \(p. 964\)](#)) is selected in the **Species Model** dialog box.

Boudier

is available only as a time dependent kernel geometry. The geometric growth rate is the same as that used for the basic spark model with other combustion models. See [Boudier Model](#).

Teraji

is available only as a time dependent kernel geometry. See [Teraji Model](#).

Zimont

operates in the same way as the spark model used with the Zimont combustion model. The geometry of the spark may be time dependent or fixed. See [Zimont Model](#).

Constant Value

allows you to specify the **Flame Surface Density**. See for details [Constant Value Model](#)

User Defined Sigma Source

allows you to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel.

Shape Parameters

contains the parameters needed to define the shape and size of the spark.

X, Y, and Z-Center

specifies the points in x, y, and z direction.

X, Y, and Z-Length

specifies the length in x, y, and z direction.

Initial Radius

specifies the initial spark radius.

Final Radius

specifies the final spark radius.

User Geometry

allows you to hook a user-defined function to define custom spark kernel volume shapes. For details about this user-defined function, please refer to [DEFINE_SPARK_GEOM](#) in the [UDF Manual](#).

Model Parameters

contains the parameters needed to define the spark.

Energy

contains the total energy input by the spark.

Start Time

is the time of spark ignition initialization.

Duration

is the duration of the spark ignition.

Diffusion Time

is the spark diffusion time in seconds.

Time Exponent

is the time exponent specified when the **Time-Varying Spark Radius** is used.

Flame Surface Density

is defined by [Equation 13–5](#), when the extended coherent flamelet (ECFM) combustion model is used. The value of the flame surface density must be set within the spark region and can be specified when **Constant Value** is selected under [ECFM Spark Model](#).

User Sigma Source

allows you to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, please refer to [Hooking](#)

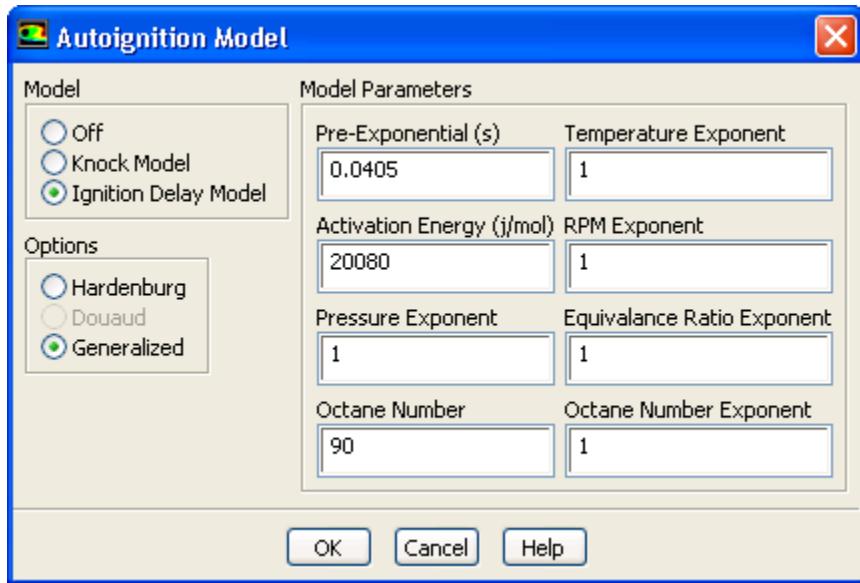

[DEFINE_ECFM_SPARK_SOURCE UDFs](#) of the [UDF Manual](#). This selection is available when **User Defined Sigma Source** is enabled under **ECFM Spark Model**.

Select Points with Mouse

allows to select the shape parameters of the spherical spark using mouse.

36.3.26. Autoignition Model Dialog Box

The **Autoignition Model** dialog box allows you to set the parameters related to the **Knock Model** or the **Ignition Delay Model**. See [Modeling Engine Ignition \(p. 995\)](#) for details.

Controls

Model

contains options to disable or enable models.

Off

disables the model.

Knock Model

enables the knock model. With the **Premixed Combustion** or **Partially Premixed Combustion** models selected, only the **Knock Model** can be turned on.

Ignition Delay Model

enables the ignition delay model.

Options

contains two correlation options that exist with each model.

Douaud

option is used for knock in spark ignition engines. The modeling parameters that are specified in the GUI for this option are the **Pre Exponential**, **Pressure Exponent**, **Activation Temperature**, **Octane Number**, and **Octane Exponent** ([Equation 13–12](#) in the [Theory Guide](#)).

Generalized

enables generalized correlation described by [Equation 13–13](#) in the [Theory Guide](#). It requires the same parameters as in the ignition delay model.

Hardenburg

enables Hardenburg correlation, which is used for heavy-duty diesel engines. This option is activated only for the ignition delay model.

Model Parameters

contains parameters related to the selected model. See [Using the Autoignition Models \(p. 999\)](#) for the details about the parameters in this dialog box.

Pre-Exponential

see [Equation 13–13](#) and [Equation 13–12](#) in the [Theory Guide](#).

Activation Temperature

see [Equation 13–12](#) in the [Theory Guide](#).

Pressure Exponent

see [Equation 13–13](#) and [Equation 13–12](#) in the [Theory Guide](#).

Octane Number

see [Equation 13–13](#) and [Equation 13–12](#) in the [Theory Guide](#).

Octane Number Exponent

see [Equation 13–13](#) and [Equation 13–12](#) in the [Theory Guide](#).

Activation Energy

see [Equation 13–13](#) and [Equation 13–15](#) in the [Theory Guide](#).

Temperature Exponent

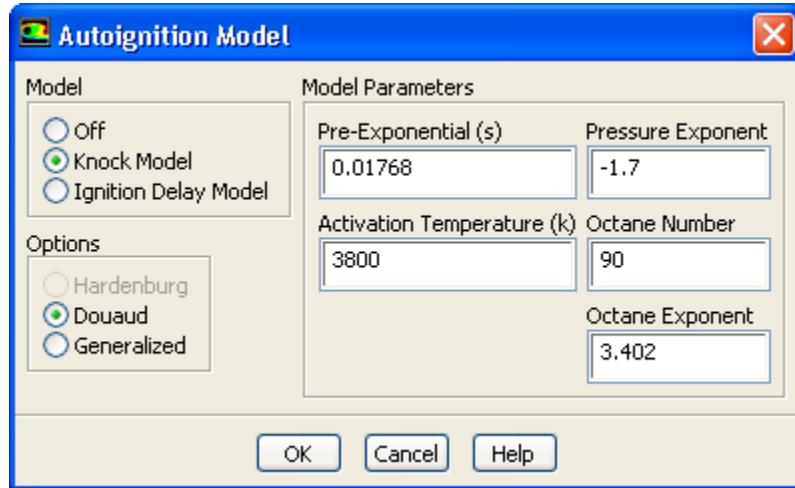

see [Equation 13–13](#) in the [Theory Guide](#).

RPM Exponent

see [Equation 13–13](#) in the [Theory Guide](#).

Equivalence Ratio Exponent

see [Equation 13–13](#) in the [Theory Guide](#).

**Options**

contains two correlation options that exist with this model.

Douaud

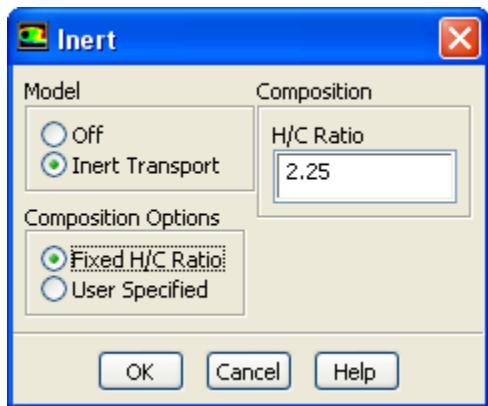

enables Douaud correlation ([Equation 13–12](#) in the [Theory Guide](#)) used for knock in SI engines.

Generalized

option ([Equation 13–13](#) in the [Theory Guide](#)) in the knock model require the same parameters as in the ignition delay model.

36.3.27. Inert Dialog Box

The **Inert** dialog box allows you to set the parameters related to the inert model. For details, see [Setting Up the Inert Model \(p. 943\)](#).

Controls

Model

allows you to enable or disable the inert model.

Off

disables the model.

Inert Transport

enables the inert model.

Composition Options

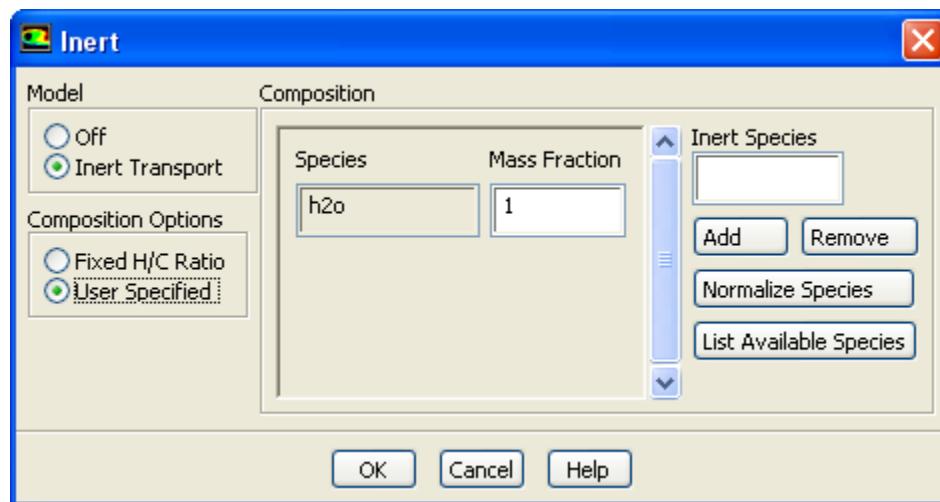

allows you to select a fixed H/C ratio or to specify the composition.

Fixed H/C Ratio

allows you to specify a fixed ratio of hydrogen to carbon in the **H/C Ratio** field.

User Specified

allows you to specify an arbitrary composition for the inert stream.

Composition

allows you to set the H/C ratio or the mass fraction.

When **Fixed H/C Ratio** is selected under **Composition Options**, the following option(s) are available:

H/C Ratio

specifies the fixed ratio of hydrogen to carbon when the **Fixed H/C Ratio** option is enabled.

When **User Specified** is selected under **Composition Options**, the following option(s) are available:

Species

lists the inert species name.

Mass Fraction

displays the mass fraction of the corresponding species.

Inert Species

allows you to specify the name of the inert species.

Add

adds the specified inert species to the species list.

Remove

removes the specified inert species from the species list.

Normalize Species

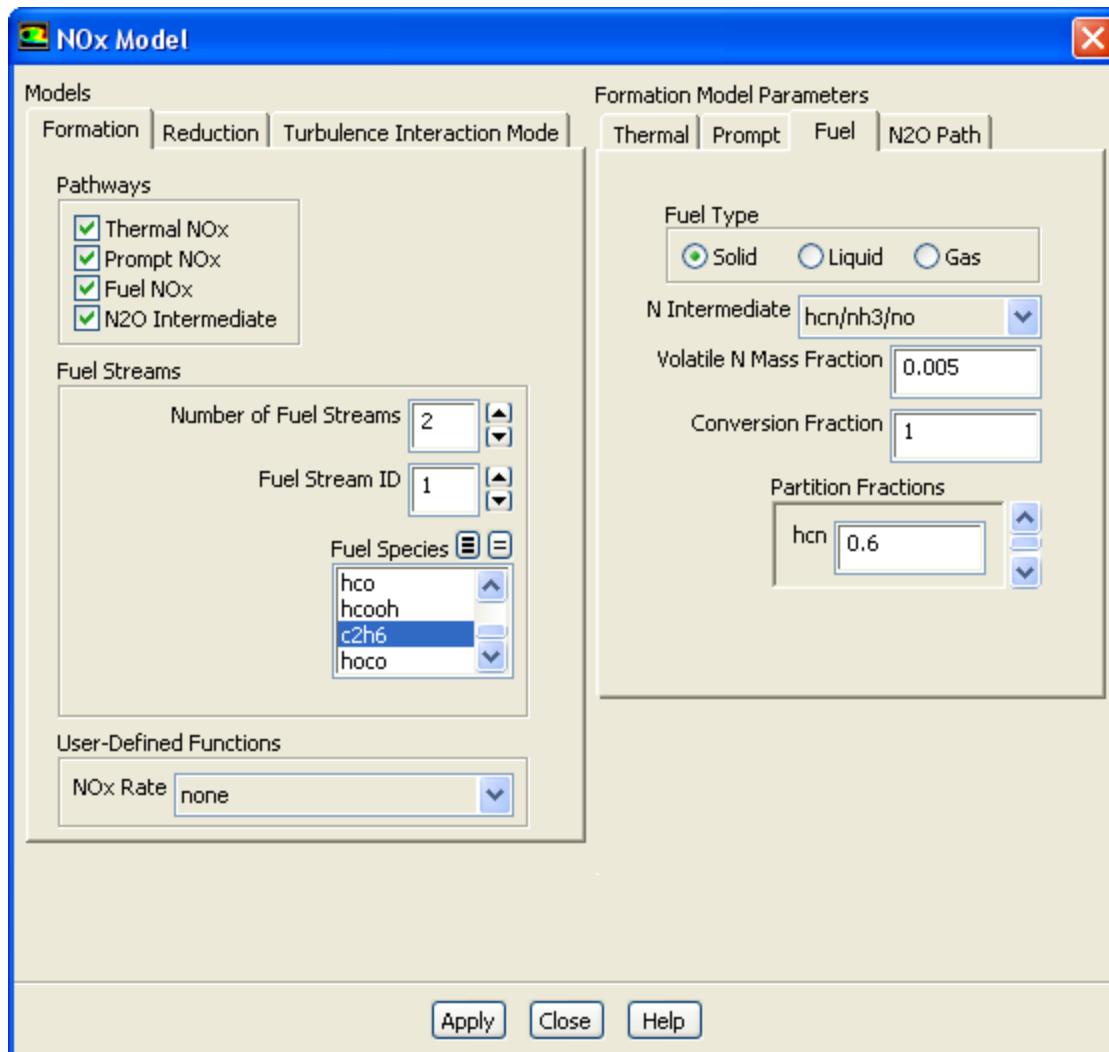

makes sure the species mass fractions add up to 1.

List Available Species

lists all species in the thermodynamic database file (`thermo.db`) in the console window,

36.3.28. NOx Model Dialog Box

The **NOx Model** dialog box allows you to set parameters related to the NOx postprocessor. See [Using the NOx Model \(p. 1009\)](#) for details about the items below.

Controls

Models

contains tabs for defining the models used to calculate the NOx production.

Formation

contains the parameters to define the NOx model formation.

Pathways

contains toggle buttons for activating the NOx models to be used for the calculation of NO and HCN concentrations.

Thermal NOx

enables calculation of thermal NOx.

Prompt NOx

enables the calculation of prompt NOx.

Fuel NOx

enables the calculation of fuel NOx. When using the non-premixed combustion model, the **Fuel NOx** option is only available if the DPM model is also enabled.

N2O Intermediate

enables the formation of NOx through an N₂O intermediate. This option will only appear if one of the previously listed NOx models is enabled.

Fuel Streams

allows you to define multiple fuel streams for prompt NOx and fuel NOx formation.

Number of Fuel Streams

sets the number of fuel streams. You are allowed up to three fuel streams.

Fuel Stream ID

specifies the fuel stream you are defining in the **PDF Stream** drop-down list, the **Fuel Species** selection list, the **Prompt** tab, and the **Fuel** tab.

PDF Stream

specifies the PDF stream species associated with a particular **Fuel Stream ID**, when calculating fuel NOx formation in conjunction with the non-premixed combustion model. You can select either the **primary** or **secondary** fuel streams, as defined in the PDF table.

Fuel Species

is a list containing all of the defined species, which allows you to specify the species that is the fuel associated with a particular **Fuel Stream ID**. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10. Note that when the non-premixed combustion model is enabled, your selection in the **Fuel Species** list only applies to prompt NOx calculations.

User-Defined Functions

contains the **NOx Rate** drop-down list, which allows you to use a user-defined function (UDF) to contribute to the rate of NOx production. See the separate [UDF Manual](#) for details. Note that you may also use a UDF to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

Reduction

allows you to specify the reduction methods.

Methods

contains the list of reduction methods.

Reburn

enables the calculation of NOx reburning effects.

SNCR

enables the calculation of NOx reduction by the SNCR method.

Turbulence Interaction Mode

contains parameters related to the effect of turbulent fluctuations on the NOx formation. See [NOx Formation in Turbulent Flows](#) in the [Theory Guide](#) for details.

PDF Mode

is a drop-down list containing options that take into account turbulent fluctuations when you compute the specified NOx formation. See [Setting Turbulence Parameters \(p. 1022\)](#) for details.

none

specifies the use of laminar NOx rate calculations, so that the effects of turbulence are ignored.

temperature

includes fluctuations of temperature.

temperature/species

includes fluctuations of the temperature and the mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction

includes fluctuations of the mixture fraction(s). This is available for non-premixed combustion calculations only.

PDF Type

allows you to specify the shape of the PDF.

beta

models the PDF using Equation 14–108 in the [Theory Guide](#).

gaussian

models the PDF using Equation 14–111 in the [Theory Guide](#).

PDF Points

controls the number of points at which the beta function in Equation 14–105 or Equation 14–106 in the [Theory Guide](#) will be integrated. The default value of 10, which indicates that the beta function will be integrated at 10 points on a histogram basis. The default value should yield an accurate solution with a reasonable computation time. Increasing this value may improve accuracy, but will also increase the computation time. This text box is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance

allows you to specify the form of the transport equation that is solved to calculate the temperature variance.

algebraic

is an approximate form of the transport equation (see Equation 14–114 in the [Theory Guide](#)).

transported

solves Equation 14–113 in the [Theory Guide](#).

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax

sets the limit as the maximum temperature in the flow field.

local-tmax-factor

yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

specified-tmax

sets the limit for each cell to be the value entered in **Tmax**.

user-defined

allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a UDF and selected it in the **Formation** tab.

Species

is a drop-down list which appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the NOx rate calculations.

Formation Model Parameters

contains the tabs used to define the NOx pathways.

Thermal

contains parameters for modeling thermal NOx. (The contents of this tab will appear only if **Thermal NOx** is enabled in the **Formation** tab.)

[O] Model

is a drop-down list in which you can select the method to be used for calculation of thermal NOx. To choose the equilibrium method, select **equilibrium**. To choose the partial equilibrium method, select **partial-equilibrium**. To choose the predicted O concentration method, select **instantaneous**. See [Method 1: Equilibrium Approach](#), [Method 2: Partial Equilibrium Approach](#), and [Method 3: Predicted O Approach](#) in the Theory Guide for details.

[OH] Model

is a drop-down list in which you can select the method to be used for calculation of thermal NOx. To exclude OH, select **none**. To choose the partial equilibrium method, select **partial-equilibrium**. To choose the predicted OH concentration method, select **instantaneous**. See [Method 1: Exclusion of OH Approach](#), [Method 2: Partial Equilibrium Approach](#), and [Method 3: Predicted OH Approach](#) in the Theory Guide for details.

UDF Rate

provides options for the treatment of the NOx production specified by the UDF selected in the **Formation** tab.

Replace FLUENT Rate

replaces ANSYS FLUENT's thermal NOx rate calculations with the custom NOx rate produced by your UDF.

Add to FLUENT Rate

adds the custom NOx rate produced by your UDF to ANSYS FLUENT's thermal NOx rate calculations.

Prompt

contains parameters for modeling prompt NOx. (The contents of this tab will appear only if **Prompt NOx** is enabled in the **Formation** tab.) The settings made in this tab will be associated with a particular fuel stream, specified in the **Fuel Stream ID** text box in the **Formation** tab.

Fuel Carbon Number

specifies the number of carbon atoms per fuel molecule.

Equivalence Ratio

is the ratio of the actual fuel/air ratio to the stoichiometric fuel/air ratio.

UDF Rate

provides options for the treatment of the NOx production specified by the UDF selected in the **Formation** tab.

Replace FLUENT Rate

replaces ANSYS FLUENT's prompt NOx rate calculations with the custom NOx rate produced by your UDF.

Add to FLUENT Rate

adds the custom NOx rate produced by your UDF to ANSYS FLUENT's prompt NOx rate calculations.

Fuel

contains parameters for modeling fuel NOx. (The contents of this tab will appear only if **Fuel NOx** is enabled in the **Formation** tab.) The settings made in this tab will be associated with a particular fuel stream, specified in the **Fuel Stream ID** text box in the **Formation** tab.

Fuel Type

specifies the type of fuel NOx to be calculated.

Solid

enables the calculation of solid fuel NOx.

Liquid

enables the calculation of liquid fuel NOx.

Gas

enables the calculation of gas fuel NOx.

N Intermediate

allows you to specify any one of the **hcn**, **nh3**, or **hcn/nh3/no** as the intermediate species. See [Fuel NOx Formation](#) in the [Theory Guide](#) for details.

Volatile N Mass Fraction

specifies the mass fraction of nitrogen in the volatiles. This parameter appears only for **Solid** fuel NOx calculations.

Fuel N Mass Fraction

specifies the mass fraction of nitrogen in the fuel. This parameter appears only for **Gas** or **Liquid** fuel NOx calculations.

Conversion Fraction

specifies the overall mass fraction of fuel N (for gas and liquid fuels), or volatile N or char N (for solid fuels), that will be converted to intermediate species and/or product NO.

Partition Fractions

specifies the mass fraction of the converted fuel N (for gas and liquid fuels), or volatile N or char N (for solid fuels), that will become **hcn** and **nh3**. The fraction that will become NO will be calculated by the remainder. This option will appear only if you have selected **hcn/nh3/no** for the **N Intermediate** or **Char N Conversion** drop-down lists.

Char N Conversion

is a drop-down list in which you can select **no**, **hcn**, **nh3**, or **hcn/nh3/no** as the species to which the char N is converted (when you are calculating solid fuel NOx). This parameter appears only for **Solid** fuel NOx calculations. See [Setting Solid \(Coal\) Fuel NOx Parameters \(p. 1017\)](#) for details.

Char N Mass Fraction

specifies the mass fraction of nitrogen in the char. This parameter appears only for **Solid** fuel NOx calculations.

BET Surface Area

sets the BET internal pore surface area (see [BET Surface Area](#) in the [Theory Guide](#) for details) of the particles. This parameter appears only for **Solid** fuel NOx calculations.

UDF Rate

provides options for the treatment of the NOx production specified by the UDF selected in the **Formation** tab.

Replace FLUENT Rate

replaces ANSYS FLUENT's fuel NOx rate calculations with the custom NOx rate produced by your UDF.

Add to FLUENT Rate

adds the custom NOx rate produced by your UDF to ANSYS FLUENT's fuel NOx rate calculations.

N₂O Path

contains the method to be used for formation of NO through an N_2O intermediate. (The contents of this tab will appear only if **N₂O Intermediate** is enabled in the **Formation** tab.)

N₂O Model

contains the drop-down list of available N₂O models.

quasi-steady

enables the quasi-steady-state method of calculation (The transport equation for the species N_2O will not be solved).

transported-simple

enables the transported simple method of calculation (The pollutant species N_2O is added in the species list and its mass fraction will be calculated using the transport equations).

UDF Rate

provides options for the treatment of the NOx production specified by the UDF selected in the **Formation** tab.

Replace ANSYS FLUENT Rate

replaces the NOx rate calculated by ANSYS FLUENT using N_2O intermediates with the custom NOx rate produced by your UDF.

Add to ANSYS FLUENT Rate

adds the custom NOx rate produced by your UDF to the NOx rate calculated by ANSYS FLUENT using N_2O intermediates.

Reduction Method Parameters

contains tabs that allow you to define the methods of reduction. (These tabs are do not appear unless a reduction method has been enabled in the **Reduction** tab.)

Reburn

allows you to define the NOx reduction when **Reburn** is enabled in the **Reduction** tab.

Reburn Model

contains the drop-down list of reburn methods.

instantaneous[CH]

activates instantaneous method in the **Reburn Model**. When you choose this method a warning to include CH , CH_2 , and CH_3 will be displayed.

partial-equilibrium

activates partial method in the **Reburn Model**.

Reburn Fuel Species

contains reburn fuel species drop-down list.

Equivalent Fuel Type

contains equivalent fuel type drop-down list.

SNCR

allows you to define the NOx reduction when **SNCR** is enabled in the **Reduction** tab.

Injection Method

contains the parameters for NOx reduction by SNCR method.

gaseous

includes ammonia or urea as a gas-phase pollutant species from the injection locations.

liquid

includes ammonia or urea as a liquid-phase pollutant species from the injection locations.

Reagent Species

allows you to specify the reagent species as either ammonia (**nh3**) or urea (**co<nh2>2**)

Reagent Fraction in Stream

allows you to specify the mass fraction of the reagent in the reagent stream. The remaining mass fraction is assumed to be water. If you enabled a secondary stream in your PDF calculation, by

default the secondary stream will act as the reagent stream. Note that the **Reagent Fraction in Stream** text box is only available when using the non-premixed combustion model with a liquid-phase reagent injection.

Urea Decomposition

allows you to specify the decomposition model to use when the selected **Reagent Species** is CO<nh2>2.

rate-limiting

specifies that the source terms be calculated according to the rates given in [Table 14.3: "Two-Step Urea Breakdown Process"](#).

user-specified

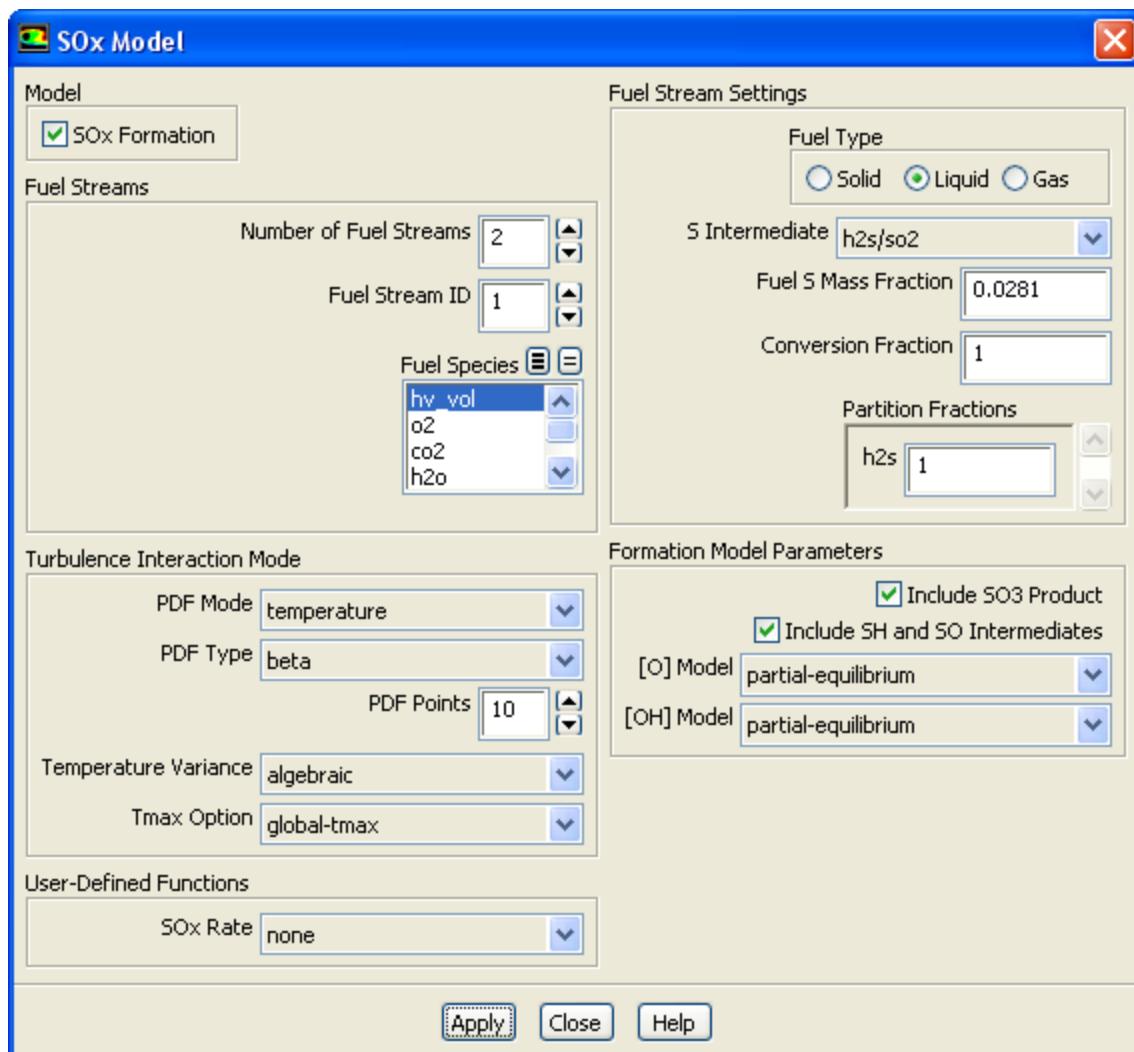

allows you to specify the molar conversion fraction for ammonia, assuming that the rest of the urea is converted to HNCO.

NH₃ Conversion

is the mole fraction of NH₃ in the mixture of NH₃ and HNCO instantly created from the reagent injection. The **NH₃ Conversion** text box only appears when **user-specified** is selected for **Urea Decomposition**.

36.3.29. SOx Model Dialog Box

The **SOx Model** dialog box allows you to set parameters related to the SOx postprocessor. See [Using the SOx Model \(p. 1026\)](#) for details about the items below.

Controls

Model

contains the control to enable the model.

SOx Formation

enables the model.

Fuel Streams

allows you to define multiple fuel streams for SOx formation.

Number of Fuel Streams

sets the number of fuel streams. You are allowed up to three fuel streams.

Fuel Stream ID

specifies the fuel stream you are defining in the **Fuel Species** selection list and the **Formation Model Parameters** group box.

Fuel Species

is a list containing all of the defined species. This list is used to specify the species that is the fuel associated with a particular **Fuel Stream ID**, for any combustion model other than non-premixed combustion. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10.

PDF Stream ID

specifies the PDF stream species associated with a particular **Fuel Stream ID**, when calculating SOx formation in conjunction with the non-premixed combustion model.

primary

indicates the primary fuel stream species, as defined in the PDF table.

secondary

indicates the secondary fuel stream species, as defined in the PDF table.

Turbulence Interaction Mode

contains parameters related to the effect of turbulent fluctuations on the SOx formation. See [SOx Formation in Turbulent Flows](#) in the [Theory Guide](#) for details.

PDF Mode

is a drop-down list containing options that take into account turbulent fluctuations when you compute the specified SO₂ formation. See [Setting Turbulence Parameters \(p. 1022\)](#) for details.

none

specifies the use of laminar SOx rate calculations, so that the effects of turbulence are ignored.

temperature

includes fluctuations of temperature.

temperature/species

includes fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction

includes fluctuations of the mixture fraction(s). This is available for non-premixed combustion calculations only.

PDF Type

allows you to specify the shape of the PDF.

beta

models the PDF using [Equation 14–108](#) in the [Theory Guide](#).

gaussian

models the PDF using [Equation 14–111](#) in the [Theory Guide](#).

PDF Points

controls the number of points at which the beta function in [Equation 14–105](#) or [Equation 14–106](#) in the [Theory Guide](#) will be integrated. The default value of 10, which indicates that the beta function will be integrated at 10 points on a histogram basis, will yield an accurate solution with reasonable computation time. Increasing this value may improve accuracy, but will also increase the computation time. This text box is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance.

algebraic

is an approximate form of the transport equation (see [Equation 14–114](#) in the [Theory Guide](#)).

transported

solves [Equation 14–113](#) in the [Theory Guide](#).

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax

sets the limit as the maximum temperature in the flow field.

local-tmax-factor

yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

specified-tmax

sets the limit for each cell to be the value entered in **Tmax**.

user-defined

allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a UDF and selected it in the **SOx Rate** drop-down list in the **User-Defined Functions** group box.

Species

is a drop-down list which appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the SOx rate calculations.

User-Defined Functions

allows you to use a user-defined function (UDF) to contribute to the rate of SOx production. See the separate UDF Manual for details. Note that you may also use a UDF to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

SOx Rate

allows you to select a compiled UDF.

UDF Rate

provides options for the treatment of the SOx production specified by the UDF.

Replace FLUENT Rate

replaces ANSYS FLUENT's SOx rate calculations with the custom SOx rate produced by your UDF.

Add to FLUENT Rate

adds the custom SOx rate produced by your UDF to ANSYS FLUENT's SOx rate calculations.

Fuel Stream Settings

contains the parameters associated with a particular fuel stream of the SOx model, as specified in the **Fuel Stream ID** text box in the **Fuel Streams** group box.

Fuel Type

enables selection of the fuel.

Solid

enables the calculation of solid fuel SOx.

Liquid

enables the calculation of liquid fuel SOx.

Gas

enables the calculation of gas fuel SOx.

S Intermediate

drop-down list enables you to select intermediate species (**h2s**, **so2**, or **h2s/so2**).

Volatile S Mass Fraction

specifies the mass fraction of sulfur in the volatiles. This parameter appears only for **Solid** fuel streams.

Fuel S Mass Fraction

field sets the value for correct mass fraction of sulfur in the fuel (kg sulfur per kg fuel). This parameter appears only for **Liquid** and **Gas** fuel streams.

Conversion Fraction

specifies the overall mass fraction of the fuel S (for liquid or gas fuels), or the volatile S or char S (for solid fuels), that will be converted to the intermediate species and/or product SO₂. The **S Intermediate Conversion Fraction** has a default value of 1.

Partition Fractions

specifies the mass fraction of the fuel S (for liquid or gas fuels), or the volatile S or char S (for solid fuels) that will become **h2s**. The remainder will become SO₂. This parameter only appears when you select **h2s/so2** for the **S Intermediate** or **Char S Conversion** drop-down lists.

Char S Conversion

drop-down list selects the char S conversion path as **so2**, **h2s**, or **so2/h2s**. This parameter appears only for **Solid** fuel streams.

Char S Mass Fraction

specifies the mass fraction of sulfur in the char. This parameter appears only for **Solid** fuel streams.

Formation Model Parameters

allows you to include SOx products and intermediates.

Include SO3 Product

includes **SO3** as a product in all of the fuel streams, as described in [Reaction Mechanisms for Sulfur Oxidation](#) in the [Theory Guide](#).

Include SH and SO Intermediaries

includes **SH** and **SO** as intermediates in all of the fuel streams, as described in [Reaction Mechanisms for Sulfur Oxidation](#) in the [Theory Guide](#).

[O] Model

drop-down list specifies the method by which **O** will be calculated in all of the fuel streams, i.e., **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[O] Model**.

[OH] Model

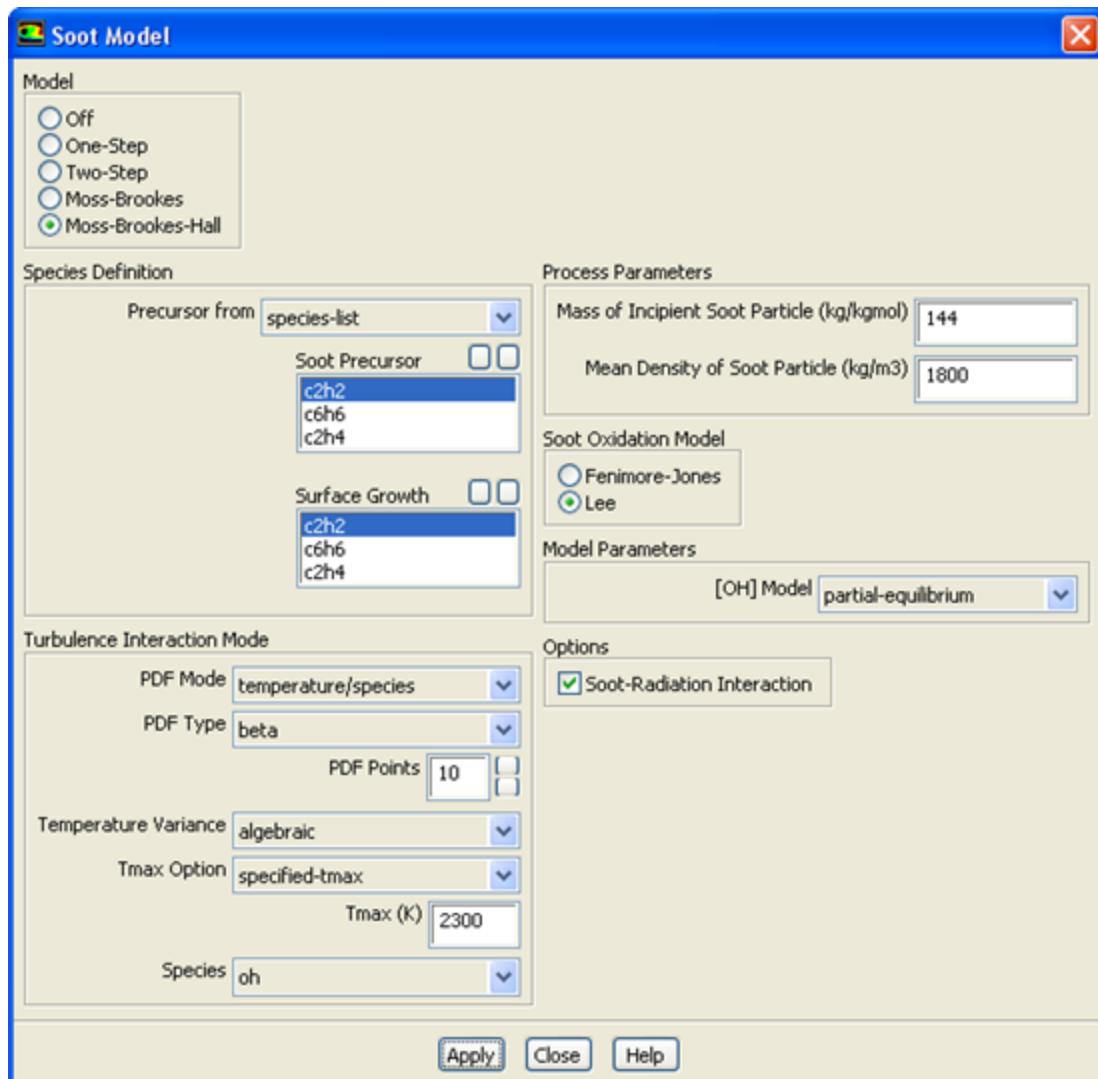

drop-down list specifies the method by which **OH** will be calculated in all of the fuel streams, i.e., **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[OH] Model**.

Important

To use the predicted O and/or OH concentration, select **instantaneous** in the **[O] Model** or **[OH] Model** drop-down list.

36.3.30. Soot Model Dialog Box

The **Soot Model** dialog box allows you to set parameters related to the soot model. See [Using the Soot Models](#) (p. 1040) for details about the items below.

Controls

Model

specifies which model should be used for computing soot formation.

Off

disables the calculation of soot formation.

One-Step

enables the one-step soot model described in [The One-Step Soot Formation Model](#) in the [Theory Guide](#).

Two-Step

enables the two-step soot model described in [The Two-Step Soot Formation Model](#).

Moss-Brookes

enables the Moss-Brookes soot model described in [The Moss-Brookes Model](#) in the [Theory Guide](#).

Moss-Brookes-Hall

enables the Moss-Brookes-Hall soot model described in [The Moss-Brookes-Hall Model](#) in the [Theory Guide](#). This option is only available when C₂H₂, C₆H₆, C₆H₅, and H₂ are present in the gas phase species list.

Species Definition

contains inputs for specifying the chemical species for your model.

Fuel

is a drop-down list containing all of the defined species. Here you will select the species that is the fuel for the **One-Step** and **Two-Step** models, as well as the **Moss-Brookes** model when a precursor species is not identified in the defined species list.

Oxidant

is a drop-down list containing all of the defined species. Here you will select the species that is the oxidizer for the **One-Step** and **Two-Step** models.

Precursor from

allows you to select from a list of species or enter the correlation values of species. This selection is available when using the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Soot Precursor

is a selection list containing all of the possible precursor species found via a query of the defined species list. By default, ANSYS FLUENT only considers c2h2, c6h6, and c2h4 as possible precursor species. For information about including other species in the possible precursor species search, contact your ANSYS FLUENT support engineer. From this list you will select the species that are the soot precursor species for the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Surface Growth

is a selection list containing all of the possible surface growth species, as explained previously for the **Soot Precursor** selection list. Here you will select the species that are the surface growth species for the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Fuel Carbon Number

is the number of carbon atoms in the species selected in the **Fuel** drop-down list. This text box appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

Fuel Hydrogen Number

is the number of hydrogen atoms in the species selected in the **Fuel** drop-down list. This text box appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

Molecular Weight of Precursor

is the molecular weight of the precursor species. This text box appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list. The default value is the weight of acetylene.

Precursor Correlation

is a drop-down list you can use to define a laminar diffusion profile which relates mixture fraction to precursor mass fraction. This text box appears only for the **Moss-Brookes** and **Moss-Brookes-Hall** model, when **user-correlation** is selected in the **Precursor from** drop-down list.

piecewise-polynomial

specifies that the precursor mass fraction is a piecewise-polynomial function of mixture fraction. The default values used by ANSYS FLUENT correspond to a methane diffusion flame simulation, in which both the air and fuel initial temperatures are set to 290 K, and acetylene is assumed as the soot precursor. These values can be revised via the **Edit...** button.

constant

specifies that the precursor mass fraction is a constant function of mixture fraction, the value of which is specified in the text box below the **Precursor Correlation** drop-down list.

Edit...

opens the [Piecewise-Polynomial Profile Dialog Box \(p. 1898\)](#) when **piecewise-polynomial** is selected from the **Precursor Correlation** drop-down list, thus allowing you to revise the default values.

Turbulence Interaction Mode

contains inputs that specify how turbulent fluctuations are accounted for in the soot formation calculations for the **Moss-Brookes** and **Moss-Brookes-Hall** models. For further details on these inputs, see [Setting Up the Moss-Brookes Model and the Hall Extension \(p. 1045\)](#).

PDF Mode

is a drop-down list that contains the options for addressing turbulent fluctuations in the soot rate calculations. Note that **mixture fraction** is the most accurate option, and should be used if it is available.

none

specifies the use of laminar soot rate calculations, so that the effects of turbulence are ignored.

temperature

specifies that the soot rate calculations include the effect of temperature fluctuations.

temperature/species

specifies that the soot rate calculations include the effect of fluctuations of temperature, as well as fluctuations of the mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).

mixture fraction

is the most accurate option, specifying that the soot rate calculations include the effect of fluctuations of mixture fraction(s). Note that this option is not available if you are using the eddy-dissipation model.

PDF Type

allows you to specify the shape of the PDF.

beta

models the PDF using [Equation 14–108](#) in the [Theory Guide](#).

gaussian

models the PDF using [Equation 14–111](#) in the [Theory Guide](#).

PDF Points

controls the number of points at which the beta function will be integrated on a histogram basis. Increasing this number may improve accuracy, but will also increase compute time. This text box is only available when **temperature** or **temperature/species** is selected from the **PDF Mode** drop-down list.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance.

algebraic

is an approximate form of the transport equation (see [Equation 14–114](#) in the [Theory Guide](#)).

transported

solves [Equation 14–113](#) in the [Theory Guide](#).

Tmax Option

provides various options for determining the maximum limit(s) for the integration of the PDF used to calculate the temperature.

global-tmax

sets the limit as the maximum temperature in the flow field.

local-tmax-factor

yields cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.

specified-tmax

sets the limit for each cell to be the value entered in **Tmax**.

user-defined

allows you to hook a user-defined function that specifies custom values for the maximum limit (T_{max}), which is used for the integration of the temperature PDF. This option is only available if you have already compiled a UDF.

Species

is a drop-down list which appears when **temperature/species** is selected from the **PDF Mode** drop-down list. Here you will select the species whose mass fraction fluctuations will be factored into the soot rate calculations.

Process Parameters

contains parameters that control the combustion process modeling.

Mean Diameter of Soot Particle

is the assumed average diameter of the soot particles in the combustion system, used to compute the soot particle mass m_p in [Equation 14–134](#) in the [Theory Guide](#) for the **Two-Step** model.

Mean Density of Soot Particle

is the assumed average density of the soot particles in the combustion system. For the **Two-Step** model, it is used to compute the soot particle mass m_p in [Equation 14–134](#) in the [Theory Guide](#). For the **Moss-Brookes** and **Moss-Brookes-Hall** models, it is ρ_{soot} in [Equation 14–141](#) and ρ in [Equation 14–144](#) in the [Theory Guide](#). The default value supplied by ANSYS FLUENT is 1800 kg/m³ (as was used in the work of Brookes and Moss [12] (p. 2367)).

Stoichiometry for Soot Combustion

is the mass stoichiometry v_{soot} in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate in the **One-Step** and **Two-Step** models. The default value supplied by ANSYS FLUENT (2.6667) assumes that the soot is pure carbon and that the oxidizer is O₂.

Stoichiometry for Fuel Combustion

is the mass stoichiometry v_{fuel} in [Equation 14–131](#) in the [Theory Guide](#), which computes the soot combustion rate in the **One-Step** and **Two-Step** models. The default value supplied by ANSYS FLUENT (3.6363) is for combustion of propane (C₃H₈) by oxygen (O₂).

Mass of Incipient Soot Particle

is M_p in [Equation 14–142](#) and [Equation 14–144](#), which is used in the **Moss-Brookes** and **Moss-Brookes-Hall** model computations. The default value supplied by ANSYS FLUENT (144 kg/mol) is the mass of 12 carbon atoms. Note that for the original implementation of the Hall extension, the model assumed this mass to be 100 carbon atoms.

Soot Oxidation Model

contains model options that determine the form of the soot oxidation term in the calculations of the **Moss-Brookes** and **Moss-Brookes-Hall** models.

Fenimore-Jones

takes into account the soot oxidation due to the hydroxyl radical.

Lee

takes into account the soot oxidation due to the hydroxyl radical and molecular oxygen.

Model Parameters

contains parameters that control the soot formation model.

Soot Formation Constant

is the parameter C_s in [Equation 14–128](#) in the [Theory Guide](#). This item appears only for the **One-Step** soot model.

Equivalence Ratio Exponent

is the exponent r in [Equation 14–128](#) in the [Theory Guide](#). This item appears only for the **One-Step** soot model.

Equivalence Ratio Minimum

and **Equivalence Ratio Maximum** are the minimum and maximum values of the fuel equivalence ratio ϕ in [Equation 14–128](#) in the [Theory Guide](#). [Equation 14–128](#) will be solved only if **Equivalence Ratio Minimum** < ϕ < **Equivalence Ratio Maximum**; if ϕ is outside of this range, there is no soot formation. This item appears only for the **One-Step** soot model.

Activation Temperature of Soot Formation Rate

is the term E/R in [Equation 14–128](#) in the [Theory Guide](#). This item appears only for the **One-Step** soot model.

Magnussen Constant for Soot Combustion

is the constant A used in the rate expressions governing the soot combustion rate ([Equation 14–130](#) and [Equation 14–131](#)) in the [Theory Guide](#). This item appears only for the **One-Step** and the **Two-Step** soot models. For the **Two-Step** model, this input will be called **Magnussen Constant for Soot and Nuclei Combustion**.

Limiting Nuclei Formation Rate

is the limiting value of the kinetic nuclei formation rate η_0 in [Equation 14–137](#) in the [Theory Guide](#).

Below this limiting value, the branching and termination term, ($f - g$) in [Equation 14–136](#) in the [Theory Guide](#), is not included. This item appears only for the **Two-Step** soot model.

Nuclei Branching-Termination Coefficient

is the term ($f - g$) in [Equation 14–136](#) in the [Theory Guide](#). This item appears only for the **Two-Step** soot model.

Nuclei Coefficient of Linear Termination on Soot
