Release 14.0
November 2011

ANSYS, Inc. is
certified to ISO
9001:2008.

Copyright and Trademark Information

© 2011 SAS IP, Inc. All rights reserved. Unauthorized use, distribution or duplication is prohibited.

ANSYS, ANSYS Workbench, Ansoft, AUTODYN, EKM, Engineering Knowledge Manager, CFX, FLUENT, HFSS and any and all ANSYS, Inc. brand, product, service and feature names, logos and slogans are registered trademarks or trademarks of ANSYS, Inc. or its subsidiaries in the United States or other countries. ICEM CFD is a trademark used by ANSYS, Inc. under license. CFX is a trademark of Sony Corporation in Japan. All other brand, product, service and feature names or trademarks are the property of their respective owners.

Disclaimer Notice

THIS ANSYS SOFTWARE PRODUCT AND PROGRAM DOCUMENTATION INCLUDE TRADE SECRETS AND ARE CONFIDENTIAL AND PROPRIETARY PRODUCTS OF ANSYS, INC., ITS SUBSIDIARIES, OR LICENSORS. The software products and documentation are furnished by ANSYS, Inc., its subsidiaries, or affiliates under a software license agreement that contains provisions concerning non-disclosure, copying, length and nature of use, compliance with exporting laws, warranties, disclaimers, limitations of liability, and remedies, and other provisions. The software products and documentation may be used, disclosed, transferred, or copied only in accordance with the terms and conditions of that software license agreement.

ANSYS, Inc. is certified to ISO 9001:2008.

U.S. Government Rights

For U.S. Government users, except as specifically granted by the ANSYS, Inc. software license agreement, the use, duplication, or disclosure by the United States Government is subject to restrictions stated in the ANSYS, Inc. software license agreement and FAR 12.212 (for non-DOD licenses).

Third-Party Software

See the [legal information](#) in the product help files for the complete Legal Notice for ANSYS proprietary software and third-party software. If you are unable to access the Legal Notice, please contact ANSYS, Inc.

Table of Contents

Using This Manual	lxi
1. The Contents of This Manual	lxi
2. The Contents of the FLUENT Manuals	lxiii
3. Typographical Conventions	lxiv
4. Mathematical Conventions	lxv
5. Technical Support	lxvi
1. Starting and Executing ANSYS FLUENT	1
1.1. Starting ANSYS FLUENT	1
1.1.1. Starting ANSYS FLUENT Using FLUENT Launcher	1
1.1.1.1. Setting General Options in FLUENT Launcher	2
1.1.1.2. Single-Precision and Double-Precision Solvers	4
1.1.1.3. Setting Parallel Options in FLUENT Launcher	4
1.1.1.4. Setting Remote Options in FLUENT Launcher	5
1.1.1.5. Setting Scheduler Options in FLUENT Launcher	6
1.1.1.6. Setting Environment Options in FLUENT Launcher	7
1.1.2. Starting ANSYS FLUENT on a Windows System	8
1.1.3. Starting ANSYS FLUENT on a Linux System	9
1.1.4. Command Line Startup Options	9
1.1.4.1. Graphics Options	11
1.1.4.2. Parallel Options	11
1.1.4.3. Postprocessing Option	12
1.1.4.4. SGE Options	12
1.1.4.5. LSF Options	12
1.1.4.6. Version and Release Options	12
1.1.4.7. System Coupling Options	13
1.1.4.8. Other Startup Options	13
1.2. Running ANSYS FLUENT in Batch Mode	13
1.2.1. Background Execution on Linux Systems	14
1.2.2. Background Execution on Windows Systems	15
1.2.3. Batch Execution Options	15
1.3. Checkpointing an ANSYS FLUENT Simulation	16
1.4. Cleaning Up Processes From an ANSYS FLUENT Simulation	18
1.5. Exiting ANSYS FLUENT	19
2. Graphical User Interface (GUI)	21
2.1. GUI Components	21
2.1.1. The Menu Bar	22
2.1.2. Toolbars	23
2.1.2.1. The Standard Toolbar	23
2.1.2.2. The Graphics Toolbar	24
2.1.3. The Navigation Pane	25
2.1.4. Task Pages	26
2.1.5. The Console	26
2.1.6. Dialog Boxes	27
2.1.6.1. Input Controls	29
2.1.6.1.1. Tabs	29
2.1.6.1.2. Buttons	29
2.1.6.1.3. Check Boxes	29
2.1.6.1.4. Radio Buttons	29
2.1.6.1.5. Text Entry Boxes	29
2.1.6.1.6. Integer Number Entry Boxes	29

2.1.6.1.7. Real Number Entry Boxes	30
2.1.6.1.8. Single-Selection Lists	30
2.1.6.1.9. Multiple-Selection Lists	30
2.1.6.1.10. Drop-Down Lists	31
2.1.6.1.11. Scales	31
2.1.6.2. Types of Dialog Boxes	32
2.1.6.2.1. Information Dialog Boxes	32
2.1.6.2.2. Warning Dialog Boxes	32
2.1.6.2.3. Error Dialog Boxes	32
2.1.6.2.4. The Working Dialog Box	32
2.1.6.2.5. Question Dialog Box	33
2.1.6.2.6. The Select File Dialog Box	33
2.1.6.2.6.1. The Select File Dialog Box (Windows)	33
2.1.6.2.6.2. The Select File Dialog Box (Linux)	34
2.1.7. Graphics Windows	37
2.1.7.1. Printing the Contents of the Graphics Window (Windows Systems Only)	39
2.1.7.2. Using the Page Setup Dialog Box (Windows Systems Only)	39
2.2. Customizing the Graphical User Interface (Linux Systems Only)	41
2.3. Using the GUI Help System	42
2.3.1. Task Page and Dialog Box Help	43
2.3.2. Context-Sensitive Help (Linux Only)	43
2.3.3. Opening the User's Guide Table of Contents	43
2.3.4. Opening the User's Guide Index	44
2.3.5. Opening the Reference Guide	44
2.3.6. Help on Help	45
2.3.7. Accessing Printable Manuals	45
2.3.8. Help for Text Interface Commands	45
2.3.9. Accessing the Customer Portal Web Site	45
2.3.10. Obtaining License Use Information	45
2.3.11. Version and Release Information	46
3. Text User Interface (TUI)	47
3.1. Text Menu System	47
3.1.1. Command Abbreviation	48
3.1.2. Command Line History	48
3.1.3. Scheme Evaluation	49
3.1.4. Aliases	49
3.2. Text Prompt System	50
3.2.1. Numbers	50
3.2.2. Booleans	50
3.2.3. Strings	51
3.2.4. Symbols	51
3.2.5. Filenames	51
3.2.6. Lists	51
3.2.7. Evaluation	53
3.2.8. Default Value Binding	54
3.3. Interrupts	54
3.4. System Commands	54
3.4.1. System Commands for Linux-based Operating Systems	54
3.4.2. System Commands for Windows Operating Systems	55
3.5. Text Menu Input from Character Strings	55
3.6. Using the Text Interface Help System	56
4. Reading and Writing Files	59

4.1. Shortcuts for Reading and Writing Files	59
4.1.1. Default File Suffixes	60
4.1.2. Binary Files	61
4.1.3. Detecting File Format	61
4.1.4. Recent File List	61
4.1.5. Reading and Writing Compressed Files	61
4.1.5.1. Reading Compressed Files	61
4.1.5.2. Writing Compressed Files	62
4.1.6. Tilde Expansion (Linux Systems Only)	63
4.1.7. Automatic Numbering of Files	63
4.1.8. Disabling the Overwrite Confirmation Prompt	64
4.1.9. Toolbar Buttons	64
4.2. Reading Mesh Files	64
4.2.1. Reading TGrid Mesh Files	65
4.2.2. Reading Surface Meshes	65
4.2.3. Reading GAMBIT and GeoMesh Mesh Files	65
4.2.4. Reading PreBFC Unstructured Mesh Files	65
4.3. Reading and Writing Case and Data Files	66
4.3.1. Reading and Writing Case Files	66
4.3.2. Reading and Writing Data Files	67
4.3.3. Reading and Writing Case and Data Files Together	67
4.3.4. Automatic Saving of Case and Data Files	68
4.4. Reading and Writing Parallel Data Files	70
4.4.1. Writing Parallel Data Files	71
4.4.2. Reading Parallel Data Files	71
4.4.3. Availability and Limitations	71
4.5. Reading FLUENT/UNS and RAMPANT Case and Data Files	72
4.6. Reading and Writing Profile Files	72
4.6.1. Reading Profile Files	73
4.6.2. Writing Profile Files	73
4.7. Reading and Writing Boundary Conditions	74
4.8. Writing a Boundary Mesh	75
4.9. Reading Scheme Source Files	75
4.10. Creating and Reading Journal Files	75
4.10.1. Procedure	77
4.11. Creating Transcript Files	77
4.12. Importing Files	78
4.12.1. ABAQUS Files	80
4.12.2. CFX Files	80
4.12.3. Meshes and Data in CGNS Format	81
4.12.4. EnSight Files	81
4.12.5. ANSYS FIDAP Neutral Files	81
4.12.6. GAMBIT and GeoMesh Mesh Files	82
4.12.7. HYPERMESH ASCII Files	82
4.12.8. IC3M Files	82
4.12.9. I-deas Universal Files	83
4.12.10. LSTC Files	83
4.12.11. Marc POST Files	84
4.12.12. Mechanical APDL Files	84
4.12.13. NASTRAN Files	84
4.12.14. PATRAN Neutral Files	85
4.12.15. PLOT3D Files	85

4.12.16. PTC Mechanica Design Files	85
4.12.17. Tecplot Files	85
4.12.18. FLUENT 4 Case Files	86
4.12.19. PreBFC Files	86
4.12.20. Partition Files	86
4.12.21. CHEMKIN Mechanism	86
4.13. Exporting Solution Data	86
4.13.1. Exporting Limitations	87
4.14. Exporting Solution Data after a Calculation	88
4.14.1. ABAQUS Files	90
4.14.2. Mechanical APDL Files	90
4.14.3. Mechanical APDL Input Files	91
4.14.4. ASCII Files	92
4.14.5. AVS Files	92
4.14.6. ANSYS CFD-Post-Compatible Files	92
4.14.7. CGNS Files	93
4.14.8. Data Explorer Files	94
4.14.9. EnSight Case Gold Files	94
4.14.10. FAST Files	97
4.14.11. FAST Solution Files	97
4.14.12. Fieldview Unstructured Files	97
4.14.13. I-deas Universal Files	98
4.14.14. NASTRAN Files	99
4.14.15. PATRAN Files	99
4.14.16. RadTherm Files	100
4.14.17. Tecplot Files	100
4.15. Exporting Steady-State Particle History Data	100
4.16. Exporting Data During a Transient Calculation	102
4.16.1. Creating Automatic Export Definitions for Solution Data	104
4.16.2. Creating Automatic Export Definitions for Transient Particle History Data	106
4.17. Exporting to ANSYS CFD-Post	108
4.18. Managing Solution Files	110
4.19. Mesh-to-Mesh Solution Interpolation	111
4.19.1. Performing Mesh-to-Mesh Solution Interpolation	111
4.19.2. Format of the Interpolation File	113
4.20. Mapping Data for Fluid-Structure Interaction (FSI) Applications	114
4.20.1. FEA File Formats	114
4.20.2. Using the FSI Mapping Dialog Boxes	114
4.21. Saving Picture Files	119
4.21.1. Using the Save Picture Dialog Box	119
4.21.1.1. Choosing the Picture File Format	120
4.21.1.2. Specifying the Color Mode	120
4.21.1.3. Choosing the File Type	121
4.21.1.4. Defining the Resolution	121
4.21.1.5. Picture Options	121
4.21.2. Picture Options for PostScript Files	121
4.21.2.1. Window Dumps (Linux Systems Only)	122
4.21.2.2. Previewing the Picture Image	122
4.22. Setting Data File Quantities	122
4.23. The .fluent File	124
5. Unit Systems	125
5.1. Restrictions on Units	125

5.2. Units in Mesh Files	126
5.3. Built-In Unit Systems in ANSYS FLUENT	126
5.4. Customizing Units	126
5.4.1. Listing Current Units	127
5.4.2. Changing the Units for a Quantity	127
5.4.3. Defining a New Unit	127
5.4.3.1. Determining the Conversion Factor	128
6. Reading and Manipulating Meshes	129
6.1. Mesh Topologies	129
6.1.1. Examples of Acceptable Mesh Topologies	130
6.1.2. Face-Node Connectivity in ANSYS FLUENT	135
6.1.2.1. Face-Node Connectivity for Triangular Cells	136
6.1.2.2. Face-Node Connectivity for Quadrilateral Cells	137
6.1.2.3. Face-Node Connectivity for Tetrahedral Cells	138
6.1.2.4. Face-Node Connectivity for Wedge Cells	139
6.1.2.5. Face-Node Connectivity for Pyramidal Cells	140
6.1.2.6. Face-Node Connectivity for Hex Cells	141
6.1.2.7. Face-Node Connectivity for Polyhedral Cells	142
6.1.3. Choosing the Appropriate Mesh Type	142
6.1.3.1. Setup Time	142
6.1.3.2. Computational Expense	143
6.1.3.3. Numerical Diffusion	143
6.2. Mesh Requirements and Considerations	144
6.2.1. Geometry/Mesh Requirements	144
6.2.2. Mesh Quality	145
6.2.2.1. Mesh Element Distribution	147
6.2.2.2. Cell Quality	148
6.2.2.3. Smoothness	148
6.2.2.4. Flow-Field Dependency	148
6.3. Mesh Import	149
6.3.1. GAMBIT Mesh Files	149
6.3.2. GeoMesh Mesh Files	149
6.3.3. TGrid Mesh Files	149
6.3.4. PreBFC Mesh Files	150
6.3.4.1. Structured Mesh Files	150
6.3.4.2. Unstructured Triangular and Tetrahedral Mesh Files	150
6.3.5. ICEM CFD Mesh Files	150
6.3.6. I-deas Universal Files	150
6.3.6.1. Recognized I-deas Datasets	151
6.3.6.2. Grouping Nodes to Create Face Zones	151
6.3.6.3. Grouping Elements to Create Cell Zones	151
6.3.6.4. Deleting Duplicate Nodes	151
6.3.7. NASTRAN Files	151
6.3.7.1. Recognized NASTRAN Bulk Data Entries	152
6.3.7.2. Deleting Duplicate Nodes	152
6.3.8. PATRAN Neutral Files	152
6.3.8.1. Recognized PATRAN Datasets	153
6.3.8.2. Grouping Elements to Create Cell Zones	153
6.3.9. Mechanical APDL Files	153
6.3.9.1. Recognized ANSYS 5.4 and 5.5 Datasets	154
6.3.10. CFX Files	154
6.3.11. Using the fe2ram Filter to Convert Files	155

6.3.12. Using the <code>tpoly</code> Filter to Remove Hanging Nodes / Edges	156
6.3.12.1. Limitations	156
6.3.13. FLUENT/UNS and RAMPANT Case Files	157
6.3.14. FLUENT 4 Case Files	157
6.3.15. ANSYS FIDAP Neutral Files	157
6.3.16. Reading Multiple Mesh/Case/Data Files	158
6.3.16.1. Using ANSYS FLUENT's Ability to Read Multiple Mesh Files	158
6.3.16.2. Using TGrid or tmerge	160
6.3.17. Reading Surface Mesh Files	161
6.4. Non-Conformal Meshes	162
6.4.1. Non-Conformal Mesh Calculations	162
6.4.1.1. The Periodic Boundary Condition Option	164
6.4.1.2. The Periodic Repeats Option	165
6.4.1.3. The Coupled Wall Option	167
6.4.2. Non-Conformal Interface Algorithm	168
6.4.3. Requirements and Limitations of Non-Conformal Meshes	169
6.4.4. Using a Non-Conformal Mesh in ANSYS FLUENT	170
6.5. Checking the Mesh	173
6.5.1. Mesh Check Report	174
6.5.2. Repairing Meshes	175
6.6. Reporting Mesh Statistics	178
6.6.1. Mesh Size	178
6.6.2. Memory Usage	178
6.6.2.1. Linux Systems	179
6.6.2.2. Windows Systems	179
6.6.3. Mesh Zone Information	179
6.6.4. Partition Statistics	180
6.7. Converting the Mesh to a Polyhedral Mesh	180
6.7.1. Converting the Domain to a Polyhedra	180
6.7.1.1. Limitations	183
6.7.2. Converting Skewed Cells to Polyhedra	184
6.7.2.1. Limitations	184
6.7.2.2. Using the Convert Skewed Cells Dialog Box	185
6.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra	185
6.7.3.1. Limitations	186
6.8. Modifying the Mesh	186
6.8.1. Merging Zones	187
6.8.1.1. When to Merge Zones	187
6.8.1.2. Using the Merge Zones Dialog Box	188
6.8.2. Separating Zones	188
6.8.2.1. Separating Face Zones	189
6.8.2.1.1. Methods for Separating Face Zones	189
6.8.2.1.2. Inputs for Separating Face Zones	189
6.8.2.2. Separating Cell Zones	191
6.8.2.2.1. Methods for Separating Cell Zones	191
6.8.2.2.2. Inputs for Separating Cell Zones	191
6.8.3. Fusing Face Zones	193
6.8.3.1. Inputs for Fusing Face Zones	193
6.8.3.1.1. Fusing Zones on Branch Cuts	194
6.8.4. Creating Conformal Periodic Zones	195
6.8.5. Slitting Periodic Zones	195
6.8.6. Slitting Face Zones	196

6.8.6.1. Inputs for Slitting Face Zones	197
6.8.7. Orienting Face Zones	197
6.8.8. Extruding Face Zones	197
6.8.8.1. Specifying Extrusion by Displacement Distances	197
6.8.8.2. Specifying Extrusion by Parametric Coordinates	198
6.8.9. Replacing, Deleting, Deactivating, and Activating Zones	198
6.8.9.1. Replacing Zones	198
6.8.9.2. Deleting Zones	199
6.8.9.3. Deactivating Zones	200
6.8.9.4. Activating Zones	201
6.8.10. Copying Cell Zones	202
6.8.11. Replacing the Mesh	202
6.8.11.1. Inputs for Replacing the Mesh	203
6.8.11.2. Limitations	203
6.8.12. Reordering the Domain and Zones	204
6.8.12.1. About Reordering	204
6.8.13. Scaling the Mesh	205
6.8.13.1. Using the Scale Mesh Dialog Box	206
6.8.13.1.1. Changing the Unit of Length	206
6.8.13.1.2. Unscaling the Mesh	206
6.8.13.1.3. Changing the Physical Size of the Mesh	207
6.8.14. Translating the Mesh	207
6.8.14.1. Using the Translate Mesh Dialog Box	207
6.8.15. Rotating the Mesh	208
6.8.15.1. Using the Rotate Mesh Dialog Box	208
7. Cell Zone and Boundary Conditions	211
7.1. Overview	211
7.1.1. Available Cell Zone and Boundary Types	211
7.1.2. The Cell Zone and Boundary Conditions Task Page	212
7.1.3. Changing Cell and Boundary Zone Types	213
7.1.3.1. Categories of Zone Types	214
7.1.4. Setting Cell Zone and Boundary Conditions	214
7.1.5. Copying Cell Zone and Boundary Conditions	215
7.1.6. Changing Cell or Boundary Zone Names	215
7.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions	216
7.1.8. Defining and Viewing Parameters	216
7.1.8.1. Creating a New Parameter	218
7.1.9. Selecting Cell or Boundary Zones in the Graphics Display	219
7.1.10. Operating and Periodic Conditions	220
7.1.11. Highlighting Selected Boundary Zones	220
7.1.12. Saving and Reusing Cell Zone and Boundary Conditions	220
7.2. Cell Zone Conditions	221
7.2.1. Fluid Conditions	221
7.2.1.1. Inputs for Fluid Zones	221
7.2.1.1.1. Defining the Fluid Material	222
7.2.1.1.2. Defining Sources	223
7.2.1.1.3. Defining Fixed Values	223
7.2.1.1.4. Specifying a Laminar Zone	223
7.2.1.1.5. Specifying a Reaction Mechanism	223
7.2.1.1.6. Specifying the Rotation Axis	223
7.2.1.1.7. Defining Zone Motion	224
7.2.1.1.8. Defining Radiation Parameters	227

7.2.2. Solid Conditions	227
7.2.2.1. Inputs for Solid Zones	227
7.2.2.1.1. Defining the Solid Material	228
7.2.2.1.2. Defining a Heat Source	228
7.2.2.1.3. Defining a Fixed Temperature	228
7.2.2.1.4. Specifying the Rotation Axis	229
7.2.2.1.5. Defining Zone Motion	229
7.2.2.1.6. Defining Radiation Parameters	229
7.2.3. Porous Media Conditions	229
7.2.3.1. Limitations and Assumptions of the Porous Media Model	230
7.2.3.2. Momentum Equations for Porous Media	230
7.2.3.2.1. Darcy's Law in Porous Media	231
7.2.3.2.2. Inertial Losses in Porous Media	232
7.2.3.3. Treatment of the Energy Equation in Porous Media	233
7.2.3.3.1. Equilibrium Thermal Model Equations	233
7.2.3.3.2. Non-Equilibrium Thermal Model Equations	234
7.2.3.4. Treatment of Turbulence in Porous Media	235
7.2.3.5. Effect of Porosity on Transient Scalar Equations	235
7.2.3.6. User Inputs for Porous Media	235
7.2.3.6.1. Defining the Porous Zone	236
7.2.3.6.2. Defining the Porous Velocity Formulation	236
7.2.3.6.3. Defining the Fluid Passing Through the Porous Medium	237
7.2.3.6.4. Enabling Reactions in a Porous Zone	237
7.2.3.6.5. Including the Relative Velocity Resistance Formulation	237
7.2.3.6.6. Defining the Viscous and Inertial Resistance Coefficients	237
7.2.3.6.7. Deriving Porous Media Inputs Based on Superficial Velocity, Using a Known Pressure Loss	240
7.2.3.6.8. Using the Ergun Equation to Derive Porous Media Inputs for a Packed Bed	241
7.2.3.6.9. Using an Empirical Equation to Derive Porous Media Inputs for Turbulent Flow Through a Perforated Plate	242
7.2.3.6.10. Using Tabulated Data to Derive Porous Media Inputs for Laminar Flow Through a Fibrous Mat	243
7.2.3.6.11. Deriving the Porous Coefficients Based on Experimental Pressure and Velocity Data	243
7.2.3.6.12. Using the Power-Law Model	245
7.2.3.6.13. Defining Porosity	245
7.2.3.6.14. Specifying the Heat Transfer Settings	245
7.2.3.6.14.1. Equilibrium Thermal Model	245
7.2.3.6.14.2. Non-Equilibrium Thermal Model	246
7.2.3.6.15. Defining Sources	248
7.2.3.6.16. Defining Fixed Values	248
7.2.3.6.17. Suppressing the Turbulent Viscosity in the Porous Region	248
7.2.3.6.18. Specifying the Rotation Axis and Defining Zone Motion	248
7.2.3.7. Modeling Porous Media Based on Physical Velocity	248
7.2.3.7.1. Single Phase Porous Media	249
7.2.3.7.2. Multiphase Porous Media	250
7.2.3.7.2.1. The Continuity Equation	251
7.2.3.7.2.2. The Momentum Equation	251
7.2.3.7.2.3. The Energy Equation	251
7.2.3.8. Solution Strategies for Porous Media	252
7.2.3.9. Postprocessing for Porous Media	253
7.2.4. Fixing the Values of Variables	253

7.2.4.1. Overview of Fixing the Value of a Variable	254
7.2.4.1.1. Variables That Can Be Fixed	254
7.2.4.2. Procedure for Fixing Values of Variables in a Zone	255
7.2.4.2.1. Fixing Velocity Components	255
7.2.4.2.2. Fixing Temperature and Enthalpy	256
7.2.4.2.3. Fixing Species Mass Fractions	256
7.2.4.2.4. Fixing Turbulence Quantities	256

7.3.10.3. Mass Flow Split Boundary Conditions	308
7.3.10.4. Other Inputs at Outflow Boundaries	309
7.3.10.4.1. Radiation Inputs at Outflow Boundaries	309
7.3.10.4.2. Defining Discrete Phase Boundary Conditions	309
7.3.11. Outlet Vent Boundary Conditions	309
7.3.11.1. Inputs at Outlet Vent Boundaries	309
7.3.11.1.1. Specifying the Loss Coefficient	311
7.3.12. Exhaust Fan Boundary Conditions	311

7.3.12.1. Inputs at Exhaust Fan Boundaries	311
7.3.12.1.1. Specifying the Pressure Jump	312
7.3.13. Wall Boundary Conditions	313
7.3.13.1. Inputs at Wall Boundaries	313
7.3.13.1.1. Summary	313
7.3.13.2. Wall Motion	313
7.3.13.2.1. Defining a Stationary Wall	314
7.3.13.2.2. Velocity Conditions for Moving Walls	314
7.3.13.2.3. Shear Conditions at Walls	316
7.3.13.2.4. No-Slip Walls	316
7.3.13.2.5. Specified Shear	316
7.3.13.2.6. Specularity Coefficient	317
7.3.13.2.7. Marangoni Stress	318
7.3.13.2.8. Wall Roughness Effects in Turbulent Wall-Bounded Flows	319
7.3.13.2.9. Law-of-the-Wall Modified for Roughness	319
7.3.13.2.10. Setting the Roughness Parameters	322
7.3.13.3. Thermal Boundary Conditions at Walls	322
7.3.13.3.1. Heat Flux Boundary Conditions	324
7.3.13.3.2. Temperature Boundary Conditions	324
7.3.13.3.3. Convective Heat Transfer Boundary Conditions	324
7.3.13.3.4. External Radiation Boundary Conditions	324
7.3.13.3.5. Combined Convection and External Radiation Boundary Conditions	324
7.3.13.3.6. Thin-Wall Thermal Resistance Parameters	324
7.3.13.3.7. Thermal Conditions for Two-Sided Walls	326
7.3.13.3.8. Shell Conduction in Thin-Walls	327
7.3.13.4. Species Boundary Conditions for Walls	328
7.3.13.4.1. Reaction Boundary Conditions for Walls	329
7.3.13.5. Radiation Boundary Conditions for Walls	330
7.3.13.6. Discrete Phase Model (DPM) Boundary Conditions for Walls	330
7.3.13.6.1. Wall Adhesion Contact Angle for VOF Model	330
7.3.13.7. User-Defined Scalar (UDS) Boundary Conditions for Walls	330
7.3.13.8. Wall Film Boundary Conditions for Walls	330
7.3.13.9. Default Settings at Wall Boundaries	330
7.3.13.10. Shear-Stress Calculation Procedure at Wall Boundaries	331
7.3.13.10.1. Shear-Stress Calculation in Laminar Flow	331
7.3.13.10.2. Shear-Stress Calculation in Turbulent Flows	331
7.3.13.11. Heat Transfer Calculations at Wall Boundaries	331
7.3.13.11.1. Temperature Boundary Conditions	331
7.3.13.11.2. Heat Flux Boundary Conditions	332
7.3.13.11.3. Convective Heat Transfer Boundary Conditions	332
7.3.13.11.4. External Radiation Boundary Conditions	333
7.3.13.11.5. Combined External Convection and Radiation Boundary Conditions	333
7.3.13.11.6. Calculation of the Fluid-Side Heat Transfer Coefficient	333
7.3.14. Symmetry Boundary Conditions	334
7.3.14.1. Examples of Symmetry Boundaries	334
7.3.14.2. Calculation Procedure at Symmetry Boundaries	335
7.3.15. Periodic Boundary Conditions	336
7.3.15.1. Examples of Periodic Boundaries	336
7.3.15.2. Inputs for Periodic Boundaries	336
7.3.15.3. Default Settings at Periodic Boundaries	338
7.3.15.4. Calculation Procedure at Periodic Boundaries	338
7.3.16. Axis Boundary Conditions	338

7.3.16.1. Calculation Procedure at Axis Boundaries	339
7.3.17. Fan Boundary Conditions	339
7.3.17.1. Fan Equations	339
7.3.17.1.1. Modeling the Pressure Rise Across the Fan	339
7.3.17.1.2. Modeling the Fan Swirl Velocity	340
7.3.17.2. User Inputs for Fans	340
7.3.17.2.1. Identifying the Fan Zone	341
7.3.17.2.2. Defining the Pressure Jump	341
7.3.17.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function	342
7.3.17.2.2.2. Constant Value	343
7.3.17.2.2.3. User-Defined Function or Profile	343
7.3.17.2.2.4. Example: Determining the Pressure Jump Function	343
7.3.17.2.3. Defining Discrete Phase Boundary Conditions for the Fan	344
7.3.17.2.4. Defining the Fan Swirl Velocity	344
7.3.17.2.4.1. Polynomial Function	345
7.3.17.2.4.2. Constant Value	345
7.3.17.2.4.3. User-Defined Function or Profile	345
7.3.17.3. Postprocessing for Fans	345
7.3.17.3.1. Reporting the Pressure Rise Through the Fan	345
7.3.17.3.2. Graphical Plots	346
7.3.18. Radiator Boundary Conditions	346
7.3.18.1. Radiator Equations	346
7.3.18.1.1. Modeling the Pressure Loss Through a Radiator	346
7.3.18.1.2. Modeling the Heat Transfer Through a Radiator	347
7.3.18.1.2.1. Calculating the Heat Transfer Coefficient	347
7.3.18.2. User Inputs for Radiators	348
7.3.18.2.1. Identifying the Radiator Zone	349
7.3.18.2.2. Defining the Pressure Loss Coefficient Function	349
7.3.18.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function	349
7.3.18.2.2.2. Constant Value	350
7.3.18.2.2.3. Example: Calculating the Loss Coefficient	350
7.3.18.2.3. Defining the Heat Flux Parameters	351
7.3.18.2.3.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function	351
7.3.18.2.3.2. Constant Value	352
7.3.18.2.3.3. Example: Determining the Heat Transfer Coefficient Function	352
7.3.18.2.4. Defining Discrete Phase Boundary Conditions for the Radiator	352
7.3.18.3. Postprocessing for Radiators	352
7.3.18.3.1. Reporting the Radiator Pressure Drop	352
7.3.18.3.2. Reporting Heat Transfer in the Radiator	353
7.3.18.3.3. Graphical Plots	353
7.3.19. Porous Jump Boundary Conditions	353
7.3.19.1. User Inputs for the Porous Jump Model	353
7.3.19.1.1. Identifying the Porous Jump Zone	354
7.3.19.1.2. Defining Discrete Phase Boundary Conditions for the Porous Jump	355
7.3.19.2. Postprocessing for the Porous Jump	355
7.4. Non-Reflecting Boundary Conditions	355
7.4.1. Turbo-Specific Non-Reflecting Boundary Conditions	355
7.4.1.1. Overview	355
7.4.1.2. Limitations	356
7.4.1.3. Theory	358
7.4.1.3.1. Equations in Characteristic Variable Form	358
7.4.1.3.2. Inlet Boundary	360

7.4.1.3.3. Outlet Boundary	364
7.4.1.3.4. Updated Flow Variables	366
7.4.1.4. Using Turbo-Specific Non-Reflecting Boundary Conditions	366
7.4.1.4.1. Using the NRBCs with the Mixing-Plane Model	367
7.4.1.4.2. Using the NRBCs in Parallel ANSYS FLUENT	367
7.4.2. General Non-Reflecting Boundary Conditions	368
7.4.2.1. Overview	368
7.4.2.2. Restrictions and Limitations	368
7.4.2.3. Theory	368
7.4.2.4. Using General Non-Reflecting Boundary Conditions	373
7.5. User-Defined Fan Model	375
7.5.1. Steps for Using the User-Defined Fan Model	375
7.5.2. Example of a User-Defined Fan	376
7.5.2.1. Setting the User-Defined Fan Parameters	376
7.5.2.2. Sample User-Defined Fan Program	377
7.5.2.3. Initializing the Flow Field and Profile Files	379
7.5.2.4. Selecting the Profiles	379
7.5.2.5. Performing the Calculation	380
7.5.2.6. Results	381
7.6. Profiles	382
7.6.1. Profile Specification Types	382
7.6.2. Profile File Format	383
7.6.2.1. Example	384
7.6.3. Using Profiles	385
7.6.3.1. Checking and Deleting Profiles	386
7.6.3.2. Viewing Profile Data	387
7.6.3.3. Example	387
7.6.4. Reorienting Profiles	388
7.6.4.1. Steps for Changing the Profile Orientation	388
7.6.4.2. Profile Orienting Example	391
7.6.5. Defining Transient Cell Zone and Boundary Conditions	393
7.6.5.1. Standard Transient Profiles	394
7.6.5.2. Tabular Transient Profiles	395
7.7. Coupling Boundary Conditions with GT-Power	396
7.7.1. Requirements and Restrictions	396
7.7.2. User Inputs	397
7.8. Coupling Boundary Conditions with WAVE	398
7.8.1. Requirements and Restrictions	398
7.8.2. User Inputs	399
8. Physical Properties	403
8.1. Defining Materials	403
8.1.1. Physical Properties for Solid Materials	404
8.1.2. Material Types and Databases	404
8.1.3. Using the Materials Task Page	405
8.1.3.1. Modifying Properties of an Existing Material	406
8.1.3.2. Renaming an Existing Material	406
8.1.3.3. Copying Materials from the ANSYS FLUENT Database	407
8.1.3.4. Creating a New Material	408
8.1.3.5. Saving Materials and Properties	408
8.1.3.6. Deleting a Material	409
8.1.3.7. Changing the Order of the Materials List	409
8.1.4. Using a User-Defined Materials Database	409

8.1.4.1. Opening a User-Defined Database	410
8.1.4.2. Viewing Materials in a User-Defined Database	410
8.1.4.3. Copying Materials from a User-Defined Database	411
8.1.4.4. Copying Materials from the Case to a User-Defined Database	412
8.1.4.5. Modifying Properties of an Existing Material	413
8.1.4.6. Creating a New Materials Database and Materials	413
8.1.4.7. Deleting Materials from a Database	416
8.2. Defining Properties Using Temperature-Dependent Functions	417
8.2.1. Inputs for Polynomial Functions	417
8.2.2. Inputs for Piecewise-Linear Functions	418
8.2.3. Inputs for Piecewise-Polynomial Functions	420
8.2.4. Checking and Modifying Existing Profiles	421
8.3. Density	421
8.3.1. Defining Density for Various Flow Regimes	421
8.3.1.1. Mixing Density Relationships in Multiple-Zone Models	421
8.3.2. Input of Constant Density	422
8.3.3. Inputs for the Boussinesq Approximation	422
8.3.4. Density as a Profile Function of Temperature	422
8.3.5. Incompressible Ideal Gas Law	423
8.3.5.1. Density Inputs for the Incompressible Ideal Gas Law	423
8.3.6. Ideal Gas Law for Compressible Flows	424
8.3.6.1. Density Inputs for the Ideal Gas Law for Compressible Flows	424
8.3.7. Composition-Dependent Density for Multicomponent Mixtures	425
8.4. Viscosity	426
8.4.1. Input of Constant Viscosity	427
8.4.2. Viscosity as a Function of Temperature	427
8.4.2.1. Sutherland Viscosity Law	427
8.4.2.1.1. Inputs for Sutherland's Law	428
8.4.2.2. Power-Law Viscosity Law	429
8.4.2.2.1. Inputs for the Power Law	430
8.4.3. Defining the Viscosity Using Kinetic Theory	430
8.4.4. Composition-Dependent Viscosity for Multicomponent Mixtures	430
8.4.5. Viscosity for Non-Newtonian Fluids	431
8.4.5.1. Temperature Dependent Viscosity	432
8.4.5.2. Power Law for Non-Newtonian Viscosity	433
8.4.5.2.1. Inputs for the Non-Newtonian Power Law	433
8.4.5.3. The Carreau Model for Pseudo-Plastics	433
8.4.5.3.1. Inputs for the Carreau Model	434
8.4.5.4. Cross Model	435
8.4.5.4.1. Inputs for the Cross Model	435
8.4.5.5. Herschel-Bulkley Model for Bingham Plastics	436
8.4.5.5.1. Inputs for the Herschel-Bulkley Model	437
8.5. Thermal Conductivity	437
8.5.1. Constant Thermal Conductivity	438
8.5.2. Thermal Conductivity as a Function of Temperature	439
8.5.3. Thermal Conductivity Using Kinetic Theory	439
8.5.4. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures	439
8.5.5. Anisotropic Thermal Conductivity for Solids	441
8.5.5.1. Anisotropic Thermal Conductivity	441
8.5.5.2. Biaxial Thermal Conductivity	442
8.5.5.3. Orthotropic Thermal Conductivity	443
8.5.5.4. Cylindrical Orthotropic Thermal Conductivity	445

8.6. User-Defined Scalar (UDS) Diffusivity	446
8.6.1. Isotropic Diffusion	446
8.6.2. Anisotropic Diffusion	447
8.6.2.1. Anisotropic Diffusivity	448
8.6.2.2. Orthotropic Diffusivity	449
8.6.2.3. Cylindrical Orthotropic Diffusivity	450
8.6.3. User-Defined Anisotropic Diffusivity	451
8.7. Specific Heat Capacity	452
8.7.1. Input of Constant Specific Heat Capacity	453
8.7.2. Specific Heat Capacity as a Function of Temperature	453
8.7.3. Defining Specific Heat Capacity Using Kinetic Theory	453
8.7.4. Specific Heat Capacity as a Function of Composition	454
8.8. Radiation Properties	454
8.8.1. Absorption Coefficient	454
8.8.1.1. Inputs for a Constant Absorption Coefficient	455
8.8.1.2. Inputs for a Composition-Dependent Absorption Coefficient	455
8.8.1.2.1. Path Length Inputs	455
8.8.1.2.1.1. Inputs for a Non-Gray Radiation Absorption Coefficient	456
8.8.1.2.1.2. Effect of Particles and Soot on the Absorption Coefficient	456
8.8.2. Scattering Coefficient	456
8.8.2.1. Inputs for a Constant Scattering Coefficient	456
8.8.2.2. Inputs for the Scattering Phase Function	456
8.8.2.2.1. Isotropic Phase Function	457
8.8.2.2.2. Linear-Anisotropic Phase Function	457
8.8.2.2.3. Delta-Eddington Phase Function	457
8.8.2.2.4. User-Defined Phase Function	457
8.8.3. Refractive Index	457
8.8.4. Reporting the Radiation Properties	457
8.9. Mass Diffusion Coefficients	457
8.9.1. Fickian Diffusion	458
8.9.2. Full Multicomponent Diffusion	459
8.9.2.1. General Theory	459
8.9.2.2. Maxwell-Stefan Equations	459
8.9.3. Thermal Diffusion Coefficients	461
8.9.4. Mass Diffusion Coefficient Inputs	461
8.9.4.1. Constant Dilute Approximation Inputs	462
8.9.4.2. Dilute Approximation Inputs	462
8.9.4.3. Multicomponent Method Inputs	463
8.9.4.4. Thermal Diffusion Coefficient Inputs	465
8.9.5. Mass Diffusion Coefficient Inputs for Turbulent Flow	466
8.10. Standard State Enthalpies	466
8.11. Standard State Entropies	467
8.12. Molecular Heat Transfer Coefficient	467
8.13. Kinetic Theory Parameters	467
8.13.1. Inputs for Kinetic Theory	468
8.14. Operating Pressure	468
8.14.1. The Effect of Numerical Roundoff on Pressure Calculation in Low-Mach-Number Flow	468
8.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure	469
8.14.3. Setting the Operating Pressure	469
8.14.3.1. The Significance of Operating Pressure	469
8.14.3.2. How to Set the Operating Pressure	469
8.15. Reference Pressure Location	470

8.15.1. Actual Reference Pressure Location	470
8.16. Real Gas Models	471
8.16.1. Introduction	471
8.16.2. Choosing a Real Gas Model	473
8.16.3. Cubic Equation of State Models	474
8.16.3.1. Overview and Limitations	474
8.16.3.2. Equation of State	475
8.16.3.3. Enthalpy, Entropy, and Specific Heat Calculations	477
8.16.3.4. Critical Constants for Pure Components	480
8.16.3.5. Calculations for Mixtures	480
8.16.3.5.1. Using the Cubic Equation of State Real Gas Models	482
8.16.3.5.2. Solution Strategies and Considerations for Cubic Equations of State Real Gas Models	485
8.16.3.5.3. Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models	486
8.16.3.5.4. Postprocessing the Cubic Equations of State Real Gas Model	487
8.16.4. The NIST Real Gas Models	488
8.16.4.1. Limitations of the NIST Real Gas Models	488
8.16.4.2. The REFPROP v7.0 Database	489
8.16.4.3. Using the NIST Real Gas Models	490
8.16.4.3.1. Activating the NIST Real Gas Model	490
8.16.4.4. Solution Strategies and Considerations for NIST Real Gas Model Simulation	492
8.16.4.4.1. Writing Your Case File	492
8.16.4.4.2. Postprocessing	493
8.16.5. The User-Defined Real Gas Model	493
8.16.5.1. Limitations of the User-Defined Real Gas Model	493
8.16.5.2. Writing the UDRGM C Function Library	496
8.16.5.3. Compiling Your UDRGM C Functions and Building a Shared Library File	498
8.16.5.3.1. Compiling the UDRGM Using the Graphical Interface	499
8.16.5.3.2. Compiling the UDRGM Using the Text Interface	499
8.16.5.3.3. Loading the UDRGM Shared Library File	500
8.16.5.4. UDRGM Example: Ideal Gas Equation of State	501
8.16.5.4.1. Ideal Gas UDRGM Code Listing	502
8.16.5.5. Additional UDRGM Examples	504
9. Modeling Basic Fluid Flow	505
9.1. User-Defined Scalar (UDS) Transport Equations	505
9.1.1. Introduction	505
9.1.2. UDS Theory	505
9.1.2.1. Single Phase Flow	506
9.1.2.2. Multiphase Flow	507
9.1.3. Setting Up UDS Equations in ANSYS FLUENT	508
9.1.3.1. Single Phase Flow	509
9.1.3.2. Multiphase Flow	513
9.2. Periodic Flows	514
9.2.1. Overview and Limitations	514
9.2.1.1. Overview	515
9.2.1.2. Limitations for Modeling Streamwise-Periodic Flow	515
9.2.2. User Inputs for the Pressure-Based Solver	516
9.2.2.1. Setting Parameters for the Calculation of β	517
9.2.3. User Inputs for the Density-Based Solvers	517
9.2.4. Monitoring the Value of the Pressure Gradient	518
9.2.5. Postprocessing for Streamwise-Periodic Flows	518

9.3. Swirling and Rotating Flows	519
9.3.1. Overview of Swirling and Rotating Flows	519
9.3.1.1. Axisymmetric Flows with Swirl or Rotation	520
9.3.1.1.1. Momentum Conservation Equation for Swirl Velocity	520
9.3.1.2. Three-Dimensional Swirling Flows	520
9.3.1.3. Flows Requiring a Moving Reference Frame	520
9.3.2. Turbulence Modeling in Swirling Flows	521
9.3.3. Mesh Setup for Swirling and Rotating Flows	521
9.3.3.1. Coordinate System Restrictions	521
9.3.3.2. Mesh Sensitivity in Swirling and Rotating Flows	521
9.3.4. Modeling Axisymmetric Flows with Swirl or Rotation	522
9.3.4.1. Problem Setup for Axisymmetric Swirling Flows	522
9.3.4.2. Solution Strategies for Axisymmetric Swirling Flows	523
9.3.4.2.1. Step-By-Step Solution Procedures for Axisymmetric Swirling Flows	523
9.3.4.2.2. Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed	524
9.3.4.2.2.1. Postprocessing for Axisymmetric Swirling Flows	525
9.4. Compressible Flows	525
9.4.1. When to Use the Compressible Flow Model	526
9.4.2. Physics of Compressible Flows	527
9.4.2.1. Basic Equations for Compressible Flows	527
9.4.2.2. The Compressible Form of the Gas Law	527
9.4.3. Modeling Inputs for Compressible Flows	528
9.4.3.1. Boundary Conditions for Compressible Flows	529
9.4.4. Floating Operating Pressure	529
9.4.4.1. Limitations	529
9.4.4.2. Theory	530
9.4.4.3. Enabling Floating Operating Pressure	530
9.4.4.4. Setting the Initial Value for the Floating Operating Pressure	530
9.4.4.5. Storage and Reporting of the Floating Operating Pressure	531
9.4.4.6. Monitoring Absolute Pressure	531
9.4.5. Solution Strategies for Compressible Flows	531
9.4.6. Reporting of Results for Compressible Flows	531
9.5. Inviscid Flows	532
9.5.1. Setting Up an Inviscid Flow Model	532
9.5.2. Solution Strategies for Inviscid Flows	533
9.5.3. Postprocessing for Inviscid Flows	533
10. Modeling Flows with Moving Reference Frames	535
10.1. Introduction	535
10.2. Flow in Single Moving Reference Frames (SRF)	537
10.2.1. Mesh Setup for a Single Moving Reference Frame	538
10.2.2. Setting Up a Single Moving Reference Frame Problem	538
10.2.2.1. Choosing the Relative or Absolute Velocity Formulation	541
10.2.2.1.1. Example	541
10.2.3. Solution Strategies for a Single Moving Reference Frame	542
10.2.3.1. Gradual Increase of the Rotational Speed to Improve Solution Stability	543
10.2.4. Postprocessing for a Single Moving Reference Frame	543
10.3. Flow in Multiple Moving Reference Frames	544
10.3.1. The Multiple Reference Frame Model	545
10.3.1.1. Overview	545
10.3.1.2. Limitations	546
10.3.2. The Mixing Plane Model	547

10.3.2.1. Overview	547
10.3.2.2. Limitations	547
10.3.3. Mesh Setup for a Multiple Moving Reference Frame	548
10.3.4. Setting Up a Multiple Moving Reference Frame Problem	548
10.3.4.1. Setting Up Multiple Reference Frames	548
10.3.4.2. Setting Up the Mixing Plane Model	551
10.3.4.2.1. Modeling Options	554
10.3.4.2.1.1. Fixing the Pressure Level for an Incompressible Flow	554
10.3.4.2.1.2. Conserving Swirl Across the Mixing Plane	555
10.3.4.2.1.3. Conserving Total Enthalpy Across the Mixing Plane	555
10.3.5. Solution Strategies for MRF and Mixing Plane Problems	556
10.3.5.1. MRF Model	556
10.3.5.2. Mixing Plane Model	556
10.3.6. Postprocessing for MRF and Mixing Plane Problems	556
11. Modeling Flows Using Sliding and Dynamic Meshes	559
11.1. Introduction	559
11.2. Sliding Mesh Examples	559
11.3. The Sliding Mesh Technique	561
11.4. Sliding Mesh Interface Shapes	562
11.5. Using Sliding Meshes	564
11.5.1. Requirements and Constraints	565
11.5.2. Setting Up the Sliding Mesh Problem	566
11.5.3. Solution Strategies for Sliding Meshes	569
11.5.3.1. Saving Case and Data Files	569
11.5.3.2. Time-Periodic Solutions	570
11.5.4. Postprocessing for Sliding Meshes	571
11.6. Using Dynamic Meshes	573
11.6.1. Setting Dynamic Mesh Modeling Parameters	574
11.6.2. Dynamic Mesh Update Methods	575
11.6.2.1. Smoothing Methods	575
11.6.2.1.1. Spring-Based Smoothing	577
11.6.2.1.1.1. Applicability of the Spring-Based Smoothing Method	580
11.6.2.1.2. Diffusion-Based Smoothing	581
11.6.2.1.2.1. Diffusivity Based on Boundary Distance	583
11.6.2.1.2.2. Diffusivity Based on Cell Volume	585
11.6.2.1.2.3. Applicability of the Diffusion-Based Smoothing Method	586
11.6.2.1.3. Laplacian Smoothing Method	586
11.6.2.1.4. Boundary Layer Smoothing Method	587
11.6.2.2. Dynamic Layering	591
11.6.2.2.1. Applicability of the Dynamic Layering Method	594
11.6.2.3. Remeshing Methods	595
11.6.2.3.1. Local Remeshing Method	598
11.6.2.3.1.1. Local Cell Remeshing Method	599
11.6.2.3.1.2. Local Face Remeshing Method	599
11.6.2.3.1.2.1. Applicability of the Local Face Remeshing Method	599
11.6.2.3.1.3. Local Remeshing Based on Size Functions	599
11.6.2.3.2. Cell Zone Remeshing Method	605
11.6.2.3.2.1. Limitations of the Cell Zone Remeshing Method	606
11.6.2.3.3. Face Region Remeshing Method	606
11.6.2.3.3.1. Face Region Remeshing with Prism Layers	607
11.6.2.3.3.2. Applicability of the Face Region Remeshing Method	609
11.6.2.3.4. CutCell Zone Remeshing Method	610

11.6.2.3.4.1. Applicability of the CutCell Zone Remeshing Method	611
11.6.2.3.4.2. Using the CutCell Zone Remeshing Method	612
11.6.2.3.4.3. Applying the CutCell Zone Remeshing Method Manually	612
11.6.2.3.5. 2.5D Surface Remeshing Method	613
11.6.2.3.5.1. Applicability of the 2.5D Surface Remeshing Method	615
11.6.2.3.5.2. Using the 2.5D Model	615
11.6.2.3.6. Feature Detection	617
11.6.2.3.6.1. Applicability of Feature Detection	618
11.6.2.4. Volume Mesh Update Procedure	618
11.6.3. In-Cylinder Settings	618
11.6.3.1. Using the In-Cylinder Option	623
11.6.3.1.1. Overview	624
11.6.3.1.2. Defining the Mesh Topology	624
11.6.3.1.3. Defining Motion/Geometry Attributes of Mesh Zones	627
11.6.3.1.4. Defining Valve Opening and Closure	633
11.6.4. Six DOF Solver Settings	633
11.6.4.1. Using the Six DOF Solver	634
11.6.4.1.1. Setting Rigid Body Motion Attributes for the Six DOF Solver	634
11.6.5. Implicit Update Settings	635
11.6.6. Defining Dynamic Mesh Events	637
11.6.6.1. Procedure for Defining Events	637
11.6.6.2. Defining Events for In-Cylinder Applications	639
11.6.6.2.1. Events	640
11.6.6.2.2. Changing the Zone Type	640
11.6.6.2.3. Copying Zone Boundary Conditions	640
11.6.6.2.4. Activating a Cell Zone	640
11.6.6.2.5. Deactivating a Cell Zone	640
11.6.6.2.6. Creating a Sliding Interface	640
11.6.6.2.7. Deleting a Sliding Interface	642
11.6.6.2.8. Changing the Motion Attribute of a Dynamic Zone	642
11.6.6.2.9. Changing the Time Step	642
11.6.6.2.10. Changing the Under-Relaxation Factor	642
11.6.6.2.11. Inserting a Boundary Zone Layer	642
11.6.6.2.12. Removing a Boundary Zone Layer	643
11.6.6.2.13. Inserting an Interior Zone Layer	643
11.6.6.2.14. Removing an Interior Zone Layer	644
11.6.6.2.15. Inserting a Cell Layer	644
11.6.6.2.16. Removing a Cell Layer	644
11.6.6.2.17. Executing a Command	645
11.6.6.2.18. Replacing the Mesh	645
11.6.6.2.19. Resetting Inert EGR	645
11.6.6.3. Exporting and Importing Events	645
11.6.7. Specifying the Motion of Dynamic Zones	645
11.6.7.1. General Procedure	645
11.6.7.1.1. Creating a Dynamic Zone	646
11.6.7.1.2. Modifying a Dynamic Zone	646
11.6.7.1.3. Checking the Center of Gravity	646
11.6.7.1.4. Deleting a Dynamic Zone	646
11.6.7.2. Stationary Zones	646
11.6.7.3. Rigid Body Motion	649
11.6.7.4. Deforming Motion	652
11.6.7.5. User-Defined Motion	656

11.6.7.5.1. Specifying Boundary Layer Deformation Smoothing	657
11.6.7.6. System Coupling Motion	657
11.6.7.7. Solid-Body Kinematics	658
11.6.8. Previewing the Dynamic Mesh	661
11.6.8.1. Previewing Zone Motion	661
11.6.8.2. Previewing Mesh Motion	662
11.6.9. Steady-State Dynamic Mesh Applications	663
11.6.9.1. An Example of Steady-State Dynamic Mesh Usage	664
12. Modeling Flows Using the Mesh Morpher/Optimizer	667
12.1. Introduction	667
12.1.1. Limitations	667
12.2. The Optimization Process	667
12.3. Optimizers	668
12.3.1. The Compass Optimizer	668
12.3.2. The Simplex Optimizer	669
12.3.3. The Torczon Optimizer	669

14.2.5. Shell Conduction Considerations	748
14.2.5.1. Introduction	748
14.2.5.2. Physical Treatment	748
14.2.5.3. Limitations of Shell Conduction Walls	749
14.2.5.4. Managing Shell Conduction Walls	749
14.2.5.5. Initialization	751
14.2.5.6. Postprocessing	751
14.3. Modeling Radiation	751
14.3.1. Using the Radiation Models	752
14.3.2. Setting Up the P-1 Model with Non-Gray Radiation	753
14.3.3. Setting Up the DTRM	754
14.3.3.1. Defining the Rays	754
14.3.3.2. Controlling the Clusters	755
14.3.3.3. Controlling the Rays	756
14.3.3.4. Writing and Reading the DTRM Ray File	756
14.3.3.5. Displaying the Clusters	757
14.3.4. Setting Up the S2S Model	757
14.3.4.1. View Factors and Clustering Settings	758

14.3.4.1.1. Forming Surface Clusters	759
14.3.4.1.1.1. Setting the Split Angle for Clusters	761
14.3.4.1.2. Setting Up the View Factor Calculation	761
14.3.4.1.2.1. Selecting the Basis for Computing View Factors	761
14.3.4.1.2.2. Selecting the Method for Computing View Factors	762
14.3.4.1.2.3. Accounting for Blocking Surfaces	763
14.3.4.1.2.4. Specifying Boundary Zone Participation	763
14.3.4.2. Computing View Factors	765
14.3.4.2.1. Computing View Factors Inside ANSYS FLUENT	765
14.3.4.2.2. Computing View Factors Outside ANSYS FLUENT	767
14.3.4.3. Reading View Factors into ANSYS FLUENT	768
14.3.5. Setting Up the DO Model	768
14.3.5.1. Angular Discretization	769
14.3.5.2. Defining Non-Gray Radiation for the DO Model	769
14.3.5.3. Enabling DO/Energy Coupling	771
14.3.6. Defining Material Properties for Radiation	772
14.3.6.1. Absorption Coefficient for a Non-Gray Model	772
14.3.6.2. Refractive Index for a Non-Gray Model	772
14.3.7. Defining Boundary Conditions for Radiation	772
14.3.7.1. Inlet and Exit Boundary Conditions	773
14.3.7.1.1. Emissivity	773
14.3.7.1.2. Black Body Temperature	773
14.3.7.2. Wall Boundary Conditions for the DTRM, and the P-1, S2S, and Rosseland Models	774
14.3.7.2.1. Boundary Conditions for the S2S Model	774
14.3.7.3. Wall Boundary Conditions for the DO Model	774
14.3.7.3.1. Opaque Walls	774
14.3.7.3.2. Semi-Transparent Walls	777
14.3.7.4. Solid Cell Zones Conditions for the DO Model	780
14.3.7.5. Thermal Boundary Conditions	781
14.3.8. Solution Strategies for Radiation Modeling	781
14.3.8.1. P-1 Model Solution Parameters	782
14.3.8.2. DTRM Solution Parameters	782
14.3.8.3. S2S Solution Parameters	783
14.3.8.4. DO Solution Parameters	784
14.3.8.5. Running the Calculation	784
14.3.8.5.1. Residual Reporting for the P-1 Model	784
14.3.8.5.2. Residual Reporting for the DO Model	784
14.3.8.5.3. Residual Reporting for the DTRM	784
14.3.8.5.4. Residual Reporting for the S2S Model	785
14.3.8.5.5. Disabling the Update of the Radiation Fluxes	785
14.3.9. Postprocessing Radiation Quantities	785
14.3.9.1. Available Variables for Postprocessing	786
14.3.9.2. Reporting Radiative Heat Transfer Through Boundaries	786
14.3.9.3. Overall Heat Balances When Using the DTRM	787
14.3.9.4. Displaying Rays and Clusters for the DTRM	787
14.3.9.4.1. Displaying Clusters	787
14.3.9.4.2. Displaying Rays	788
14.3.9.4.3. Including the Mesh in the Display	788
14.3.9.5. Reporting Radiation in the S2S Model	788
14.3.10. Solar Load Model	789
14.3.10.1. Introduction	790
14.3.10.2. Solar Ray Tracing	790

14.3.10.2.1. Shading Algorithm	791
14.3.10.2.2. Glazing Materials	791
14.3.10.2.3. Inputs	792
14.3.10.3. DO Irradiation	793
14.3.10.4. Solar Calculator	794
14.3.10.4.1. Inputs/Outputs	794
14.3.10.4.2. Theory	795
14.3.10.4.3. Computation of Load Distribution	796
14.3.10.5. Using the Solar Load Model	797
14.3.10.5.1. User-Defined Functions (UDFs) for Solar Load	797
14.3.10.5.2. Setting Up the Solar Load Model	797
14.3.10.5.3. Setting Boundary Conditions for Solar Loading	802
14.3.10.5.4. Solar Ray Tracing	803
14.3.10.5.5. DO Irradiation	807
14.3.10.5.6. Text Interface-Only Commands	809
14.3.10.5.6.1. Automatically Saving Solar Ray Tracing Data	809
14.3.10.5.6.2. Automatically Reading Solar Data	809
14.3.10.5.6.3. Aligning the Camera Direction With the Position of the Sun	809
14.3.10.5.6.4. Specifying the Scattering Fraction	810
14.3.10.5.6.5. Applying the Solar Load on Adjacent Fluid Cells	810
14.3.10.5.6.6. Specifying Quad Tree Refinement Factor	810
14.3.10.5.6.7. Specifying Ground Reflectivity	810
14.3.10.5.6.8. Additional Text Interface Commands	811
14.3.10.6. Postprocessing Solar Load Quantities	811
14.3.10.6.1. Solar Load Animation at Different Sun Positions	812
14.3.10.6.2. Reporting and Displaying Solar Load Quantities	813
14.4. Modeling Periodic Heat Transfer	813
14.4.1. Overview and Limitations	814
14.4.1.1. Overview	814
14.4.1.2. Constraints for Periodic Heat Transfer Predictions	814
14.4.2. Theory	814
14.4.2.1. Definition of the Periodic Temperature for Constant-Temperature Wall Conditions	815
14.4.2.2. Definition of the Periodic Temperature Change σ for Specified Heat Flux Conditions	815
14.4.3. Using Periodic Heat Transfer	816
14.4.4. Solution Strategies for Periodic Heat Transfer	817
14.4.5. Monitoring Convergence	818
14.4.6. Postprocessing for Periodic Heat Transfer	818
15. Modeling Heat Exchangers	819
15.1. Choosing a Heat Exchanger Model	820
15.2. The Dual Cell Model	821
15.2.1. Restrictions	822
15.2.2. Using the Dual Cell Heat Exchanger Model	822
15.3. The Macro Heat Exchanger Models	829
15.3.1. Restrictions	830
15.3.2. Using the Ungrouped Macro Heat Exchanger Model	831
15.3.2.1. Selecting the Zone for the Heat Exchanger	836
15.3.2.2. Specifying Heat Exchanger Performance Data	836
15.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions	837
15.3.2.4. Defining the Macros	837
15.3.2.4.1. Viewing the Macros	838
15.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions	838
15.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness	839

15.3.2.6.1. Using the Default Core Porosity Model	840
15.3.2.6.2. Defining a New Core Porosity Model	840
15.3.2.6.3. Reading Heat Exchanger Parameters from an External File	841
15.3.2.6.4. Viewing the Parameters for an Existing Core Model	841
15.3.3. Using the Grouped Macro Heat Exchanger Model	841
15.3.3.1. Selecting the Fluid Zones for the Heat Exchanger Group	847
15.3.3.2. Selecting the Upstream Heat Exchanger Group	847
15.3.3.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions	847
15.3.3.4. Specifying the Auxiliary Fluid Properties	847
15.3.3.5. Specifying Supplementary Auxiliary Fluid Streams	848
15.3.3.6. Initializing the Auxiliary Fluid Temperature	848
15.4. Postprocessing for the Heat Exchanger Model	848
15.4.1. Heat Exchanger Reporting	849
15.4.1.1. Computed Heat Rejection	849
15.4.1.2. Inlet/Outlet Temperature	849
15.4.1.3. Mass Flow Rate	850
15.4.1.4. Specific Heat	851
15.4.2. Total Heat Rejection Rate	852
15.5. Useful Reporting TUI Commands	853
16. Modeling Species Transport and Finite-Rate Chemistry	855
16.1. Volumetric Reactions	855
16.1.1. Overview of User Inputs for Modeling Species Transport and Reactions	855
16.1.1.1. Mixture Materials	856
16.1.2. Enabling Species Transport and Reactions and Choosing the Mixture Material	857
16.1.3. Defining Properties for the Mixture and Its Constituent Species	861
16.1.3.1. Defining the Species in the Mixture	862
16.1.3.1.1. Overview of the Species Dialog Box	863
16.1.3.1.2. Adding Species to the Mixture	863
16.1.3.1.3. Removing Species from the Mixture	864
16.1.3.1.4. Reordering Species	864
16.1.3.1.5. The Naming and Ordering of Species	865
16.1.3.2. Defining Reactions	865
16.1.3.2.1. Inputs for Reaction Definition	865
16.1.3.2.2. Defining Species and Reactions for Fuel Mixtures	872
16.1.3.3. Defining Zone-Based Reaction Mechanisms	872
16.1.3.3.1. Inputs for Reaction Mechanism Definition	872
16.1.3.4. Defining Physical Properties for the Mixture	874
16.1.3.5. Defining Physical Properties for the Species in the Mixture	875
16.1.4. Setting up Coal Simulations with the Coal Calculator Dialog Box	876
16.1.5. Defining Cell Zone and Boundary Conditions for Species	878
16.1.5.1. Diffusion at Inlets with the Pressure-Based Solver	878
16.1.6. Defining Other Sources of Chemical Species	878
16.1.7. Solution Procedures for Chemical Mixing and Finite-Rate Chemistry	879
16.1.7.1. Stability and Convergence in Reacting Flows	879
16.1.7.2. Two-Step Solution Procedure (Cold Flow Simulation)	879
16.1.7.3. Density Under-Relaxation	880
16.1.7.4. Ignition in Combustion Simulations	880
16.1.7.5. Solution of Stiff Laminar Chemistry Systems	880
16.1.7.6. Eddy-Dissipation Concept Model Solution Procedure	881
16.1.8. Postprocessing for Species Calculations	882
16.1.8.1. Averaged Species Concentrations	883
16.1.9. Importing a Volumetric Kinetic Mechanism in CHEMKIN Format	883

16.2. Wall Surface Reactions and Chemical Vapor Deposition	886
16.2.1. Overview of Surface Species and Wall Surface Reactions	886
16.2.2. User Inputs for Wall Surface Reactions	886
16.2.3. Including Mass Transfer To Surfaces in Continuity	888
16.2.4. Wall Surface Mass Transfer Effects in the Energy Equation	888
16.2.5. Modeling the Heat Release Due to Wall Surface Reactions	888
16.2.6. Solution Procedures for Wall Surface Reactions	888
16.2.7. Postprocessing for Surface Reactions	889
16.2.8. Importing a Surface Kinetic Mechanism in CHEMKIN Format	889
16.2.8.1. Compatibility and Limitations for Gas Phase Reactions	891
16.2.8.2. Compatibility and Limitations for Surface Reactions	892
16.3. Particle Surface Reactions	892
16.3.1. User Inputs for Particle Surface Reactions	892
16.3.2. Modeling Gaseous Solid Catalyzed Reactions	893
16.3.3. Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion	893
16.4. Species Transport Without Reactions	894
16.5. Reacting Channel Model	895
16.5.1. Overview and Limitations of the Reacting Channel Model	895
16.5.2. Enabling the Reacting Channel Model	895
16.5.3. Boundary Conditions for Channel Walls	898
16.5.4. Postprocessing for Reacting Channel Model Calculations	899
17. Modeling Non-Premixed Combustion	901
17.1. Steps in Using the Non-Premixed Model	901
17.1.1. Preliminaries	901
17.1.2. Defining the Problem Type	902
17.1.3. Overview of the Problem Setup Procedure	902
17.2. Setting Up the Equilibrium Chemistry Model	905
17.2.1. Choosing Adiabatic or Non-Adiabatic Options	906
17.2.2. Specifying the Operating Pressure for the System	907
17.2.3. Enabling a Secondary Inlet Stream	907
17.2.4. Choosing to Define the Fuel Stream(s) Empirically	908
17.2.5. Enabling the Rich Flammability Limit (RFL) Option	909
17.3. Setting Up the Steady and Unsteady Laminar Flamelet Models	909
17.3.1. Choosing Adiabatic or Non-Adiabatic Options	910
17.3.2. Specifying the Operating Pressure for the System	910
17.3.3. Specifying a Chemical Mechanism File for Flamelet Generation	911
17.3.4. Importing a Flamelet	911
17.3.5. Using the Unsteady Laminar Flamelet Model	912
17.3.6. Using the Diesel Unsteady Laminar Flamelet Model	913
17.4. Defining the Stream Compositions	913
17.4.1. Setting Boundary Stream Species	915
17.4.1.1. Including Condensed Species	916
17.4.2. Modifying the Database	916
17.4.3. Composition Inputs for Empirically-Defined Fuel Streams	916
17.4.4. Modeling Liquid Fuel Combustion Using the Non-Premixed Model	917
17.4.5. Modeling Coal Combustion Using the Non-Premixed Model	917
17.4.5.1. Defining the Coal Composition: Single-Mixture-Fraction Models	918
17.4.5.2. Defining the Coal Composition: Two-Mixture-Fraction Models	919
17.4.5.3. Additional Coal Modeling Inputs in ANSYS FLUENT	921
17.4.5.4. Postprocessing Non-Premixed Models of Coal Combustion	922
17.4.5.5. The Coal Calculator	922
17.5. Setting Up Control Parameters	924

17.5.1. Forcing the Exclusion and Inclusion of Equilibrium Species	924
17.5.2. Defining the Flamelet Controls	925
17.5.3. Zeroing Species in the Initial Unsteady Flamelet	927
17.6. Calculating the Flamelets	927
17.6.1. Steady Flamelet	927
17.6.2. Unsteady Flamelet	929
17.6.3. Saving the Flamelet Data	931
17.6.4. Postprocessing the Flamelet Data	931
17.7. Calculating the Look-Up Tables	933
17.7.1. Full Tabulation of the Two-Mixture-Fraction Model	936
17.7.2. Stability Issues in Calculating Chemical Equilibrium Look-Up Tables	937
17.7.3. Saving the Look-Up Tables	937
17.7.4. Postprocessing the Look-Up Table Data	937
17.7.4.1. Files for Flamelet Modeling	941
17.7.4.1.1. Standard Flamelet Files	941
17.7.4.1.1.1. Sample File	942
17.7.4.1.1.2. Missing Species	942
17.7.4.5. Setting Up the Inert Model	943
17.7.5.1. Setting Boundary Conditions for Inert Transport	944
17.7.5.2. Initializing the Inert Stream	944
17.7.5.2.1. Inert Fraction	944
17.7.5.2.2. Inert Composition	945
17.7.5.3. Resetting Inert EGR	945
17.8. Defining Non-Premixed Boundary Conditions	946
17.8.1. Input of Mixture Fraction Boundary Conditions	946
17.8.2. Diffusion at Inlets	947
17.8.3. Input of Thermal Boundary Conditions and Fuel Inlet Velocities	948
17.9. Defining Non-Premixed Physical Properties	948
17.10. Solution Strategies for Non-Premixed Modeling	949
17.10.1. Single-Mixture-Fraction Approach	949
17.10.2. Two-Mixture-Fraction Approach	949
17.10.3. Starting a Non-Premixed Calculation From a Previous Case File	949
17.10.3.1. Retrieving the PDF File During Case File Reads	950
17.10.4. Solving the Flow Problem	950
17.10.4.1. Under-Relaxation Factors for PDF Equations	951
17.10.4.2. Density Under-Relaxation	951
17.10.4.3. Tuning the PDF Parameters for Two-Mixture-Fraction Calculations	951
17.11. Postprocessing the Non-Premixed Model Results	952
17.11.1. Postprocessing for Inert Calculations	954
18. Modeling Premixed Combustion	957
18.1. Overview and Limitations	957
18.1.1. Limitations of the Premixed Combustion Model	958
18.2. Using the Premixed Combustion Model	958
18.2.1. Enabling the Premixed Combustion Model	959
18.2.2. Choosing an Adiabatic or Non-Adiabatic Model	960
18.3. Setting Up the C-Equation and G-Equation Models	960
18.3.1. Modifying the Constants for the Zimont Flame Speed Model	962
18.3.2. Modifying the Constants for the Peters Flame Speed Model	962
18.3.3. Additional Options for the G-Equation Model	962
18.3.4. Defining Physical Properties for the Unburnt Mixture	962
18.3.5. Setting Boundary Conditions for the Progress Variable	963
18.3.6. Initializing the Progress Variable	963

18.4. Setting Up the Extended Coherent Flame Model	964
18.4.1. Modifying the ECFM Model Variant	964
18.4.2. Modifying the Constants for the ECFM Flame Speed Closure	964
18.4.3. Setting Boundary Conditions for the ECFM Transport	965
18.4.4. Initializing the Flame Area Density	965
18.5. Postprocessing for Premixed Combustion Calculations	965
18.5.1. Computing Species Concentrations	967
19. Modeling Partially Premixed Combustion	969
19.1. Overview and Limitations	969
19.1.1. Overview	969
19.1.2. Limitations	969
19.2. Using the Partially Premixed Combustion Model	969
19.2.1. Setup and Solution Procedure	970
19.2.2. Modifying the Unburnt Mixture Property Polynomials	972
19.2.3. Modeling In Cylinder Combustion	974
20. Modeling a Composition PDF Transport Problem	975
20.1. Overview and Limitations	975
20.2. Steps for Using the Composition PDF Transport Model	975
20.3. Enabling the Lagrangian Composition PDF Transport Model	977
20.4. Enabling the Eulerian Composition PDF Transport Model	979
20.4.1. Defining Species Boundary Conditions	980
20.4.1.1. Equilibrating Inlet Streams	981
20.5. Initializing the Solution	981
20.6. Monitoring the Solution	982
20.6.1. Running Unsteady Composition PDF Transport Simulations	983
20.6.2. Running Compressible Lagrangian PDF Transport Simulations	984
20.6.3. Running Lagrangian PDF Transport Simulations with Conjugate Heat Transfer	984
20.7. Postprocessing for Lagrangian PDF Transport Calculations	984
20.7.1. Reporting Options	984
20.7.2. Particle Tracking Options	985
20.8. Postprocessing for Eulerian PDF Transport Calculations	986
20.8.1. Reporting Options	986
21. Using Chemistry Acceleration	987
21.1. Using ISAT	988
21.1.1. ISAT Parameters	988
21.1.2. Monitoring ISAT	989
21.1.3. Using ISAT Efficiently	989
21.1.4. Reading and Writing ISAT Tables	990
21.2. Using Chemistry Agglomeration	991
21.3. Dimension Reduction	991
22. Modeling Engine Ignition	995
22.1. Spark Model	995
22.1.1. Using the Spark Model	995
22.1.2. Using the ECFM Spark Model	998
22.2. Autoignition Models	999
22.2.1. Using the Autoignition Models	999
22.3. Crevice Model	1002
22.3.1. Using the Crevice Model	1002
22.3.2. Crevice Model Solution Details	1004
22.3.3. Postprocessing for the Crevice Model	1004
22.3.3.1. Using the Crevice Output File	1006
23. Modeling Pollutant Formation	1009

23.1. NOx Formation	1009
23.1.1. Using the NOx Model	1009
23.1.1.1. Decoupled Analysis: Overview	1009
23.1.1.2. Enabling the NOx Models	1010
23.1.1.3. Defining the Fuel Streams	1012
23.1.1.4. Specifying a User-Defined Function for the NOx Rate	1014
23.1.1.5. Setting Thermal NOx Parameters	1014
23.1.1.6. Setting Prompt NOx Parameters	1015
23.1.1.7. Setting Fuel NOx Parameters	1015
23.1.1.7.1. Setting Gaseous and Liquid Fuel NOx Parameters	1016
23.1.1.7.2. Setting Solid (Coal) Fuel NOx Parameters	1017
23.1.1.8. Setting N ₂ O Pathway Parameters	1018
23.1.1.9. Setting Parameters for NOx Reburn	1019
23.1.1.10. Setting SNCR Parameters	1020
23.1.1.11. Setting Turbulence Parameters	1022
23.1.1.12. Defining Boundary Conditions for the NOx Model	1025
23.1.2. Solution Strategies	1025
23.1.3. Postprocessing	1025
23.2. SOx Formation	1026
23.2.1. Using the SOx Model	1026
23.2.1.1. Enabling the SOx Model	1027
23.2.1.2. Defining the Fuel Streams	1028
23.2.1.3. Defining the SOx Fuel Stream Settings	1030
23.2.1.3.1. Setting SOx Parameters for Gaseous and Liquid Fuel Types	1031
23.2.1.3.2. Setting SOx Parameters for a Solid Fuel	1032
23.2.1.4. Setting Turbulence Parameters	1034
23.2.1.5. Specifying a User-Defined Function for the SOx Rate	1037
23.2.1.6. Defining Boundary Conditions for the SOx Model	1037
23.2.2. Solution Strategies	1038
23.2.3. Postprocessing	1039
23.3. Soot Formation	1040
23.3.1. Using the Soot Models	1040
23.3.1.1. Setting Up the One-Step Model	1041
23.3.1.2. Setting Up the Two-Step Model	1042
23.3.1.3. Setting Up the Moss-Brookes Model and the Hall Extension	1045
23.3.1.3.1. Species Definition for the Moss-Brookes Model with a User-Defined Precursor Correlation	1048
23.3.1.4. Defining Boundary Conditions for the Soot Model	1051
23.3.1.5. Reporting Soot Quantities	1051
23.4. Using the Decoupled Detailed Chemistry Model	1052
24. Predicting Aerodynamically Generated Noise	1055
24.1. Overview	1055
24.1.1. Direct Method	1055
24.1.2. Integral Method Based on Acoustic Analogy	1056
24.1.3. Broadband Noise Source Models	1056
24.2. Using the Ffowcs-Williams and Hawkings Acoustics Model	1057
24.2.1. Enabling the FW-H Acoustics Model	1058
24.2.1.1. Setting Model Constants	1059
24.2.1.2. Computing Sound "on the Fly"	1060
24.2.1.3. Writing Source Data Files	1060
24.2.1.3.1. Exporting Source Data Without Enabling the FW-H Model: Using the ANSYS FLUENT ASD Format	1062

24.2.1.3.2. Exporting Source Data Without Enabling the FW-H Model: Using the CGNS Format	1062
24.2.2. Specifying Source Surfaces	1063
24.2.2.1. Saving Source Data	1065
24.2.3. Specifying Acoustic Receivers	1066
24.2.4. Specifying the Time Step	1068
24.2.5. Postprocessing the FW-H Acoustics Model Data	1069
24.2.5.1. Writing Acoustic Signals	1069
24.2.5.2. Reading Unsteady Acoustic Source Data	1070
24.2.5.2.1. Pruning the Signal Data Automatically	1071
24.2.5.3. Reporting the Static Pressure Time Derivative	1072
24.2.5.4. Using the FFT Capabilities	1072
24.3. Using the Broadband Noise Source Models	1072
24.3.1. Enabling the Broadband Noise Source Models	1073
24.3.1.1. Setting Model Constants	1073
24.3.2. Postprocessing the Broadband Noise Source Model Data	1074
25. Modeling Discrete Phase	1075
25.1. Introduction	1075
25.1.1. Overview	1076
25.1.2. Limitations	1076
25.1.2.1. Limitation on the Particle Volume Fraction	1076
25.1.2.2. Limitation on Modeling Continuous Suspensions of Particles	1076
25.1.2.3. Limitations on Using the Discrete Phase Model with Other ANSYS FLUENT Models	1076
25.2. Steps for Using the Discrete Phase Models	1077
25.2.1. Options for Interaction with the Continuous Phase	1078
25.2.2. Steady/Transient Treatment of Particles	1078
25.2.3. Tracking Parameters for the Discrete Phase Model	1080
25.2.4. Drag Laws	1082
25.2.5. Physical Models for the Discrete Phase Model	1083
25.2.5.1. Including Radiation Heat Transfer Effects on the Particles	1084
25.2.5.2. Including Thermophoretic Force Effects on the Particles	1084
25.2.5.3. Including Brownian Motion Effects on the Particles	1085
25.2.5.4. Including Saffman Lift Force Effects on the Particles	1085
25.2.5.5. Monitoring Erosion/Accretion of Particles at Walls	1085
25.2.5.6. Enabling Pressure Dependent Boiling	1085
25.2.5.7. Including the Effect of Droplet Temperature on Latent Heat	1086
25.2.5.8. Including the Effect of Particles on Turbulent Quantities	1086
25.2.5.9. Including Collision and Droplet Coalescence	1086
25.2.5.10. Including the DEM Collision Model	1086
25.2.5.11. Including Droplet Breakup	1086
25.2.5.12. Options for Spray Modeling	1086
25.2.5.12.1. Modeling Spray Breakup	1086
25.2.5.13. Modeling Collision Using the DEM Model	1088
25.2.5.13.1. Limitations	1091
25.2.5.13.2. Numeric Recommendations	1091
25.2.6. User-Defined Functions	1091
25.2.7. Numerics of the Discrete Phase Model	1092
25.2.7.1. Numerics for Tracking of the Particles	1093
25.2.7.2. Including Coupled Heat-Mass Solution Effects on the Particles	1095
25.2.7.3. Tracking in a Reference Frame	1095
25.2.7.4. Staggering of Particles in Space and Time	1096
25.3. Setting Initial Conditions for the Discrete Phase	1096

25.3.1. Injection Types	1097
25.3.2. Particle Types	1099
25.3.3. Point Properties for Single Injections	1100
25.3.4. Point Properties for Group Injections	1101
25.3.5. Point Properties for Cone Injections	1101
25.3.6. Point Properties for Surface Injections	1103
25.3.6.1. Using the Rosin-Rammler Diameter Distribution Method	1104
25.3.7. Point Properties for Plain-Orifice Atomizer Injections	1104
25.3.8. Point Properties for Pressure-Swirl Atomizer Injections	1105
25.3.9. Point Properties for Air-Blast/Air-Assist Atomizer Injections	1106
25.3.10. Point Properties for Flat-Fan Atomizer Injections	1107
25.3.11. Point Properties for Effervescent Atomizer Injections	1108
25.3.12. Point Properties for File Injections	1109
25.3.13. Using the Rosin-Rammler Diameter Distribution Method	1109
25.3.13.1. The Stochastic Rosin-Rammler Diameter Distribution Method	1112
25.3.14. Creating and Modifying Injections	1112
25.3.14.1. Creating Injections	1113
25.3.14.2. Modifying Injections	1113
25.3.14.3. Copying Injections	1113
25.3.14.4. Deleting Injections	1113
25.3.14.5. Listing Injections	1114
25.3.14.6. Reading and Writing Injections	1114

26.2.5. Including Body Forces	1180
26.2.6. Modeling Multiphase Species Transport	1181
26.2.7. Specifying Heterogeneous Reactions	1183
26.2.8. Including Mass Transfer Effects	1186
26.2.9. Defining Multiphase Cell Zone and Boundary Conditions	1189
26.2.9.1. Boundary Conditions for the Mixture and the Individual Phases	1190
26.2.9.1.1. VOF Model	1190
26.2.9.1.2. Mixture Model	1191
26.2.9.1.3. Eulerian Model	1193
26.2.9.2. Steps for Setting Boundary Conditions	1198
26.2.9.3. Steps for Copying Cell Zone and Boundary Conditions	1202
26.3. Setting Up the VOF Model	1203
26.3.1. Including Coupled Level Set with the VOF Model	1203
26.3.2. Modeling Open Channel Flows	1204
26.3.2.1. Defining Inlet Groups	1204

26.3.2.2. Defining Outlet Groups	1205
26.3.2.3. Setting the Inlet Group	1205
26.3.2.4. Setting the Outlet Group	1205
26.3.2.5. Determining the Free Surface Level	1206
26.3.2.6. Determining the Bottom Level	1206
26.3.2.7. Specifying the Total Height	1207
26.3.2.8. Determining the Velocity Magnitude	1207
26.3.2.9. Determining the Secondary Phase for the Inlet	1207
26.3.2.10. Choosing the Pressure Specification Method	1208
26.3.2.11. Limitations	1209
26.3.2.12. Choosing the Density Interpolation Method	1209
26.3.2.13. Recommendations for Setting Up an Open Channel Flow Problem	1210
26.3.3. Modeling Open Channel Wave Boundary Conditions	1210
26.3.4. Recommendations for Open Channel Initialization	1213
26.3.5. Numerical Beach Treatment for Open Channels	1216
26.3.5.1. Solution Strategies	1218
26.3.6. Defining the Phases for the VOF Model	1219
26.3.6.1. Defining the Primary Phase	1220
26.3.6.2. Defining a Secondary Phase	1220
26.3.6.3. Including Surface Tension and Adhesion Effects	1221
26.3.6.4. Discretizing Using the Phase Localized Compressive Scheme	1226
26.3.7. Setting Time-Dependent Parameters for the VOF Model	1228
26.3.8. Modeling Compressible Flows	1230
26.3.9. Modeling Solidification/Melting	1230
26.4. Setting Up the Mixture Model	1230
26.4.1. Defining the Phases for the Mixture Model	1230
26.4.1.1. Defining the Primary Phase	1231
26.4.1.2. Defining a Nongranular Secondary Phase	1231
26.4.1.3. Defining a Granular Secondary Phase	1232
26.4.1.4. Defining the Interfacial Area Concentration	1234
26.4.1.5. Defining Drag Between Phases	1237
26.4.1.6. Defining the Slip Velocity	1238
26.4.2. Including Cavitation Effects	1239
26.4.3. Modeling Compressible Flows	1239
26.5. Setting Up the Eulerian Model	1240
26.5.1. Additional Guidelines for Eulerian Multiphase Simulations	1240
26.5.2. Defining the Phases for the Eulerian Model	1240
26.5.2.1. Defining the Primary Phase	1241
26.5.2.2. Defining a Nongranular Secondary Phase	1241
26.5.2.3. Defining a Granular Secondary Phase	1242
26.5.2.4. Defining the Interfacial Area Concentration	1245
26.5.2.5. Defining the Interaction Between Phases	1247
26.5.2.5.1. Specifying the Drag Function	1247
26.5.2.5.2. Specifying the Restitution Coefficients (Granular Flow Only)	1248
26.5.2.6. Including the Lift Force	1248
26.5.2.7. Including Surface Tension and Wall Adhesion Effects	1249
26.5.2.7.1. Including the Virtual Mass Force	1250
26.5.3. Setting Time-Dependent Parameters for the Explicit Volume Fraction Scheme	1250
26.5.4. Modeling Turbulence	1250
26.5.4.1. Including Source Terms	1252
26.5.4.2. Customizing the k - ε Multiphase Turbulent Viscosity	1252
26.5.5. Including Heat Transfer Effects	1252

26.5.6. Modeling Compressible Flows	1253
26.5.7. Including the Dense Discrete Phase Model	1254
26.5.7.1. Defining a Granular Discrete Phase	1257
26.5.8. Including the Boiling Model	1258
26.5.9. Including the Multi-Fluid VOF Model	1266
26.6. Setting Up the Wet Steam Model	1267

29.15.3.1. Setting Up Force and Moment Coefficient Monitors	1390
29.15.3.1.1. Specifying the Reporting Methods	1394
29.15.3.1.1.1. Plot Parameters	1395
29.15.3.1.2. Monitoring Individual Walls	1395
29.15.3.1.3. Discarding the Monitor Data	1395
29.15.4. Monitoring Surface Integrals	1395
29.15.4.1. Overview of Defining Surface Monitors	1396
29.15.4.2. Printing, Plotting, and Saving Surface Integration Histories	1398
29.15.4.2.1. Plot Parameters	1398
29.15.5. Monitoring Volume Integrals	1398
29.15.5.1. Overview of Defining Volume Monitors	1398
29.15.5.2. Printing, Plotting, and Saving Volume Integration Histories	1400
29.15.5.2.1. Plot Parameters	1400
29.16. Executing Commands During the Calculation	1400
29.16.1. Defining Macros	1402
29.16.2. Saving Files During the Calculation	1404
29.17. Automatic Initialization of the Solution and Case Modification	1404
29.17.1. Altering the Solution Initialization and Case Modification after Calculating	1408
29.18. Animating the Solution	1409
29.18.1. Defining an Animation Sequence	1409
29.18.1.1. Guidelines for Defining an Animation Sequence	1412
29.18.2. Playing an Animation Sequence	1413
29.18.2.1. Modifying the View	1414
29.18.2.2. Modifying the Playback Speed	1414
29.18.2.3. Playing Back an Excerpt	1414
29.18.2.4. "Fast-Forwarding" the Animation	1414
29.18.2.5. Continuous Animation	1414
29.18.2.6. Stopping the Animation	1414
29.18.2.7. Advancing the Animation Frame by Frame	1414
29.18.2.8. Deleting an Animation Sequence	1415
29.18.3. Saving an Animation Sequence	1415
29.18.3.1. Solution Animation File	1415
29.18.3.2. Picture File	1416
29.18.3.3. MPEG File	1416
29.18.4. Reading an Animation Sequence	1416
29.19. Checking Your Case Setup	1417

29.19.1. Automatic Implementation	1418
29.19.2. Manual Implementation	1418
29.19.2.1. Checking the Mesh	1419
29.19.2.2. Checking Model Selections	1421
29.19.2.3. Checking Boundary and Cell Zone Conditions	1423
29.19.2.4. Checking Material Properties	1426
29.19.2.5. Checking the Solver Settings	1427
29.20. Convergence and Stability	1430
29.20.1. Judging Convergence	1430
29.20.2. Step-by-Step Solution Processes	1431
29.20.2.1. Selecting a Subset of the Solution Equations	1431
29.20.2.2. Turning Reactions On and Off	1432
29.20.3. Modifying Algebraic Multigrid Parameters	1432
29.20.4. Modifying the Multi-Stage Parameters	1433
29.20.5. Robustness on Meshes of Poor Quality	1433
29.21. Solution Steering	1435
29.21.1. Overview of Solution Steering	1435
29.21.2. Solution Steering Strategy	1435
29.21.2.1. Initialization	1436
29.21.3. Using Solution Steering	1436
30. Adapting the Mesh	1441
30.1. Using Adaption	1441
30.1.1. Adaption Example	1442
30.1.2. Adaption Guidelines	1444
30.2. Boundary Adaption	1445
30.2.1. Performing Boundary Adaption	1445
30.2.1.1. Boundary Adaption Based on Number of Cells	1445
30.2.1.2. Boundary Adaption Based on Normal Distance	1446
30.2.1.3. Boundary Adaption Based on Target Boundary Volume	1447
30.3. Gradient Adaption	1447
30.3.1. Performing Gradient Adaption	1447
30.4. Dynamic Gradient Adaption	1449
30.4.1. Dynamic Gradient Adaption Approach	1450
30.4.1.1. Examples of Dynamic Gradient Adaption	1451
30.5. Isovalue Adaption	1451
30.5.1. Performing Isovalue Adaption	1451
30.6. Region Adaption	1452
30.6.1. Performing Region Adaption	1452
30.7. Volume Adaption	1453
30.7.1. Performing Volume Adaption	1453
30.8. Yplus/Ystar Adaption	1454
30.8.1. Performing Yplus or Ystar Adaption	1454
30.9. Anisotropic Adaption	1455
30.9.1. Limitations of Anisotropic Adaption	1456
30.9.2. Performing Anisotropic Adaption	1456
30.10. Geometry-Based Adaption	1457
30.10.1. Performing Geometry-Based Adaption	1457
30.11. Registers	1458
30.11.1. Manipulating Adaption Registers	1459
30.11.1.1. Changing Register Types	1459
30.11.1.2. Combining Registers	1460
30.11.1.3. Deleting Registers	1461

30.11.2. Modifying Adaption Marks	1461
30.11.3. Displaying Registers	1462
30.11.3.1. Adaption Display Options	1462
30.11.4. Adapting to Registers	1463
30.12. Mesh Adaption Controls	1463
30.12.1. Limiting Adaption by Zone	1464
30.12.2. Limiting Adaption by Cell Volume or Volume Weight	1465
30.12.3. Limiting the Total Number of Cells	1465
30.12.4. Controlling the Levels of Refinement During Hanging Node Adaption	1465
30.13. Improving the Mesh by Smoothing and Swapping	1466
30.13.1. Smoothing	1466
30.13.1.1. Quality-Based Smoothing	1467
30.13.1.2. Laplacian Smoothing	1467
30.13.1.3. Skewness-Based Smoothing	1469
30.13.2. Face Swapping	1470
30.13.2.1. Triangular Meshes	1470
30.13.2.2. Tetrahedral Meshes	1471
30.13.3. Combining Skewness-Based Smoothing and Face Swapping	1472
31. Creating Surfaces for Displaying and Reporting Data	1473
31.1. Using Surfaces	1473
31.2. Zone Surfaces	1474
31.3. Partition Surfaces	1475
31.4. Point Surfaces	1477
31.4.1. Using the Point Tool	1478
31.4.1.1. Initializing the Point Tool	1478
31.4.1.2. Translating the Point Tool	1479
31.4.1.3. Resetting the Point Tool	1479
31.5. Line and Rake Surfaces	1479
31.5.1. Using the Line Tool	1481
31.5.1.1. Initializing the Line Tool	1481
31.5.1.2. Translating the Line Tool	1482
31.5.1.3. Rotating the Line Tool	1482
31.5.1.4. Resizing the Line Tool	1482
31.5.1.5. Resetting the Line Tool	1482
31.6. Plane Surfaces	1482
31.6.1. Using the Plane Tool	1485
31.6.1.1. Initializing the Plane Tool	1485
31.6.1.2. Translating the Plane Tool	1486
31.6.1.3. Rotating the Plane Tool	1486
31.6.1.4. Resizing the Plane Tool	1487
31.6.1.5. Resetting the Plane Tool	1487
31.7. Quadric Surfaces	1487
31.8. Isosurfaces	1489
31.9. Clipping Surfaces	1491
31.10. Transforming Surfaces	1493
31.11. Grouping, Renaming, and Deleting Surfaces	1495
31.11.1. Grouping Surfaces	1496
31.11.2. Renaming Surfaces	1496
31.11.3. Deleting Surfaces	1496
31.11.4. Surface Statistics	1497
32. Displaying Graphics	1499
32.1. Basic Graphics Generation	1499

32.1.1. Displaying the Mesh	1500
32.1.1.1. Generating Mesh or Outline Plots	1501
32.1.1.2. Mesh and Outline Display Options	1503
32.1.1.2.1. Modifying the Mesh Colors	1503
32.1.1.2.2. Adding Features to an Outline Display	1504
32.1.1.2.3. Drawing Partition Boundaries	1505
32.1.1.2.4. Shrinking Faces and Cells in the Display	1505
32.1.2. Displaying Contours and Profiles	1506
32.1.2.1. Generating Contour and Profile Plots	1507
32.1.2.2. Contour and Profile Plot Options	1509
32.1.2.2.1. Drawing Filled Contours or Profiles	1510
32.1.2.2.2. Specifying the Range of Magnitudes Displayed	1510
32.1.2.2.3. Including the Mesh in the Contour Plot	1512
32.1.2.2.4. Choosing Node or Cell Values	1512
32.1.2.2.5. Storing Contour Plot Settings	1513
32.1.3. Displaying Vectors	1513
32.1.3.1. Generating Vector Plots	1514
32.1.3.2. Displaying Relative Velocity Vectors	1515
32.1.3.3. Vector Plot Options	1515
32.1.3.3.1. Scaling the Vectors	1515
32.1.3.3.2. Skipping Vectors	1516
32.1.3.3.3. Drawing Vectors in the Plane of the Surface	1516
32.1.3.3.4. Displaying Fixed-Length Vectors	1517
32.1.3.3.5. Displaying Vector Components	1517
32.1.3.3.6. Specifying the Range of Magnitudes Displayed	1517
32.1.3.3.7. Changing the Scalar Field Used for Coloring the Vectors	1517
32.1.3.3.8. Displaying Vectors Using a Single Color	1518
32.1.3.3.9. Including the Mesh in the Vector Plot	1518
32.1.3.3.10. Changing the Arrow Characteristics	1518
32.1.3.4. Creating and Managing Custom Vectors	1518
32.1.3.4.1. Creating Custom Vectors	1518
32.1.3.4.2. Manipulating, Saving, and Loading Custom Vectors	1519
32.1.4. Displaying Pathlines	1520
32.1.4.1. Steps for Generating Pathlines	1521
32.1.4.2. Options for Pathline Plots	1522
32.1.4.2.1. Including the Mesh in the Pathline Display	1523
32.1.4.2.2. Controlling the Pathline Style	1523
32.1.4.2.3. Controlling Pathline Colors	1524
32.1.4.2.4. "Thinning" Pathlines	1524
32.1.4.2.5. Coarsening Pathlines	1524
32.1.4.2.6. Reversing the Pathlines	1524
32.1.4.2.7. Plotting Oil-Flow Pathlines	1525
32.1.4.2.8. Controlling the Pulse Mode	1525
32.1.4.2.9. Controlling the Accuracy	1525
32.1.4.2.10. Plotting Relative Pathlines	1525
32.1.4.2.11. Generating an XY Plot Along Pathline Trajectories	1525
32.1.4.2.12. Saving Pathline Data	1526
32.1.4.2.12.1. Standard Type	1526
32.1.4.2.12.2. Geometry Type	1527
32.1.4.2.12.3. EnSight Type	1528
32.1.4.2.13. Choosing Node or Cell Values	1529
32.1.5. Displaying Results on a Sweep Surface	1529

32.1.5.1. Steps for Generating a Plot Using a Sweep Surface	1529
32.1.5.2. Animating a Sweep Surface Display	1531
32.1.6. Hiding the Graphics Window Display	1531
32.2. Customizing the Graphics Display	1532
32.2.1. Overlay of Graphics	1532
32.2.2. Opening Multiple Graphics Windows	1533
32.2.2.1. Setting the Active Window	1534
32.2.3. Changing the Legend Display	1534
32.2.3.1. Enabling/Disabling the Legend, Logo, and Color Scale	1535
32.2.3.2. Editing the Legend	1535
32.2.3.3. Adding a Title to the Caption	1535
32.2.3.4. Enabling/Disabling the Axes	1535
32.2.3.5. Displaying/Hiding the Logo	1535
32.2.3.6. Colormap Alignment	1536
32.2.4. Adding Text to the Graphics Window	1536
32.2.4.1. Adding Text Using the Annotate Dialog Box	1536
32.2.4.2. Adding Text Using the Mouse-Annotate Function	1537
32.2.4.3. Editing Existing Annotation Text	1538
32.2.4.4. Clearing Annotation Text	1538
32.2.5. Changing the Colormap	1538
32.2.5.1. Predefined Colormaps	1539
32.2.5.2. Selecting a Colormap	1540
32.2.5.2.1. Specifying the Colormap Size and Scale	1540
32.2.5.2.2. Changing the Number Format	1540
32.2.5.3. Displaying Colormap Label	1540
32.2.5.4. Creating a Customized Colormap	1542
32.2.6. Adding Lights	1544
32.2.6.1. Turning on Lighting Effects with the Display Options Dialog Box	1544
32.2.6.2. Turning on Lighting Effects with the Lights Dialog Box	1544
32.2.6.3. Defining Light Sources	1545
32.2.6.3.1. Removing a Light	1546
32.2.6.3.2. Resetting the Light Definitions	1546
32.2.7. Modifying the Rendering Options	1546
32.2.7.1. Graphics Device Information	1547
32.3. Controlling the Mouse Button Functions	1548
32.3.1. Button Functions	1548
32.3.2. Modifying the Mouse Button Functions	1549
32.4. Viewing the Application Window	1550
32.4.1. Embedding the Graphics Windows	1553
32.5. Modifying the View	1554
32.5.1. Selecting a View	1555
32.5.2. Manipulating the Display	1555
32.5.2.1. Scaling and Centering	1556
32.5.2.2. Rotating the Display	1556
32.5.2.2.1. Spinning the Display with the Mouse	1557
32.5.2.3. Translating the Display	1558
32.5.2.4. Zooming the Display	1558
32.5.3. Controlling Perspective and Camera Parameters	1559
32.5.3.1. Perspective and Orthographic Views	1559
32.5.3.2. Modifying Camera Parameters	1559
32.5.4. Saving and Restoring Views	1560
32.5.4.1. Restoring the Default View	1560

32.5.4.2. Returning to Previous Views	1560
32.5.4.3. Saving Views	1561
32.5.4.4. Reading View Files	1561
32.5.4.5. Deleting Views	1561
32.5.5. Mirroring and Periodic Repeats	1562
32.5.5.1. Periodic Repeats for Graphics	1564
32.5.5.2. Mirroring for Graphics	1565
32.6. Composing a Scene	1565
32.6.1. Selecting the Object(s) to be Manipulated	1566
32.6.2. Changing an Object's Display Properties	1567
32.6.2.1. Controlling Visibility	1567
32.6.2.2. Controlling Object Color and Transparency	1568
32.6.3. Transforming Geometric Objects in a Scene	1569
32.6.3.1. Translating Objects	1570
32.6.3.2. Rotating Objects	1570
32.6.3.3. Scaling Objects	1570
32.6.3.4. Displaying the Meridional View	1571
32.6.4. Modifying Iso-Values	1571
32.6.4.1. Steps for Modifying Iso-Values	1571
32.6.4.2. An Example of Iso-Value Modification for an Animation	1571
32.6.5. Modifying Pathline Attributes	1572
32.6.5.1. An Example of Pathline Modification for an Animation	1572
32.6.6. Deleting an Object from the Scene	1573
32.6.7. Adding a Bounding Frame	1573
32.7. Animating Graphics	1575
32.7.1. Creating an Animation	1576
32.7.1.1. Deleting Key Frames	1576
32.7.2. Playing an Animation	1576
32.7.2.1. Playing Back an Excerpt	1577
32.7.2.2. "Fast-Forwarding" the Animation	1577
32.7.2.3. Continuous Animation	1577
32.7.2.4. Stopping the Animation	1577
32.7.2.5. Advancing the Animation Frame by Frame	1577
32.7.3. Saving an Animation	1578
32.7.3.1. Animation File	1578
32.7.3.2. Picture File	1578
32.7.3.3. MPEG File	1578
32.7.4. Reading an Animation File	1579
32.7.5. Notes on Animation	1579
32.8. Creating Videos	1579
32.8.1. Recording Animations To Video	1580
32.8.1.1. Computer Image vs. Video Image	1580
32.8.1.2. Real-Time vs. Frame-By-Frame	1580
32.8.2. Equipment Required	1580
32.8.3. Recording an Animation with ANSYS FLUENT	1581
32.8.3.1. Create an Animation	1582
32.8.3.2. Open a Connection to the VTR Controller	1582
32.8.3.3. Set Up Your Recording Session	1583
32.8.3.3.1. Select the Recording Source	1584
32.8.3.3.2. Choose Real-Time or Frame-By-Frame Recording	1585
32.8.3.3.3. Set the Video Frame Hold Counts	1585
32.8.3.4. Check the Picture Quality	1586

32.8.3.5. Make Sure Your Tape is Formatted (Preblacked)	1586
32.8.3.6. Start the Recording Session	1587
32.9. Histogram and XY Plots	1587
32.9.1. Plot Types	1587
32.9.1.1. XY Plots	1587
32.9.1.2. Histograms	1588
32.9.2. XY Plots of Solution Data	1589
32.9.2.1. Steps for Generating Solution XY Plots	1589
32.9.2.2. Options for Solution XY Plots	1592
32.9.2.2.1. Including External Data in the Solution XY Plot	1593
32.9.2.2.2. Choosing Node or Cell Values	1593
32.9.2.2.3. Saving the Plot Data to a File	1593
32.9.3. XY Plots of File Data	1593
32.9.3.1. Steps for Generating XY Plots of Data in External Files	1593
32.9.3.2. Options for File XY Plots	1594
32.9.3.2.1. Changing the Plot Title	1594
32.9.3.2.2. Changing the Legend Entry	1594
32.9.3.2.3. Changing the Legend Title	1595
32.9.4. XY Plots of Profiles	1595
32.9.4.1. Steps for Generating Plots of Profile Data	1595
32.9.4.2. Steps for Generating Plots of Interpolated Profile Data	1596
32.9.5. XY Plots of Circumferential Averages	1596
32.9.5.1. Steps for Generating an XY Plot of Circumferential Averages	1597
32.9.5.2. Customizing the Appearance of the Plot	1599
32.9.6. XY Plot File Format	1599
32.9.7. Residual Plots	1600
32.9.8. Histograms	1600
32.9.8.1. Steps for Generating Histogram Plots	1600
32.9.8.2. Options for Histogram Plots	1601
32.9.8.2.1. Specifying the Range of Values Plotted	1601
32.9.9. Modifying Axis Attributes	1601
32.9.9.1. Using the Axes Dialog Box	1602
32.9.9.1.1. Changing the Axis Label	1602
32.9.9.1.2. Changing the Format of the Data Labels	1602
32.9.9.1.3. Choosing Logarithmic or Decimal Scaling	1603
32.9.9.1.4. Resetting the Range of the Axis	1603
32.9.9.1.5. Controlling the Major and Minor Rules	1603
32.9.10. Modifying Curve Attributes	1603
32.9.10.1. Using the Curves Dialog Box	1604
32.9.10.1.1. Changing the Line Style	1604
32.9.10.1.2. Changing the Marker Style	1605
32.9.10.1.3. Previewing the Curve Style	1605
32.10. Turbomachinery Postprocessing	1605
32.10.1. Defining the Turbomachinery Topology	1605
32.10.1.1. Boundary Types	1607
32.10.2. Generating Reports of Turbomachinery Data	1608
32.10.2.1. Computing Turbomachinery Quantities	1610
32.10.2.1.1. Mass Flow	1610
32.10.2.1.2. Swirl Number	1610
32.10.2.1.3. Average Total Pressure	1610
32.10.2.1.4. Average Total Temperature	1611
32.10.2.1.5. Average Flow Angles	1612

32.10.2.1.6. Passage Loss Coefficient	1612
32.10.2.1.7. Axial Force	1613
32.10.2.1.8. Torque	1613
32.10.2.1.9. Efficiencies for Pumps and Compressors	1614
32.10.2.1.9.1. Incompressible Flows	1614
32.10.2.1.9.2. Compressible Flows	1615
32.10.2.1.10. Efficiencies for Turbines	1616
32.10.2.1.10.1. Incompressible Flows	1616
32.10.2.1.10.2. Compressible Flows	1617
32.10.3. Displaying Turbomachinery Averaged Contours	1618
32.10.3.1. Steps for Generating Turbomachinery Averaged Contour Plots	1618
32.10.3.2. Contour Plot Options	1620
32.10.4. Displaying Turbomachinery 2D Contours	1620
32.10.4.1. Steps for Generating Turbo 2D Contour Plots	1620
32.10.4.2. Contour Plot Options	1621
32.10.5. Generating Averaged XY Plots of Turbomachinery Solution Data	1622
32.10.5.1. Steps for Generating Turbo Averaged XY Plots	1622
32.10.6. Globally Setting the Turbomachinery Topology	1623
32.10.7. Turbomachinery-Specific Variables	1623
32.11. Fast Fourier Transform (FFT) Postprocessing	1623
32.11.1. Limitations of the FFT Algorithm	1624
32.11.2. Windowing	1624
32.11.3. Fast Fourier Transform (FFT)	1625
32.11.4. Using the FFT Utility	1626
32.11.4.1. Loading Data for Spectral Analysis	1627
32.11.4.2. Customizing the Input	1627
32.11.4.2.1. Customizing the Input Signal Data Set	1628
32.11.4.2.2. Viewing Data Statistics	1628
32.11.4.2.3. Customizing Titles and Labels	1628
32.11.4.2.4. Applying the Changes in the Input Signal Data	1629
32.11.4.3. Customizing the Output	1629
32.11.4.3.1. Specifying a Function for the y Axis	1629
32.11.4.3.2. Specifying a Function for the x Axis	1631
32.11.4.3.3. Specifying Output Options	1632
32.11.4.3.4. Specifying a Windowing Technique	1632
32.11.4.3.5. Specifying Labels and Titles	1632
33. Reporting Alphanumeric Data	1633
33.1. Reporting Conventions	1633
33.2. Creating Output Parameters	1633
33.3. Fluxes Through Boundaries	1635
33.3.1. Generating a Flux Report	1635
33.3.2. Flux Reporting for Reacting Flows	1637
33.3.2.1. Flux Reporting with Particles	1638
33.3.2.2. Flux Reporting with Multiphase	1639
33.3.2.3. Flux Reporting with Other Volumetric Sources	1640
33.4. Forces on Boundaries	1640
33.4.1. Generating a Force, Moment, or Center of Pressure Report	1640
33.4.1.1. Example	1642
33.5. Projected Surface Area Calculations	1643
33.6. Surface Integration	1644
33.6.1. Generating a Surface Integral Report	1644
33.7. Volume Integration	1646

Using This Manual

This preface is divided into the following sections:

- 1.The Contents of This Manual
- 2.The Contents of the FLUENT Manuals
- 3.Typographical Conventions
- 4.Mathematical Conventions
- 5.Technical Support

1. The Contents of This Manual

The ANSYS FLUENT [User's Guide](#) tells you what you need to know to use ANSYS FLUENT.

Important

Under U.S. and international copyright law, ANSYS, Inc. is unable to distribute copies of the papers listed in the bibliography, other than those published internally by ANSYS, Inc. Please use your library or a document delivery service to obtain copies of copyrighted papers.

A brief description of what is in each chapter follows:

- *Starting and Executing ANSYS FLUENT* (p. 1), describes options and alternatives to starting, running, and exiting ANSYS FLUENT. It also provides instructions for remote execution and batch execution.
- *Graphical User Interface (GUI)* (p. 21), describes the mechanics of using the graphical user interface and the GUI on-line help.
- *Text User Interface (TUI)* (p. 47), describes the mechanics of using the text interface and the TUI on-line help. (See the Text Command List for information about specific text interface commands.)
- *Reading and Writing Files* (p. 59), describes the files that ANSYS FLUENT can read and write, including picture files.
- *Unit Systems* (p. 125), describes how to use the standard and custom unit systems available in ANSYS FLUENT.
- *Reading and Manipulating Meshes* (p. 129), describes the various sources of computational meshes and explains how to obtain diagnostic information about the mesh and how to modify it by scaling, translating, and other methods. This chapter also contains information about the use of non-conformal meshes.
- *Cell Zone and Boundary Conditions* (p. 211), describes the different types of boundary conditions available in ANSYS FLUENT, when to use them, how to define them, and how to define boundary profiles and volumetric sources and fix the value of a variable in a particular region. It also contains information about porous media and lumped parameter models.
- *Physical Properties* (p. 403), describes the physical properties of materials and the equations that ANSYS FLUENT uses to compute the properties from the information that you input.
- *Modeling Basic Fluid Flow* (p. 505), describes the governing equations and physical models used by ANSYS FLUENT to compute fluid flow (including periodic flow, swirling and rotating flows, compressible flows, and inviscid flows), as well as the inputs you need to provide to use these models.
- *Modeling Flows with Moving Reference Frames* (p. 535), describes the use of single moving reference frames, multiple moving reference frames, and mixing planes in ANSYS FLUENT.

- [*Modeling Flows Using Sliding and Dynamic Meshes* \(p. 559\)](#), describes the use of sliding and deforming meshes in ANSYS FLUENT.
- [*Modeling Flows Using the Mesh Morpher/Optimizer* \(p. 667\)](#), describes the use of the mesh morphing capability in ANSYS FLUENT that allows you to solve shape optimization problems [37] (p. 2369).
- [*Modeling Turbulence* \(p. 683\)](#), describes the use of the turbulent flow models in ANSYS FLUENT.
- [*Modeling Heat Transfer* \(p. 737\)](#), describes the use of the physical models in ANSYS FLUENT to compute heat transfer (including convective and conductive heat transfer, natural convection, radiative heat transfer, and periodic heat transfer), as well as the inputs you need to provide to use these models.
- [*Modeling Heat Exchangers* \(p. 819\)](#), describes the use of the heat exchanger models in ANSYS FLUENT.
- [*Modeling Species Transport and Finite-Rate Chemistry* \(p. 855\)](#), describes the use of the finite-rate chemistry models in ANSYS FLUENT. This chapter also provides information about modeling species transport in non-reacting flows.
- [*Modeling Non-Premixed Combustion* \(p. 901\)](#), describes the use of the non-premixed combustion model in ANSYS FLUENT. This chapter includes details about using prePDF.
- [*Modeling Premixed Combustion* \(p. 957\)](#), describes the use of the premixed combustion model in ANSYS FLUENT.
- [*Modeling Partially Premixed Combustion* \(p. 969\)](#), describes the use of the partially premixed combustion model in ANSYS FLUENT.
- [*Modeling a Composition PDF Transport Problem* \(p. 975\)](#), describes the use of the composition PDF transport model in ANSYS FLUENT.
- [*Using Chemistry Acceleration* \(p. 987\)](#), describes the use of methods to accelerate computations for detailed chemical mechanisms involving laminar and turbulent flames.
- [*Modeling Engine Ignition* \(p. 995\)](#), describes the use of the engine ignition models in ANSYS FLUENT.
- [*Modeling Pollutant Formation* \(p. 1009\)](#), describes the use of the models for the formation of NO_x, SO_x, and soot in ANSYS FLUENT.
- [*Predicting Aerodynamically Generated Noise* \(p. 1055\)](#), describes the use of the acoustics model in ANSYS FLUENT.
- [*Modeling Discrete Phase* \(p. 1075\)](#), describes the use of the discrete phase models in ANSYS FLUENT.
- [*Modeling Multiphase Flows* \(p. 1173\)](#), describes the use of the general multiphase models in ANSYS FLUENT (VOF, mixture, and Eulerian).
- [*Modeling Solidification and Melting* \(p. 1297\)](#), describes the use of the solidification and melting model in ANSYS FLUENT.
- [*Modeling Eulerian Wall Films* \(p. 1305\)](#), describes the use of the Eulerian wall film model in ANSYS FLUENT.
- [*Using the Solver* \(p. 1311\)](#), describes the use of the ANSYS FLUENT solvers.
- [*Adapting the Mesh* \(p. 1441\)](#), describes the use of the solution-adaptive mesh refinement feature in ANSYS FLUENT.
- [*Creating Surfaces for Displaying and Reporting Data* \(p. 1473\)](#), describes how to create surfaces in the domain on which you can examine ANSYS FLUENT solution data.
- [*Displaying Graphics* \(p. 1499\)](#), describes the use of the graphics tools to examine your ANSYS FLUENT solution.
- [*Reporting Alphanumeric Data* \(p. 1633\)](#), describes how to obtain reports of fluxes, forces, surface integrals, and other solution data.

- [Field Function Definitions](#) (p. 1653), describes the flow variables that appear in the variable selection drop-down lists in ANSYS FLUENT dialog boxes, and tells you how to create your own custom field functions.
- [Parallel Processing](#) (p. 1715), describes the use of the parallel processing features in ANSYS FLUENT. This chapter also provides information about partitioning your mesh for parallel processing.
- [Task Page Reference Guide](#) (p. 1763), describes the use of the task pages within the ANSYS FLUENT user interface.
- [Menu Reference Guide](#) (p. 2203), describes the use of the menus within the ANSYS FLUENT user interface.
- [Appendix A](#) (p. 2341), presents a series of tables outlining the compatibility of several ANSYS FLUENT model categories.
- [Appendix B](#) (p. 2345), presents information about the contents and formats of ANSYS FLUENT case and data files.
- [Appendix C](#) (p. 2363), presents a brief listing of the physical properties and fluid dynamic quantities used throughout the ANSYS FLUENT documentation.

2. The Contents of the FLUENT Manuals

The manuals listed below form the FLUENT product documentation set. They include descriptions of the procedures, commands, and theoretical details needed to use FLUENT products.

[FLUENT Getting Started Guide](#) contains general information about getting started with using FLUENT.

[FLUENT User's Guide](#) contains detailed information about using FLUENT, including information about the user interface, reading and writing files, defining boundary conditions, setting up physical models, calculating a solution, and analyzing your results.

[FLUENT in Workbench User's Guide](#) contains information about getting started with and using FLUENT within the Workbench environment.

[FLUENT Theory Guide](#) contains reference information for how the physical models are implemented in FLUENT.

[FLUENT UDF Manual](#) contains information about writing and using user-defined functions (UDFs).

[FLUENT Tutorial Guide](#) contains a number of example problems with detailed instructions, commentary, and postprocessing of results.

[FLUENT Text Command List](#) contains a brief description of each of the commands in FLUENT's text interface.

[FLUENT Adjoint Solver Module Manual](#) contains information about the background and usage of FLUENT's Adjoint Solver Module that allows you to obtain detailed sensitivity data for the performance of a fluid system.

[FLUENT Battery Module Manual](#) contains information about the background and usage of FLUENT's Battery Module that allows you to analyze the behavior of electric batteries.

[FLUENT Continuous Fiber Module Manual](#) contains information about the background and usage of FLUENT's Continuous Fiber Module that allows you to analyze the behavior of fiber flow, fiber properties, and coupling between fibers and the surrounding fluid due to the strong interaction that exists between the fibers and the surrounding gas.

[FLUENT Fuel Cell Modules Manual](#) contains information about the background and the usage of two separate add-on fuel cell models for FLUENT that allow you to model polymer electrolyte membrane fuel cells (PEMFC), solid oxide fuel cells (SOFC), and electrolysis with FLUENT.

[FLUENT Magnetohydrodynamics \(MHD\) Module Manual](#) contains information about the background and usage of FLUENT's Magnetohydrodynamics (MHD) Module that allows you to analyze the behavior of electrically conducting fluid flow under the influence of constant (DC) or oscillating (AC) electromagnetic fields.

[FLUENT Migration Manual](#) contains information about transitioning from the previous release of FLUENT, including details about new features, solution changes, and text command list changes.

[FLUENT Population Balance Module Manual](#) contains information about the background and usage of FLUENT's Population Balance Module that allows you to analyze multiphase flows involving size distributions where particle population (as well as momentum, mass, and energy) require a balance equation.

[Running FLUENT Under LSF](#) contains information about the using FLUENT with Platform Computing's LSF software, a distributed computing resource management tool.

[Running FLUENT Under PBS Professional](#) contains information about the using FLUENT with Altair PBS Professional, an open workload management tool for local and distributed environments.

[Running FLUENT Under SGE](#) contains information about the using FLUENT with Sun Grid Engine (SGE) software, a distributed computing resource management tool.

3. Typographical Conventions

Several typographical conventions are used in this manual's text to facilitate your learning process.

- Different type styles are used to indicate graphical user interface menu items and text interface menu items (for example, **Iso-Surface** dialog box, surface/iso-surface command).
- The text interface type style is also used when illustrating exactly what appears on the screen or exactly what you need to type into a field in a dialog box. The information displayed on the screen is enclosed in a large box to distinguish it from the narrative text, and user inputs are often enclosed in smaller boxes.
- A mini flow chart is used to guide you through the navigation pane, which leads you to a specific task page or dialog box. For example,

 **Models** →  **Multiphase** → **Edit...**

indicates that **Models** is selected in the navigation pane, which then opens the corresponding task page. In the **Models** task page, **Multiphase** is selected from the list. Clicking the **Edit...** button opens the **Multiphase** dialog box.

Also, a mini flow chart is used to indicate the menu selections that lead you to a specific command or dialog box. For example,

Define → **Injections...**

indicates that the **Injections...** menu item can be selected from the **Define** pull-down menu, and

display → mesh

indicates that the **mesh** command is available in the **display** text menu.

In this manual, mini flow charts usually precede a description of a dialog box or command, or a screen illustration showing how to use the dialog box or command. They allow you to look up information about a command or dialog box and quickly determine how to access it without having to search the preceding material.

- The menu selections that will lead you to a particular dialog box or task page are also indicated (usually within a paragraph) using a "/". For example, **Define/Materials...** tells you to choose the **Materials...** menu item from the **Define** pull-down menu.

4. Mathematical Conventions

- Where possible, vector quantities are displayed with a raised arrow (e.g., \vec{a} , \vec{A}). Boldfaced characters are reserved for vectors and matrices as they apply to linear algebra (e.g., the identity matrix, I).
- The operator ∇ , referred to as grad, nabla, or del, represents the partial derivative of a quantity with respect to all directions in the chosen coordinate system. In Cartesian coordinates, ∇ is defined to be

$$\frac{\partial}{\partial x} \vec{i} + \frac{\partial}{\partial y} \vec{j} + \frac{\partial}{\partial z} \vec{k} \quad (1)$$

∇ appears in several ways:

- The gradient of a scalar quantity is the vector whose components are the partial derivatives; for example,

$$\nabla p = \frac{\partial p}{\partial x} \vec{i} + \frac{\partial p}{\partial y} \vec{j} + \frac{\partial p}{\partial z} \vec{k} \quad (2)$$

- The gradient of a vector quantity is a second-order tensor; for example, in Cartesian coordinates,

$$\nabla (\vec{v}) = \left(\frac{\partial}{\partial x} \vec{i} + \frac{\partial}{\partial y} \vec{j} + \frac{\partial}{\partial z} \vec{k} \right) (v_x \vec{i} + v_y \vec{j} + v_z \vec{k}) \quad (3)$$

This tensor is usually written as

$$\begin{pmatrix} \frac{\partial v_x}{\partial x} & \frac{\partial v_x}{\partial y} & \frac{\partial v_x}{\partial z} \\ \frac{\partial v_y}{\partial x} & \frac{\partial v_y}{\partial y} & \frac{\partial v_y}{\partial z} \\ \frac{\partial v_z}{\partial x} & \frac{\partial v_z}{\partial y} & \frac{\partial v_z}{\partial z} \end{pmatrix} \quad (4)$$

- The divergence of a vector quantity, which is the inner product between ∇ and a vector; for example,

$$\nabla \cdot \vec{v} = \frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} + \frac{\partial v_z}{\partial z} \quad (5)$$

- The operator $\nabla \cdot \nabla$, which is usually written as ∇^2 and is known as the Laplacian; for example,

$$\nabla^2 T = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2} \quad (6)$$

$\nabla^2 T$ is different from the expression $(\nabla T)^2$, which is defined as

$$(\nabla T)^2 = \left(\frac{\partial T}{\partial x}\right)^2 + \left(\frac{\partial T}{\partial y}\right)^2 + \left(\frac{\partial T}{\partial z}\right)^2 \quad (7)$$

- An exception to the use of ∇ is found in the discussion of Reynolds stresses in "Modeling Turbulence" in the [User's Guide](#), where convention dictates the use of Cartesian tensor notation. In this chapter, you will also find that some velocity vector components are written as u , v , and w instead of the conventional v with directional subscripts.

5. Technical Support

If you encounter difficulties while using ANSYS FLUENT, please first refer to the section(s) of the manual containing information on the commands you are trying to use or the type of problem you are trying to solve. The product documentation is available from the online help, or from the ANSYS Customer Portal (www.ansys.com/customerportal).

If you encounter an error, please write down the exact error message that appeared and note as much information as you can about what you were doing in ANSYS FLUENT.

Technical Support for ANSYS, Inc. products is provided either by ANSYS, Inc. directly or by one of our certified ANSYS Support Providers. Please check with the ANSYS Support Coordinator (ASC) at your company to determine who provides support for your company, or go to www.ansys.com and select **About ANSYS > Contacts and Locations**. The direct URL is: <http://www1.ansys.com/customer/public/supportlist.asp>. Follow the on-screen instructions to obtain your support provider contact information. You will need your customer number. If you don't know your customer number, contact the ASC at your company.

If your support is provided by ANSYS, Inc. directly, Technical Support can be accessed quickly and efficiently from the ANSYS Customer Portal, which is available from the ANSYS Website (www.ansys.com) under **Support > Technical Support** where the Customer Portal is located. The direct URL is: <http://www.ansys.com/customerportal>.

One of the many useful features of the Customer Portal is the Knowledge Resources Search, which can be found on the Home page of the Customer Portal.

Systems and installation Knowledge Resources are easily accessible via the Customer Portal by using the following keywords in the search box: Systems / Installation. These Knowledge Resources provide solutions and guidance on how to resolve installation and licensing issues quickly.

Chapter 1: Starting and Executing ANSYS FLUENT

This chapter provides instructions for starting and executing ANSYS FLUENT.

- 1.1. Starting ANSYS FLUENT
- 1.2. Running ANSYS FLUENT in Batch Mode
- 1.3. Checkpointing an ANSYS FLUENT Simulation
- 1.4. Cleaning Up Processes From an ANSYS FLUENT Simulation
- 1.5. Exiting ANSYS FLUENT

1.1. Starting ANSYS FLUENT

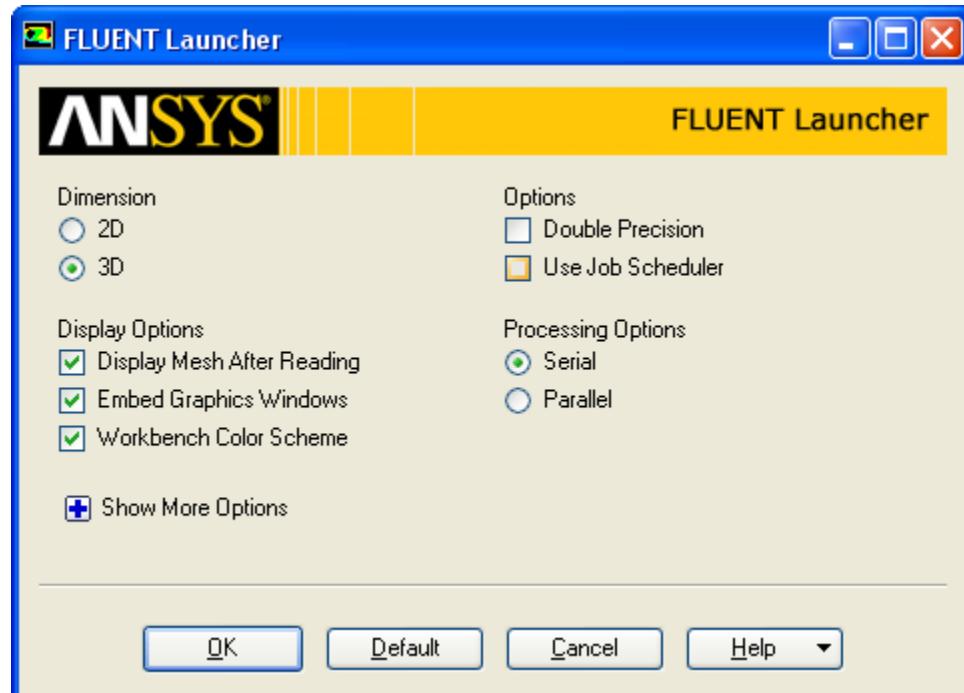

The following sections describe how start ANSYS FLUENT:

- 1.1.1. Starting ANSYS FLUENT Using FLUENT Launcher
- 1.1.2. Starting ANSYS FLUENT on a Windows System
- 1.1.3. Starting ANSYS FLUENT on a Linux System
- 1.1.4. Command Line Startup Options

1.1.1. Starting ANSYS FLUENT Using FLUENT Launcher

When you start ANSYS FLUENT from the Linux or Windows command line with no arguments, from the Windows Programs menu, or from the Windows desktop, FLUENT Launcher will appear. In the FLUENT Launcher, you can specify the dimensionality of the problem (2D or 3D), as well as other options (e.g., whether you want a single-precision or double-precision calculation):

Figure 1.1 FLUENT Launcher

Under **Dimension**, select **2D** for the two-dimensional solver, or select **3D** for the three-dimensional solver.

The **Display Options** allow you to make decisions related to the graphics windows:

- You can choose to have ANSYS FLUENT automatically display the mesh immediately after reading a mesh or case file by using the **Display Mesh After Reading** option (enabled by default). All of the boundary zones will be displayed, except for the interior zones of 3D geometries. Note that your decision regarding this option can be overridden after you have launched ANSYS FLUENT: simply change the status of the **Display Mesh After Reading** option in the **Select File** dialog box that opens when you are reading in the mesh or case file.
- You can choose to have the graphics windows embedded within the ANSYS FLUENT application window by using the **Embed Graphics Windows** option (enabled by default), rather than having floating graphics windows.
- You can choose to use the default **Workbench Color Scheme** in the graphics windows (i.e., a blue background), rather than the classic black background.

Under **Options**, you can choose to run ANSYS FLUENT in double-precision mode by selecting the **Double-Precision** check box (by default, you start ANSYS FLUENT in single-precision mode). You can also choose to use various job schedulers using the **Use Job Scheduler** option (e.g., the Microsoft Job Scheduler for Windows, or LSF, SGE, and PBS Pro on Linux). For more information about using FLUENT Launcher with job schedulers, see [Setting Scheduler Options in FLUENT Launcher \(p. 6\)](#) and [Setting Parallel Scheduler Options in FLUENT Launcher \(p. 1720\)](#). In addition, you can also choose to run parallel simulations on Linux clusters, via the Windows interface using the **Use Remote Linux Nodes** option (see [Setting Remote Options in FLUENT Launcher \(p. 5\)](#) for details).

Under **Processing Options**, select **Serial** for the serial solver, or select **Parallel** to run the solver in parallel (see [Parallel Processing \(p. 1715\)](#)).

If you select the **Show More Options** button, FLUENT Launcher expands to reveal more options. Note that once FLUENT Launcher expands, the **Show More Options** button becomes the **Show Fewer Options** button, allowing you to hide the additional options.

Important

FLUENT Launcher also appears when you start ANSYS FLUENT within ANSYS Workbench. For more information, see the separate [ANSYS FLUENT in Workbench User's Guide](#).

1.1.1.1. Setting General Options in FLUENT Launcher

The **General Options** tab allows you to specify generic settings for running ANSYS FLUENT.

Figure 1.2 The General Options Tab of FLUENT Launcher

1. Specify the version of ANSYS FLUENT by selecting the appropriate option in the **Version** drop-down list. The drop-down list contains all of the available versions of ANSYS FLUENT that exist in your ANSYS FLUENT installation.

In addition, you start ANSYS FLUENT in full simulation mode. You can choose to run ANSYS FLUENT where only the set up or postprocessing capabilities are available by selecting the **Pre/Post Only** check box. The full ANSYS FLUENT simulation allows you to set up, solve and postprocess a problem, while **Pre/Post Only** allows you to set up or postprocess a problem, but will not allow you to perform calculations.

2. Specify the path of your current working folder using the **Working Directory** field or click to browse through your directory structure. Note that a UNC path cannot be set as a working folder, and you need to map a drive to the UNC path (Windows only). The button automatically converts a local path to a UNC path if any matching shared directory is found (Windows only).

3. Specify the location of the ANSYS FLUENT installation on your system using the **FLUENT Root Path** field, or click  to browse through your directory structure to locate the installation folder (trying to use the UNC path if applicable – Windows only). Once set, various fields in FLUENT Launcher (e.g., parallel settings, etc.) are automatically populated with the available options, depending on the ANSYS FLUENT installations that are available.
4. Specify the path and name of a journal file by selecting the **Use Journal File** check box and entering the journal file location and name, or click  to browse through your directory structure to locate the file. Using the journal file, you can automatically load the case, compile any user-defined functions, iterate until the solution converges, and write results to an output file.

1.1.1.2. Single-Precision and Double-Precision Solvers

Both single-precision and double-precision versions of ANSYS FLUENT are available on all computer platforms. For most cases, the single-precision solver will be sufficiently accurate, but certain types of problems may benefit from the use of a double-precision version. Several examples are listed below:

- If your geometry has features of very disparate length scales (e.g., a very long, thin pipe), single-precision calculations may not be adequate to represent the node coordinates.
- If your geometry involves multiple enclosures connected via small-diameter pipes (e.g., automotive manifolds), mean pressure levels in all but one of the zones can be quite large (since you can set only one global reference pressure location). Double-precision calculations may therefore be necessary to resolve the pressure differences that drive the flow, since these will typically be much smaller than the pressure levels.
- For conjugate problems involving high thermal-conductivity ratios and/or high-aspect-ratio meshes, convergence and/or accuracy may be impaired with the single-precision solver, due to inefficient transfer of boundary information.
- For multiphase problems where the population balance model is used to resolve particle size distributions, which could have statistical moments whose values span many orders of magnitude.

Note

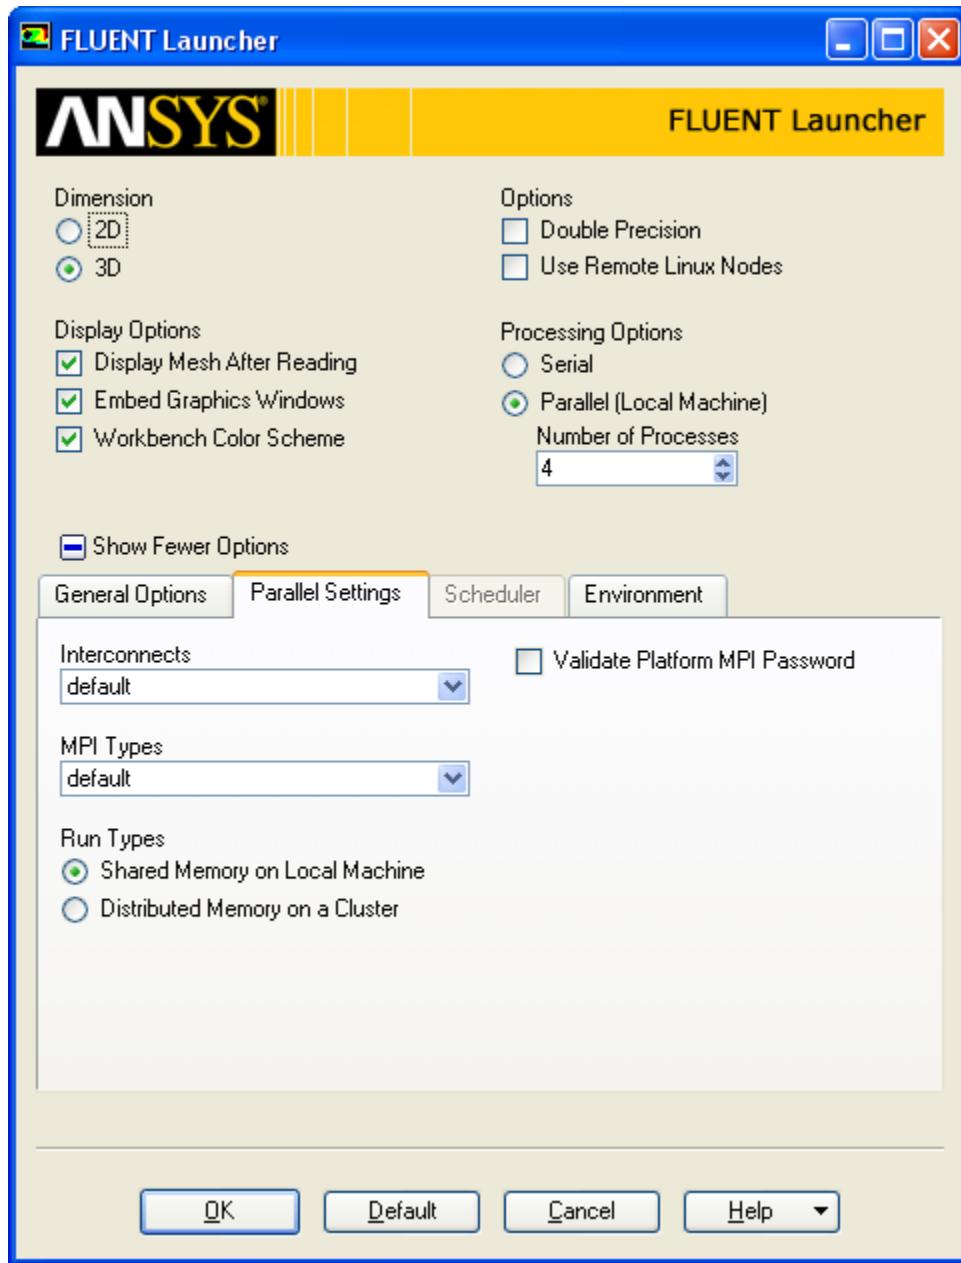

ANSYS FLUENT allows only a period to be used as a decimal separator. If your system is set to a European locale that uses a comma separator (e.g., Germany), fields that accept numeric input may accept a comma, but may ignore everything after the comma. If your system is set to a non-European locale, numeric fields will not accept a comma at all.

ANSYS Workbench accepts commas as decimal delimiters. These are translated into periods when data is passed to ANSYS FLUENT.

1.1.1.3. Setting Parallel Options in FLUENT Launcher

The **Parallel Settings** tab allows you to specify settings for running ANSYS FLUENT in parallel. This tab is only available if you have selected **Parallel** under **Processing Options**. Once you select **Parallel**, you can specify the number of processes using the **Number of Processes** field.

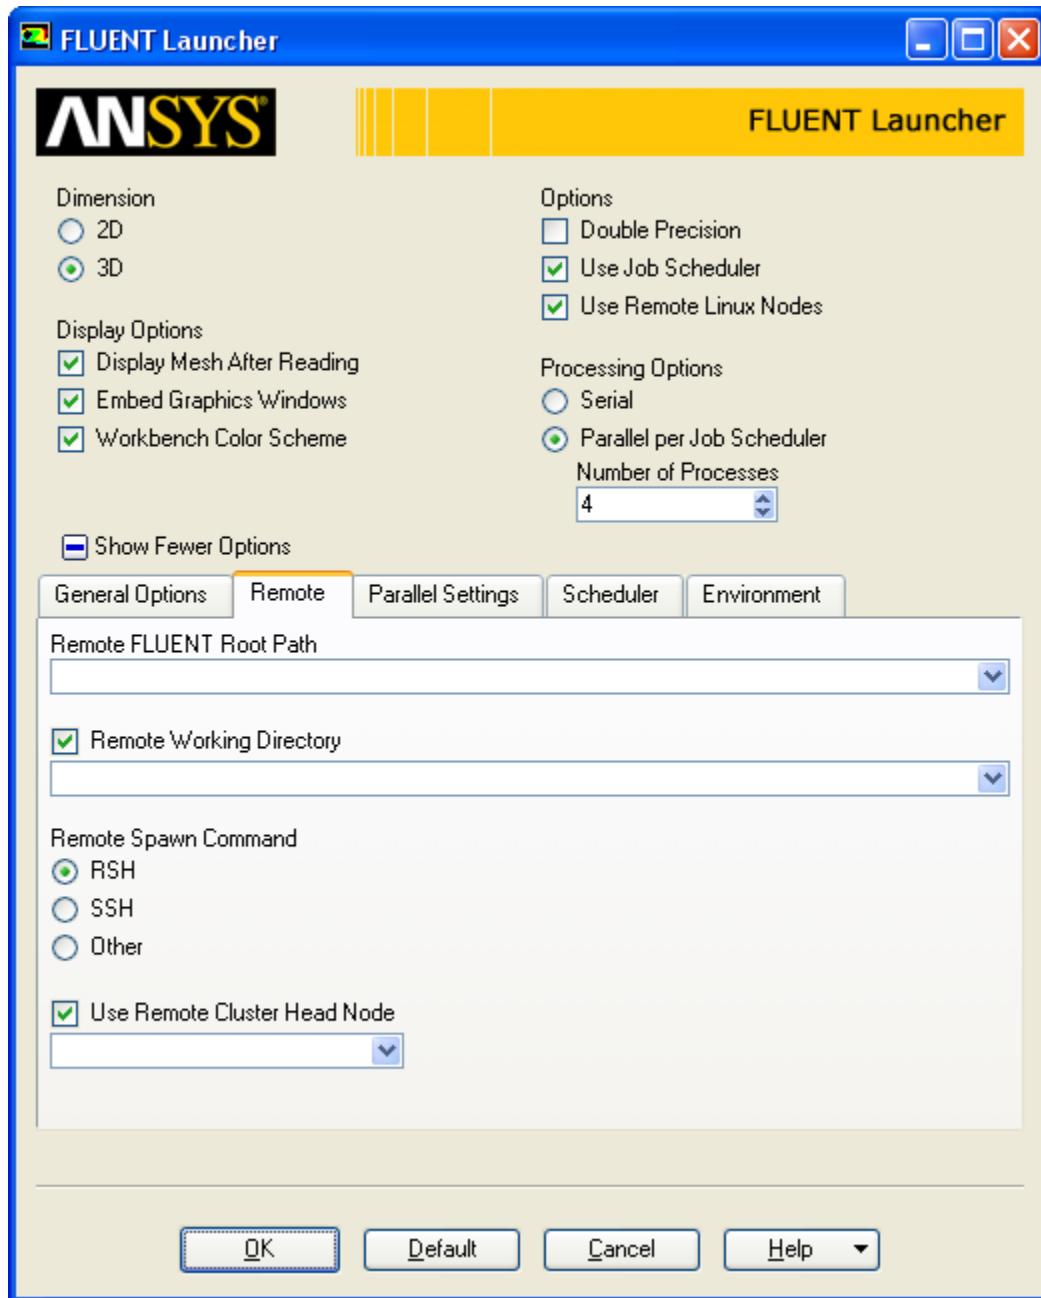

Figure 1.3 The Parallel Settings Tab of FLUENT Launcher

For additional information about this tab, see *Starting Parallel ANSYS FLUENT Using FLUENT Launcher* (p. 1718).

1.1.1.4. Setting Remote Options in FLUENT Launcher

The **Remote** tab allows you to specify settings for running ANSYS FLUENT parallel simulations on Linux clusters, via the Windows interface.

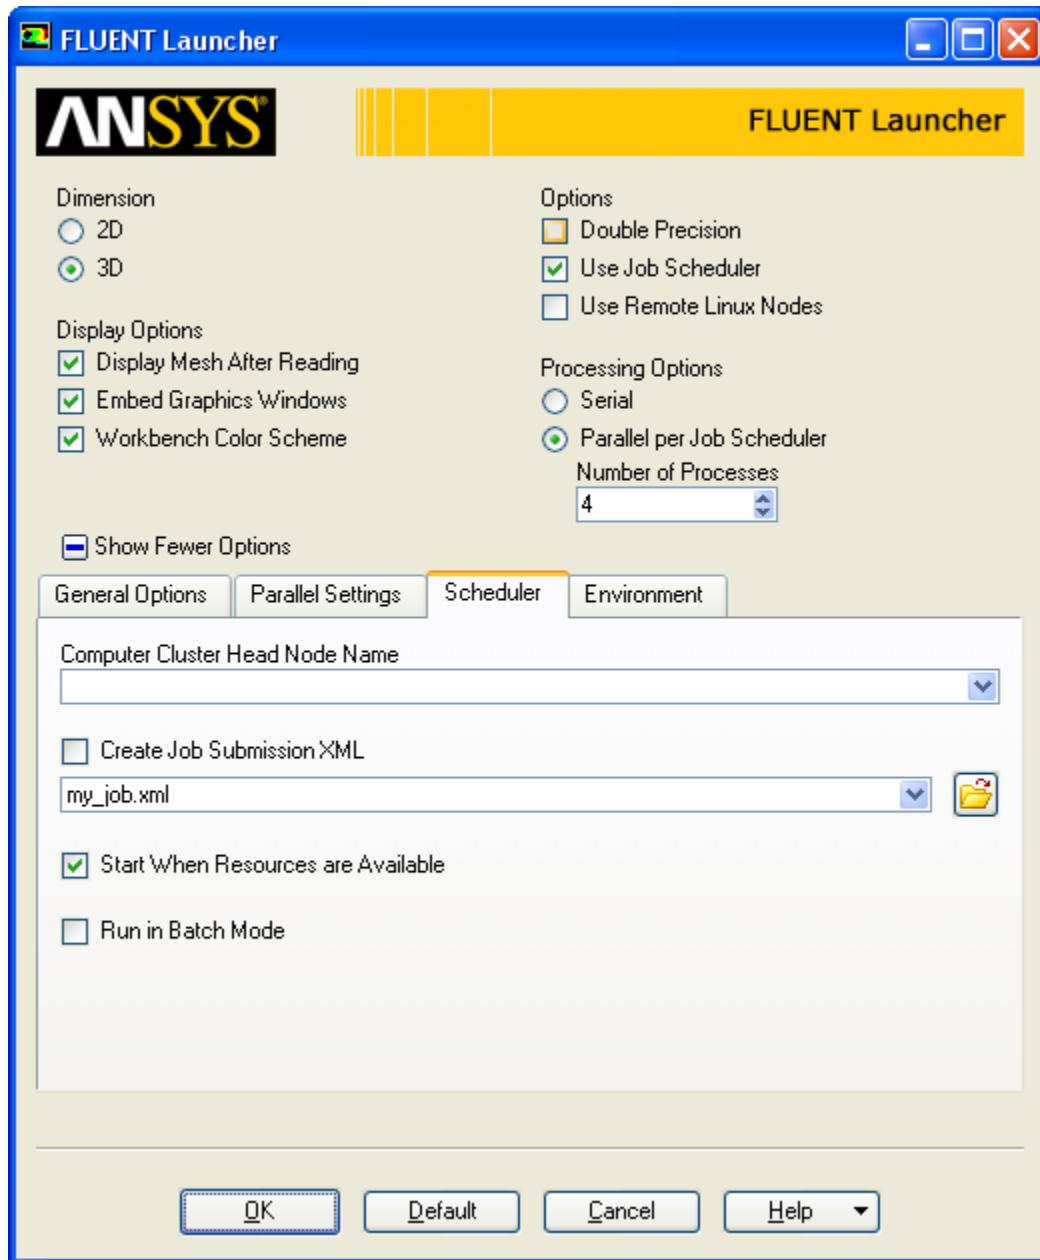

Figure 1.4 The Remote Tab of FLUENT Launcher

For additional information about this tab, see *Setting Additional Options When Running on Remote Linux Machines* (p. 1722).

1.1.1.5. Setting Scheduler Options in FLUENT Launcher

The **Scheduler** tab allows you to specify settings for running ANSYS FLUENT with various job schedulers (e.g., the Microsoft Job Scheduler for Windows (64-bit only), or LSF, SGE, and PBS Pro on Linux). This tab is available if you have selected **Use Job Scheduler** under **Options**.

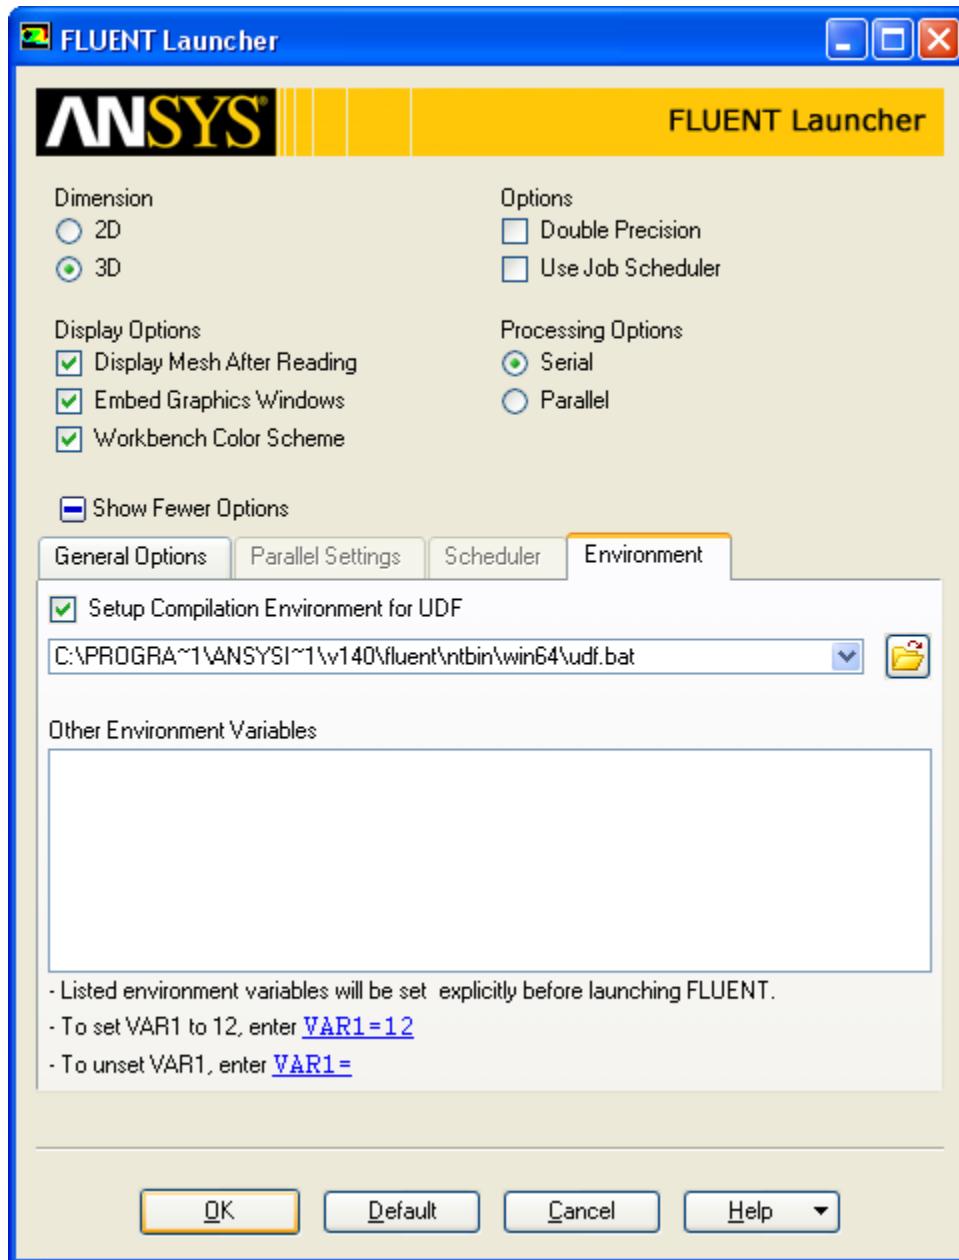

Figure 1.5 The Scheduler Tab of FLUENT Launcher (Windows 64 Version)

For additional information about this tab, see [Setting Parallel Scheduler Options in FLUENT Launcher \(p. 1720\)](#).

1.1.1.6. Setting Environment Options in FLUENT Launcher

The **Environment** tab allows you to specify compiler settings for compiling user-defined functions (UDFs) with ANSYS FLUENT (Windows only). The **Environment** tab also allows you to specify environment variable settings for running ANSYS FLUENT.

Figure 1.6 The Environment Tab of FLUENT Launcher

Specify a batch file that contains UDF compilation environment settings by selecting the **Setup Compilation Environment for UDF** check box (enabled by default). Once selected, you can then enter a batch file name in the text field. By default, FLUENT Launcher uses the `udf.bat` file that is located in the folder where ANSYS FLUENT is installed. It is recommended that you keep the default batch file, which is tested with the latest MS Visual Studio C++ compilers at the time of the ANSYS FLUENT release date. For more information about compiling UDFs, see the separate ANSYS FLUENT [UDF Manual](#).

Under **Other Environment Variables**, enter or edit license file or environment variable information in the text field. Using the **Default** button resets the default value(s).

1.1.2. Starting ANSYS FLUENT on a Windows System

There are two ways to start ANSYS FLUENT on a Windows system:

- Click the Start button, select the All Programs menu, select the ANSYS 14.0 menu, select the Fluid Dynamics menu, the select the FLUENT program item. (Note that if the default "ANSYS 14.0" program group name was changed when ANSYS FLUENT was installed, you will find the FLUENT menu item in the program group with the new name that was assigned, rather than in the ANSYS 14.0 program group.) This option starts FLUENT Launcher (see [Starting ANSYS FLUENT Using FLUENT Launcher \(p. 1\)](#)).
- Start from a Command Prompt window by typing fluent 2d (for the 2D single-precision solver), fluent 3d (for the 3D single-precision solver), fluent 2ddp (for the 2D double-precision solver), or fluent 3ddp (for the 3D double-precision solver) at the prompt. Before doing so, however, you must first modify your user environment so that the Command utility will find fluent. You can do this by executing the setenv.exe program located in the ANSYS FLUENT home directory (e.g., C:\Program Files\ANSYS Inc\v140\fluent\ntbin\win64). This program will add the ANSYS FLUENT folder to your command search path.

From the Command Prompt window, you can also start the parallel version of ANSYS FLUENT. To start the parallel version on x processors, type fluent version -tx at the prompt, replacing version with the desired solver version (2d, 3d, 2ddp, or 3ddp) and x with the number of processors (e.g., fluent 3d -t4 to run the 3D version on 4 processors). For information about the parallel version of ANSYS FLUENT for Windows, see [Starting Parallel ANSYS FLUENT on a Windows System \(p. 1725\)](#).

1.1.3. Starting ANSYS FLUENT on a Linux System

There are two ways to start ANSYS FLUENT on a Linux system:

- Start the solver from the command line without specifying a version, and then use FLUENT Launcher to choose the appropriate version along with other options. See [Starting ANSYS FLUENT Using FLUENT Launcher \(p. 1\)](#) for details.
- Start the appropriate version from the command line by typing fluent 2d (for the 2D single-precision solver), fluent 3d (for the 3D single-precision solver), fluent 2ddp (for the 2D double-precision solver), or fluent 3ddp (for the 3D double-precision solver) at the prompt.

You can also start the parallel version of ANSYS FLUENT from the command line. To start the parallel version on x processors, type fluent version -tx at the prompt, replacing version with the desired solver version (2d, 3d, 2ddp, or 3ddp) and x with the number of processors (e.g., fluent 3d -t4 to run the 3D version on 4 processors). See [Starting Parallel ANSYS FLUENT on a Linux System \(p. 1729\)](#) for more information about starting the parallel solvers.

1.1.4. Command Line Startup Options

To obtain information about available startup options, you can type fluent -help before starting up the solver. [Table 1.1: Available Command Line Options for Linux and Windows Platforms \(p. 9\)](#) lists the available command line arguments for Linux and Windows. More detailed descriptions of these options can be found in the proceeding sections.

Table 1.1 Available Command Line Options for Linux and Windows Platforms

Option	Platform	Description
-cc	all	Use the classic color scheme
-ccp x	Windows only	Use the Microsoft Job Scheduler where x is the head node name.

Option	Platform	Description
-cnf=x	all	Specify the hosts or machine list file
-driver	all	Sets the graphics driver (available drivers vary by platform – opengl or x11 or null (Linux) – opengl or msw or null (Windows))
-env	all	Show environment variables
-fgw	all	Disables the embedded graphics
-g	all	Run without the GUI or graphics (Linux); Run with the GUI minimized (Windows)
-gr	all	Run without graphics
-gu	all	Run without the GUI but with graphics (Linux); Run with the GUI minimized but with graphics (Windows)
-help	all	Display command line options
-hidden	Windows only	Run in batch mode
-host_ip=host:ip	all	Specify the IP interface to be used by the host
-i journal	all	Reads the specified journal file
-lsf	Linux only	Run ANSYS FLUENT using LSF
-mpi=	all	Specify MPI implementation
-mpitest	all	Will launch an MPI program to collect network performance data
-nm	all	Do not display mesh after reading
-pcheck	Linux only	Checks all nodes
-post	all	Run the ANSYS FLUENT post-processing-only executable
-p<ic>	all	Choose the interconnect <ic>= default or myr or inf
-r	all	List all releases installed
-rx	all	Specify release number
-schost	all	Specify a host machine for system coupling
-scport	all	Specify a port on the host machine for system coupling
-scname	all	Specify a unique name for a system coupling participant
-sge	Linux only	Run ANSYS FLUENT under Sun Grid Engine

Option	Platform	Description
-sge queue	Linux only	Name of the queue for a given computing grid
-sgeckpt ckpt_obj	Linux only	Set checkpointing object to ckpt_obj for SGE
-sgepe fluent_pe min_n-max_n	Linux only	Set the parallel environment for SGE to fluent_pe, min_n and max_n are number of min and max nodes requested
-tx	all	Specify the number of processors x

1.1.4.1. Graphics Options

fluent -driver allows you to specify the graphics driver to be used in the solver session. For example, on Linux you can specify fluent -driver opengl, fluent -driver x11, and fluent -driver null. These options are described in detail in [Hiding the Graphics Window Display \(p. 1531\)](#). On Windows you can specify fluent -driver opengl and fluent -driver msw to enable graphics display. Using msw instead of opengl instructs ANSYS FLUENT to use the Operating Systems Windows driver rather than the hardware OpenGL driver.

fluent -cc will run Cortex using the classic black background color in the graphics window.

fluent -fgw will run Cortex without the graphics window embedded in the application (e.g., "floating").

fluent -g will run Cortex without graphics and without the graphical user interface. This option is useful if you are not on an X Window display or if you want to submit a batch job.

fluent -gr will run Cortex without graphics. This option can be used in conjunction with the -i journal option to run a job in "background" mode.

fluent -gu will run Cortex without the graphical user interface but will display the graphics window(s). (On Windows systems, fluent -gu will run ANSYS FLUENT, keeping it in a minimized window; if you maximize the window, the GUI will be available.)

To start the solver and immediately read a journal file, type fluent -i journal, replacing journal with the name of the journal file you want to read.

fluent -nm will run Cortex without displaying the mesh in the graphics window.

1.1.4.2. Parallel Options

These options are used in association with the parallel solver.

-ccp x (where x is the name of the head node) runs the parallel job through the Microsoft Job Scheduler as described in [Starting Parallel ANSYS FLUENT with the Microsoft Job Scheduler \(p. 1727\)](#).

-cnf=x (where x is the name of a hosts file) spawns a compute node on each machine listed in the hosts file. Otherwise, you can spawn the processes as described in [Starting Parallel ANSYS FLUENT on a Windows System Using Command Line Options \(p. 1725\)](#) or [Starting Parallel ANSYS FLUENT on a Linux System Using Command Line Options \(p. 1730\)](#).

`-host_ip=host : ip` specifies the IP interface to be used by the host process (Linux only).

`-mpi=mpi` specifies the MPI to be used. You can skip this flag if you choose to use the default MPI.

`-mpitest` runs the mpitest program instead of ANSYS FLUENT to test the network.

`-p<ic>` specifies the use of parallel interconnect `<ic>`, where `<ic>` can be any of the interconnects listed in *Starting Parallel ANSYS FLUENT on a Windows System Using Command Line Options* (p. 1725) or *Starting Parallel ANSYS FLUENT on a Linux System Using Command Line Options* (p. 1730).

`-pcheck` checks the network connections before spawning compute nodes (Linux only).

`-tx` specifies that `x` processors are to be used. For more information about starting the parallel version of ANSYS FLUENT, see *Starting Parallel ANSYS FLUENT on a Windows System* (p. 1725) or *Starting Parallel ANSYS FLUENT on a Linux System* (p. 1729).

1.1.4.3. Postprocessing Option

`fluent -post` will run a version of the solver that allows you to set up a problem or perform post-processing, but will not allow you to perform calculations. Running ANSYS FLUENT for pre- and postprocessing requires you to use the `-post` flag on startup. To use this option on Linux, launch ANSYS FLUENT by adding the `-post` flag after the version number, for example,

```
fluent 3d -post
```

To use this same feature from the graphical interface on Windows or Linux, select the **Pre/Post** option in the **General** tab of FLUENT Launcher, as described in *Starting ANSYS FLUENT Using FLUENT Launcher* (p. 1).

1.1.4.4. SGE Options

The `-sge` option runs ANSYS FLUENT under Sun Grid Engine (SGE) software, and allows you to use the features of this software to manage your distributed computing resources. Other options that can be employed in conjunction with `-sge` are `-sge , requested, -sgeq queue, -sgeckpt ckpt_obj, and -sgepe fluent_pe min_n-max_n.`

For a detailed explanation of these options, see [Running FLUENT Under SGE](#).

1.1.4.5. LSF Options

The `-lsf` option allows you to run ANSYS FLUENT under Platform Computing Corporation's LSF software, and thereby take advantage of the checkpointing features of that load management tool. For further details about using the `-lsf` option, see [Running FLUENT Under LSF](#).

1.1.4.6. Version and Release Options

Typing `fluent version -r`, replacing `version` with the desired version, will list all releases of the specified version.

`fluent -rx` will run release `x` of ANSYS FLUENT. You may specify a version as well, or you can wait and specify the version when prompted by the solver.

`fluent -env` will list all environment variables before running ANSYS FLUENT.

1.1.4.7. System Coupling Options

These following command line options (in either Windows or Linux) can be used when ANSYS FLUENT is involved in a system coupling simulation.

`-schost=x` (where `x` is the name of the host machine, in quotes) specifies the host machine on which the coupling service is running (to which the co-simulation participant/solver must connect).

`-scport=y` (where `y` is the port number) specifies the port on the host machine upon which the coupling service is listening for connections from co-simulation participants.

`-scname=z` (where `z` is the name of the participant, in quotes) specifies the unique name used by the co-simulation participant to identify itself to the coupling service (see [System Coupling Server File \(sc-Server.scs\)](#) in the [System Coupling Guide](#) for more information).

The general syntax for invoking ANSYS FLUENT for system coupling is:

```
fluent 3d -schost=host name in quotes -scport=port number -scname=name of the solver in quotes
```

For instance:

```
fluent 3d -schost="machine1.domain.com" -scport=1234 -scname="Solution1"
```

Once ANSYS FLUENT loads and initializes the case, start the system coupling by typing the following command in the ANSYS FLUENT text user interface (TUI):

```
(sc-solve)
```

For more information, see [Performing System Coupling Simulations Using FLUENT in Workbench](#) in the [FLUENT in Workbench User's Guide](#), as well as the [System Coupling Guide](#).

1.1.4.8. Other Startup Options

There are other startup options that are not listed when you type the `fluent -help` command. These options can be used to customize your graphical user interface. For example, to change the ANSYS FLUENT window size and position you can either modify the `.Xdefaults` file (Linux only) described in [Customizing the Graphical User Interface \(Linux Systems Only\)](#) (p. 41), or you can simply type the following command at startup:

```
fluent [version] [-geometry] [XXxYY+00-50]
```

where XX and YY are the width and height in pixels, respectively, and +00-50 is the position of the window.

Therefore, typing `fluent 3d -geometry 700x500+20-400` will start the 3D version of ANSYS FLUENT, sizing the ANSYS FLUENT console to 700x500 pixels and positioning it on your monitor screen at +20-400.

1.2. Running ANSYS FLUENT in Batch Mode

ANSYS FLUENT can be used interactively, with input from and display to your computer screen, or it can be used in a batch or background mode in which inputs are obtained from and outputs are stored in files. Generally you will perform problem setup, initial calculations, and postprocessing of results in an interactive mode. However, when you are ready to perform a large number of iterative calculations, you may want to run ANSYS FLUENT in batch or background mode. This allows the computer resources

to be prioritized, enables you to control the process from a file (eliminating the need for you to be present during the calculation), and also provides a record of the calculation history (residuals) in an output file. While the procedures for running ANSYS FLUENT in a batch mode differ depending on your computer operating system, *Background Execution on Linux Systems* (p. 14) provides guidance for running in batch/background on Linux systems, and *Background Execution on Windows Systems* (p. 15) provides guidance for running in batch/background on Windows systems.

For additional information, please see the following sections:

- 1.2.1. [Background Execution on Linux Systems](#)
- 1.2.2. [Background Execution on Windows Systems](#)
- 1.2.3. [Batch Execution Options](#)

1.2.1. Background Execution on Linux Systems

To run ANSYS FLUENT in the background in a C-shell (csh) on a Linux system, type a command of the following form at the system-level prompt:

```
fluent 2d -g < inputfile > & outputfile &
```

or in a Bourne/Korn-shell, type:

```
fluent 2d -g < inputfile > outputfile 2>&1 &
```

In these examples,

- fluent is the command you type to execute ANSYS FLUENT interactively.
- -g indicates that the program is to be run without the GUI or graphics (see [Starting ANSYS FLUENT](#) (p. 1)).
- inputfile is a file of ANSYS FLUENT commands that are identical to those that you would type interactively.
- outputfile is a file that the background job will create and which will contain the output that ANSYS FLUENT would normally print to the screen (e.g., the menu prompts and residual reports).
- & tells the Linux system to perform this task in background and to send all standard system errors (if any) to outputfile.

The file inputfile can be a journal file created in an earlier ANSYS FLUENT session, or it can be a file that you have created using a text editor. In either case, the file must consist only of text interface commands (since the GUI is disabled during batch execution). A typical inputfile is shown below:

```
; Read case file
rc example.cas
; Initialize the solution
/solve/initialize/initialize-flow
; Calculate 50 iterations
it 50
; Write data file
wd example50.dat
; Calculate another 50 iterations
it 50
; Write another data file
wd example100.dat
; Exit FLUENT
exit
yes
```

This example file reads a case file example.cas, initializes the solution, and performs 100 iterations in two groups of 50, saving a new data file after each 50 iterations. The final line of the file terminates the session. Note that the example input file makes use of the standard aliases for reading and writing case and data files and for iterating. (it is the alias for /solve/iterate, rc is the alias for

/file/read-case, wd is the alias for /file/write-data, etc.) These predefined aliases allow you to execute commonly-used commands without entering the text menu in which they are found. In general, ANSYS FLUENT assumes that input beginning with a / starts in the top-level text menu, so if you use any text commands for which aliases do not exist, you must be sure to type in the complete name of the command (e.g., /solve/initialize/initialize-flow). Note also that you can include comments in the file. As in the example above, comment lines must begin with a ; (semicolon).

An alternate strategy for submitting your batch run, as follows, has the advantage that the `outputfile` will contain a record of the commands in the `inputfile`. In this approach, you would submit the batch job in a C-shell using:

```
fluent 2d -g -i inputfile >& outputfile &
```

or in a Bourne/Korn-shell using:

```
fluent 2d -g -i inputfile > outputfile 2>&1 &
```

1.2.2. Background Execution on Windows Systems

To run ANSYS FLUENT in the background on a Windows system, the following commands can be used:

```
fluent 3d -g -i journal
fluent 3d -g -wait -i journal
fluent 3d -hidden -i journal
```

In these examples,

- fluent is the command you type to execute ANSYS FLUENT interactively.
- -g indicates that the program is to be run minimized in the task bar.
- -i journal reads the specified journal file.
- -wait is the command you type in a DOS batch file or some other script in a situation where the script needs to wait until ANSYS FLUENT has completed its run.
- -hidden is similar to the -wait command, but also executes ANSYS FLUENT completely hidden and noninteractively.

To get an output (or transcript) file while running ANSYS FLUENT in the background on a Windows system, the journal file must contain the following command to write a transcript file:

```
; start transcript file
/file/start-transcript outputfile.trn
```

where the `outputfile` is a file that the background job will create and which will contain the output that ANSYS FLUENT would normally print to the screen (e.g., the menu prompts and residual reports).

See [Creating and Reading Journal Files \(p. 75\)](#) for details about journal files. See [Creating Transcript Files \(p. 77\)](#) for details about transcript files.

1.2.3. Batch Execution Options

During a typical session, ANSYS FLUENT may require feedback from you in the event of a problem it encounters. ANSYS FLUENT usually communicates problems or questions through the use of **Error** dialog boxes, **Warning** dialog boxes, or **Question** dialog boxes. While executing ANSYS FLUENT in batch mode, you may want to suppress this type of interaction in order to, for example, create journal files more easily.

There are three common batch configuration options available to you when running ANSYS FLUENT in batch mode. You can access these options using the **Batch Options** dialog box (see *Batch Options Dialog Box (p. 2228)*).

File → Batch Options...

Figure 1.7 The Batch Options Dialog Box

The **Batch Options** dialog box contains the following items:

Confirm File Overwrite

determines whether ANSYS FLUENT confirms a file overwrite. This option is turned on by default.

Hide Questions

allows you to hide **Question** dialog boxes. This option is turned off by default.

Exit on Error

allows you to automatically exit from batch mode when an error occurs. This option is turned off by default.

Note that these options are also available in the `file/set-batch-options` command in the text interface.

`file → set-batch-options`

Any combination of these options can be turned on or off at any given time prior to running in batch mode.

Important

Batch option settings are *not* saved with case files. They are meant to apply for the duration of the current ANSYS FLUENT session only. If you read in additional mesh or case files during this session, the batch option settings will not be altered. As batch options are not saved with case files, journal files developed for use in batch mode should begin by enabling the desired batch option settings (if different from the default settings).

1.3. Checkpointing an ANSYS FLUENT Simulation

The checkpointing feature of ANSYS FLUENT allows you to save case and data files while your simulation is running. While similar to the autosave feature of ANSYS FLUENT (*Automatic Saving of Case and Data Files (p. 68)*), which allows you to save files throughout a simulation, checkpointing allows you slightly more control in that you can save an ANSYS FLUENT job even after you have started the job and did not set the autosave option. Checkpointing also allows you to save case and data files and then exit

out of ANSYS FLUENT. This feature is especially useful when you need to stop an ANSYS FLUENT job abruptly and save its data.

There are two different ways to checkpoint an ANSYS FLUENT simulation, depending upon how the simulation has been started.

1. ANSYS FLUENT running under LSF or SGE

ANSYS FLUENT is integrated with load management tools like LSF and SGE. These two tools allow you to checkpoint any job running under them. You can use the standard method provided by these tools to checkpoint the ANSYS FLUENT job.

For more information on using ANSYS FLUENT and SGE or LSF, see [Running FLUENT Under SGE](#) or [Running FLUENT Under LSF](#), respectively.

2. Independently running ANSYS FLUENT

When not using tools such as LSF or SGE, a different checkpointing mechanism can be used when running an ANSYS FLUENT simulation. You can checkpoint an ANSYS FLUENT simulation while iterating/time-stepping, so that ANSYS FLUENT saves the case and data files and then continues the calculation, or so that ANSYS FLUENT saves the case and data files and then exits.

- Saving case and data files and continuing the calculation:

On Linux, create a file called `check-fluent`, i.e.,

```
/tmp/check-fluent
```

On Windows, create a file called `check-fluent.txt`, i.e.,

```
C:\temp\check-fluent.txt
```

- Saving case and data files and exiting ANSYS FLUENT:

On Linux, create a file called `exit-fluent`, i.e.,

```
/tmp/exit-fluent
```

On Windows, create a file called `exit-fluent.txt`, i.e.,

```
C:\temp\exit-fluent.txt
```

The saved case and data files will have the current iteration number appended to their file names.

ANSYS FLUENT offers an alternate way to checkpoint an unsteady simulation. While the default behavior is to checkpoint the simulation at the end of the current iteration, for unsteady simulations you have the option of completing all of the iterations in the current time-step before checkpointing. This can be set by entering the following Scheme command prior to running the unsteady simulation:

```
(ckpt/time-step?  
#t)
```

Now when you save the checkpoint file (as described previously), the case and data file will be saved at the end of the current time-step and named accordingly. To switch back to the default checkpointing mechanism at the end of the current iteration, use the following Scheme command:

```
(ckpt/time-step? #f)
```

Important

Note that the (`ckpt/time-step? #t`) command will have the effect only in the case of an unsteady simulation.

Note

It is recommended that you do *not* use checkpointing when using ANSYS FLUENT in Workbench. However, if checkpointing is necessary, the `exit-fluent/exit-fluent.txt` file can be used and the file will be checked in its default location (the FFF/FLU system directory containing the `*.set` file). If ANSYS FLUENT is calculating, then the existence of the file is equivalent to an **interrupt** command. Similarly, the `check-fluent/check-fluent.txt` file can be used to save the project on demand when ANSYS FLUENT is calculating.

1.4. Cleaning Up Processes From an ANSYS FLUENT Simulation

ANSYS FLUENT lets you easily remove extraneous processes in the event that an ANSYS FLUENT simulation needs to be stopped.

When a session is started, ANSYS FLUENT creates a `cleanup-fluent` script file. The script can be used to clean up all ANSYS FLUENT-related processes. ANSYS FLUENT creates the cleanup-script file in the current working folder with a file name that includes the machine name and the process identification number (PID) (e.g., `cleanup-fluent-mymachine-1234`).

If the current directory does not possess the proper write permissions, then ANSYS FLUENT will write the cleanup-script file to your home directory.

If, for example, ANSYS FLUENT is started on a machine called `thor` and the process identification number is 32895, ANSYS FLUENT will create a cleanup-script called `cleanup-fluent-thor-32895` in the current folder. To run the cleanup-script, and clean up all ANSYS FLUENT processes related to your session, on Linux platforms, type the following command in the console window:

```
sh cleanup-fluent-thor-32895
```

Or, if the shell script already has executable permissions, simply type:

```
cleanup-fluent-thor-32895
```

To clean up extraneous ANSYS FLUENT processes on Windows (serial or parallel), double-click the corresponding batch file (e.g., `cleanup-fluent-thor-32895.bat`) that ANSYS FLUENT generates at the beginning of each session.

Important

During a normal run, this file will be deleted automatically after exiting ANSYS FLUENT. In abnormal situations, you may use this batch file to clean up the ANSYS FLUENT processes. Once an ANSYS FLUENT session has been closed, you can safely delete any left over cleanup scripts from your working folder.

1.5. Exiting ANSYS FLUENT

You can exit ANSYS FLUENT by selecting **Exit** in the **File** pull-down menu. If the present state of the program has not been written to a file, a **Question** dialog box will open to confirm if you want to proceed. You can cancel the exit and write the appropriate file(s) or you can continue to exit without saving the case or data.

Chapter 2: Graphical User Interface (GUI)

The ANSYS FLUENT graphical interface consists of a menu bar to access the menus, a toolbar, a navigation pane, a task page, a graphics toolbar, graphics windows, and a console, which is a textual command line interface (described in [Text User Interface \(TUI\) \(p. 47\)](#)). You will have access to the dialog boxes via the task page or the menus.

[2.1. GUI Components](#)

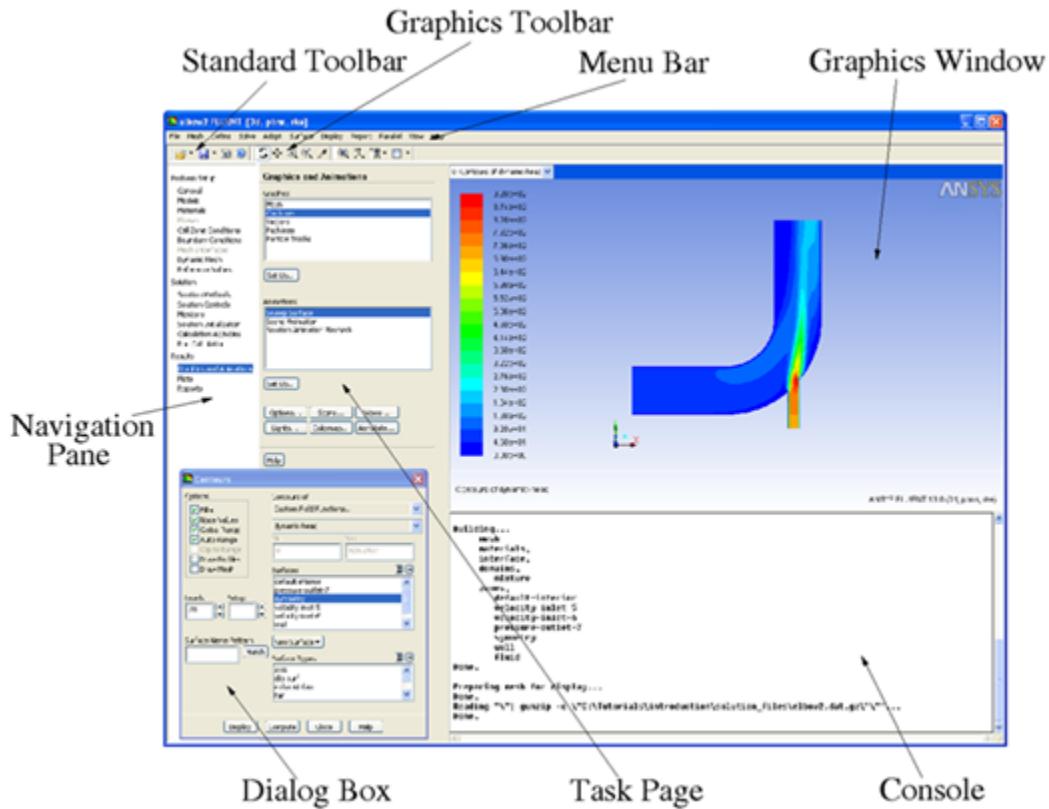

[2.2. Customizing the Graphical User Interface \(Linux Systems Only\)](#)

[2.3. Using the GUI Help System](#)

2.1. GUI Components

The graphical user interface (GUI) is made up of seven main components: the menu bar, toolbars, a navigation pane, task pages, a console, dialog boxes, and graphics windows. When you use the GUI, you will be interacting with one of these components at all times. [Figure 2.1 \(p. 22\)](#) is a sample screen shot showing all of the GUI components. The seven GUI components are described in detail in the subsequent sections.

On Linux systems, the attributes of the GUI (including colors and text fonts) can be customized to better match your platform environment. This is described in [Customizing the Graphical User Interface \(Linux Systems Only\) \(p. 41\)](#).

Figure 2.1 The GUI Components

For additional information, please see the following sections:

- [2.1.1. The Menu Bar](#)
- [2.1.2. Toolbars](#)
- [2.1.3. The Navigation Pane](#)
- [2.1.4. Task Pages](#)
- [2.1.5. The Console](#)
- [2.1.6. Dialog Boxes](#)
- [2.1.7. Graphics Windows](#)

2.1.1. The Menu Bar

The menu bar organizes the GUI menu hierarchy using a set of pull-down menus. A pull-down menu contains items that perform commonly executed actions. [Figure 2.2 \(p. 22\)](#) shows the ANSYS FLUENT menu bar. Menu items are arranged to correspond to the typical sequence of actions that you perform in ANSYS FLUENT (i.e., from left to right and from top to bottom).

Figure 2.2 The ANSYS FLUENT Menu Bar

To select a pull-down menu item with the mouse, follow the procedure outlined below:

1. Move the pointer to the name of the pull-down menu.
2. Click the left mouse button to display the pull-down menu.

3. Move the pointer to the item you wish to select and click it.

In addition to using the mouse, you can also select a pull-down menu item using the keyboard. If you press the **Alt** key, each pull-down menu label or menu item will display one underlined character, known as the mnemonic. If you then press the mnemonic character of a pull-down menu, the associated menu will be displayed (note that the mnemonic character is not case sensitive). After the pull-down menu is selected and displayed, you can type a mnemonic character associated with an item to select that item. For example, to display the **Help** menu and select the **Using Help...** option, press **Alt**, then **h**, and then **h** again. If at any time you wish to cancel a menu selection while a pull-down menu is displayed, you can press the **Esc** key.

2.1.2. Toolbars

The ANSYS FLUENT GUI includes toolbars located within the application window. These toolbars provide shortcuts to performing common tasks in ANSYS FLUENT. By default, the toolbars are docked to the ANSYS FLUENT interface but can also be detached and moved to a new location. You can detach a toolbar by clicking the left mouse button on the outer portion of it, holding down the mouse, and dragging the toolbar to a new location. To move the detached toolbar, select the title bar and drag the toolbar to a new position in the application window. Once detached, the toolbars can be restored to their location in the interface by double-clicking the title region of the toolbar.

Important

Toolbars that are detached or moved to a new location will return to their original positions each time ANSYS FLUENT is launched.

The small arrow button in some ANSYS FLUENT toolbars can be used to access additional functionality in ANSYS FLUENT. For instance, there are additional selections available when you click the small arrow in the standard toolbar.

The ANSYS FLUENT graphical user interface includes a standard toolbar and a graphics toolbar.

2.1.2.1. The Standard Toolbar

The standard toolbar (*Figure 2.3* (p. 23)) contains options for working with ANSYS FLUENT case files, saving images, and accessing the ANSYS FLUENT documentation.

Figure 2.3 The Standard Toolbar

The following is a brief description of each of the standard toolbar options.

- **Read a file** allows you to read in a mesh, open existing ANSYS FLUENT case files, and other file types using a file selection dialog box. Here, you can browse through your collection of folders, and locate a file. For more information, see *Reading and Writing Case and Data Files* (p. 66).

- **Write a file** saves the current ANSYS FLUENT case, data, or other file types. For more information, see *Reading and Writing Case and Data Files* (p. 66).

- **Save Picture**  allows you to capture an image of the active graphics window. For more information, see [Saving Picture Files \(p. 119\)](#).
- **Help**  allows you to access the ANSYS FLUENT User's Guide for help topics. For more information, see [Using the GUI Help System \(p. 42\)](#).

2.1.2.2. The Graphics Toolbar

The graphics toolbar ([Figure 2.4 \(p. 24\)](#)) contains options that allow you to modify the way in which you view your model or select objects in the graphics window.

Figure 2.4 The Graphics Toolbar

The following is a description of each of the graphics toolbar options.

- **Rotate View**  lets you rotate your model about a central point in the graphics window. For more information, see [Button Functions \(p. 1548\)](#).
- **Pan**  allows you to pan horizontally or vertically across the view using the left mouse button. For more information, see [Button Functions \(p. 1548\)](#).
- **Zoom In/Out**  allows you to zoom into and out of the model by holding the left mouse button down and moving the mouse down or up. For more information, see [Button Functions \(p. 1548\)](#). You can also roll the view by holding the left mouse button down and moving the mouse left or right.
- **Zoom to Area**  allows you to focus on any part of your model. After selecting this option, position the mouse pointer at a corner of the area to be magnified, hold down the left mouse button and drag open a box to the desired size, and then release the mouse button. The enclosed area will then fill the graphics window. Note that you must drag the mouse to the right in order to zoom in. To zoom out, you must drag the mouse to the left. For more information, see [Button Functions \(p. 1548\)](#).
- **Print information about selected item**  allows you to select items from the graphics windows and request information about displayed scenes. This behaves as a mouse probe button. For more information, see [Button Functions \(p. 1548\)](#).
- **Fit to Window**  adjusts the overall size of your model to take maximum advantage of the graphics window's width and height.
- **Isometric view**  contains a drop-down of views, allowing you to display the model from the direction of the vector equidistant to all three axes, as well as in different axes orientations.

- **Arrange the workspace**  provides you with several application window layout options. For example, you can choose to hide certain windows, or view multiple graphics windows. This is essentially the shortcut to the **View** menu. For information about the various layouts, see [Viewing the Application Window \(p. 1550\)](#).
- **Arrange the graphics window layout**  allows you to specify the number and layout of the graphics windows, when they are embedded in the ANSYS FLUENT application window. You can have up to four graphics window embedded at one time. This is essentially a shortcut to the **View/Graphics Window Layout** menu. See [Viewing the Application Window \(p. 1550\)](#) for further details.

2.1.3. The Navigation Pane

The navigation pane, located on the left side of the ANSYS FLUENT GUI, contains a list of task pages, as shown in [Figure 2.5 \(p. 25\)](#).

Figure 2.5 The ANSYS FLUENT Navigation Pane

The list consists of **Problem Setup** task pages, **Solution**-related activities, and a **Results** section for postprocessing.

When any of the items under **Problem Setup**, **Solution**, or **Results** is highlighted, the **task page** ([Task Pages \(p. 26\)](#)) will be displayed to the right of the navigation pane. The items in the navigation pane are listed in the order in which you would normally set up, solve, and postprocess a case.

Using the navigation pane is an alternative to using the menu bar. For example, there are two ways you can access the **Viscous Model** dialog box (see [Viscous Model Dialog Box \(p. 1778\)](#)). To access it using the navigation pane, highlight **Models** in the navigation pane by clicking on it with your left mouse

button. The **Models** task page (see [Models Task Page \(p. 1771\)](#)) will appear to the right of the navigation pane. Select **Viscous** from the **Models** list and click the **Edit...** button (or simply double-click **Viscous**) to open the **Viscous Model** dialog box (see [Viscous Model Dialog Box \(p. 1778\)](#)).

◆ **Models** →  **Viscous** → **Edit...**

You can also access the **Viscous Model** dialog box (see [Viscous Model Dialog Box \(p. 1778\)](#)) using the following menu path:

Define → **Models...**

This will open the **Models** task page (see [Models Task Page \(p. 1771\)](#)), where you will select **Viscous** from the **Models** list and click the **Edit...** button (or simply double-click on **Viscous**) to open the **Viscous Model** dialog box (see [Viscous Model Dialog Box \(p. 1778\)](#)).

Note that while most of the task pages can be accessed using the navigation pane, there are some dialog boxes that can only be accessed using the menu path. For example, to access the **Custom Field Function Calculator** dialog box (see [Custom Field Function Calculator Dialog Box \(p. 2264\)](#)), use the following menu path:

Define → **Custom Field Functions...**

2.1.4. Task Pages

Task pages appear on the right side of the navigation pane when an item is highlighted in the navigation pane (see [Figure 2.1 \(p. 22\)](#)). The expected workflow is that you travel down the navigation pane, setting the controls provided in each task page until you are ready to run the calculation. Note that you can access the task pages through the menu items, as described in the example in [The Navigation Pane \(p. 25\)](#).

Some of your setup will occur in dialog boxes, while others in task pages. For example, if **General** is selected in the navigation pane, this task page is displayed. Global settings are made in this task page, which are saved to the case definition.

Each task page has a **Help** button. Clicking this button opens the related help topic in the Reference Guide. See [Using the GUI Help System \(p. 42\)](#) for more information.

2.1.5. The Console

The console is located below the graphics window, as shown in [Figure 2.1 \(p. 22\)](#). ANSYS FLUENT communicates with you through the console. It is used to display various kinds of information (i.e., messages relating to meshing or solution procedures, etc.). ANSYS FLUENT saves a certain amount of information that is written to the console into memory. You can review this information at any time by using the scroll bar on the right side of the console. The size of the console can be adjusted by raising or lowering the bottom frame of the graphics window.

The console is similar in behavior to “xterm” or other Linux command shell tools, or to the MS-DOS Command Prompt window on Windows systems. It allows you to interact with the TUI menu. More information on the TUI can be found in [Text User Interface \(TUI\) \(p. 47\)](#).

The console accepts a “break” command (pressing the **Ctrl** key and the **c** key at the same time) to let you interrupt the program while it is working. It also lets you perform text copy and paste operations between the console and other X Window (or Windows) applications that support copy and paste. The following steps show you how to perform a copy and paste operation on a Windows system:

1. Move the pointer to the beginning of the text to be copied.
2. Press and hold down the left mouse button.
3. Move the pointer to the end of the text (text should be highlighted).
4. Release the left mouse button.
5. Press the **Ctrl** and <Insert> keys at the same time.
6. Move the pointer to the target window and click the left mouse button.
7. Press the **Ctrl** and v keys at the same time.

On a Linux system, you will follow the steps below to copy text to the clipboard:

1. Move the pointer to the beginning of the text to be copied.
2. Press and hold down the left mouse button.
3. Move the pointer to the end of the text (text should be highlighted).
4. Release the left mouse button.
5. Move the pointer to the target window.
6. Press the middle mouse button to "paste" the text.

2.1.6. Dialog Boxes

There are two types of dialog boxes in ANSYS FLUENT. Some dialog boxes are used to perform simple input/output tasks, such as issuing warning and error messages, or asking a question requiring a yes or no answer. Other forms of dialog boxes allow you to perform more complicated input tasks.

A dialog box is a separate "temporary" window that appears when ANSYS FLUENT needs to communicate with you, or when various types of input controls are employed to set up your case. The types of controls you will see are described further in this section.

When you have finished entering data in a dialog box's controls, you will need to apply the changes you have made, or cancel the changes, if desired. For this task, each dialog box falls into one of two behavioral categories, depending on how it was designed.

The first category of dialog boxes is used in situations where it is desirable to apply the changes and immediately close the dialog box. This type of dialog box includes two button controls as described below:

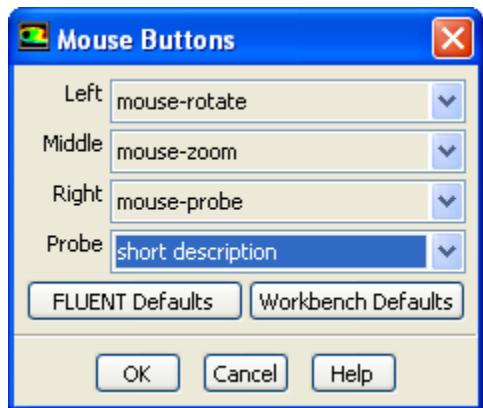

OK

applies any changes you have made to the dialog box, then closes the dialog box.

Cancel

closes the dialog box, ignoring any changes you have made.

An example of this type of dialog box is shown in the following figure:

The other category of dialog boxes is used in situations where it is desirable to keep the dialog box displayed on the screen after changes have been applied. This makes it easy to quickly go back to that dialog box and make more changes. Dialog boxes used for postprocessing and mesh adaption often fall into this category. This type of dialog box includes two button controls as described below:

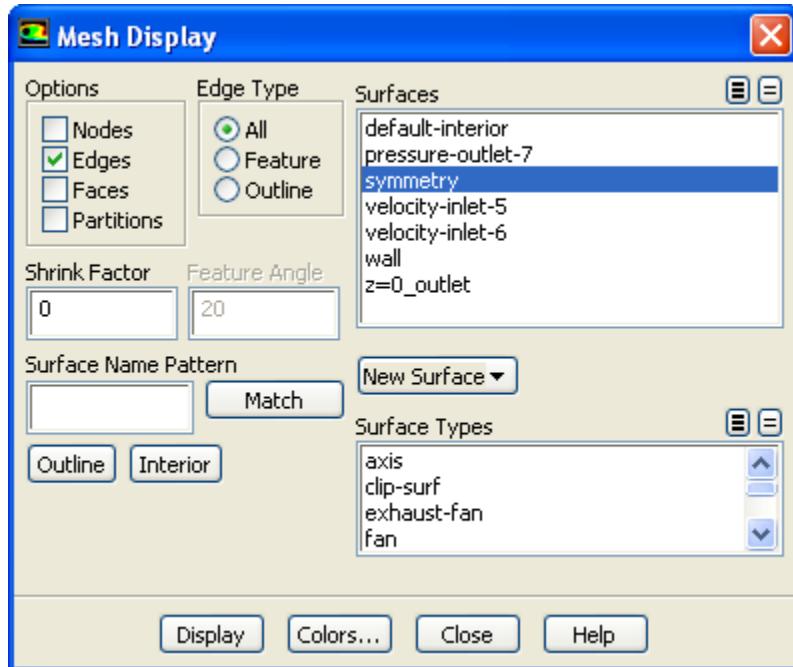

Apply

applies any changes you have made to the dialog box, but does not close the dialog box. The name of this button is often changed to something more descriptive. For example, many of the postprocessing dialog boxes use the name **Display** for this button, and the adaption dialog boxes use the name **Adapt**.

Close

closes the dialog box.

An example of this type of dialog box is shown in the following figure:

All dialog boxes include the following button used to access ANSYS Help:

Help

displays information about the controls in the dialog box. The help information will appear in the ANSYS Help Viewer.

2.1.6.1. Input Controls

Each type of input control utilized by the dialog boxes is described below. Note that the examples shown here are for a Windows system; if you are working on a Linux system, your dialog box controls may look slightly different, but they will work exactly as described here.

2.1.6.1.1. Tabs

Much like the tabs on a notebook divider, tabs in dialog boxes are used to mark the different sections into which a dialog box is divided. A dialog box that contains many controls may be divided into different sections to reduce the amount of screen space it occupies. You can access each section of the dialog box by “clicking” the left mouse button on the corresponding tab. A click is one press and release of the mouse button.

2.1.6.1.2. Buttons

A button, also referred to as a push button, is used to perform a function indicated by the button label. To activate a button, place the pointer over the button and click the left mouse button.

2.1.6.1.3. Check Boxes

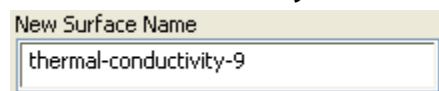

A check box, also referred to as a check button, is used to enable / disable an item or action indicated by the check box label. Click the left mouse button on the check box to toggle the state.

2.1.6.1.4. Radio Buttons

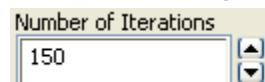

Radio buttons are a set of check boxes with the condition that only one can be set in the “on” position at a time. When you click the left mouse button on a radio button, it will be turned on, and all others will be turned off. Radio buttons appear either as diamonds (in Linux systems) or as circles (as shown above).

2.1.6.1.5. Text Entry Boxes

A text entry box lets you type text input. It will often have a label associated with it to indicate the purpose of the entry.

2.1.6.1.6. Integer Number Entry Boxes

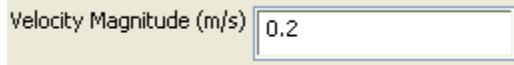

An integer number entry box is similar to a text entry except it allows only integer numbers to be entered (e.g., 10, -10, 50000 and 5E4). You may find it easier to enter large integer numbers using scientific notation. For example, you could enter 350000 or 3.5E5.

The integer number entry also has arrow buttons that allow you to easily increase or decrease its value. For most integer number entry controls, the value will be increased (or decreased) by one when you click an arrow button. You can increase the size of the increment by holding down a keyboard key while clicking the arrow button. The keys used are shown below:

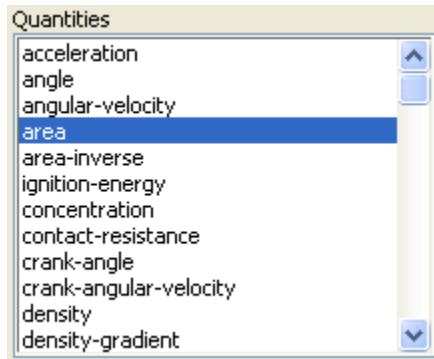

Key	Factor of Increase
Shift	10
Ctrl	100

2.1.6.1.7. Real Number Entry Boxes

A real number entry box is similar to a text entry, except it allows only real numbers to be entered (e.g., 10, -10.538, 50000.45 and 5.72E-4). In most cases, the label will show the units associated with the real number entry.

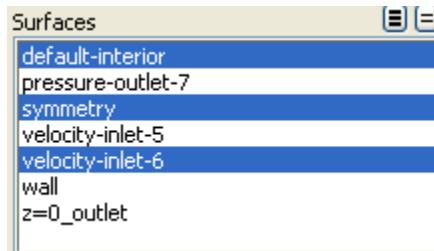

2.1.6.1.8. Single-Selection Lists

A single-selection list presents a list of items, with each item printed on a separate line. You can select an item by placing the pointer over the item line and clicking with the left mouse button. The selected item will become highlighted. Selecting another item will deselect the previously selected item in the list.

Many dialog boxes will also accept a double-click in order to invoke the dialog box action that is associated with the list selection (see information on the dialog box of interest for more details).

2.1.6.1.9. Multiple-Selection Lists

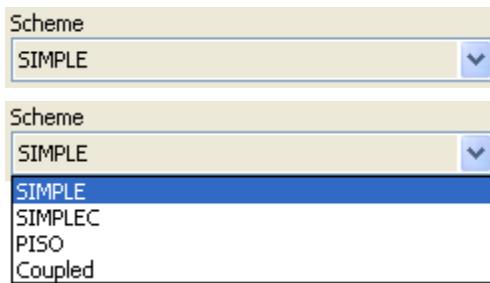

A multiple-selection list is similar to a single-selection list, except it allows for more than one selected item at a time. When you click the left mouse button on an item, its selection state will toggle. Clicking on an unselected item will select it. Clicking on a selected item will deselect it.

To select a range of items in a multiple-selection list, you can select the first desired item, and then select the last desired item while holding down the **Shift** key. The first and last items, and all the items between them, will be selected. You can also click and drag the left mouse button to select multiple items.

There are two small buttons in the upper right corner of the multiple selection list that accelerate the task of selecting or deselecting all the items in the list. Clicking the left button will select all items. Clicking the right button will deselect all items.

2.1.6.1.10. Drop-Down Lists

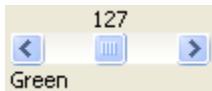

A drop-down list is a hidden single-selection list that shows only the current selection to save space.

When you want to change the selection, follow the steps below:

1. Click the arrow button to display the list.
2. Place the pointer over the new list item.
3. Click the left mouse button on the item to make the selection and close the list.

If you wish to abort the selection operation while the list is displayed, you can move the pointer anywhere outside the list and click the left mouse button.

2.1.6.1.11. Scales

A scale is used to select a value from a predefined range by moving a slider. The number shows the current value. You can change the value by clicking the arrow buttons, or by following one of the procedures below:

1. Place the pointer over the slider.
2. Press and hold down the left mouse button.
3. Move the pointer along the slider bar to change the value.
4. Release the left mouse button.

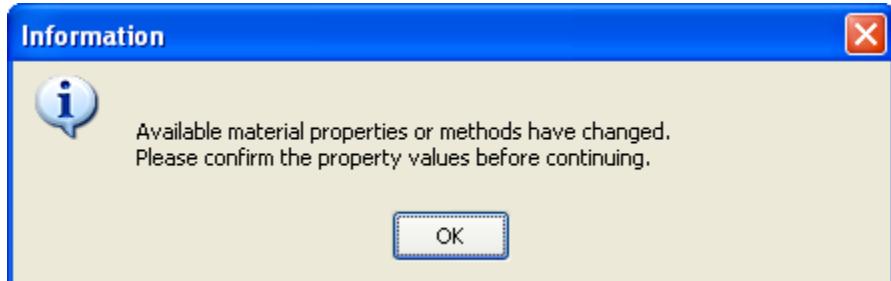

or

1. Place the pointer over the slider and click the left mouse button.
2. Using the arrow keys on the keyboard, move the slider bar left or right to change the value.

2.1.6.2. Types of Dialog Boxes

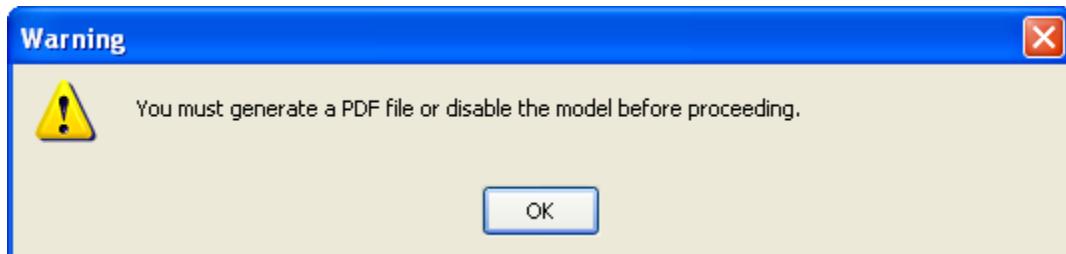

The following sections describe the various types of dialog boxes.

2.1.6.2.1. Information Dialog Boxes

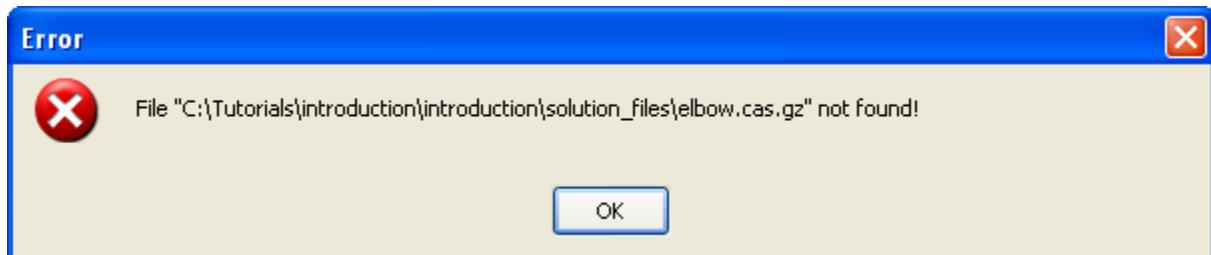

The **Information** dialog box is used to report some information that ANSYS FLUENT thinks you should know. After you have read the information, you can click the **OK** button to close the dialog box.

2.1.6.2.2. Warning Dialog Boxes

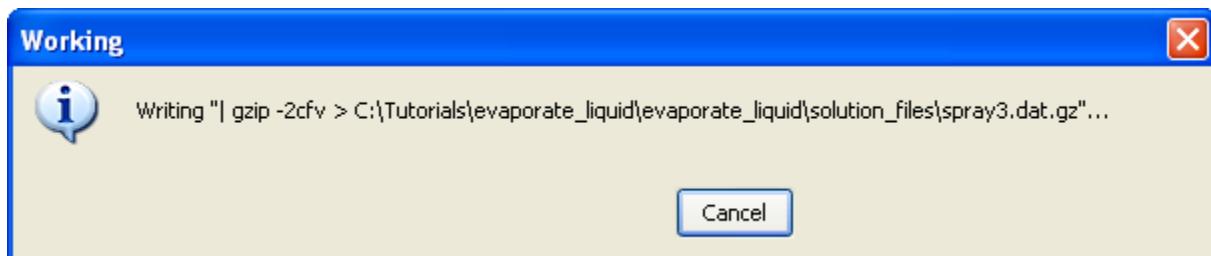

The **Warning** dialog box is used to warn you of a potential problem or deliver an important message. Your control of ANSYS FLUENT will be suspended until you acknowledge the warning by clicking the **OK** button.

2.1.6.2.3. Error Dialog Boxes

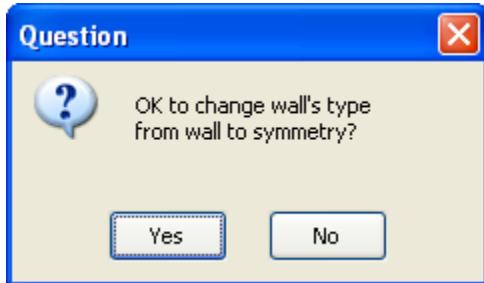

The **Error** dialog box is used to alert you of an error that has occurred. After you have read the error information, you can click the **OK** button to close the dialog box.

2.1.6.2.4. The Working Dialog Box

The **Working** dialog box is displayed when ANSYS FLUENT is busy performing a task. This is a special dialog box, because it requires no action by you. It is there to let you know that you must wait. When the program is finished, it will close the dialog box automatically. You can, however, abort the task that is being performed by clicking the **Cancel** button.

2.1.6.2.5. Question Dialog Box

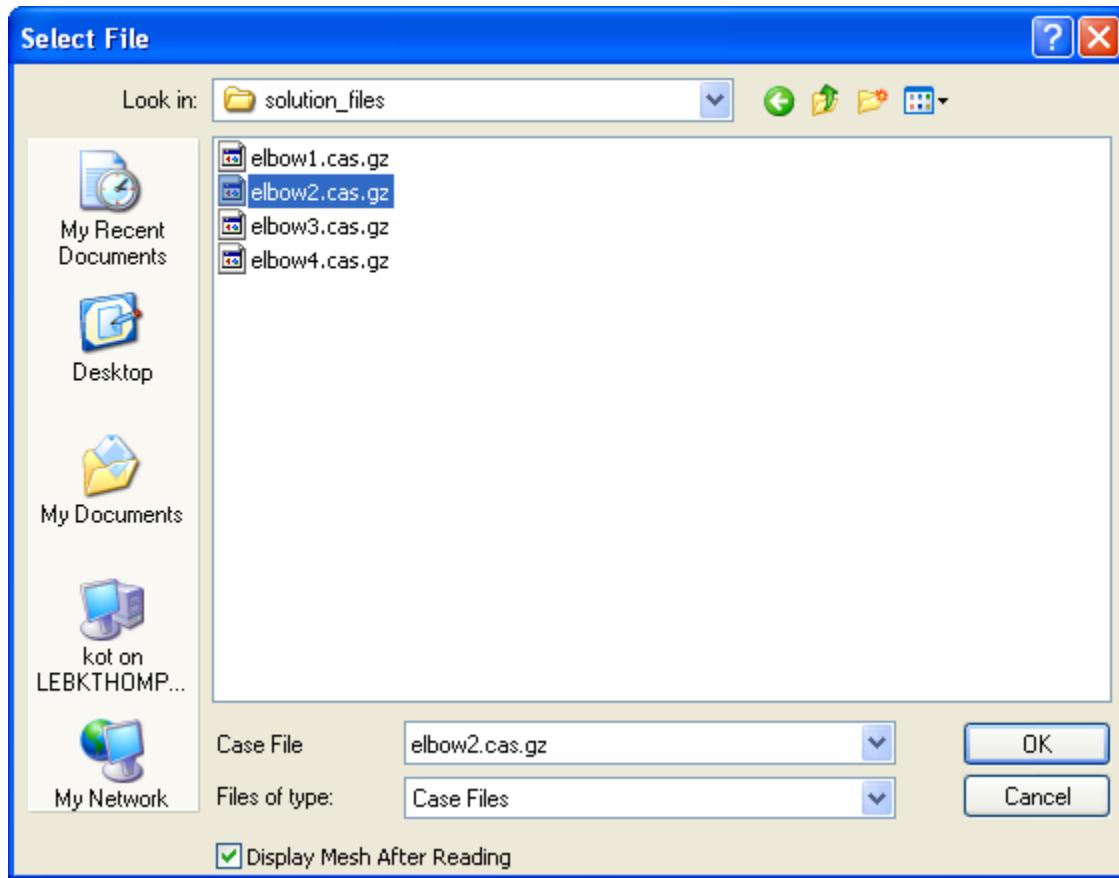

The **Question** dialog box is used to ask you a question. Sometimes the question will require a **Yes** or **No** answer, while other times it will require that you either allow an action to proceed (**OK**) or **Cancel** the action. You can click the appropriate button to answer the question.

2.1.6.2.6. The Select File Dialog Box

File selection is accomplished using the **Select File** dialog box (*The Select File Dialog Box (Windows)* (p. 33) or *The Select File Dialog Box (Linux)* (p. 34)).

2.1.6.2.6.1. The Select File Dialog Box (Windows)

File selection on Windows systems is accomplished using the standard Windows **Select File** dialog box (*Figure 2.6* (p. 34)).

Figure 2.6 The Select File Dialog Box for Windows

See documentation regarding your Windows system for further instructions on file selection.

2.1.6.2.6.2. The Select File Dialog Box (Linux)

For Linux systems, note that the appearance of the **Select File** dialog box will not always be the same.

The version shown in [Figure 2.7 \(p. 35\)](#) will appear in almost all cases, but it will be different if you are loading external data files for use in an XY plot (see [Including External Data in the Solution XY Plot \(p. 1593\)](#) for more information). In such cases, the dialog box will look like [Figure 2.8 \(p. 36\)](#).

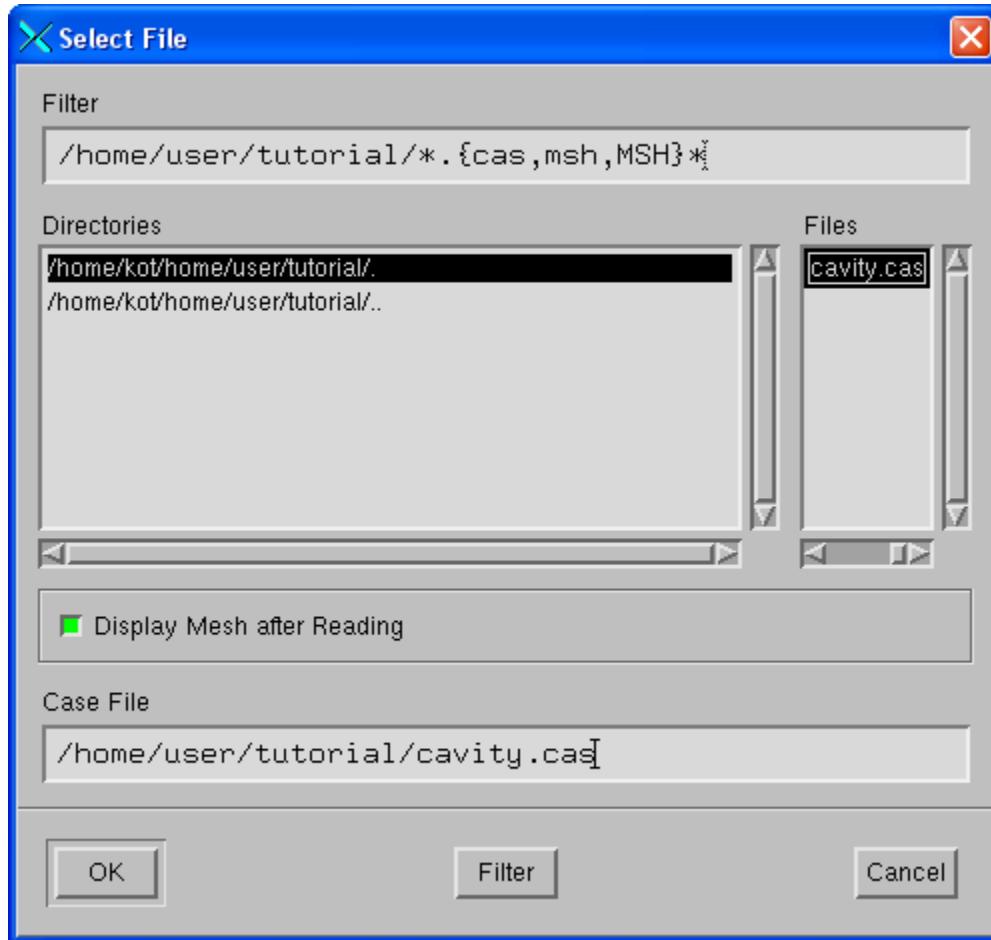

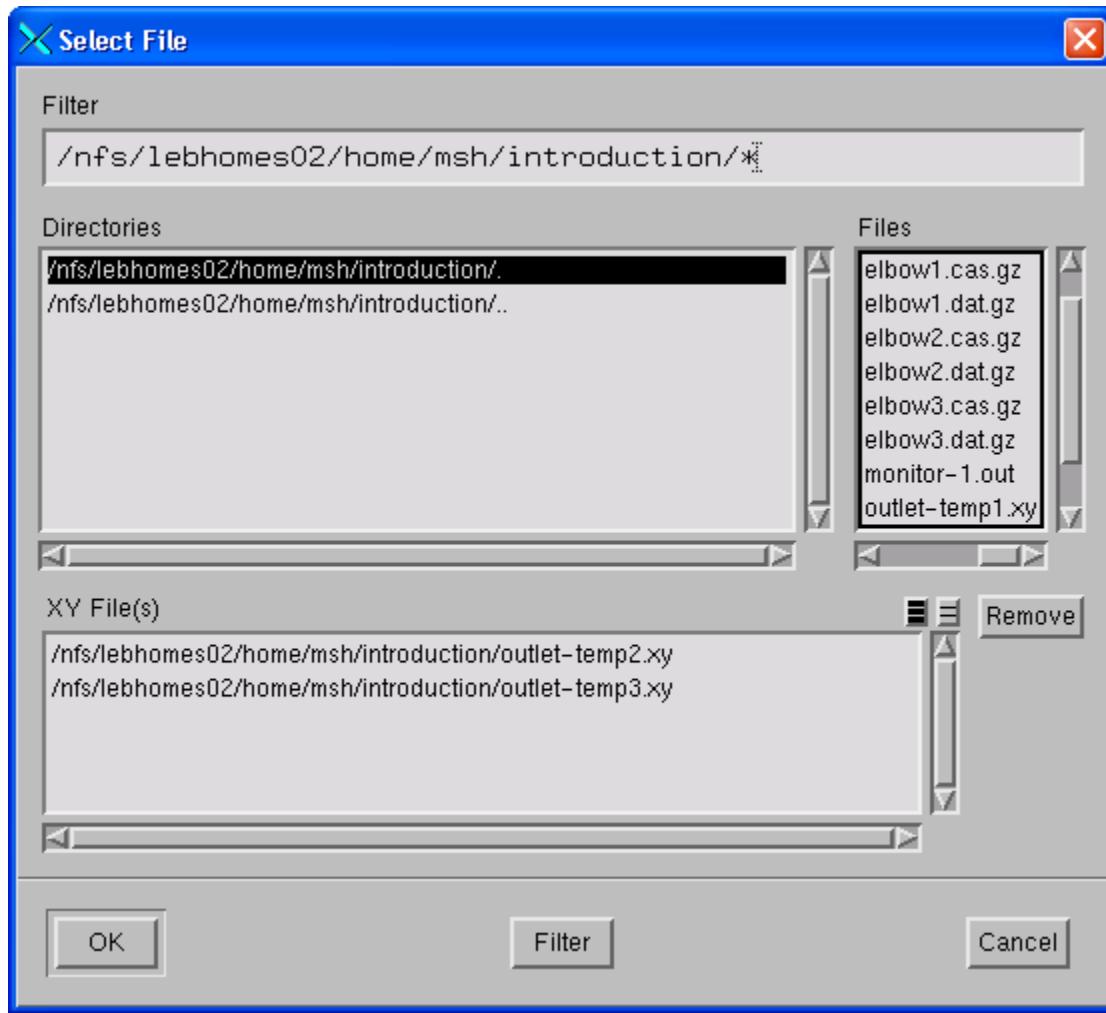

Figure 2.7 The Select File Dialog Box for Linux Platforms

Figure 2.8 Another Version of the Select File Dialog Box for Linux Platforms

The steps for file selection are as follows:

1. Go to the appropriate directory. You can do this in two different ways:
 - Enter the path to the desired directory in the **Filter** text entry box and then press the <Enter> key or click the **Filter** button. Be sure to include the final / character in the pathname, before the optional search pattern (described below).
 - Double-click a directory, and then a subdirectory, etc. in the **Directories** list until you reach the directory you want. You can also click once on a directory and then click the **Filter** button, instead of double-clicking. Note that the “.” item represents the current directory and the “..” item represents the parent directory.
2. Specify the file name by selecting it in the **Files** list or entering it in the **File** text entry box (if available) at the bottom of the dialog box. The name of this text entry box will change depending on the type of file you are selecting (**Case File**, **Journal File**, etc.).

Important

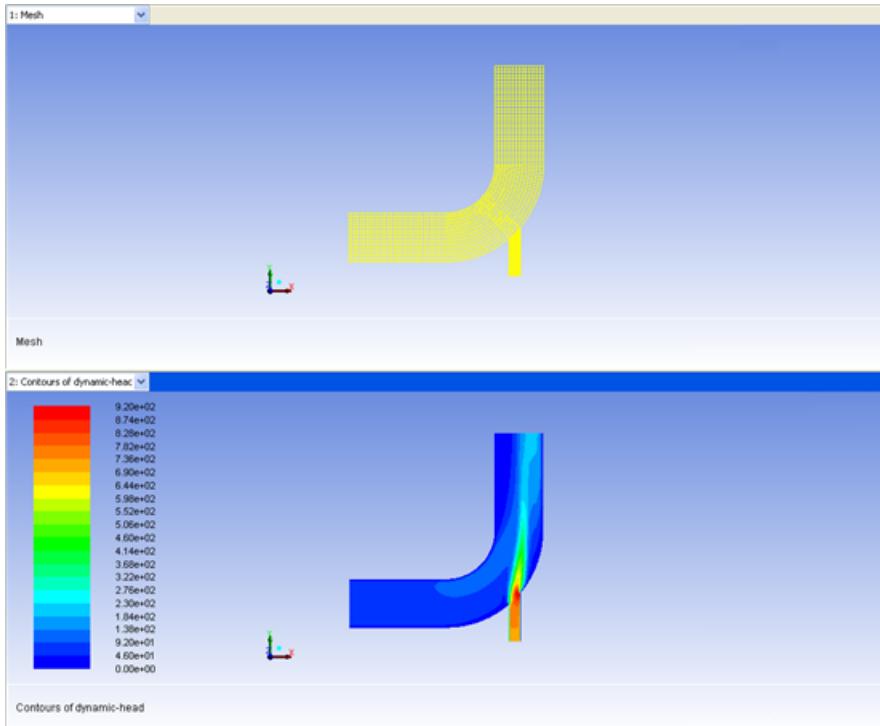

Note that if you are searching for an existing file with a nonstandard extension, you may need to modify the “search pattern” at the end of the path in the **Filter** text entry box. For example, if you are reading a data file, the default extension in the search path will be `*.dat*`, and only those files that have a `.dat` extension will appear in the **Files** list. If you want files with a `.DAT` extension to appear in the **Files** list, you can change the search pattern to `*.DAT*`. If you want all files in the directory to be listed in the **Files** list, enter just `*` as the search pattern.

3. If you are reading a mesh or case file, use the **Display Mesh after Reading** option to specify whether you want ANSYS FLUENT to automatically display the mesh after the file is read. All of the boundary zones will be displayed, except for the interior zones of 3D geometries. The default status of this option (i.e., enabled or disabled) is determined by your decision regarding the **Display Mesh After Reading** option in FLUENT Launcher.
4. If you are using the **Mesh/Replace...** menu item to replace a mesh for which data exists, you can enable the **Interpolate Data Across Zones** option to interpolate the data across cell zones. This option is appropriate when the matching zone pairs (i.e., the zones with the same names in both the current mesh and the replacement mesh) do not have the same interior zone boundaries. See *Replacing the Mesh* (p. 202) for details.
5. If you are reading multiple XY-plot data files, the selected file will be added to the list of **XY File(s)**. You can choose another file, following the instructions above, and it will also be added to this list. (If you accidentally select the wrong file, you can choose it in the **XY File(s)** list and click the **Remove** button to remove it from the list of files to be read.) Repeat until all of the desired files are in the **XY File(s)** list.
6. If you are writing a case, data, or radiation file, use the **Write Binary Files** check box to specify whether the file should be written as a text or binary file. You can read and edit a text file, but it will require more storage space than the same file in binary format. Binary files take up less space and can be read and written by ANSYS FLUENT more quickly.
7. Click the **OK** button to read or write the specified file. Shortcuts for this step are as follows:
 - If your file appears in the **Files** list and you are *not* reading an XY file, double-click it instead of just selecting it. This will automatically activate the **OK** button. (If you are reading an XY file, you will always have to click **OK** yourself. Clicking or double-clicking will just add the selected file to the **XY File(s)** list.)
 - If you entered the name of the file in the **File** text entry box, you can press the `<Enter>` key instead of clicking the **OK** button.

2.1.7. Graphics Windows

Graphics windows display the program’s graphical output, and may be viewed within the ANSYS FLUENT application window or in separate windows. The decision to embed the graphics window or to have floating graphics windows is made when you start ANSYS FLUENT using FLUENT Launcher. For information about FLUENT Launcher, refer to *Setting General Options in FLUENT Launcher* (p. 2). When viewed within the application window, the graphics windows will be placed below the toolbar on the right, as shown in *Figure 2.1* (p. 22).

Figure 2.9 Displaying Two Graphics Windows

In [Figure 2.9](#) (p. 38), two graphics windows are displayed by selecting the menu item **View/Graphics Window Layout**, then selecting . Although this setup only allows two windows to be visible at a given time, any number of graphics windows can be created. You can select any existing graphics window to be displayed in either location through the drop-down menu, which appears in the top left corner of the embedded graphics window. This drop-down displays the title of the window.

Important

You can change the text that appears in the graphics window title section by simply clicking in the area and editing it as you would in a text editor.

The **Display Options** dialog box (see [Display Options Dialog Box](#) (p. 2148)) can be used to change the attributes of the graphics window or to open another graphics window. The **Mouse Buttons** dialog box (see [Mouse Buttons Dialog Box](#) (p. 2315)) can be used to set the action taken when a mouse button is pressed in the graphics window.

Important

To cancel a display operation, press the **Ctrl** and the **c** keys together while the data is being processed in preparation for graphical display. You cannot cancel the operation after the program begins to draw in the graphics window.

For Windows systems, there are special features for printing the contents of the graphics window directly. These features are not available on Linux systems.

2.1.7.1. Printing the Contents of the Graphics Window (Windows Systems Only)

If you are using the Windows version of ANSYS FLUENT with free floating graphics windows (i.e., they are not embedded in the application window), you can display the graphics window's system menu by right-clicking in the uppermost portion of the graphics window. This menu contains the usual system commands, such as move, size, and close. Along with the system commands, ANSYS FLUENT includes three commands in the menu for printer and clipboard support (these three commands are also available for embedded graphics windows). These commands are described below:

Page Setup...

displays the **Page Setup** dialog box (see [Using the Page Setup Dialog Box \(Windows Systems Only\) \(p. 39\)](#)), which allows you to change attributes of the picture copied to the clipboard, or sent to a printer. Further details about this dialog box are included in the following section.

Print...

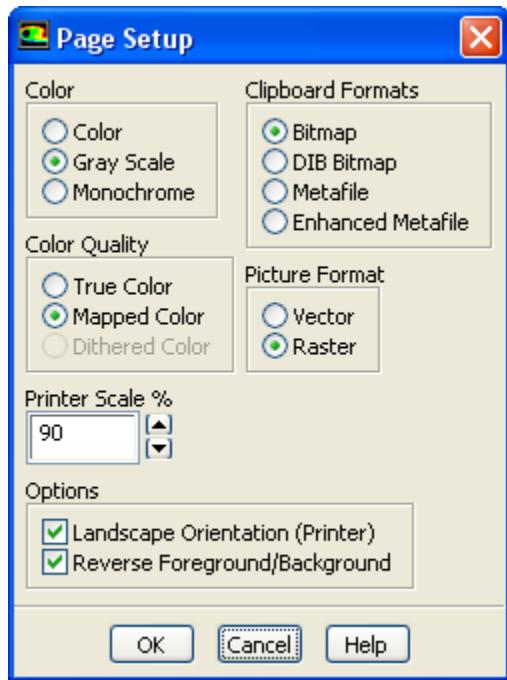

displays the Microsoft Windows **Print** dialog box (see [Printing the Contents of the Graphics Window \(Windows Systems Only\) \(p. 39\)](#)), which enables you to send a copy of the picture to a printer. Some attributes of the copied picture can be changed using the **Page Setup** dialog box (see [Using the Page Setup Dialog Box \(Windows Systems Only\) \(p. 39\)](#)). Still more attributes of the final print can be specified within the Microsoft Windows **Print** and **Print Setup** dialog boxes (see documentation for Microsoft Windows and your printer for details).

Copy to Clipboard

places a copy of the current picture into the Microsoft Windows clipboard. Some attributes of the copied picture can be changed using the **Page Setup** dialog box (see [Using the Page Setup Dialog Box \(Windows Systems Only\) \(p. 39\)](#)). The size of your graphics window affects the size of the text fonts used in the picture. For best results, experiment with the graphics window size and examine the resulting clipboard picture using the Windows clipboard viewer.

2.1.7.2. Using the Page Setup Dialog Box (Windows Systems Only)

To open the **Page Setup** dialog box (see [Using the Page Setup Dialog Box \(Windows Systems Only\) \(p. 39\)](#)) ([Figure 2.10 \(p. 40\)](#)), select the **Page Setup...** menu item in the system menu of the graphics window.

Figure 2.10 The Page Setup Dialog Box (Windows Systems Only)

Controls

Color

allows you to specify a color or non-color picture.

Color

selects a color picture.

Gray Scale

selects a gray-scale picture.

Monochrome

selects a black-and-white picture.

Color Quality

allows you to specify the color mode used for the picture.

True Color

creates a picture defined by RGB values. This assumes that your printer or display has at least 65536 colors, or "unlimited colors".

Mapped Color

creates a picture that uses a colormap. This is the right choice for devices that have 256 colors.

Clipboard Formats

allows you to choose the desired format copied to the clipboard. The size of your graphics window can affect the size of the clipboard picture. For best results, experiment with the graphics window size and examine the resulting clipboard picture using the Windows clipboard viewer.

Bitmap

is a bitmap copy of the graphics window.

DIB Bitmap

is a device-independent bitmap copy of the graphics window.

Metafile

is a Windows Metafile.

Enhanced Metafile

is a Windows Enhanced Metafile.

Picture Format

allows you to specify a raster or a vector picture.

Vector

creates a vector picture. This format will have a higher resolution when printed, but some large 3D pictures may take a long time to print.

Raster

creates a raster picture. This format will have a lower resolution when printed, but some large 3D pictures may take much less time to print.

Printer Scale %

controls the amount of the page that the printed picture will cover. Decreasing the scaling will effectively increase the margin between the picture and the edge of the paper.

Options

contains options that control other attributes of the picture.

Landscape Orientation (Printer)

specifies the orientation of the picture. If selected, the picture is made in landscape mode; otherwise, it is made in portrait mode. This option is applicable only when printing.

Reverse Foreground/Background

specifies that the foreground and background colors of the picture will be swapped. This feature allows you to make a copy of the picture with a white background and a black foreground, while the graphics window is displayed with a black background and white foreground.

2.2. Customizing the Graphical User Interface (Linux Systems Only)

On Linux systems, you may wish to customize the graphical user interface by changing attributes such as text color, background color, and text fonts. The program will try to provide default text fonts that are satisfactory for your platform's display size, but in some cases customization may be necessary if the default text fonts make the GUI too small or too large on your display, or if the default colors are undesirable.

The GUI in ANSYS FLUENT is based on the **X Window System Toolkit** and **OSF/Motif**. The attributes of the GUI are represented by X Window "resources". If you are unfamiliar with the **X Window System Resource Database**, please refer to any documentation you may have that describes how to use the **X Window System** or **OSF/Motif** applications.

The default X Window resource values for a medium resolution display are shown below:

```
!
! General resources
!Fluent*geometry:           +0-0
Fluent*fontList:            *-helvetica-bold-r-normal--12-
Fluent*MenuBar*fontList:    *-helvetica-bold-r-normal--12-
Fluent*XmText*fontList:     *-fixed-medium-r-normal--13-
Fluent*XmTextField*fontList: *-fixed-medium-r-normal--13-
Fluent*foreground:          black
Fluent*background:          gray75
Fluent*activeForeground:    black
Fluent*activeBackground:   gray85
Fluent*disabledTextColor:  gray55
Fluent*XmToggleButton.selectColor: green
Fluent*XmToggleButtonGadget.selectColor: green
```

```

Fluent*XmText.translations:\n    #override<Key>Delete: delete-previous-character()\nFluent*XmTextField.translations:\n    #override<Key>Delete: delete-previous-character()\n!\n! Console resources\n!\nFluent*ConsoleText.rows:      24\nFluent*ConsoleText.columns:   80\nFluent*ConsoleText.background: linen\n!\n! Help Viewer resources\n!\nFluent*Hyper.foreground:      black\nFluent*Hyper.background:      linen\nFluent*Hyper.hyperColor:      SlateBlue3\nFluent*Hyper*normalFont:\n    *-new century schoolbook-medium-r-normal--12-\nFluent*Hyper*hyperFont:\n    *-new century schoolbook-bold-r-normal--12-\nFluent*Hyper*texLargeFont:\n    *-new century schoolbook-bold-r-normal--14-\nFluent*Hyper*texBoldFont:\n    *-new century schoolbook-bold-r-normal--12-\nFluent*Hyper*texFixedFont:\n    *-courier-bold-r-normal--12-\nFluent*Hyper*texItalicFont:\n    *-new century schoolbook-medium-i-normal--12-\nFluent*Hyper*texMathFont:\n    *-symbol-medium-r-normal--14-\nFluent*Hyper*texSansFont:\n    *-helvetica-bold-r-normal--12-

```

To customize one or more of the resources for a particular user, place appropriate resource specification lines in that user's file `$HOME/.Xdefaults` or whatever resource file is loaded by the X Window System on the user's platform.

To customize one or more of the resources for several users at a site, place the resource specification lines in an application defaults resource file called `Fluent`. This file should then be installed in a directory such as `/usr/lib/X11/app-defaults`, or on SUN workstations, the directory may be `/usr/openwin/lib/app-defaults`. See documentation regarding your platform for more information.

2.3. Using the GUI Help System

ANSYS FLUENT includes an integrated help system that provides easy access to the program documentation. Through the graphical user interface, you have the entire [User's Guide](#) and other documentation available to you with the click of a mouse button. The User's Guide and other manuals are displayed in the help viewer, which allows you to use hypertext links and the browser's search and index tools to find the information you need.

There are many ways to access the information contained in the online help. You can get reference information from within a task page or dialog box, or (on Linux machines) request context-sensitive help for a particular menu item or dialog box. You can also go to the [User's Guide](#) contents page or the viewer index, and use the hypertext links to find the information you are looking for. In addition to the [User's Guide](#), you can also access the other ANSYS FLUENT documentation (e.g., the [Tutorial Guide](#) or [UDF Manual](#)).

Note that the last two chapters of the [User's Guide \(Task Page Reference Guide \(p. 1763\) and Menu Reference Guide \(p. 2203\)\)](#) are also referred to as the Reference Guide, and contain a description of each task page, menu item, and dialog box.

The sections that follow provide information on how to get help for a task page or dialog box, and brief descriptions of the **Help** menu items in ANSYS FLUENT. For more information, please refer to the information available from the **Help** menu in the viewer itself.

- 2.3.1. Task Page and Dialog Box Help
- 2.3.2. Context-Sensitive Help (Linux Only)
- 2.3.3. Opening the User's Guide Table of Contents
- 2.3.4. Opening the User's Guide Index
- 2.3.5. Opening the Reference Guide
- 2.3.6. Help on Help
- 2.3.7. Accessing Printable Manuals
- 2.3.8. Help for Text Interface Commands
- 2.3.9. Accessing the Customer Portal Web Site
- 2.3.10. Obtaining License Use Information
- 2.3.11. Version and Release Information

2.3.1. Task Page and Dialog Box Help

To get help about a task page or dialog box that you are currently using, click the **Help** button in the task page or dialog box. The help viewer will open to the section of the [User's Guide](#) that explains the function of each item in the task page or dialog box. In this section, you will also find hypertext links to more specific section(s) of the [User's Guide](#) that discuss how to use the task page or dialog box and provide related information.

2.3.2. Context-Sensitive Help (Linux Only)

If you want to find out how or when a particular menu item or dialog box is used, you can use the context-sensitive help feature. Select the **Context-Sensitive Help** item in the **Help** pull-down menu.

Help → Context-Sensitive Help

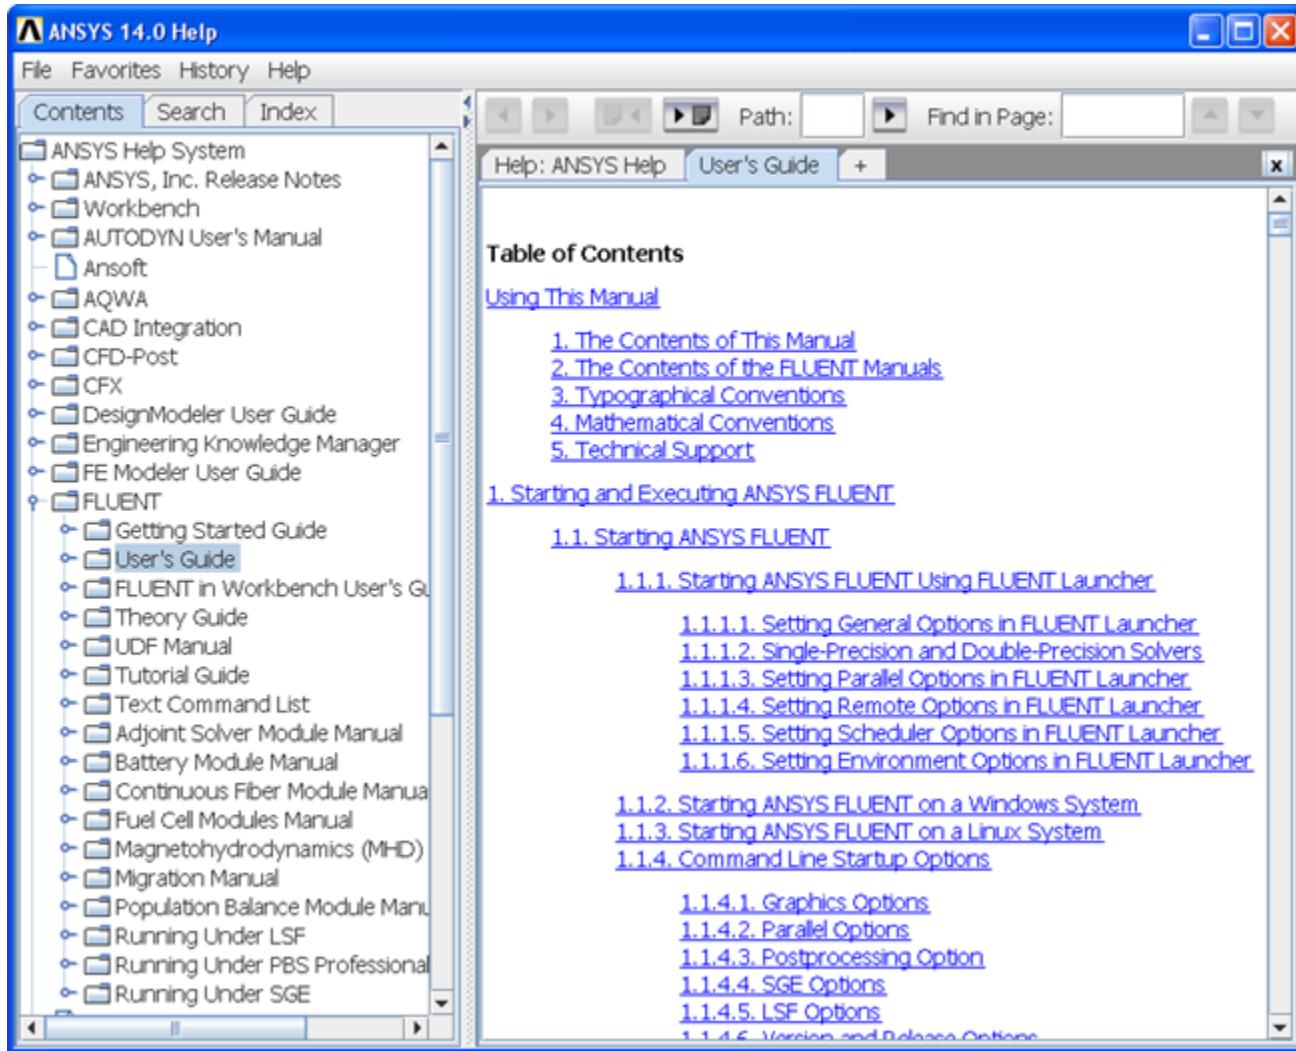

With the resulting question-mark cursor, select an item from a pull-down menu. The help viewer will open to the section of the [User's Guide](#) that discusses the selected item.

2.3.3. Opening the User's Guide Table of Contents

To see the [User's Guide](#) table of contents, select the **User's Guide Contents...** menu item in the **Help** pull-down menu.

Help → User's Guide Contents...

Selecting this item will open the help viewer to the contents page of the [User's Guide](#) (*Figure 2.11 (p. 44)*). Each item in the table of contents is a hypertext link that you can click to view that chapter or section.

Figure 2.11 The ANSYS FLUENT User's Guide Contents Page

In addition, the FLUENT documents are listed in the **Contents** tab of the help viewer. These listings can be expanded by clicking the icon to the left of the document title. The expanded list will contain hyperlinks to particular chapters or sections, and may also be expandable. For more information on navigation within the help viewer, please refer to the information available from the **Help** menu in the viewer itself.

2.3.4. Opening the User's Guide Index

Help → User's Guide Index...

The help viewer has a built-in index that contains entries for most of the ANSYS product documentation. The **Index** tab allows you to search index terms, display product-specific index terms, and display the associated help topics.

To find a topic using the index, type the first few letters of a keyword in the field at the top of the **Index** tab.

2.3.5. Opening the Reference Guide

To open the help system to the first page of the Reference Guide, which contains information about each dialog box or menu item, arranged by pull-down menu, do the following in the help viewer:

1. Expand the FLUENT **User's Guide** in the left pane of the viewer by clicking the icon to the left of the document title.
2. Scroll down to the **Task Page Reference Guide** or **Menu Reference Guide** item in the left pane of the viewer and click the one of interest.
3. Use the hyperlinks in the main viewer window to find the topic of interest, or, expand the item in the left pane of the viewer and scroll to the topic of interest.

2.3.6. Help on Help

Help → Using Help...

When you select this item, the help viewer will open to the beginning of this section.

You can obtain information about using online help by selecting the **Using Help...** menu item in the **Help** pull-down menu in the help viewer itself.

2.3.7. Accessing Printable Manuals

As noted above, you can access other manuals (in addition to the [User's Guide](#)) through the online help. You can also access the [User's Guide](#) and other manuals in printable format (PDF). To see ANSYS FLUENT manuals available in PDF, select the **PDF** menu item in the FLUENT **Help** pull-down menu.

Help → PDF

When you select this item, a list of documents will be shown in a submenu. Click the appropriate item to open that document with Acrobat Reader (version 5.0 or higher).

If you do not have Acrobat Reader, you can download it for free from Adobe (www.adobe.com).

See the [Getting Started Guide](#) for more information.

2.3.8. Help for Text Interface Commands

There are two ways to find information about text interface commands. You can either go to the **Text Command List** (which can be accessed using the **Help/More Documentation...** menu item, as described below), or use the text interface help system described in [Using the Text Interface Help System](#) (p. 56).

2.3.9. Accessing the Customer Portal Web Site

You can access the ANSYS Customer Portal web site by selecting the **Online Technical Resources...** menu item in the **Help** pull-down menu.

Help → Online Technical Resources...

ANSYS FLUENT will direct your web browser to the appropriate web address.

2.3.10. Obtaining License Use Information

If you are running with an existing ANSYS FLUENT license (FluentLM) you can obtain a listing of current ANSYS FLUENT users when you select the **License Usage...** menu item in the **Help** pull-down menu.

Help → License Usage...

ANSYS FLUENT will display a list of the current users of the ANSYS FLUENT license feature in the console.

If your installation of ANSYS FLUENT is managed by the ANSYS License Manager (ANSLIC_ADMIN), you will see a message that will indicate that licensing is managed by ANSLIC_ADMIN. For additional information on licensing information, please refer to the **Installation and Licensing Documentation** within the help viewer. This information can be found by doing the following in the help viewer:

1. Scroll down to the **Installation and Licensing Documentation** item in the left pane of the viewer.
2. Expand this document by clicking on the icon to the left of the document title.
3. Use the hyperlinks in the main viewer window to find the desired information, or, expand the items in the left pane of the viewer and scroll to the topic of interest.

2.3.11. Version and Release Information

You can obtain information about the version and release of ANSYS FLUENT you are running by selecting the **Version...** menu item in the **Help** pull-down menu.

Help → Version...

Chapter 3: Text User Interface (TUI)

In addition to the graphical user interface described in *Graphical User Interface (GUI)* (p. 21), the user interface in ANSYS FLUENT includes a textual command line interface.

- 3.1.Text Menu System
- 3.2.Text Prompt System
- 3.3.Interrupts
- 3.4.System Commands
- 3.5.Text Menu Input from Character Strings
- 3.6.Using the Text Interface Help System

The text interface (TUI) uses, and is written in, a dialect of Lisp called Scheme. Users familiar with Scheme will be able to use the interpretive capabilities of the interface to create customized commands.

3.1. Text Menu System

The text menu system provides a hierarchical interface to the program's underlying procedural interface. Because it is text based, you can easily manipulate its operation with standard text-based tools: input can be saved in files, modified with text editors, and read back in to be executed. Because the text menu system is tightly integrated with the Scheme extension language, it can easily be programmed to provide sophisticated control and customized functionality.

The menu system structure is similar to the directory tree structure of Linux operating systems. When you first start ANSYS FLUENT, you are in the "root" menu and the menu prompt is a greater-than symbol.

>

To generate a listing of the submenus and commands in the current menu, simply press **Enter**.

```
><Enter>
adapt/      file/      report/
define/     mesh/      solve/
display/    parallel/   surface/
exit        plot/      views/
```

By convention, submenu names end with a / to differentiate them from menu commands. To execute a command, just type its name (or an abbreviation). Similarly, to move down into a submenu, enter its name or an abbreviation. When you move into the submenu, the prompt will change to reflect the current menu name.

```
>display
/display> set
/display/set>
```

To move back to the previously occupied menu, type q or quit at the prompt.

```
/display/set> q
/display>
```

You can move directly to a menu by giving its full pathname.

```
/display> /file  
/display//file>
```

In the above example, control was passed from /display to /file without stopping in the root menu. Therefore, when you quit from the /file menu, control will be passed directly back to /display.

```
/display//file> q  
/display>
```

Furthermore, if you execute a command without stopping in any of the menus along the way, control will again be returned to the menu from which you invoked the command.

```
/display> /file start-journal jrnl  
Opening input journal to file "jrnl".  
/display>
```

The text menu system provides on-line help for menu commands. The text menu on-line help system is described in [Using the Text Interface Help System \(p. 56\)](#).

To edit the current command, you can position the cursor with the left and right arrow keys, delete with the **Backspace** key, and insert text simply by typing.

For additional information, please see the following sections:

- [3.1.1. Command Abbreviation](#)
- [3.1.2. Command Line History](#)
- [3.1.3. Scheme Evaluation](#)
- [3.1.4. Aliases](#)

3.1.1. Command Abbreviation

To select a menu command, you do not need to type the entire name; you can type an abbreviation that matches the command. The rules for matching a command are as follows: A command name consists of phrases separated by hyphens. A command is matched by matching an initial sequence of its phrases. Matching of hyphens is optional. A phrase is matched by matching an initial sequence of its characters. A character is matched by typing that character.

If an abbreviation matches more than one command, then the command with the greatest number of matched phrases is chosen. If more than one command has the same number of matched phrases, then the first command to appear in the menu is chosen.

For example, each of the following will match the command set-ambient-color: set- ambient-color, s-a-c, sac, and sa. When abbreviating commands, sometimes your abbreviation will match more than one command. In such cases, the first command is selected. Occasionally, there is an anomaly such as lint not matching lighting-interpolation because the li gets absorbed in lights-on? and then the nt does not match interpolation. This can be resolved by choosing a different abbreviation, such as liin, or l-int.

3.1.2. Command Line History

You can use the up and down arrow keys on your keyboard to go through recently used commands that are stored in history. By default, command-history will store only the last ten commands. This can be changed (for example to 15) by using the following command:

```
> (set! *cmd-history-length* 15)
```

Important

Command-history is not available if the ANSYS FLUENT application is started with -g options (see [Command Line Startup Options \(p. 9\)](#)).

Important

The user inputs supplied as the arguments of the TUI command or alias will not be saved in history. By way of illustration, consider the following entry in the TUI:

```
> rc new_file.cas
```

Important

In history, only `rc` (an alias for `read-case`) will be saved, since `new_file.cas` is a user input to the alias-function.

Commands recalled from history can be edited or corrected using the **Backspace** key and the left and right arrow keys.

3.1.3. Scheme Evaluation

If you enter an open parenthesis, (, at the menu prompt, then that parenthesis and all characters up to and including the matching closing parenthesis are passed to Scheme to be evaluated, and the result of evaluating the expression is displayed.

```
> (define a 1)
a
> (+ a 2 3 4)
10
```

3.1.4. Aliases

Command aliases can be defined within the menu system. As with the Linux `csh` shell, aliases take precedence over command execution. The following aliases are predefined in Cortex: `error`, `pwd`, `chdir`, `ls`, ., and `alias`.

error

displays the Scheme object that was the “irritant” in the most recent Scheme error interrupt.

pwd

prints the working directory in which all file operations will take place.

chdir

will change the working directory.

ls

lists the files in the working directory.

alias

displays the list of symbols currently aliased.

3.2. Text Prompt System

Commands require various arguments, including numbers, filenames, yes/no responses, character strings, and lists. A uniform interface to this input is provided by the text prompt system. A prompt consists of a prompt string, followed by an optional units string enclosed in parentheses, followed by a default value enclosed in square brackets. The following shows some examples of prompts:

```
filled-mesh? [no] <Enter>  
shrink-factor [0.1] <Enter>  
line-weight [1] <Enter>  
title ["] <Enter>
```

The default value for a prompt is accepted by pressing **Enter** on the keyboard or typing a , (comma).

Important

Note that a comma is not a separator. It is a separate token that indicates a default value. The sequence "1, 2" results in three values; the number 1 for the first prompt, the default value for the second prompt, and the number 2 for the third prompt.

A short help message can be displayed at any prompt by entering a ?. (See [Using the Text Interface Help System \(p. 56\)](#).)

To abort a prompt sequence, simply press **Ctrl** and the **c** keys together.

For additional information, please see the following sections:

- [3.2.1. Numbers](#)
- [3.2.2. Booleans](#)
- [3.2.3. Strings](#)
- [3.2.4. Symbols](#)
- [3.2.5. Filenames](#)
- [3.2.6. Lists](#)
- [3.2.7. Evaluation](#)
- [3.2.8. Default Value Binding](#)

3.2.1. Numbers

The most common prompt type is a number. Numbers can be either integers or reals. Valid numbers are, for example, 16, -2.4, .9E5, and +1E-5. Integers can also be specified in binary, octal, and hexadecimal form. The decimal integer 31 can be entered as 31, #b11111, #o37, or #x1f. In Scheme, integers are a subset of reals, so you do not need a decimal point to indicate that a number is real; 2 is just as much a real as 2.0. If you enter a real number at an integer prompt, any fractional part will simply be truncated; 1.9 will become 1.

3.2.2. Booleans

Some prompts require a yes-or-no response. A yes/no prompt will accept either **yes** or **y** for a positive response, and **no** or **n** for a negative response. Yes/no prompts are used for confirming potentially dangerous actions such as overwriting an existing file, exiting without saving case, data, mesh, etc.

Some prompts require actual Scheme boolean values (true or false). These are entered with the Scheme symbols for true and false, #t and #f.

3.2.3. Strings

Character strings are entered in double quotes, e.g., "red". Plot titles and plot legend titles are examples of character strings. Character strings can include any characters, including blank spaces and punctuation.

3.2.4. Symbols

Symbols are entered *without* quotes. Zone names, surface names, and material names are examples of symbols. Symbols must start with an alphabetical character (i.e., a letter), and cannot include any blank spaces or commas.

3.2.5. Filenames

Filenames are actually just character strings. For convenience, filename prompts do not require the string to be surrounded with double quotes. If, for some exceptional reason, a filename contains an embedded space character, then the name must be surrounded with double quotes.

One consequence of this convenience is that filename prompts do not evaluate the response. For example, the sequence

```
> (define fn "valve.ps")
fn
> hc fn
```

will end up writing a picture file with the name `fn`, not `valve.ps`. Since the filename prompt did not evaluate the response, `fn` did not get a chance to evaluate "`valve.ps`" as it would for most other prompts.

3.2.6. Lists

Some functions in ANSYS FLUENT require a "list" of objects such as numbers, strings, booleans, etc. A list is a Scheme object that is simply a sequence of objects terminated by the empty list, ' (). Lists are prompted for an element at a time, and the end of the list is signaled by entering an empty list. This terminating list forms the tail of the prompted list, and can either be empty or can contain values. For convenience, the empty list can be entered as () as well as the standard form ' (). Normally, list prompts save the previous argument list as the default. To modify the list, overwrite the desired elements and terminate the process with an empty list. For example,

```
element(1) [( )] 1
element(2) [( )] 10
element(3) [( )] 100
element(4) [( )] <Enter>
```

creates a list of three numbers: 1, 10, and 100. Subsequently,

```
element(1) [1] <Enter>
element(2) [10] <Enter>
element(3) [100] <Enter>
```

```
element(4) [()] 1000  
element(5) [()] <Enter>
```

adds a fourth element. Then

```
element(1) [1] <Enter>  
element(2) [10] <Enter>  
element(3) [100] ()
```

leaves only 1 and 10 in the list. Subsequently entering

```
element(1) [1] ,,'(11 12 13)
```

creates a five element list: 1, 10, 11, 12, and 13. Finally, a single empty list removes all elements

```
element(1) [1] ()
```

A different type of list, namely, a “list-of-scalars” contains pick menu items (and not list items) for which a selection has to be made from listed quantities, which are available at the **Enter** prompt. Hence, a list-of-scalars cannot be entered as a list.

An example of a “list-of-scalars” consists of the following:

ASCII scalar(1)>		
abs-angular-coordinate	cell-warp	radial-velocity
absolute-pressure	cell-weight	rel-tangential-velocity
adaption-curvature	cell-zone	rel-total-pressure
adaption-function	custom-function-0	rel-velocity-magnitude
adaption-iso-value	density	relative-velocity-angle
adaption-space-gradient	density-all	relative-x-velocity
angular-coordinate	dp-dx	relative-y-velocity
axial-coordinate	dp-dy	relative-z-velocity
axial-velocity	dp-dz	tangential-velocity
boundary-cell-dist	dynamic-pressure	total-pressure
boundary-normal-dist	existing-value	velocity-angle
boundary-volume-dist	face-area-magnitude	velocity-magnitude
cell-children	face-handedness	x-coordinate
cell-element-type	face-squish-index	x-face-area
cell-equiangle-skew	interface-wall-zone	x-velocity
cell-equivolume-skew	mass-imbalance	x-velocity-residual
cell-partition	mesh-x-velocity	y-coordinate
cell-refine-level	mesh-y-velocity	y-face-area
cell-squish-index	mesh-z-velocity	y-velocity
cell-surface-area	partition-neighbors	y-velocity-residual
cell-type	pressure	z-coordinate
cell-volume	pressure-coefficient	z-face-area
cell-volume-change	pressure-residual	z-velocity
cell-wall-distance	radial-coordinate	z-velocity-residual

ASCII scalar(1)> pressure

ASCII scalar(2)> z-coordinate

ASCII scalar(3)> cell-volume

ASCII scalar(4)> dynamic-pressure velocity-magnitude x-face-area

ASCII scalar(7)> █

3.2.7. Evaluation

All responses to prompts (except filenames, see above) are evaluated by the Scheme interpreter before they are used. You can therefore enter any valid Scheme expression as the response to a prompt. For example, to enter a unit vector with one component equal to 1/3 (without using your calculator),

```
/foo> set-xy
x-component [1.0] (/ 1 3)

y-component [0.0] (sqrt (/ 8 9))
```

or, you could first define a utility function to compute the second component of a unit vector,

```
> (define (unit-y x) (sqrt (- 1.0 (* x x))))  
unit-y  
/foo> set-xy
```

```
x-component [1.0] (/ 1 3)  
y-component [0.0] (unit-y (/ 1 3))
```

3.2.8. Default Value Binding

The default value at any prompt is bound to the Scheme symbol “`_`” (underscore) so that the default value can form part of a Scheme expression. For example, if you want to decrease a default value so that it is one-third of the original value, you could enter

```
shrink-factor [0.8] (/ _ 3)
```

3.3. Interrupts

The execution of the code can be halted by pressing the **Ctrl** and the **c** keys together, at which time the present operation stops at the next recoverable location.

3.4. System Commands

The way you execute system commands with the `!` (bang) shell escape character will be slightly different for Linux and Windows systems.

For additional information, please see the following sections:

- [3.4.1. System Commands for Linux-based Operating Systems](#)
- [3.4.2. System Commands for Windows Operating Systems](#)

3.4.1. System Commands for Linux-based Operating Systems

If you are running ANSYS FLUENT under a Linux-based operating system, all characters following the `!` up to the next newline character will be executed in a subshell. Any further input related to these system commands must be entered in the window in which you started the program, and any screen output will also appear in that window. (Note that if you started ANSYS FLUENT remotely, this input and output will be in the window in which you started Cortex.)

```
> !rm junk.*  
> !vi script.rp
```

`!pwd` and `!ls` will execute the Linux commands in the directory in which Cortex was started. The screen output will appear in the window in which you started ANSYS FLUENT, unless you started it remotely, in which case the output will appear in the window in which you started Cortex. (Note that `!cd` executes in a subshell, so it will not change the working directory either for ANSYS FLUENT or for Cortex, and is therefore not useful.) Typing `cd` with no arguments will move you to your home directory in the console.

ANSYS FLUENT includes three system command aliases (`pwd`, `ls`, and `chdir`) that will be executed in your working directory with output displayed in the ANSYS FLUENT console. Note that these aliases will invoke the corresponding Linux commands with respect to the parent directory of the case file. For example, `pwd` prints the parent directory of the case file in the ANSYS FLUENT console, while `!pwd` prints the directory from which you started ANSYS FLUENT in the Linux shell window where you started ANSYS FLUENT.

Several examples of system commands entered in the console are shown below. The screen output that will appear in the window in which ANSYS FLUENT was started (or, if you started the program remotely, in the window in which Cortex was started) follows the examples.

Example input (in the ANSYS FLUENT console):

```
> !pwd
> !ls valve*.*
```

Example output (in the window in which ANSYS FLUENT—or Cortex, if you started the program remotely—was started):

```
/home/cfd/run valve
valve1.cas valve1.msh valve2.cas valve2.msh
```

3.4.2. System Commands for Windows Operating Systems

If you are running ANSYS FLUENT under a Windows operating system, all characters following the ! up to the next newline character will be executed. The results of a command will appear in the ANSYS FLUENT console, or in a separate window if the command starts an external program, such as Notepad.

```
> !del junk.*
> !notepad script.rp
```

`!cd` and `!dir` will execute the DOS commands and the screen output will appear in the ANSYS FLUENT console. The `!cd` command with no argument will display the current working directory in the ANSYS FLUENT console.

Several examples of system commands entered in the console are shown below.

Example input (in boxes) and output (in the ANSYS FLUENT console):

```
> !cd
p:/cfb/run/valve
> !dir valve*.* /w

Volume in drive P is users
Volume Serial Number is 1234-5678
Directory of p:/cfb/run/valve
valve1.cas      valve1.msh      valve2.cas      valve2.msh
        4 File(s)           621,183 bytes
        0 Dir(s)          1,830,088,704 bytes free
```

3.5. Text Menu Input from Character Strings

Often, when writing a Scheme extension function for ANSYS FLUENT, it is convenient to be able to include menu commands in the function. This can be done with `ti-menu-load-string`. For example, to open graphics window 2, use

```
(ti-menu-load-string "di ow 2")
```

A Scheme loop that will open windows 1 and 2 and display the front view of the mesh in window 1 and the back view in window 2 is given by

```
(for-each
  (lambda (window view)
    (ti-menu-load-string (format #f "di ow ~a gr view rv ~a"
      window view)))
  '(1 2)
  '(front back))
```

This loop makes use of the `format` function to construct the string used by `menu-load-string`. This simple loop could also be written without using menu commands at all, but you need to know the Scheme functions that get executed by the menu commands to do it:

```
(for-each
  (lambda (window view)
    (cx-open-window window)
    (display-mesh)
    (cx-restore-view view))
  '(1 2) '(front back))
```

String input can also provide an easy way to create aliases within ANSYS FLUENT. For example, to create an alias that will display the mesh, you could type the following:

```
(alias 'dg (lambda () (ti-menu-load-string "/di gr"))))
```

Then any time you enter dg from anywhere in the menu hierarchy, the mesh will be drawn in the active window.

Important

ti-menu-load-string evaluates the string argument in the top level menu. It ignores any menu you may be in when you invoke ti-menu-load-string.

As a result, the command

```
(ti-menu-load-string "open-window 2 gr") ; incorrect usage
```

will not work even if you type it from within the display/ menu—the string itself must cause control to enter the display/ menu, as in

```
(ti-menu-load-string "display open-window 2 mesh")
```

3.6. Using the Text Interface Help System

The text user interface provides context-sensitive on-line help. Within the text menu system, you can obtain a brief description of each of the commands by entering a ? followed by the command in question.

Example:

```
> ?dis
display/: Enter the display menu.
```

You can also enter a lone ? to enter “help mode.” In this mode, you need only enter the command or menu name to display the help message. To exit the help mode type q or quit as for a normal menu.

Example:

```
> ?
[help-mode]> di
display/: Enter the display menu.

[help-mode]> pwd
pwd: #[alias]
(LAMBDA ()
(BEGIN
(SET! pwd-cmd ((LAMBDA n
n) 'system (IF (cx-send '(unix?))
"pwd"
"cd")))
(cx-send pwd-cmd)))
```

```
[help-mode]> q
```

To access the help, type a ? at the prompt when you are prompted for information.

Example:

```
> display/annotate Annotation text ["] ?
Annotation text ["]
```

Chapter 4: Reading and Writing Files

During an ANSYS FLUENT session you may need to import and export several kinds of files. Files that are read include mesh, case, data, profile, Scheme, and journal files. Files that are written include case, data, profile, journal, and transcript files. ANSYS FLUENT also has features that allow you to save pictures of graphics windows. You can also export data for use with various visualization and postprocessing tools. These operations are described in the following sections.

- 4.1. Shortcuts for Reading and Writing Files
- 4.2. Reading Mesh Files
- 4.3. Reading and Writing Case and Data Files
- 4.4. Reading and Writing Parallel Data Files
- 4.5. Reading FLUENT/UNS and RAMPANT Case and Data Files
- 4.6. Reading and Writing Profile Files

- 4.22. Setting Data File Quantities
- 4.23. The .fluent File

4.1. Shortcuts for Reading and Writing Files

The following features in ANSYS FLUENT make reading and writing files convenient:

- Automatic appending or detection of default file name suffixes
- Binary file reading and writing
- Automatic detection of file format (text/binary)
- Recent file list
- Reading and writing of compressed files
- Tilde expansion
- Automatic numbering of files
- Ability to disable the overwrite confirmation prompt
- Standard toolbar buttons for reading and writing files

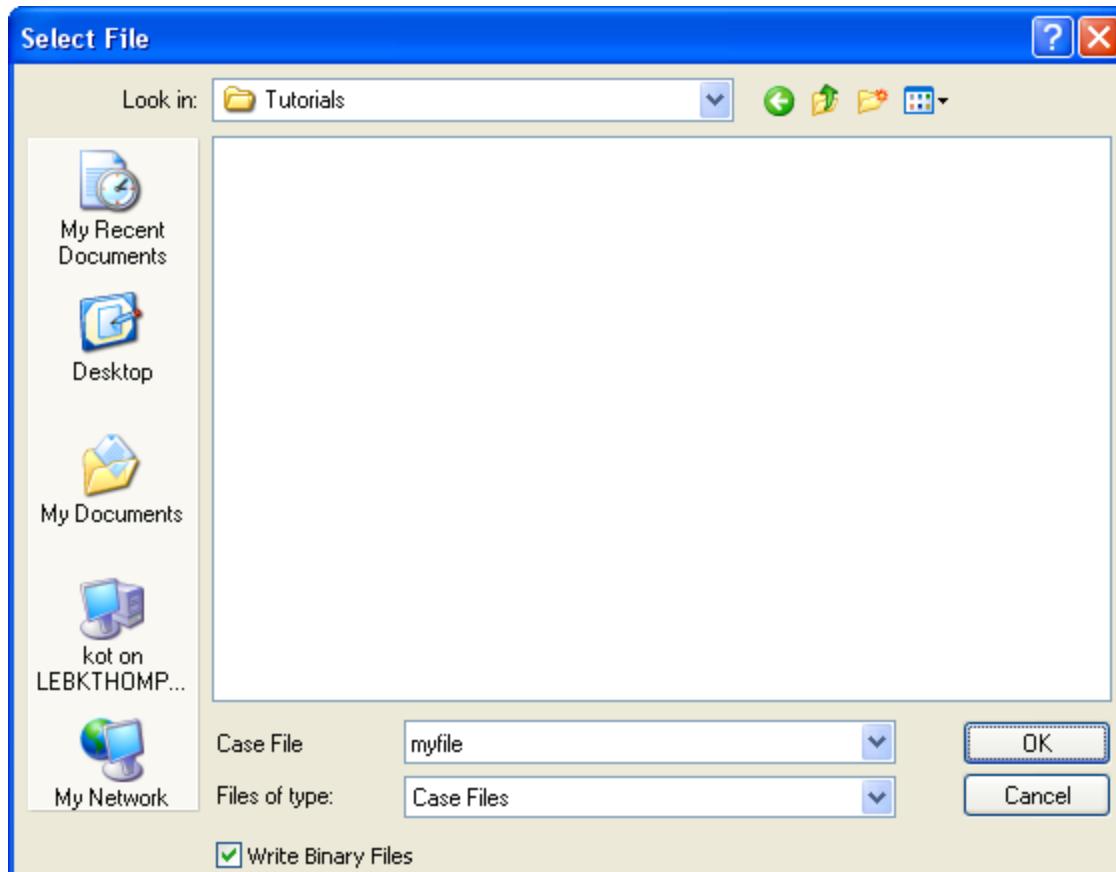

For additional information, please see the following sections:

- 4.1.1. Default File Suffixes
- 4.1.2. Binary Files
- 4.1.3. Detecting File Format
- 4.1.4. Recent File List
- 4.1.5. Reading and Writing Compressed Files
- 4.1.6. Tilde Expansion (Linux Systems Only)
- 4.1.7. Automatic Numbering of Files
- 4.1.8. Disabling the Overwrite Confirmation Prompt
- 4.1.9. Toolbar Buttons

4.1.1. Default File Suffixes

Each type of file read or written in ANSYS FLUENT has a default file suffix associated with it. When you specify the first part of the file name (the prefix) for the commonly used files, the solver automatically appends or detects the appropriate suffix. For example, to write a case file named `myfile.cas`, just specify the prefix `myfile` in the **Select File** dialog box ([Figure 4.1 \(p. 60\)](#)) and `.cas` is automatically appended. Similarly, to read the case file named `myfile.cas` into the solver, you can just specify `myfile` and ANSYS FLUENT automatically searches for a file of that name with the suffix `.cas`.

Figure 4.1 The Select File Dialog Box

The default file suffix for case and data files, PDF (Probability Density Function) files, DTRM ray files, profiles, scheme files, journal files, etc., are automatically detected and appended. The appropriate default file suffix appears in the **Select File** dialog box for each type of file.

4.1.2. Binary Files

When you write a case, data, or ray file, a binary file is saved by default. Binary files take up less memory than text files and can be read and written by ANSYS FLUENT more quickly.

Note

You cannot read and edit a binary file, as you can do for a text file.

To save a text file, turn off the **Write Binary Files** option in the **Select File** dialog box when you are writing the file.

4.1.3. Detecting File Format

When you read a case, data, mesh, PDF, or ray file, the solver automatically determines whether it is a text (formatted) or binary file.

4.1.4. Recent File List

At the bottom of the **File/Read** submenu there is a list of four ANSYS FLUENT case files that you most recently read or wrote. To read one of these files into ANSYS FLUENT, select it in the list. This allows you to read a recently used file without selecting it in the **Select File** dialog box.

Note that the files listed in this submenu may not be appropriate for your current session (e.g., a 3D case file can be listed even if you are running a 2D version of ANSYS FLUENT). Also, if you read a case file using this shortcut, the corresponding data file is read only if it has the same base name as the case file (e.g., `file1.cas` and `file1.dat`) *and* it was read/written with the case file the last time the case file was read/written.

4.1.5. Reading and Writing Compressed Files

For more information, see the following sections:

- [4.1.5.1. Reading Compressed Files](#)
- [4.1.5.2. Writing Compressed Files](#)

4.1.5.1. Reading Compressed Files

You can use the **Select File** dialog box to read files compressed using `compress` or `gzip`. If you select a compressed file with a `.Z` extension, ANSYS FLUENT automatically invokes `zcat` to import the file. If you select a compressed file with a `.gz` extension, the solver invokes `gunzip` to import the file.

For example, if you select a file named `flow.msh.gz`, the solver reports the following message indicating that the result of the `gunzip` is imported into ANSYS FLUENT via an operating system pipe.

```
Reading "" | gunzip -c \"Y:\flow.msh.gz\"..."
```

You can also type in the file name without any suffix (e.g., if you are not sure whether or not the file is compressed). First, the solver attempts to open a file with the input name. If it cannot find a file with that name, it attempts to locate files with default suffixes and extensions appended to the name.

For example, if you enter the name `file-name`, the solver traverses the following list until it finds an existing file:

- file-name
- file-name.gz
- file-name.Z
- file-name.*suffix*
- file-name.*suffix*.gz
- file-name.*suffix*.Z

where *suffix* is a common extension to the file, such as .cas or .msh. The solver reports an error if it fails to find an existing file with one of these names.

Note

In addition to .gz and .Z compression, ANSYS FLUENT can also handle .bz2 compressed files.

Important

- For Windows systems, only files that were compressed with gzip (i.e., files with a .gz extension) can be read. Files that were compressed with compress cannot be read into ANSYS FLUENT on a Windows machine.
- Do not read a compressed ray file; ANSYS FLUENT cannot access the ray tracing information properly from a compressed ray file.

4.1.5.2. Writing Compressed Files

You can use the **Select File** dialog box to write a compressed file by appending a .Z or .gz extension onto the file name.

For example, if you enter flow.gz as the name for a case file, the solver reports the following message:

```
Writing " | gzip -cfv > Y:\flow.cas.gz"...
```

The status message indicates that the case file information is being piped into the gzip command, and that the output of the compression command is being redirected to the file with the specified name. In this particular example, the .cas extension is added automatically.

Note

In addition to .gz and .Z compression, ANSYS FLUENT can also handle .bz2 compressed files.

Important

- For Windows systems, compression can be performed only with gzip. That is, you can write a compressed file by appending .gz to the name, but appending .Z does not compress the file.
- Do not write a compressed ray file; ANSYS FLUENT cannot access the ray tracing information properly from a compressed ray file.
- To compress parallel data files (i.e., files saved with a .pdat extension), you must use asynchronous file compression. (For details, see [Reading and Writing Case and Data Files \(p. 66\)](#)).

4.1.6. Tilde Expansion (Linux Systems Only)

On Linux systems, if you specify ~/ as the first two characters of a file name, the ~ is expanded as your home directory. Similarly, you can start a file name with ~username/, and the ~username is expanded to the home directory of "username". If you specify ~/file as the case file to be written, ANSYS FLUENT saves the file file.cas in your home directory. You can specify a subdirectory of your home directory as well: if you enter ~/cases/file.cas, ANSYS FLUENT saves the file file.cas in the cases subdirectory.

4.1.7. Automatic Numbering of Files

There are several special characters that you can include in a file name. Using one of these character strings in your file name provides a shortcut for numbering the files based on various parameters (i.e., iteration number, time step, or total number of files saved so far), because you need not enter a new file name each time you save a file. (See also [Automatic Saving of Case and Data Files \(p. 68\)](#) for information about saving and numbering case and data files automatically.)

- For transient calculations, you can save files with names that reflect the time step at which they are saved by including the character string %t in the file name. For example, you can specify contours-%t.ps for the file name, and the solver saves a file with the appropriate name (e.g., contours-0001.ps if the solution is at the first time step).

This automatic saving of files with the time step should not be used for steady-state cases, since the time step will always remain zero.

- For transient calculations, you can save files with names that reflect the flow-time at which they are saved by including the character string %f in the file name. The usage is similar to %t. For example, when you specify filename-%f.ps for the file name, the solver will save a file with the appropriate name (e.g., filename-005.000000.ps for a solution at a flow-time of 5 seconds). By default, the flow-time that is included in the file name will have a field width of 10 and 6 decimal places. To modify this format, use the character string %x.yf, where x and y are the preferred field width and number of decimal places, respectively. ANSYS FLUENT will automatically add zeros to the beginning of the flow-time to achieve the prescribed field width. To eliminate these zeros and left align the flow-time, use the character string %-x.yf instead.

This automatic saving of files with flow-time should not be used for steady-state cases, since the flow-time will always remain zero.

- To save a file with a name that reflects the iteration at which it is saved, use the character string %I in the file name. For example, you can specify contours-%i.ps for the file name, and the solver saves a file with the appropriate name (e.g., contours-0010.ps if the solution is at the 10th iteration).

- To save a picture file with a name that reflects the total number of picture files saved so far in the current solver session, use the character string %n in the file name. This option can be used only for picture files.

The default field width for %I, %t, and %n formats is 4. You can change the field width by using %xi, %xt, and %xn in the file name, where x is the preferred field width.

4.1.8. Disabling the Overwrite Confirmation Prompt

By default, if you ask ANSYS FLUENT to write a file with the same name as an existing file in that folder, it will ask you to confirm that it is “OK to overwrite” the existing file. If you do not want the solver to ask you for confirmation before it overwrites existing files, you can use the **Batch Options** dialog box (For details, see *Batch Execution Options* (p. 15)). Alternatively, enter the `file/confirm-overwrite?` text command and answer `no` (see *Text User Interface (TUI)* (p. 47) for the text user interface commands).

4.1.9. Toolbar Buttons

The standard toolbar provides buttons that make it easier to read and write files:

- The **Read a file** button () allows you to read existing files using a file selection dialog box. The files available for reading include all those available through the **File/Read** menu item, as described in this chapter.
- The **Write a file** button () allows you to write various types of files. The files available for writing include all those available through the **File/Write** menu item, as described in this chapter.

4.2. Reading Mesh Files

Mesh files are created using the mesh generators (GAMBIT, TGrid, GeoMesh, and PreBFC), or by several third-party CAD packages. From the point of view of ANSYS FLUENT, a mesh file is a subset of a case file (described in *Reading and Writing Case Files* (p. 66)). The mesh file contains the coordinates of all the nodes, connectivity information that tells how the nodes are connected to one another to form faces and cells, and the zone types and numbers of all the faces (e.g., wall-1, pressure-inlet-5, symmetry-2).

The mesh file does not contain any information on boundary conditions, flow parameters. For information about meshes, see *Reading and Manipulating Meshes* (p. 129).

To read a native-format mesh file (i.e., a mesh file that is saved in ANSYS FLUENT format) into the solver, use the **File/Read/Mesh...** menu item. Note that you can also use the **File/Read/Case...** menu item (described in *Reading and Writing Case Files* (p. 66)), because a mesh file is a subset of a case file. GAMBIT, TGrid, GeoMesh, and PreBFC can all write a native-format mesh file. For information about reading these files, see *GAMBIT Mesh Files* (p. 149), *GeoMesh Mesh Files* (p. 149), *TGrid Mesh Files* (p. 149), and *PreBFC Mesh Files* (p. 150).

If after reading in a mesh file (or a case and data file), you would like to read in another mesh file, the *Read Mesh Options Dialog Box* (p. 2204) will open, where you can choose to

- Discard the case and read in a new mesh.
- Replace the existing mesh.

You also have the option to have the **Scale Mesh** dialog box appear automatically for you to check or scale your mesh, which in general is the recommended practice. For this to happen, enable **Show Scale Mesh Panel After Replacing Mesh**.

For information on importing an unpartitioned mesh file into the parallel solver using the partition filter, see [Using the Partition Filter \(p. 1753\)](#).

For additional information, please see the following sections:

- [4.2.1. Reading TGrid Mesh Files](#)
- [4.2.2. Reading Surface Meshes](#)
- [4.2.3. Reading GAMBIT and GeoMesh Mesh Files](#)
- [4.2.4. Reading PreBFC Unstructured Mesh Files](#)

4.2.1. Reading TGrid Mesh Files

TGrid has the same file format as ANSYS FLUENT. Hence you can read a TGrid mesh into the solver using the **File/Read/Mesh...** menu item.

File → Read → Mesh...

For information about reading TGrid mesh files, see [TGrid Mesh Files \(p. 149\)](#).

4.2.2. Reading Surface Meshes

You can read surface mesh files into ANSYS FLUENT using the **Surface Meshes** dialog box, which is opened through the **Geometry Based Adaption** dialog box.

Adapt → Geometry...

Click the **Surface Meshes...** button to open the **Surface Meshes** dialog box.

For further details about reading surface mesh files, see [Reading Surface Mesh Files \(p. 161\)](#).

4.2.3. Reading GAMBIT and GeoMesh Mesh Files

If you create a FLUENT 5/6, FLUENT/UNS, or RAMPANT mesh in GAMBIT or GeoMesh, you can read it into ANSYS FLUENT using the **File/Read/Mesh...** menu item.

File → Read → Mesh...

Specify the name of the file to be read the **Select File** dialog box that opens.

4.2.4. Reading PreBFC Unstructured Mesh Files

Since PreBFC's unstructured triangular meshes have the same file format as ANSYS FLUENT, you can read a PreBFC triangular mesh into the solver using the **File/Read/Mesh...** menu item.

File → Read → Mesh...

Important

Save the file using the MESH-RAMPANT/TGRID command.

For information about reading PreBFC mesh files, see [PreBFC Mesh Files](#) (p. 150).

4.3. Reading and Writing Case and Data Files

Information related to the ANSYS FLUENT simulation is stored in both the case file and the data file. The commands for reading and writing these files are described in the following sections, along with commands for the automatic saving of case and data at specified intervals.

ANSYS FLUENT can read and write either text or binary case and data files. Binary files require less storage space and are faster to read and write. By default, ANSYS FLUENT writes files in binary format. To write a text file, disable the **Write Binary Files** check button in the **Select File** dialog box. In addition, you can read and write either text or binary files in compressed formats (For details, see [Reading and Writing Compressed Files](#) (p. 61)). ANSYS FLUENT automatically detects the file type when reading.

Furthermore, when writing case and data files, ANSYS FLUENT can improve I/O performance using asynchronous file compression which can be enabled using the **Optimize Using Asynchronous I/O** check button in the **Select File** dialog box.

This option is particularly beneficial if you want to improve the overall performance of simulations involving solution check-pointing. Performance is improved by overlapping the file compression and file system copy operations with subsequent iterations or other solver operations. It is best if the front end Cortex process has its own dedicated processor core (or machine) not used by the ANSYS FLUENT compute-node processes, even though the option would aid performance even if they reside on the same machine.

Important

- The **Optimize Using Asynchronous I/O** option is not available on Windows machines.
- If you adapt the mesh, you must save a new case file as well as a data file. Otherwise, the new data file will not correspond to the case file (for example, they will have different numbers of cells). If you have not saved the latest case or data file, ANSYS FLUENT will warn you when you try to exit the program.

For additional information, please see the following sections:

- 4.3.1. [Reading and Writing Case Files](#)
- 4.3.2. [Reading and Writing Data Files](#)
- 4.3.3. [Reading and Writing Case and Data Files Together](#)
- 4.3.4. [Automatic Saving of Case and Data Files](#)

4.3.1. Reading and Writing Case Files

Case files contain the mesh, boundary and cell zone conditions, and solution parameters for a problem. It also contains the information about the user interface and graphics environment. For information about the format of case files see [Appendix B](#) (p. 2345). The commands used for reading case files can also be used to read native-format mesh files (as described in [Reading Mesh Files](#) (p. 64)) because the mesh information is a subset of the case information. Select the **File/Read/Case...** menu item to invoke the **Select File** dialog box.

File → **Read** → **Case...**

Read a case file using the **Select File** dialog box. Note that the **Display Mesh After Reading** option in the **Select File** dialog box allows you to have the mesh displayed automatically after it is read.

Select the **File/Write/Case...** menu item to invoke the **Select File** dialog box.

File → Write → Case...

Write a case file using the **Select File** dialog box.

When ANSYS FLUENT reads a case file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions (*Reading and Writing Compressed Files (p. 61)*). When ANSYS FLUENT writes a case file, .cas is added to the name you type unless the name already ends with .cas.

4.3.2. Reading and Writing Data Files

Data files contain the values of the specified flow field quantities in each mesh element and the convergence history (residuals) for that flow field. For information about the format of data files see *Appendix B (p. 2345)*.

After reading a mesh or case file, select the **File/Read/Data...** menu item to invoke the **Select File** dialog box.

File → Read → Data...

Read a data file using the **Select File** dialog box.

After generating data for a case file, select the **File/Write/Data...** menu item to invoke the **Select File** dialog box.

File → Write → Data...

Write a data file using the **Select File** dialog box.

When ANSYS FLUENT reads a data file, it first looks for a file with the exact name you typed. If a file with that name is not found, it searches for the same file with different extensions (*Reading and Writing Compressed Files (p. 61)*). When ANSYS FLUENT writes a data file, .dat is added to the name you type unless the name already ends with .dat.

4.3.3. Reading and Writing Case and Data Files Together

A case file and a data file together contain all the information required to restart a solution. Case files contain the mesh, boundary and cell zone conditions, and solution parameters. Data files contain the values of the flow field in each mesh element and the convergence history (residuals) for that flow field.

You can read a case file and a data file together by using the **Select File** dialog box invoked by selecting the **File/Read/Case & Data...** menu item. To read both files, select the appropriate case file, and the corresponding data file (same name with .dat suffix) is also read. Note that the **Display Mesh After Reading** option in the **Select File** dialog box allows you to have the mesh displayed automatically after it is read.

File → Read → Case & Data...

To write a case file and a data file, select the **File/Write/Case & Data...** menu item.

File → Write → Case & Data...

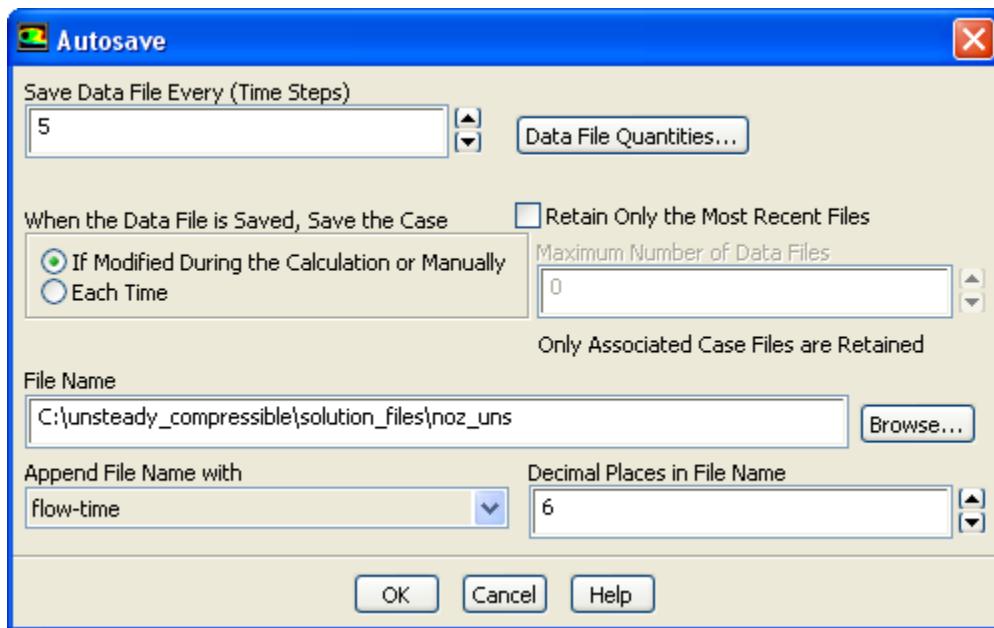

4.3.4. Automatic Saving of Case and Data Files

You can request ANSYS FLUENT to automatically save case and data files at specified intervals during a calculation. This is especially useful for time-dependent calculations, since it allows you to save the results at different time steps or flow times without stopping the calculation and performing the save manually. You can also use the autosave feature for steady-state problems, and thus examine the solution at different stages in the iteration history.

Automatic saving is specified using the [Autosave Dialog Box \(p. 2095\)](#) (*Figure 4.2 (p. 68)*), which is opened by clicking the **Edit...** button next to the **Autosave Every** text box in the **Calculation Activities** task page.

Calculation Activities

Figure 4.2 The Autosave Dialog Box

Specify how often you would like to save your modified files by entering the frequency in the **Save Data File Every** number-entry field. **Save Data File Every** is set to zero by default, indicating that no automatic saving is performed.

If you choose to save the case file only if it is modified, then select **If Modified During the Calculation or Manually** under **When the Data File is Saved, Save the Case File**. Note that the case file will be saved whether you make a manual change, or if ANSYS FLUENT makes a change internally during the calculation. If you choose to save the case file every time the data file is saved, then select **Each Time**.

Important

To save only the data files, use the following TUI option:

```
file → auto-save → case-frequency → if-mesh-is-modified
```

This will result in the options in the **When the Data File is Saved, Save the Case** group box being disabled in the **Autosave** dialog box. In essence, this TUI command forces ANSYS FLUENT to the save case file only when the mesh is modified. It does not disable case file saving, but reduces it to an absolute minimum. This is necessary to do so since you cannot read a data file without a case file containing a matching mesh.

For steady-state solutions, specify the frequency in iterations. For transient solutions, specify it in time steps (unless you are using the explicit time stepping formulation, in which case specify the frequency in iterations). If you define a frequency of 5, for example, a case file is saved every 5 iterations or time steps.

If you have limited disk space, restrict the number of files saved by ANSYS FLUENT by enabling the **Retain Only the Most Recent Files** option. When enabled, enter the **Maximum Number of Data Files** you would like to retain. Note that the case and data files are treated separately with regard to the maximum number of files saved when overwriting. For example, if the value of **Maximum Number of Data Files** is set to five, ANSYS FLUENT saves a maximum of five case and five data files, irrespective of the frequency. After the maximum limit of files has been saved, ANSYS FLUENT begins overwriting the earliest existing file.

If you have generated data (either by initializing the solution or running the calculation) you can view the list of standard quantities that will be written to the data file as a result of the autosave, and even select additional quantities for postprocessing in alternative applications. Click the **Data File Quantities...** button to open the **Data File Quantities** dialog box, and make any necessary selections. For details, see [Setting Data File Quantities \(p. 122\)](#).

Enter a root name for the autosave files in the **File Name** text box. When the files are saved, a number will be appended to this root name to indicate the point at which it was saved during the calculation: for steady-state solutions, this will be the iteration number, whereas for transient solutions it will be either the time step number or flow time (depending on your selection in the step that follows). An extension will also be automatically added to the root name (.cas or .dat). If the specified **File Name** ends in .gz or .Z, appropriate file compression is performed. For details about file compression see [Reading and Writing Compressed Files \(p. 61\)](#).

For transient calculations, make a selection from the **Append File Name with** drop-down list to indicate whether you want the root file name to be appended with the **time-step** or **flow-time** (see [Figure 4.2 \(p. 68\)](#)). If you select the latter, you can set the **Decimal Places in File Name** to determine the ultimate width of the file name.

Consider a transient case for which you want to save your case and data files at known time steps. The procedure you would follow is to first set the frequency in the **Save Data File Every** text box. Select **Each Time** if you want both case and data files saved at the same interval. Then enter my_file for the **File Name**. Finally, select **time-step** from the **Append File Name with** drop-down list. An example of the resulting files saved would be

my_file-0005.cas

my_file-0005.dat

indicating that these files were saved at the fifth time step.

You can revise the instructions for the previous example to instead save case and data files at known flow times, by selecting **flow-time** from the **Append File Name with** drop-down list. The default **Decimal Places in File Name** will be six. An example of the resulting files saved would be

my_file-0.500000.cas

my_file-0.500000.dat

indicating that these files were saved at a flow time of 0.5 seconds.

For steady-state and transient cases, you have the option of automatically numbering the files (as described in [Automatic Numbering of Files \(p. 63\)](#)), and thereby include further information about when the files were saved. This involves the addition of special characters to the **File Name**. For example, you may want the file names to convey the flow times with their corresponding time steps (transient cases only). Select **time-step** from the **Append File Name with**, and enter a **File Name** that ends with `-%f` to automatically number the files with the flow time. Thus, entering a **File Name** of `filename-%f` could result in a saved case file named `filename-000.500000-0010.cas`. The conventions used in this example can be explained as follows:

- `filename-` is the file name you entered when autosaving your solution.
- `000.500000` is the result of the special character `%f` added to the file name, and is the flow time. This flow time has a field width of ten characters, which allows for six decimal places (as discussed in [Automatic Numbering of Files \(p. 63\)](#)).
- `-0010` is the appended **time-step**, as designated by the selection in the **Append File Name with** drop-down list.
- `.cas` is the file extension automatically added when using the autosave option.

All of the autosave inputs are stored in memory when you click **OK** in the **Autosave** dialog box, and can then be saved with the case file.

4.4. Reading and Writing Parallel Data Files

When performing parallel processing, you have the option of utilizing the parallel input/output (I/O) capability of ANSYS FLUENT. This capability permits the writing and reading of data files directly to and from the node processes in a parallel fashion. This is in contrast to the standard ANSYS FLUENT I/O approach, in which all data is passed from the node processes to the host process where it is then written out to disk in serial. The motivation for performing the I/O directly from the node processes is to reduce the time for the data file I/O operations.

During parallel I/O operations, all the node processes write to or read from the same file, that is, they concurrently access a single file. The format of this parallel data file is different than the format of the standard ANSYS FLUENT data file. The format has been revised to permit more efficient concurrent access. The order of data written to the parallel data file is dependent on the number of processes involved in the session and on the partitioning. However, a parallel data file written from any parallel session on a given platform (i.e., any number of processes or partitioning) can be read by any other parallel session on the same platform. In other words, analyses may be freely restarted using a different number of processes, as long as the files are being written or read from the same platform.

For information about parallel processing, see [Parallel Processing \(p. 1715\)](#).

For additional information, please see the following sections:

- 4.4.1. Writing Parallel Data Files
- 4.4.2. Reading Parallel Data Files
- 4.4.3. Availability and Limitations

4.4.1. Writing Parallel Data Files

To write a parallel data file, select the **File/Write/Data...** menu item to invoke the **Select File** dialog box.

File → Write → Data...

In the **Select File** dialog box, enter the name of the output data file with a .pdat extension. The parallel data files are always binary, so you do not have to enable the **Write Binary Files** option.

Note that parallel data files written from sessions with different numbers of processes may be slightly different in size. However, they contain essentially the same information.

You can also use the text command `file/write-pdat?` to write a .pdat file. This is particularly useful if you want to write a .pdat file using the autosave data file option, after reading in a data file. The .pdat files will be saved during the autosave.

4.4.2. Reading Parallel Data Files

To read parallel data files, select the **File/Read/Data...** menu item to invoke the **Select File** dialog box.

File → Read → Data...

In the **Select File** dialog box, enter the name of the input data file with a .pdat extension.

Note that a parallel file will be read slightly quicker into a session that uses the same number of processes as the session that originally wrote the file, as opposed to a session with a different number.

4.4.3. Availability and Limitations

The conditions in which parallel I/O is available and the limitations related to this capability are as follows:

- The parallel I/O capability is only available for parallel ANSYS FLUENT sessions. Parallel data files cannot be read into a serial ANSYS FLUENT session, although they can be read if ANSYS FLUENT is launched with the number of processes set to one (e.g., enter 1 for **Number of Processes** in FLUENT Launcher).
- On a given platform, compatibility of data files will be a function of MPI type, but not interconnect.
 - Within the same MPI on a given platform, data files will be compatible regardless of the interconnect (i.e., writing with Platform MPI/ ethernet and reading with Platform MPI/ infiniband is allowed).
 - Inter-MPI compatibility on the same platform may also exist, since most of the MPIS use the same MPI-O implementation (ROMIO), but this is not guaranteed.
- Parallel data files written on one platform may not necessarily be able readable on other platforms. For example, compatibility across 64-bit platforms with the same endianness (byte order) may even exist (e.g., lnia64 and lnamd64); however, this is not guaranteed by the standard (since the “native” format is used) and should be investigated on a case-by-case basis.
- No parallel I/O capabilities are currently available for case files.
- The parallel/I/O capability is designed to work on true parallel file systems designed for concurrent, single-file access. The capability is not supported on NFS, for example.

- File compression with parallel I/O is supported via asynchronous operation. Inline compression as with standard I/O is not possible. (For details, see [Reading and Writing Case and Data Files \(p. 66\)](#)).
- The general parallel I/O capability is only available with certain MPIs on certain platforms. The supported combinations are listed in [Table 4.1: Architecture/MPI Combinations Compatible with Parallel I/O \(p. 72\)](#). Some of the MPIs currently used on Linux systems do not support MPI-2 features used in the parallel I/O. The default MPIs on all Linux and Windows systems should support the capability.

Important

Not all MPIs on a given platform work with all interconnects. For information about compatibility, see [Table 35.6: Supported MPIs for Linux Architectures \(Per Interconnect\) \(p. 1731\)](#).

Table 4.1 Architecture/MPI Combinations Compatible with Parallel I/O

Architecture	MPI
lnamd64	hp, intel, openmpi
lnia64	hp, sgi
ntx86	hp, intel
win64	hp, intel, ms

- The parallel I/O capability is available with certain file systems on certain platforms. The supported combinations are listed in [Table 4.2: Architecture/File System with Parallel I/O \(p. 72\)](#).

Table 4.2 Architecture/File System with Parallel I/O

Architecture	File System
lnamd64	Panasas, GPFS, SFS, LUSTRE, PVFS2, MPFS

4.5. Reading FLUENT/UNS and RAMPANT Case and Data Files

Case files created by FLUENT/UNS 3 or 4 or RAMPANT 2, 3, or 4 can be read into ANSYS FLUENT in the same way that current case files are read (see [Reading and Writing Case and Data Files \(p. 66\)](#)). If you read a case file created by FLUENT/UNS, ANSYS FLUENT selects **Pressure-Based** in the **Solver** group box of the [General Task Page \(p. 1763\)](#). If you read a case file created by RAMPANT, ANSYS FLUENT selects **Density-Based** in the **Solver** group box of the [General Task Page \(p. 1763\)](#), as well as **Explicit** from the **Formulation** drop-down menu in the [Solution Methods Task Page \(p. 2048\)](#).

Data files created by FLUENT/UNS 4 or RAMPANT 4 can be read into ANSYS FLUENT in the same way that current data files are read (see [Reading and Writing Case and Data Files \(p. 66\)](#)).

4.6. Reading and Writing Profile Files

Boundary profiles are used to specify flow conditions on a boundary zone of the solution domain. For example, they can be used to prescribe a velocity field on an inlet plane. For information on boundary profiles, see [Profiles \(p. 382\)](#). For information about transient profiles, see [Defining Transient Cell Zone and Boundary Conditions \(p. 393\)](#).

For additional information, please see the following sections:

4.6.1. Reading Profile Files

4.6.2. Writing Profile Files

4.6.1. Reading Profile Files

To read the boundary profile files, invoke the **Select File** dialog box by selecting the **File/Read/Profile...** menu item.

File → Read → Profile...

This opens the **Select File** dialog box so that you can read a boundary profile with the standard extension **.prof** or a transient profile in tabular format with the standard extension **.ttab**. If a profile in the file has the same name as an existing profile, the old profile will be overwritten.

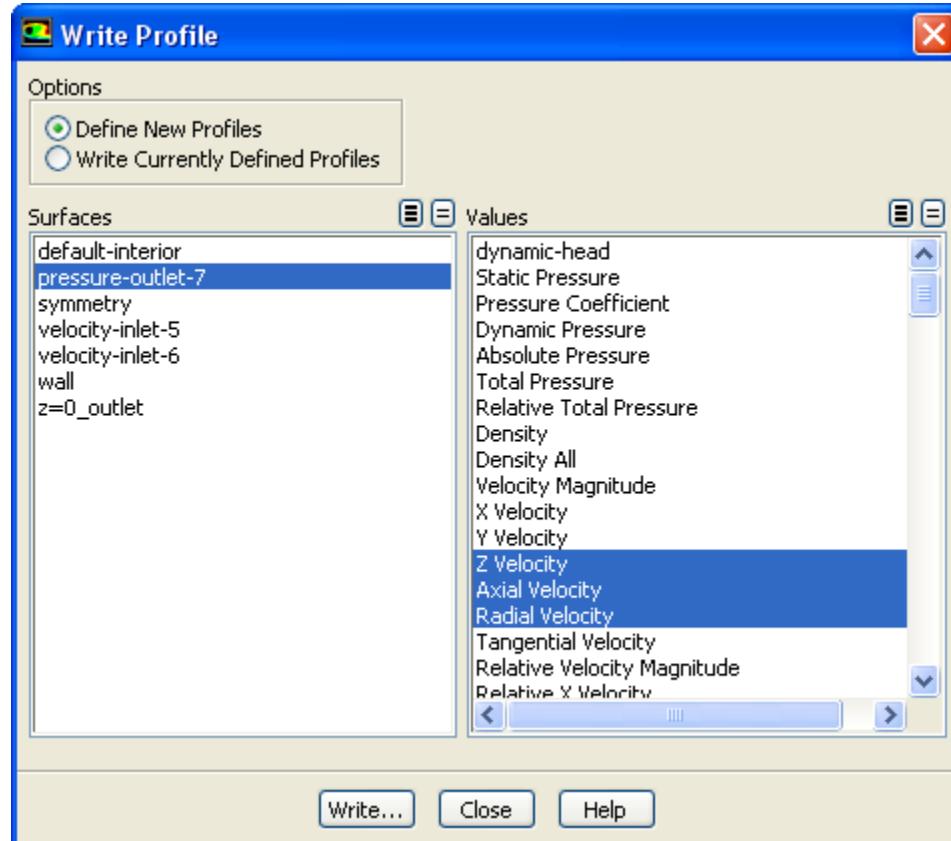

4.6.2. Writing Profile Files

You can also create a profile file from the conditions on a specified boundary or surface. For example, you can create a profile file from the outlet conditions of one case. Then you can read that profile into another case and use the outlet profile data as the inlet conditions for the new case.

To write a profile file, use the *Write Profile Dialog Box* (p. 1957) (*Figure 4.3 (p. 73)*).

File → Write → Profile...

Figure 4.3 The Write Profile Dialog Box

1. Retain the default option of **Define New Profiles**.
2. Select the surface(s) from which you want to extract data for the profile(s) in the **Surfaces** list.

3. Choose the variable(s) for which you want to create profiles in the **Values** list.
4. Click **Write...** and specify the profile file name in the resulting **Select File** dialog box.

ANSYS FLUENT saves the mesh coordinates of the data points for the selected surface(s) and the values of the selected variables at those positions. When you read the profile file back into the solver, you can select the profile values from the relevant drop-down lists in the boundary condition dialog boxes. The names of the profile values in the drop-down lists will consist of the surface name and the particular variable.

5. Select the **Write Currently Defined Profiles** option:
 - if you have made any modifications to the boundary profiles since you read them in (e.g., if you reoriented an existing profile to create a new one).
 - if you wish to store all the profiles used in a case file in a separate file.
6. Click **Write...** and specify the file name in the resulting **Select File** dialog box. All currently defined profiles are saved in this file. This file can be read back into the solver whenever you wish to use these profiles again.

4.7. Reading and Writing Boundary Conditions

To save all currently defined boundary conditions to a file, enter the `file/write-settings` text command and specify a name for the file.

`file → write-settings`

ANSYS FLUENT writes the boundary and cell zone conditions, the solver, and model settings to a file using the same format as the "zone" section of the case file. See [Appendix B \(p. 2345\)](#) for details about the case file format.

To read boundary conditions from a file and to apply them to the corresponding zones in your model, enter the `file/read-settings` text command.

`file → read-settings`

ANSYS FLUENT sets the boundary and cell zone conditions in the current model by comparing the zone name associated with each set of conditions in the file with the zone names in the model. If the model does not contain a matching zone name for a set of boundary conditions, those conditions are ignored.

If you read boundary conditions into a model that contains a different mesh topology (e.g., a cell zone has been removed), check the conditions at boundaries within and adjacent to the region of the topological change. This is important for wall zones.

Note

If the boundary conditions are not checked and some remain uninitialized, the case will not run successfully.

When the `file/read-settings` text command is not used, all boundary conditions get the default settings when a mesh file is imported, allowing the case to run with the default values.

If you want ANSYS FLUENT to apply a set of conditions to multiple zones with similar names, or to a single zone with a name you are not sure of in advance, you can edit the boundary-condition file saved with the `file/write-settings` command to include *wildcards* (*) within the zone names. For ex-

ample, if you want to apply a particular set of conditions to **wall-12**, **wall-15**, and **wall-17** in your current model, edit the boundary-condition file so that the zone name associated with the desired conditions is **wall-***.

Note

The settings file contains only the user modified settings and does not include default ANSYS FLUENT parameters. The default parameters may be updated with each new release. Consequently, the usage of the same settings file in different releases of ANSYS FLUENT does not guarantee the same setup which can cause solution differences.

4.8. Writing a Boundary Mesh

You can write the boundary zones (surface mesh) to a file. This file can be read and used by TGrid to produce a volume mesh. You may find this feature useful if you are unsatisfied with a mesh obtained from another mesh generation program.

A boundary mesh can be written using the **Select File** dialog box invoked by selecting the **File/Write/Boundary Mesh...** menu item.

File → Write → Boundary Mesh...

4.9. Reading Scheme Source Files

A Scheme source file can be loaded in three ways: through the menu system as a scheme file, through the menu system as a journal file, or through Scheme itself.

For large source files, use the **Select File** dialog box invoked by selecting the **File/Read/Scheme...** menu item

File → Read → Scheme...

or use the Scheme load function in the console, as shown in the following example:

```
> (load "file.scm")
```

Shorter files can also be loaded with the **File/Read/Journal...** menu item or the `file/ read-journal` command in the text interface (or its `.` or `source` alias, as shown in the example that follows).

```
>. file.scm
> source file.scm
```

In this case, each character of the file is echoed to the console as it is read, in the same way as if you were typing in the contents of the file.

4.10. Creating and Reading Journal Files

A journal file contains a sequence of ANSYS FLUENT commands, arranged as they would be typed interactively into the program or entered through the GUI or TUI. The GUI and TUI commands are recorded as Scheme code lines in journal files. You can also create journal files manually with a text editor. If you want to include comments in your file, be sure to put a semicolon (`;`) at the beginning of each comment line. See [Background Execution on Linux Systems \(p. 14\)](#) for an example.

The purpose of a journal file is to automate a series of commands instead of entering them repeatedly on the command line. Another use is to produce a record of the input to a program session for later reference, although transcript files are often more useful for this purpose. (For details, see [Creating Transcript Files \(p. 77\)](#)).

Command input is taken from the specified journal file until its end is reached, at which time control is returned to the standard input (usually the keyboard). Each line from the journal file is echoed to the standard output (usually the screen) as it is read and processed.

Important

A journal file is, by design, just a simple record and playback facility. It contains no information about the state in which it was recorded or the state in which it is being played back.

- Be careful not to change the folder while recording a journal file. Also, try to re-create the state in which the journal was written before you read it into the program. For example, if your journal file includes an instruction to save a new file with a specified name, you should check that if a file with that name exists in your folder before you read in your journal file. If a file with that name exists and you read in your journal file, when the program reaches the write instruction, it will prompt for a confirmation if it is OK to overwrite the old file.

Since the journal file does not contain any response to the confirmation request, ANSYS FLUENT cannot continue to follow the instructions of the journal file.

- Other conditions that may affect the program's ability to perform the instructions contained in a journal file can be created by modifications or manipulations that you make within the program.

For example, if your journal file creates several surfaces and displays data on those surfaces, you must be sure to read in appropriate case and data files before reading the journal file.

Important

At a point of time, only one journal file can be open for recording, but you can write a journal and a transcript file simultaneously. You can also read a journal file at any time.

Whether you choose to type the text command in full or use partial strings (as described in [Command Abbreviation \(p. 48\)](#)), complete commands are recorded in the journal files. Consider the following examples:

- Typing in the TUI

```
solve/set/expert , , yes , ,
```

will be recorded in the journal file as

```
/solve/set/expert yes no yes no no
```

where **,** or **Enter** signifies default values or entries, as described in [Text Prompt System \(p. 50\)](#).

- Typing in the TUI

```
so set ur mom 0.2 pres 0.4
```

will be recorded in the journal file as two separate commands:

```
/solve/set/under-relaxation/mom 0.2
/solve/set/under-relaxation/pressure 0.4
```

Important

- Only successfully completed commands are recorded. For example, if you stopped an execution of a command using the **Ctrl** key and the **c** key, it will not be recorded in the journal file.
- If a GUI event happens while a text command is in progress, the GUI event is recorded first.
- All default values are recorded (as in the first example above).

For additional information, please see the following section:

[4.10.1. Procedure](#)

4.10.1. Procedure

To start the journaling process, select the **File/Write/Start Journal...** menu item.

File → Write → Start Journal...

After you enter a name for the file in the **Select File** dialog box, journal recording begins. The **Start Journal...** menu item becomes the **Stop Journal** menu item. You can end journal recording by selecting **Stop Journal**, or by exiting the program.

File → Write → Stop Journal

You can read a journal file into the program using the **Select File** dialog box invoked by selecting the **File/Read/Journal...** menu item.

File → Read → Journal...

Journal files are always loaded in the main (i.e., top-level) text menu, regardless of where you are in the text menu hierarchy when you invoke the read command.

4.11. Creating Transcript Files

A transcript file contains a complete record of all standard input to and output from ANSYS FLUENT (usually all keyboard and GUI input and all screen output). GUI commands are recorded as Scheme code lines in transcript files. ANSYS FLUENT creates a transcript file by recording everything typed as input or entered through the GUI, and everything printed as output in the text window.

The purpose of a transcript file is to produce a record of the program session for later reference. Because they contain messages and other output, transcript files (unlike journal files), cannot be read back into the program.

Important

Only one transcript file can be open for recording at a time, but you can write a transcript and a journal file simultaneously. You can also read a journal file while a transcript recording is in progress.

To start the transcription process, select the **File/Write/Start Transcript...** menu item.

File → Write → Start Transcript...

After you enter a name for the file in the **Select File** dialog box, transcript recording begins and the **Start Transcript...** menu item becomes the **Stop Transcript** menu item.

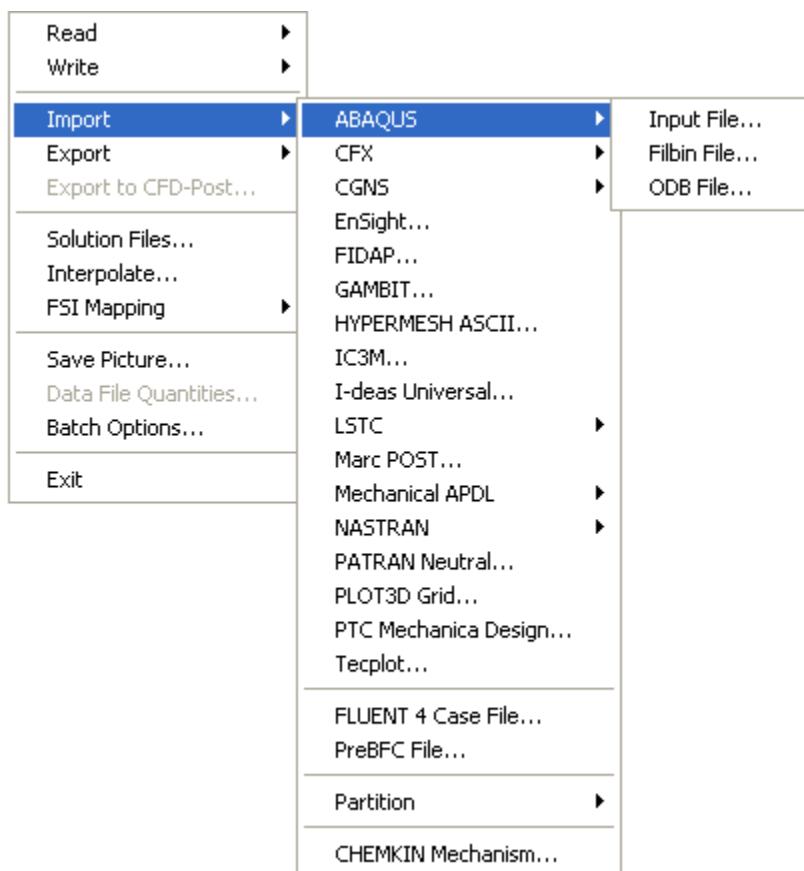

You can end transcript recording by selecting **Stop Transcript**, or by exiting the program.

File → Write → Stop Transcript

4.12. Importing Files

ANSYS FLUENT allows you to import the following file formats:

- ABAQUS .inp, .fil, and .odb files.
- CFX .def and .res files.
- CGNS files.
- EnSight files.
- ANSYS FIDAP files.
- GAMBIT files.
- HYPERMESH ASCII files.
- IC3M files.
- I-deas Universal files.
- LSTC/DYNA keyword input files and state databases.
- Marc POST files.
- Mechanical APDL .inp, .cdb, .rst, .rmrg, and .rfl files.
- NASTRAN Bulk Data files.
- PATRAN Neutral files.
- PLOT3D mesh files.
- PTC Mechanica Design studies.
- Tecplot files.

Figure 4.4 The Import Menu

For information on importing particle history data, see *Importing Particle Data* (p. 1150).

For additional information, please see the following sections:

- [4.12.1. ABAQUS Files](#)
- [4.12.2. CFX Files](#)
- [4.12.3. Meshes and Data in CGNS Format](#)
- [4.12.4. EnSight Files](#)
- [4.12.5. ANSYS FIDAP Neutral Files](#)
- [4.12.6. GAMBIT and GeoMesh Mesh Files](#)
- [4.12.7. HYPERMESH ASCII Files](#)
- [4.12.8. IC3M Files](#)
- [4.12.9. I-deas Universal Files](#)
- [4.12.10. LSTC Files](#)
- [4.12.11. Marc POST Files](#)
- [4.12.12. Mechanical APDL Files](#)
- [4.12.13. NASTRAN Files](#)
- [4.12.14. PATRAN Neutral Files](#)
- [4.12.15. PLOT3D Files](#)
- [4.12.16. PTC Mechanica Design Files](#)
- [4.12.17. Tecplot Files](#)
- [4.12.18. FLUENT 4 Case Files](#)
- [4.12.19. PreBFC Files](#)
- [4.12.20. Partition Files](#)
- [4.12.21. CHEMKIN Mechanism](#)

4.12.1. ABAQUS Files

To import an ABAQUS input file, use the **File/Import/ABAQUS/Input File...** menu item.

File → Import → ABAQUS → Input File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **Input File** to be read. The ABAQUS input file (.inp) is a text file which contains the input description of a finite element model for the ABAQUS finite element program. The interface only produces datasets associated with the finite element model, no results of datasets are produced. Element types commonly associated with structural analysis are supported by this file format. There is a list of input keywords that are recognized in the ABAQUS **Input File** [3] (p. 2367).

To import an ABAQUS filbin file, use the **File/Import/ABAQUS/Filbin File...** menu item.

File → Import → ABAQUS → Filbin File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **Filbin File** to be read. This output file has a .fil extension and consists of finite element model and results data.

To import an ABAQUS ODB file, use the **File/Import/ABAQUS/ODB File...** menu item.

File → Import → ABAQUS → ODB File...

Select this menu item to open the **Select File** dialog box. Specify the name of the ABAQUS **ODB File** to be read. This output database file has a .odb extension and consists of finite element model and results data in the OpenDocument format.

4.12.2. CFX Files

To import a CFX definition file, use the **File/Import/CFX/Definition File...** menu item.

File → Import → CFX → Definition File...

Select this menu item to invoke the **Select File** dialog box. Specify the name of the CFX **Definition File** to be read. The solver reads mesh information from the CFX file with .def extensions. For information about importing CFX files, see [CFX Files \(p. 154\)](#).

To import a CFX result file, use the **File/Import/CFX/Result File...** menu item.

File → Import → CFX → Result File...

In the **Select File** dialog box, specify the name of the CFX **Result File** to be read. Those imported files will have .res extensions.

Note that the **Create Zones from CCL Physics Data** option in the **Select File** dialog boxes allows you to create zones from the physics data objects or the primitive mesh region objects.

Important

CFX file import is available for 3D cases only.

4.12.3. Meshes and Data in CGNS Format

To import meshes in CFD general notation system (CGNS) format (.cgns) into ANSYS FLUENT, use the **File/Import/CGNS/Mesh...** menu item.

File → Import → CGNS → Mesh...

To import a mesh and the corresponding CGNS data, use the **File/Import/CGNS/Mesh & Data...** menu item.

File → Import → CGNS → Mesh & Data...

To import only the CGNS data, use the **File/Import/CGNS/Data...** menu item.

File → Import → CGNS → Data...

Important

- To import data correctly, first import the mesh using the mesh only option (**Mesh...**), set up the boundary conditions, and read the data using the data only option (**Data...**). For example, if a boundary zone is of type **pressure-outlet** and is read as **outlet**, it should be changed to **pressure-outlet** before importing the data.
- The new and original meshes should have the same zones, numbered in the same order. A warning is issued if they do not, because inconsistencies can create problems with the boundary conditions.

4.12.4. EnSight Files

You can import an EnSight file using the **File/Import/EnSight...** menu item.

File → Import → EnSight...

This file format is applied to both unstructured and structured data, where each part contains its own local coordinate array. The EnSight Gold software package, which uses this file format, allows you to analyze, visualize, and communicate engineering datasets. It allows the you to take full advantage of parallel processing and rendering and supports a range of virtual reality devices. Furthermore, it enables real-time collaboration.

When selecting this option, the **Select File** dialog box will appear, where you will specify a file name. This file will have an .encas or .case extension.

Only the mesh file is read into ANSYS FLUENT, and any data present is discarded.

4.12.5. ANSYS FIDAP Neutral Files

You can read an ANSYS FIDAP neutral file using the **File/Import/FIDAP...** menu item.

File → Import → FIDAP...

In the **Select File** dialog box, specify the name of the ANSYS FIDAP **Neutral File** to be read. This file will have an .FDNEUT or .unv file extension. ANSYS FLUENT reads mesh information and zone types

from the ANSYS FIDAP file. You must specify boundary conditions and other information after reading this file. For information about importing ANSYS FIDAP Neutral files, see [ANSYS FIDAP Neutral Files \(p. 157\)](#).

4.12.6. GAMBIT and GeoMesh Mesh Files

If you have saved a neutral file from GAMBIT, rather than an ANSYS FLUENT mesh file, you can import it into ANSYS FLUENT using the **File/Import/GAMBIT...** menu item.

File → Import → GAMBIT...

For information about importing files from GAMBIT and GeoMesh, see [GAMBIT Mesh Files \(p. 149\)](#) and [GeoMesh Mesh Files \(p. 149\)](#).

4.12.7. HYPERMESH ASCII Files

You can read a HYPERMESH ASCII file using the **File/Import/HYPERMESH ASCII...** menu item.

File → Import → HYPERMESH ASCII...

HYPERMESH is a high-performance finite element pre- and postprocessor for popular finite element solvers, allowing engineers to analyze product design performance in a highly interactive and visual environment.

When selecting this option, the **Select File** dialog box will appear, where you will specify a file name. This file should have an .hm, .hma, or .hmascii extension.

4.12.8. IC3M Files

ANSYS FLUENT has the ability to import in-cylinder simulation files that have been created using the IC3M preprocessor of ICEM CFD. For information about creating and setting up such files, see the IC3M User Guide and Tutorial Manual (available to licensed ICEM CFD IC3M users).

When importing IC3M files, first make sure that all of the relevant files exported from ICEM CFD IC3M are in the same folder and uncompressed. Then import the files, using the **File/Import/IC3M...** menu item.

File → Import → IC3M...

Important

- IC3M files can only be imported into the 3D version of ANSYS FLUENT (single or double precision).
- IC3M files should not be used with ANSYS FLUENT in Workbench.

In the **Select File** dialog box, specify the name of the mesh file, which should have a .msh extension. After the file is selected, ANSYS FLUENT will read in the mesh and automatically set up the case file to run a dynamic mesh simulation, using the parameters defined in the IC3M preprocessor. You can make certain changes to the dynamic mesh setup, but this is not necessary. See [Using Dynamic Meshes \(p. 573\)](#) for further details about setting up the dynamic mesh. Note that you cannot change the engine parameters for an engine set up using IC3M, except for the time step size.

The information read in from the IC3M files includes the starting and ending crank angle for the simulation. After reading the .msh file, ANSYS FLUENT will position the mesh such that it corresponds to

the starting crank angle. This process may take a few minutes. You will be informed of the status of this process through messages in the console.

Save the case file at this point, to retain a copy of the settings from the IC3M files. You may start the simulation from this case file, as long as it is in a folder that contains *all* of the uncompressed files exported by ICEM CFD IC3M. It is recommended that you preview the mesh motion prior to running the simulation, using the same time step size that will be used in the simulation. See [Previewing the Dynamic Mesh \(p. 661\)](#) for further details.

Important

- You will not be able to run the mesh preview or simulation beyond the ending crank angle specified in the IC3M preprocessor, even if the motion is periodic. ANSYS FLUENT sets the end crank angle based on the information imported from the IC3M files, and will automatically stop when this angle is reached.
- You cannot reuse the same ANSYS FLUENT session for engines set up using IC3M, i.e., for each new calculation, you must exit ANSYS FLUENT and begin a new session.

4.12.9. I-deas Universal Files

I-deas Universal files can be read into ANSYS FLUENT with the **File/Import/I-deas Universal...** menu item.

File → Import → I-deas Universal...

Select the **I-deas Universal...** menu item to invoke the **Select File** dialog box.

Specify the name of the I-deas Universal file to be read. The solver reads mesh information and zone types from the I-deas Universal file. For information about importing I-deas Universal files, see [I-deas Universal Files \(p. 150\)](#).

4.12.10. LSTC Files

To import an LSTC input file, use the **File/Import/LSTC/Input File...** menu item.

File → Import → LSTC → Input File...

The LSTC input file is a text file which contains the input description of a finite element model for the LS-DYNA finite element program. This interface only produces datasets associated with the mesh, no results datasets are produced. The element types commonly associated with structural analysis are supported.

LSTC input files have the following file extensions: .k, .key, and .dyn

To import an LSTC state file, use the **File/Import/LSTC/State File...** menu item.

File → Import → LSTC → State File...

The state file consists of three major sections: control data, geometry data, and state data. Each dataset in the state data section corresponds to the time and global data items associated with each state on the database. Dataset attributes include such things as time, energy, and momentum.

An LSTC state file has a .d3plot file extension.

4.12.11. Marc POST Files

Marc POST files can be read into ANSYS FLUENT using the **File/Import/Marc POST...** menu item.

File → Import → Marc POST...

Select the **Marc POST...** menu item and in the **Select File** dialog box, specify the name of the file to be read.

These files are generated using MSC Marc, a nonlinear finite element program. MSC Marc allows you to study deformations that exceed the linear elastic range of some materials, enabling you to assess the structural integrity and performance of the material. It also allows you to simulate deformations that are part-to-part or part-to-self contact under a range of conditions.

4.12.12. Mechanical APDL Files

To import a Mechanical APDL input file, use the **File/Import/Mechanical APDL/Input File...** menu item.

File → Import → Mechanical APDL → Input File...

Select this menu item to invoke the **Select File** dialog box. Specify the name of the Mechanical APDL **Prep7 File** to be read. The solver reads mesh information from the Mechanical APDL file with .ans, .neu, .cdb, and .prep7 extensions. For information about importing Mechanical APDL files, see [Mechanical APDL Files \(p. 153\)](#).

To import a Mechanical APDL result file, use the **File/Import/Mechanical APDL/Result File...** menu item.

File → Import → Mechanical APDL → Result File...

In the **Select File** dialog box. Specify the name of the Mechanical APDL **Result File** to be read. Those imported files will have .rfl, .rst, .rth, and .rmg extensions.

4.12.13. NASTRAN Files

You can read NASTRAN Bulkdata files into ANSYS FLUENT with the **File/Import/NASTRAN/Bulkdata File...** menu item.

File → Import → NASTRAN → Bulkdata File...

When you select the **Bulkdata File...** menu item, the **Select File** dialog box will appear and you will specify the name of the NASTRAN **File** to be read. This file will have .nas, .dat, .bdf file extensions. The solver reads mesh information from the NASTRAN file. For information about importing NASTRAN files, see [NASTRAN Files \(p. 151\)](#).

To import NASTRAN Op2 files into ANSYS FLUENT, use the **File/Import/NASTRAN/Op2 File...** menu item.

File → Import → NASTRAN → Op2 File...

In the **Select File** dialog box, specify the name of the NASTRAN **Output2 File** to be read. This file is an output binary data file that contains data used in the NASTRAN finite element program. This file will have .op2 file extension.

4.12.14. PATRAN Neutral Files

To read a PATRAN Neutral file zoned by named components (that is, a file in which you have grouped nodes with the same specified group name), use the **File/Import/PATRAN Neutral...** menu item.

File → Import → PATRAN Neutral...

Selecting this menu item invokes the **Select File** dialog box. Specify the name of the PATRAN Neutral file to be read (extension .neu, .out, or .pat). The solver reads mesh information from the PATRAN Neutral file. For information about importing PATRAN Neutral files, see *PATRAN Neutral Files (p. 152)*.

4.12.15. PLOT3D Files

To import a PLOT3D mesh file, use the **File/Import/PLOT3D Grid...** menu item.

File → Import → PLOT3D Grid...

The PLOT3D mesh files have .p3d, .bin, .x, .xyz, or .grd file extensions.

These file formats may be formatted, unformatted or binary.

4.12.16. PTC Mechanica Design Files

To import a PTC Mechanica Design file, use the **File/Import/PTC Mechanica Design...** menu item.

File → Import → PTC Mechanica Design...

This will open the **Select File** dialog box. Specify the name of the neutral file to be read.

The PTC Mechanica Design file contains analysis, model and results data. Only the binary form of the results data files is supported.

The form of the file must have the .neu extension.

Important

Mechanica results consists of an entire directory structure of files, called a “study” in Mechanica terminology, which must be used in exactly the form that Mechanica originally generates it. ANSYS FLUENT’s VKI interface keys on the .neu file and can traverse the directory structure from there to access the other files that it needs.

4.12.17. Tecplot Files

To import a Tecplot file, use the **File/Import/Tecplot...** menu item.

File → Import → Tecplot...

This will open the **Select File** dialog box. Specify the name of the neutral file to be read.

The Tecplot file is a binary file. Only the mesh is read into ANSYS FLUENT and any data present is discarded.

The form of the file must have the `.plt` extension. ANSYS FLUENT supports the importation of polyhedral cells and files created by Tecplot version 7.1–11.2, except for version 11.0 (which is unsupported).

4.12.18. FLUENT 4 Case Files

You can read a FLUENT 4 case file using the **File/Import/FLUENT 4 Case File...** menu item.

File → Import → FLUENT 4 Case File...

Select the **FLUENT 4 Case File...** menu item to invoke the **Select File** dialog box. Specify the name of the FLUENT 4 case file to be read. ANSYS FLUENT reads *only* mesh information and zone types from the FLUENT 4 case file. You must specify boundary and cell zone conditions, model parameters, material properties, and other information after reading this file. For information about importing FLUENT 4 case files, see *FLUENT 4 Case Files* (p. 157).

4.12.19. PreBFC Files

You can read a PreBFC structured mesh file into ANSYS FLUENT using the **File/Import/PreBFC File...** menu item.

File → Import → PreBFC File...

Select the **PreBFC File...** menu item to invoke the **Select File** dialog box. Specify the name of the PreBFC structured mesh file to be read. The solver reads mesh information and zone types from the PreBFC mesh file. For information about importing PreBFC mesh files, see *PreBFC Mesh Files* (p. 150).

4.12.20. Partition Files

To perform METIS partitioning on an unpartitioned mesh, use the **File/Import/Partition/Metis...** menu item.

File → Import → Partition → Metis...

You may also partition each cell zone individually, using the **File/Import/Partition/Metis Zone...** menu item.

File → Import → Partition → Metis Zone...

See *Using the Partition Filter* (p. 1753) for detailed information about partitioning.

4.12.21. CHEMKIN Mechanism

To import a CHEMKIN format, you can import the mechanism file into ANSYS FLUENT using the **File/Import/CHEMKIN Mechanism...** menu item (*Figure 16.11* (p. 884)).

File → Import → CHEMKIN Mechanism...

See *Importing a Volumetric Kinetic Mechanism in CHEMKIN Format* (p. 883) for detailed information on importing a CHEMKIN Mechanism file.

4.13. Exporting Solution Data

The current release of ANSYS FLUENT allows you to export data to ABAQUS, Mechanical APDL, Mechanical APDL Input, ASCII, AVS, ANSYS CFD-Post, CGNS, Data Explorer, EnSight, FAST, FIELDVIEW, I-deas,

NASTRAN, PATRAN, RadTherm, and Tecplot formats. [Exporting Solution Data after a Calculation \(p. 88\)](#) explains how to export solution data in these formats after the calculation is complete, and [ABAQUS Files \(p. 90\)](#) to [Tecplot Files \(p. 100\)](#) provide specific information for each type of **File Type**. For information about exporting solution data during transient flow solutions, see [Exporting Data During a Transient Calculation \(p. 102\)](#).

For NASTRAN, ABAQUS, Mechanical APDL Input, I-deas Universal, and PATRAN file formats, the following quantities are exported [3] ([p. 2367](#)):

- Nodes, Elements
- Node Sets (Boundary Conditions)
- Temperature
- Pressure
- Heat Flux
- Heat Transfer Coefficient
- Force

To generate the force data that is exported for nodes at boundaries, ANSYS FLUENT performs the following steps:

1. Facial force for each wall face is calculated by summing the pressure force, viscous force and surface tension force of the face.
2. Partial force for each wall face is calculated by dividing its facial force by its number of shared nodes.
3. Total force for each wall node is calculated by summing the partial forces of all the wall faces sharing that node.

For additional information, please see the following section:

[4.13.1. Exporting Limitations](#)

4.13.1. Exporting Limitations

Note the following limitations when exporting solution data:

- When using the parallel version of ANSYS FLUENT, you can only export to the following packages:
 - ABAQUS
 - ANSYS CFD-Post
 - ASCII
 - CGNS
 - EnSight Case Gold
 - Fieldview Unstructured
 - I-deas Universal
 - Mechanical APDL Input
 - NASTRAN
 - PATRAN
 - Tecplot

The exported file will be written by the host process (see [Introduction to Parallel Processing \(p. 1715\)](#)).

Note that the memory required to write the file may exceed the memory available to the host process.

- When using the parallel version of ANSYS FLUENT, the only packages to which you can export custom field functions are the following:
 - ANSYS CFD-Post
 - EnSight Case Gold
 - Fieldview Unstructured

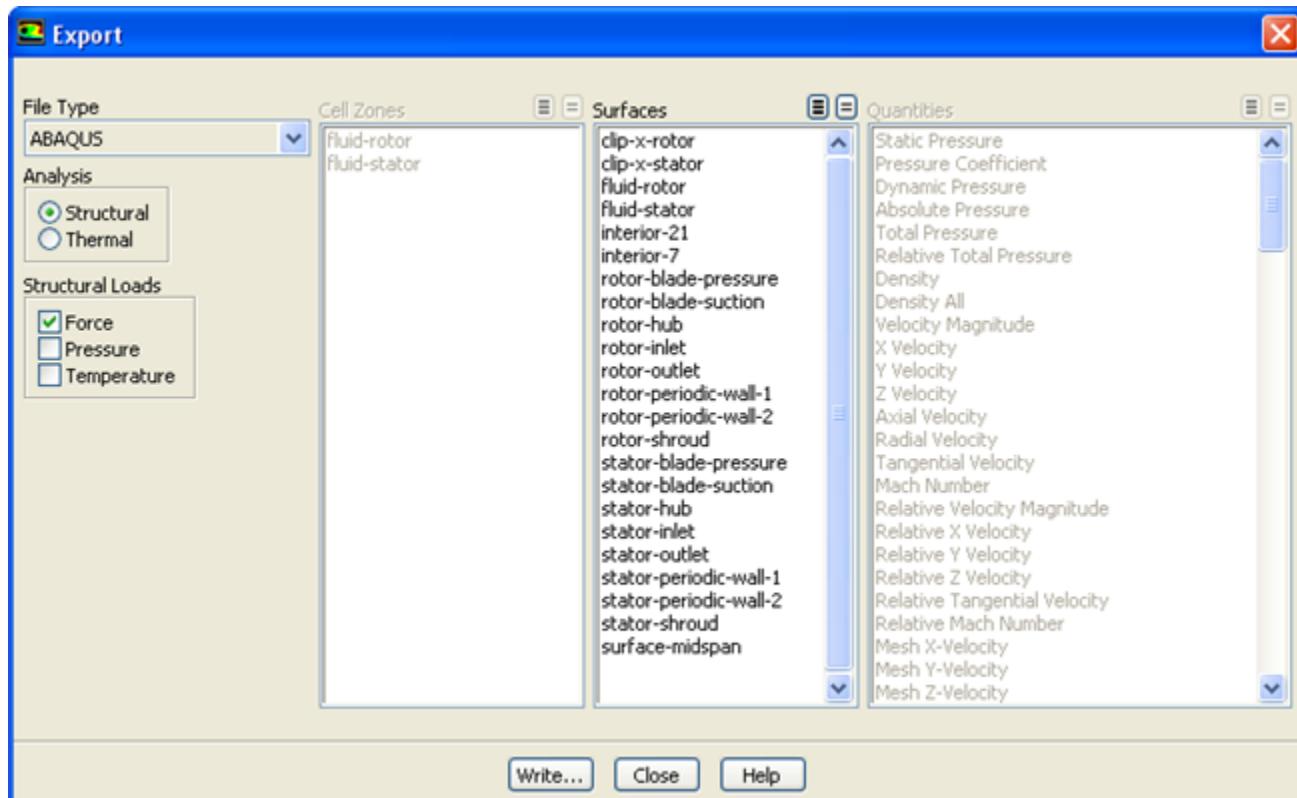

For further information about custom field functions, see [Custom Field Functions \(p. 1708\)](#).

- ANSYS FLUENT cannot import surfaces. Consequently, if you export a file from ANSYS FLUENT with surfaces selected, you may not be able to read these files back into ANSYS FLUENT. However, TGrid can import surface data (For details, see the TGrid User's Guide for details).
- ANSYS FLUENT supports exporting polyhedral data only for ASCII, EnSight Case Gold, and Fieldview Unstructured file formats. For further details, see [ASCII Files \(p. 92\)](#), [EnSight Case Gold Files \(p. 94\)](#), and [Fieldview Unstructured Files \(p. 97\)](#).
- If the files that are exported during multiple transient simulations are to be used as a set, you must make sure that all of the simulations are run on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.

4.14. Exporting Solution Data after a Calculation

To export solution data to a different file format after a calculation is complete, use the [Export Dialog Box \(p. 2214\)](#) ([Figure 4.5 \(p. 89\)](#)).

File → Export → Solution Data...

Figure 4.5 The Export Dialog Box

Information concerning the necessary steps and available options for each **File Type** are listed in *[ABAQUS Files](#)* (p. 90) to *[Tecplot Files](#)* (p. 100).

For details about general limitations for exporting solution data and the manner in which it is exported, see *[Exporting Solution Data](#)* (p. 86).

For additional information, please see the following sections:

- [4.14.1. ABAQUS Files](#)
- [4.14.2. Mechanical APDL Files](#)
- [4.14.3. Mechanical APDL Input Files](#)
- [4.14.4. ASCII Files](#)
- [4.14.5. AVS Files](#)
- [4.14.6. ANSYS CFD-Post-Compatible Files](#)
- [4.14.7. CGNS Files](#)
- [4.14.8. Data Explorer Files](#)
- [4.14.9. EnSight Case Gold Files](#)
- [4.14.10. FAST Files](#)
- [4.14.11. FAST Solution Files](#)
- [4.14.12. Fieldview Unstructured Files](#)
- [4.14.13. I-deas Universal Files](#)
- [4.14.14. NASTRAN Files](#)
- [4.14.15. PATRAN Files](#)
- [4.14.16. RadTherm Files](#)
- [4.14.17. Tecplot Files](#)

4.14.1. ABAQUS Files

Select ABAQUS from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported.

When the **Energy Equation** is enabled in the *Energy Dialog Box* (p. 1778), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**. Note the following limitations with these loads:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (i.e., if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. The exported file format of ABAQUS (`file.inp`) contains coordinates, connectivity, zone groups, and optional loads.

Export of data to ABAQUS is valid only for solid zones or for those surfaces that lie at the intersection of solid zones. Temperature data is exported for the whole domain.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 102) for the complete details.

4.14.2. Mechanical APDL Files

Export to Mechanical APDL can only be invoked using the `file/export/mechanical-apdl` text command. You will be prompted to enter a Mechanical APDL file name and the Zone to Export.

The file written is a Mechanical APDL results file with a `.rfl` extension. This file preserves the cell zones defined in ANSYS FLUENT. The Mechanical APDL file is a single file containing coordinates, connectivity, and the scalars listed below:

```
''x-velocity'', ''y-velocity'', ''z-velocity'', ''pressure'',  
''temperature'', ''turb-kinetic-energy'', ''turb-diss-rate'',  
''density'', ''viscosity-turb'', ''viscosity-lam'', ''viscosity-eff'',  
''thermal-conductivity-lam'', ''thermal-conductivity-eff'',  
''total-pressure'', ''total-temperature'', ''pressure-coefficient'',  
''mach-number'', ''stream-function'', ''heat-flux'',  
''heat-transfer-coef'', ''wall-shear'', ''specific-heat-cp''
```

Important

Export to ANSYS is available on a limited number of platforms (ntx86).

To read this file into Mechanical APDL, do the following:

1. In Mechanical APDL, expand the **General Postproc** item in the **ANSYS Main Menu**, and click **Data & File Opt**s. Then perform the following steps in the **Data and File Options** dialog box that opens.
 - a. Make sure that **Read single result file** is enabled.

- b. Click the browse button to open the **Open** dialog box, and select the **.rf1** file generated by ANSYS FLUENT.
- c. Click **Open** in the **Open** dialog box.
- d. Click **OK** in the **Data and File Options** dialog box.
2. In the **ANSYS Main Menu**, click **Results Summary** in the expanded **General Postproc** list. A **SET,LIST Command** window will open, displaying a summary of the file contents.
3. In the expanded **General Postproc** list, expand the **Read Results** item and click **First Set** to read the data from the file.
4. Display the data from the file. You can display mesh information by selecting either the **Plot/Nodes** menu item or the **Plot/Elements** menu item from the Mechanical APDL menu bar. You can display results by selecting either the **Plot/Results/Contour Plot/Nodal Solution...** menu item or the **Plot/Results/Contour Plot/Elem Solution...** menu item, and then using the dialog box that opens.

You have the option of using the **Execute Commands** dialog box to export data to Mechanical APDL at specified intervals during the calculation. The text command for exporting can be entered directly into the **Command** text box (or the ANSYS FLUENT console, if you are defining a macro). It is of the following form:

```
file/export/mechanical-apdl file_name list_of_cell_zones ()
```

where

- *file_name* specifies the name (without the extension) of the file that you wish to write. You should include a special character string in the file name, so that the solver assigns a new name to each file it saves. For details, see [Automatic Numbering of Files \(p. 63\)](#). By using a special character string, you can have the files numbered by time step, flow time, etc.
- *list_of_cell_zones* specifies the list of cell zones (separated by commas) from which you want to export data. The **()** input terminates the list. For example, the input **fluid-rotor, fluid-stator()** will select the cell zones named **fluid-rotor** and **fluid-stator**.

See [Executing Commands During the Calculation \(p. 1400\)](#) for information about executing commands and creating and using command macros.

4.14.3. Mechanical APDL Input Files

Select Mechanical APDL Input from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported.

When the **Energy Equation** is enabled in the [Energy Dialog Box \(p. 1778\)](#), you can choose the loads to be written based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**. Note the following limitations with these loads:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (i.e., if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. ANSYS FLUENT exports an input file that contains Mechanical APDL finite element information including nodes, elements, and

loads that can be used to do finite element analysis in Mechanical APDL with minimal effort. The file format is written in .cdb format. The export of Mechanical APDL Input files is in ASCII format and thus is available on all platforms.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.4. ASCII Files

Select **ASCII** from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported. Also select the variable(s) for which data is to be saved in the **Quantities** list.

When exporting ASCII files, you have the following options:

- Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.
- Select the **Delimiter** separating the fields (**Comma** or **Space**).

Click the **Write...** button to save the file, using the **Select File** dialog box. ANSYS FLUENT will export a single ASCII file containing coordinates, optional loads, and specified scalar function data.

Important

ANSYS FLUENT supports exporting polyhedral data to ASCII.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.5. AVS Files

Select **AVS** from the **File Type** drop-down list and specify the scalars you want in the **Quantities** list.

Click the **Write...** button to save the file, using the **Select File** dialog box. An AVS version 4 UCD file contains coordinate and connectivity information and specified scalar function data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.6. ANSYS CFD-Post-Compatible Files

To export data to files that are compatible with ANSYS CFD-Post, select **CFD-Post Compatible** from the **File Type** drop-down list. Next, specify the cell zones from which you want data exported by making selections in the **Cell Zones** list (you must select at least one zone); note that by default, all of the cell zones will be exported. Then select the variables for which you want data saved from the **Quantities** selection list. When selecting the variables, be sure to include any variable that was used to create an isosurface or clipped surface (as described in [Isosurfaces \(p. 1489\)](#) and [Clipping Surfaces \(p. 1491\)](#), respectively); otherwise, the surface will not be created properly if you try to read the exported state file in CFD-Post.

Specify the format of the .cdat file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported data into ANSYS CFD-Post and requires less storage space. Note that the format for the .cst will always be ASCII.

By default, FLUENT will write a case file (i.e., .cas) along with the **CFD-Post Compatible** files. If you do not want such a case file for any reason (e.g., to improve I/O performance or save disc space), disable the **Write Case File** option. Disabling this option is only recommended if you are performing multiple export operations for a case file that is not changing.

Click the **Write...** button to save the files, using the **Select File** dialog box. A .cdat file is written, containing the specified variable data for the specified cell zones and all of the boundary zones. A state file (i.e., .cst) is also written, which contains the following surfaces that you created in FLUENT for postprocessing: point surfaces, line surfaces, plane surfaces, isosurfaces, and clipped surfaces (see [Creating Surfaces for Displaying and Reporting Data](#) (p. 1473)).

Important

When you read the .cdat file into ANSYS CFD-Post, the application will attempt to read in the case file that produced the data by looking in the folder for a .cas file with the same prefix. If the case file is not in that folder (e.g., if you disabled the **Write Case File** option when exporting), ANSYS CFD-Post will prompt you to specify the appropriate case file.

Important

Before loading the .cst file into ANSYS CFD-Post, make sure that the .cas and .cdat files are already loaded for the session.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation](#) (p. 102) for the complete details.

4.14.7. CGNS Files

Select **CGNS** from the **File Type** drop-down list and specify the scalars you want in the **Quantities** list.

Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.

Click the **Write...** button to save the file, using the **Select File** dialog box. CGNS (CFD general notation system) is a single file (e.g., file.cgns) containing coordinates, connectivity, zone information, velocity, and selected scalars.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation](#) (p. 102) for the complete details.

4.14.8. Data Explorer Files

Select **Data Explorer** from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported. Also specify the scalars you want in the **Quantities** list.

Important

When you are exporting data for Data Explorer, EnSight Case Gold, or I-deas Universal and the reference zone is not a stationary zone, the data in the velocity fields is exported by default as velocities relative to the motion specification of that zone. This data is always exported, even if you do not choose to export any scalars. Any velocities that you select to export as scalars in the **Quantities** list (e.g., **X Velocity**, **Y Velocity**, **Radial Velocity**, etc.) are exported as absolute velocities. For all other types of exported files, the velocities exported by default are absolute velocities.

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file (e.g., `file.dx`) is exported, containing coordinate, connectivity, velocity, and specified function data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.9. EnSight Case Gold Files

When exporting to EnSight, you can choose to export the data associated with a single data file, or you can export the data associated with multiple files that were generated by a transient solution.

- To export the solution data from a single data file, read in the case and data file and open the **Export** dialog box.

File → **Export** → **Solution Data...**

Then perform the following steps in the **Export** dialog box:

1. Select **EnSight Case Gold** from the **File Type** drop-down list.
2. Select the **Location** from which the values of scalar functions are to be taken. If you specify the data **Location** as **Node**, then the data values at the node points are exported. If you choose **Cell Center**, then the data values from the cell centers are exported. For boundary faces, it is the face center values that are exported when the **Cell Center** option is selected.
3. Specify the format of the file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported files into EnSight.
4. (optional) Select the **Cell Zones** from which you want data exported (you must select at least one zone). By default, all of the cell zones are selected.
5. (optional) Select the **Interior Zone Surfaces** from which you want data exported. By default, the data being exported is taken from the entire ANSYS FLUENT domain. The **Interior Zone Surfaces** selection list allows you to also specify that the data be taken from selected zone surfaces whose **Type** is identified as **interior** in the **Boundary Conditions** task page.
6. Select the scalars you want to write from the **Quantities** selection list.

7. Click the **Write...** button to open the **Select File** dialog box, which you can use to save a file that contains the specified variable data for the specified cell zones, the specified interior zone surfaces, and all of the boundary zones.
- To export solution data associated with multiple files that were generated by a transient solution, you must first make sure that the following criteria are met:
 - All of the relevant case and data files must be in the working folder.
 - The data files must be separated by a consistent number of time steps.

Next, enter the following text command in the console:

```
file → transient-export → ensight-gold-from-existing-files
```

Then, enter responses to the following prompts in the console:

1. EnSight Case Gold file name

Enter the name you want assigned to the exported files.

2. Case / Data file selection by base name?

Enter yes if the case and data files share a “base name” (i.e., a common initial string of characters). The alphanumeric order of the full names must correspond to the order in which the files were created. You will then be prompted to enter the base name at the Case / Data file base name prompt that follows. For example, with a set of files named elbow-0001, elbow-0002, elbow-0003, etc., enter elbow- for the base name.

Enter no if you have created an ASCII file in the working folder that lists the names of the data files in order of when they were created. The file should list one data file name per line. You will then be prompted to enter the name of this file at the Provide the file name which contains the data file names prompt that follows. Note that you must include the file extension if any in your entry at the prompt.

3. Specify Skip Value

Enter an integer value to specify the number of files you want to skip in between exporting files from the sequence. For example, enter 1 to export every other file, enter 2 to export every third file, etc.

4. Cell-Centered?

Enter yes if you want to export the data values from the cell centers (or face center values, for boundary faces).

Enter no if you want to export the data values from the node points.

5. Write separate file for each time step for each variable?

Enter yes if you want separate EnSight Case Gold files written for each time step. Otherwise, all of the data for the .sc11 and .vel files will be combined into a single file for each.

6. Write in binary format?

Enter yes to write the files in binary format. Otherwise, they will be written in ASCII format. The advantage of the binary format is that it takes less time to load the exported files into EnSight.

7. Specify Data File Frequency

Enter the number of time steps between the data files being exported.

8. Separate case file for each time step?

Enter no if all the data files were generated from the same case file (i.e., the simulation involved a static mesh). Note that the name of the case file must be the same (not including the extension) as the name of the first data file in the sequence.

Enter yes if the data files were generated from the different case files (i.e., the simulation involved a sliding or dynamic mesh). Note that the names of the case files must be the same (not including the extension) as the names of the corresponding data files.

9. Read the case file?

Enter no if the first (or only, for a static mesh) case file is already in memory.

Enter yes if the first (or only, for a static mesh) case file is *not* already in memory.

10. cell zone id/name(1)

Enter the name or ID of any cell zone from which you want data exported. By default, the data being exported is taken from the entire ANSYS FLUENT domain. After you specify the first cell zone, you will be prompted to specify the second one, and so on, until you press **Enter** without typing any characters.

11. Interior Zone Surfaces(1)

Enter the name of any interior zone surface from which you want data exported. By default, the data being exported is taken from the entire ANSYS FLUENT domain. This prompt allows you to also specify that the data be taken from selected zone surfaces whose **Type** is identified as **interior** in the **Boundary Conditions** task page. After you specify the first interior zone surface, you will be prompted to specify the second one, and so on, until you press **Enter** without typing any characters.

12. EnSight Case Gold scalar(1) else q to continue

Enter in the first scalar quantity you want exported. You can press the **Enter** key to print a list of available scalar quantities in the console. After you enter the first quantity, you will be prompted to enter the second quantity, and so on, until you enter q. The EnSight Case Gold files will then be written.

When exporting to EnSight Case Gold, files will be created with the following four formats:

- A geometry file (e.g., `file.geo`) containing the coordinates and connectivity information.
 - A velocity file (e.g., `file.vel`) containing the velocity.
 - A scalar file (e.g., `file.scl1`) for each selected variable or function.
 - An EnSight case file (e.g., `file.encas`) that contains details about the other exported files.
-

Important

- For non-stationary reference zones, all the velocities are exported to EnSight as velocities relative to the selected reference zone. See the informational note in [Data Explorer Files \(p. 94\)](#) for further details.
- ANSYS FLUENT supports exporting polyhedral data to EnSight.

You also have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see *Exporting Data During a Transient Calculation* (p. 102).

4.14.10. FAST Files

This file type is valid only for triangular and tetrahedral meshes. Select **FAST** from the **File Type** drop-down list and select the scalars you want to write in the **Quantities** list.

Click the **Write...** button to save the file for the specified function(s), using the **Select File** dialog box. The following files are written:

- A mesh file in extended Plot3D format containing coordinates and connectivity.
- A velocity file containing the velocity.
- A scalar file for each selected variable or function.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 102) for the complete details.

4.14.11. FAST Solution Files

This file type is valid only for triangular and tetrahedral meshes. Select **FAST Solution** from the **File Type** drop-down list and click the **Write...** button. A single file is written containing density, velocity, and total energy data.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 102) for the complete details.

4.14.12. Fieldview Unstructured Files

Select **Fieldview Unstructured** from the **File Type** drop-down list. Next, specify the cell zones from which you want data exported by making selections in the **Cell Zones** list (you must select at least one zone); note that by default, all of the cell zones will be exported. Then select the scalars you want to write in the **Quantities** list. Finally, click the **Write...** button to open the **Select File** dialog box, which you can use to save a file that contains the specified function(s) for the specified cell zones and associated boundary zones.

The following files are written:

- A binary file (e.g., `file.fvuns`) containing coordinate and connectivity information and specified scalar function data.
- A regions file (e.g., `file.fvuns.fvreg`) containing information about the cell zones and the frame of reference.

The cell zone information includes the names of the cell zones along with the mesh numbers. For the moving frame of reference, the regions file contains information about the origin, the axis of rotation and the rotation speed. Volume data is written using the absolute frame of reference.

If you are running multiple steady-state solutions on the same mesh, you can export only the data files and avoid the repeated writing of the mesh file by using the following TUI command:

```
file/export/fieldview-unstruct-data file_name (list_of_zones) list_of_scalars q
```

where

- *file_name* specifies the name (without the extension) of the file that you wish to write.
- *list_of_zones* specifies the list of cell zones (separated by spaces, i.e., no commas) from which you want data exported. If you want to specify all of the cell zones, enter * within the parentheses.
- *list_of_scalars* specifies the list of cell functions (separated by spaces, i.e., no commas) that you want to write to the exported file. The q input terminates the list. For example, the input x-velocity cell-zone q will select x velocity and the cell volume.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.13. I-deas Universal Files

Important

If you intend to export data to I-deas, ensure that the mesh does not contain pyramidal elements, as these are currently not supported by I-deas.

Select **I-deas Universal** from the **File Type** drop-down list. Select the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported. You can specify which scalars you want in the **Quantities** list.

You have the option of selecting loads to be included in the exported file. When the **Energy Equation** is enabled in the [Energy Dialog Box \(p. 1778\)](#), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**.

These loads have the following limitations:

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (i.e., if no **Surfaces** are selected).

Important

For non-stationary reference zones, all the velocities are exported to I-deas Universal as velocities relative to the selected reference zone. See the informational note in [Data Explorer Files \(p. 94\)](#) for further details.

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file is written containing coordinates, connectivity, optional loads, zone groups, velocity, and selected scalars.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See [Exporting Data During a Transient Calculation \(p. 102\)](#) for the complete details.

4.14.14. NASTRAN Files

Select **NASTRAN** from the **File Type** drop-down list. Select the surface(s) for which you want to write data in the **Surfaces** list. If you do not select any surfaces, the entire domain is exported. You can specify which scalars you want in the **Quantities** list.

You have the option of selecting loads to be included in the exported file. When the **Energy Equation** is enabled in the [Energy Dialog Box \(p. 1778\)](#), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**.

These loads have the following limitations :

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (i.e., if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file (e.g., `file.bdf`) is written containing coordinates, connectivity, optional loads, zone groups, and velocity. Pressure is written as `PLOAD4`, and heat flux is written as `QHBDYE` data. If you select wall zones in the **Surfaces** list, nodal forces are written for the walls. When data is written for the heat transfer coefficient, it is based on the wall faces rather than the nodes.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see [Exporting Data During a Transient Calculation \(p. 102\)](#).

4.14.15. PATRAN Files

Select **PATRAN** from the **File Type** drop-down list. Select the surface(s) for which you want to write data in the **Surfaces** list. If you do not select any surfaces, the entire domain is exported. You can specify which scalars you want in the **Quantities** list.

You have the option of selecting loads to be included in the exported file. When the **Energy Equation** is enabled in the [Energy Dialog Box \(p. 1778\)](#), you can choose the loads based on the kind of finite element analysis you intend to undertake. By selecting **Structural** in the **Analysis** list, you can select the following **Structural Loads: Force, Pressure, and Temperature**. By selecting **Thermal** in the **Analysis** list, you can select the following **Thermal Loads: Temperature, Heat Flux, and Heat Trans Coeff**.

These loads have the following limitations :

- When the **Energy Equation** is disabled, only the **Structural Loads** options of **Force** and **Pressure** are available.
- Loads are written only on boundary walls when the entire domain is exported (i.e., if no **Surfaces** are selected).

Click the **Write...** button to save the file, using the **Select File** dialog box. A neutral file (e.g., `file.out`) is written containing coordinates, connectivity, optional loads, zone groups, velocity, and selected scalars. Pressure is written as a distributed load. If wall zones are selected in the **Surfaces** list, nodal forces are written for the walls. The PATRAN result template file (e.g., `file.res_tmpl`) is written, which lists the scalars present in the nodal result file (e.g., `file.rst`).

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. For details, see *Exporting Data During a Transient Calculation* (p. 102).

4.14.16. RadTherm Files

The option to export a RadTherm file type is available only when the **Energy Equation** is enabled in the *Energy Dialog Box* (p. 1778). Select **RadTherm** from the **File Type** drop-down list and select the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the entire domain is exported.

Select the method of writing the heat transfer coefficient (**Heat Transfer Coefficient**), which can be **Flux Based** or, if a turbulence model is enabled, **Wall Function** based.

Click the **Write...** button to save the file, using the **Select File** dialog box. A PATRAN neutral file (e.g., `file.neu`) is written containing element velocity components (i.e., the element that is just touching the wall), heat transfer coefficients, and temperatures of the wall for any selected wall surface. If the wall is one-sided, the data is written for one side of the wall. If the wall is two-sided (a wall-wall shadow pair), the values are written only for the original wall face, not for the shadow face (which is a duplicate).

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 102) for the complete details.

4.14.17. Tecplot Files

Select **Tecplot** from the **File Type** drop-down list and choose the surface(s) for which you want to write data in the **Surfaces** list. If no surfaces are selected, the data is written for the entire domain. Select the variable(s) for which data is to be saved in the **Quantities** list.

Click the **Write...** button to save the file, using the **Select File** dialog box. A single file is written containing the coordinates and scalar functions in the appropriate tabular format.

Important

- ANSYS FLUENT exports Tecplot files in **FEBLOCK** format. The **utility fe2ram** can import Tecplot files only in **FEPOINT** format.
- If you intend to postprocess ANSYS FLUENT data with Tecplot, you can either export data from ANSYS FLUENT and import it into Tecplot, or use the Tecplot ANSYS FLUENT Data Loader included with your Tecplot distribution. The data loader reads native ANSYS FLUENT case and data files directly. If you are interested in this option, contact Tecplot, Inc. for assistance or visit www.tecplot.com.

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation* (p. 102) for the complete details.

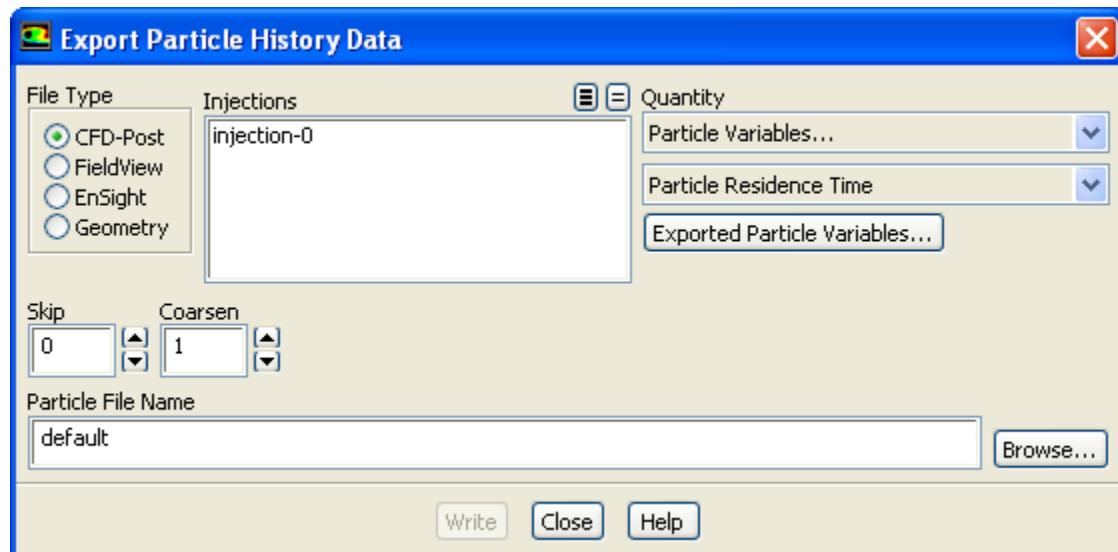

4.15. Exporting Steady-State Particle History Data

Particle history data can be exported for steady-state solutions or for single transient particle steps by selecting the **Particle History Data...** option under the **File/Export** menu and performing the steps

described in this section. For details about exporting particle history data automatically during transient simulations, see [Creating Automatic Export Definitions for Transient Particle History Data \(p. 106\)](#).

File → Export → Particle History Data...

Figure 4.6 The Export Particle History Data Dialog Box

1. Specify the **File Type** you want to export by selecting one of the following:
 - **CFD-Post** for the CFD-Post compatible format
 - **FieldView** for the FIELDVIEW format
 - **EnSight** for the EnSight format
 - **Geometry** for the .ibl format (not available when **Unsteady Particle Tracking** is enabled in the **Discrete Phase Model** dialog box)

Important

If you plan to export particle data to EnSight, you should first verify that you have already written the files associated with the EnSight Case Gold file type by using the **File/Export/Solution Data...** menu option (see [EnSight Case Gold Files \(p. 94\)](#)).

Select the predefined injections that are the source of the particles from the **Injections** selection list. See [Creating and Modifying Injections \(p. 1112\)](#) for details about creating injections.

2. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box ([Figure 25.40 \(p. 1160\)](#)), as described in [Reporting of Current Positions for Unsteady Tracking \(p. 1161\)](#).
3. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.
4. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.
5. To control the exported file size, the number of points of the particle trajectories can be reduced using the **Coarsen** value. This is only valid for steady-state particle trajectories.

6. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.
7. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Use the **Browse...** button to select the .encas file that was created when you exported the file with the **File/Export/Solution Data...** menu option. The selected file will be modified and renamed as a new file that contains information about all of the related particle files that are generated during the export process (including geometry, velocity, scalars, particle and particle scalar files).

The name of the new file will be the root of the original file with .new appended to it (e.g., if test.encas is selected, a file named test.new.encas will be written). It is this new file that should be read into EnSight. If you do not specify a **EnSight Encas File Name**, then you will need to create an appropriate .encas file manually.

8. If you selected **EnSight** under **File Type**, and you are exporting steady-state particle tracks, enter the **Number of Particle Time Steps**.
9. Click **Write** to export the particle history data. If you selected **EnSight** under **File Type**, data files will be written in both .mpg and .mscl formats.
10. Click **Close** to close the dialog box.

4.16. Exporting Data During a Transient Calculation

Before you run a transient flow solution, you can set up the case file so that solution data and particle history data is exported as the calculation progresses. This is accomplished by creating automatic export definitions using the *Calculation Activities Task Page* (p. 2093) (*Figure 4.7* (p. 103)), as described in the following sections.

Figure 4.7 The Calculation Activities Task Page

The names of the automatic export definitions you create are displayed in the **Automatic Export** selection list, along with the format in which it will be exported. You can edit or delete the definition by selecting a definition in the list and clicking the **Edit...** or **Delete** button.,

For additional information, please see the following sections:

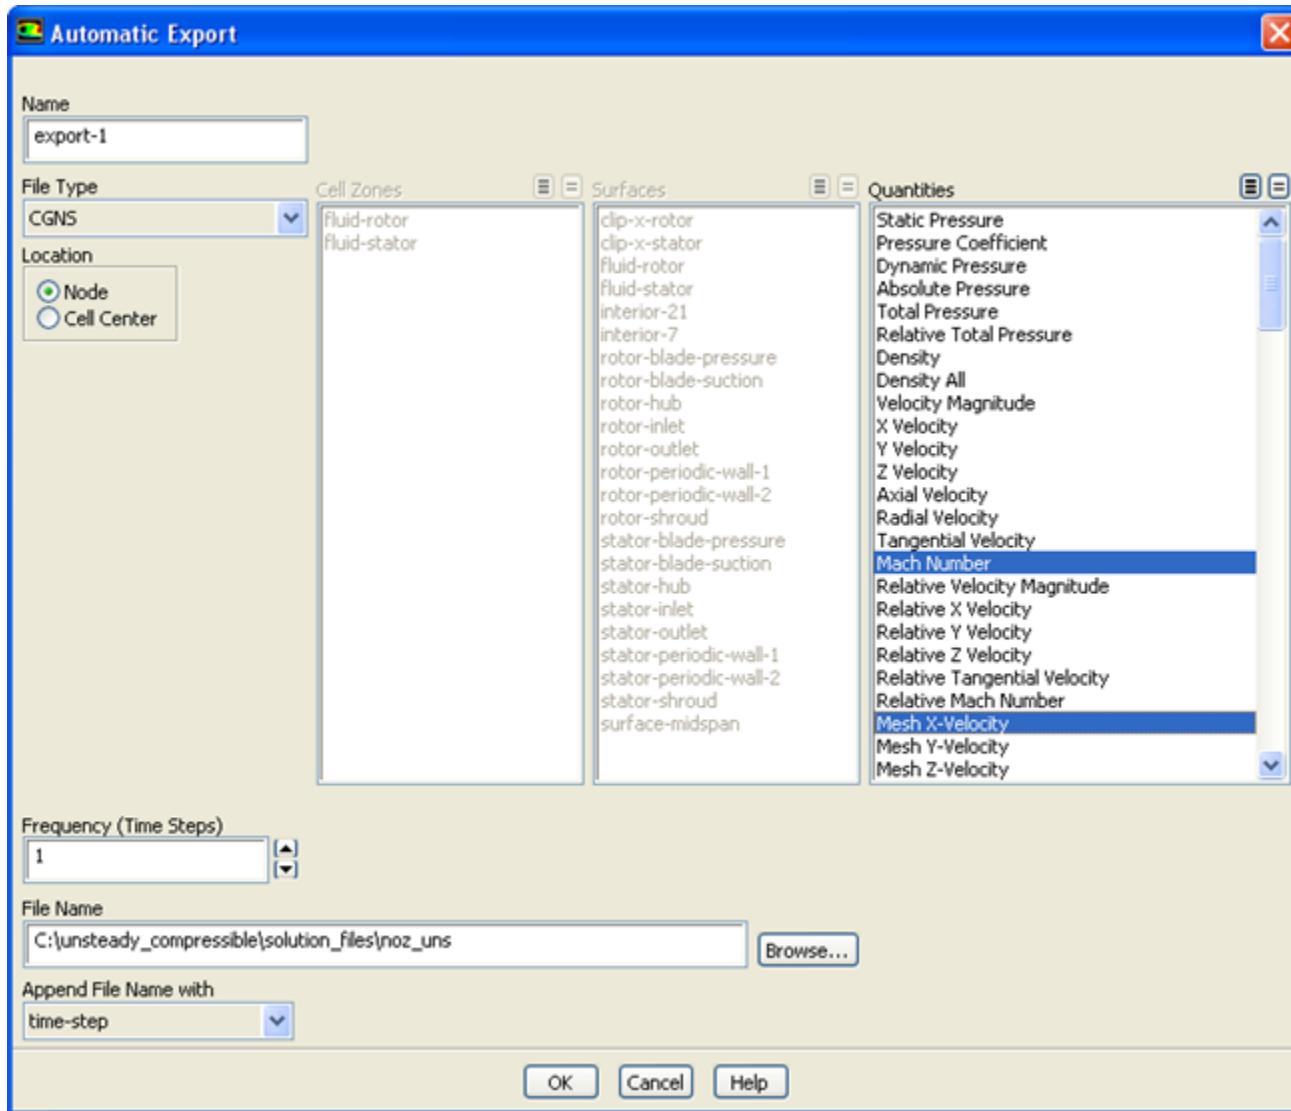

[4.16.1. Creating Automatic Export Definitions for Solution Data](#)

[4.16.2. Creating Automatic Export Definitions for Transient Particle History Data](#)

4.16.1. Creating Automatic Export Definitions for Solution Data

To create an automatic export definition for solution data, begin by making sure that **Transient** is selected for **Time** in the [General Task Page \(p. 1763\)](#). Next, click the **Create** button under the **Automatic Export** selection list in the **Calculation Activities** task page (a drop-down list will appear). Select **Solution Data Export...** from the drop-down list to open the **Automatic Export** dialog box ([Figure 4.8 \(p. 104\)](#)).

Figure 4.8 The Automatic Export Dialog Box

Then perform the following steps:

1. Enter a name for the automatic export definition in the **Name** text box. This is the name that will be displayed in the **Automatic Export** selection list in the **Calculation Activities** task page.
2. Define the data to be exported by making selections in the relevant group boxes and selection lists: **File Type**, **Cell Zones**, **Surfaces**, **Interior Zone Surfaces**, **Quantities**, **Analysis**, **Structural Loads**, **Thermal Loads**, **Location**, **Delimiter**, **Format**, and **Heat Transfer Coefficient**. See [ABAQUS Files \(p. 90\) – Tecplot Files \(p. 100\)](#) for details about the specific options available for the various file types.

3. Set the **Frequency** at which the solution data will be exported during the calculation. If you enter 10 in the **Frequency** text box, for example, a file will be written after every 10 time steps.
4. If you selected **EnSight Case Gold** from the **File Type** drop-down list, the **Separate Files for Each Time Step** option allows you to specify that separate files are written at the prescribed time steps. This option is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (e.g., from a network failure) before it is complete. If you choose to disable this option, all of the data for the .scl1 and .vel files will be combined into a single file for each.
5. If you selected **CFD-Post Compatible** from the **File Type** drop-down list, by default ANSYS FLUENT will save a case (.cas) file with every .cdat file (i.e., at the specified **Frequency**). You can change the criteria for when case files are saved by disabling the **Write Case File Every Time** option; then, ANSYS FLUENT will save case files according to the settings specified by the following text command:

```
file → transient-export → settings → cfd-post-compatible
```

By default, the cfd-post-compatible text command is set to save a case file only if ANSYS FLUENT detects that the mesh or case file has been modified.

Note that regardless of the settings, only a single .cst file will be written when exporting during a transient calculation.

For more information about the **CFD-Post Compatible** file type, go to [ANSYS CFD-Post-Compatible Files \(p. 92\)](#).

6. Specify how the exported files will be named. Every file saved will begin with the characters entered in the **File Name** text box (note that a file extension is not necessary). You can specify a folder path if you do not want it written in the current folder. The **File Name** can also be specified through the **Select File** dialog box, which is opened by clicking the **Browse...** button.

Next, make a selection in the **Append File Name with** drop-down list, to specify that the **File Name** be followed by either the time step or flow time at which it was saved. Note that this selection is not available when exporting to EnSight. When **EnSight Case Gold** is selected from the **File Type** drop-down list, the time step is always appended if the **Separate Files for Each Time Step** option is enabled; otherwise, no digits are appended.

When appending the file name with the flow time, you can specify the number of decimal places that will be used by making an entry in the **Decimal Places in File Name** text box. By default, six decimal places will be used.

7. Click **OK** to save the settings for the automatic export definition.

For details about general limitations for exporting solution data and the manner in which it is exported, see [Exporting Solution Data \(p. 86\)](#).

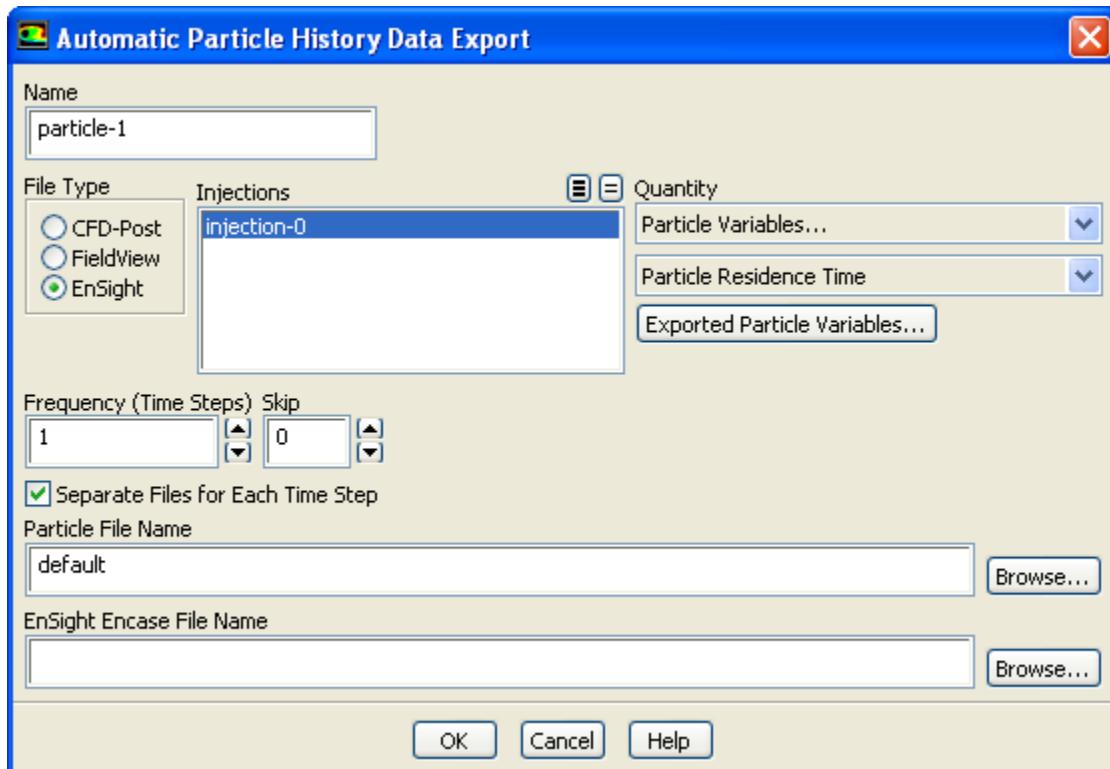

Important

- If the files that are exported during multiple transient simulations are to be used as a set, you should run all of the simulations on the same platform, using the same number of processors. This ensures that all of the files are compatible with each other.
- If you selected **EnSight Case Gold** from the **File Type** drop-down list, note the following:
 - Though it is possible for ANSYS FLUENT to export a file that is greater than 2 Gbytes, such a file could not be read using EnSight when it is run on 32-bit Windows, as this exceeds EnSight's maximum file size.
 - ANSYS FLUENT does not support exporting data files to EnSight during a transient calculation in which a new cell zone or surface is created after the calculation has begun (as can be the case for an in-cylinder simulation, for example).

4.16.2. Creating Automatic Export Definitions for Transient Particle History Data

To create an automatic export definition for particle history data, begin by making sure that **Unsteady Particle Tracking** is selected in the **Discrete Phase Model** dialog box. Next, click the **Create** button under the **Automatic Export** selection list in the **Calculation Activities** task page (a drop-down list will appear). Select **Particle History Data Export...** from the drop-down list to open the **Automatic Particle History Data Export** dialog box (*Figure 4.9 (p. 106)*).

Figure 4.9 The Automatic Particle History Data Export Dialog Box

Then perform the following steps:

1. Enter a name for the automatic export definition in the **Name** text box. This is the name that will be displayed in the **Automatic Export** selection list in the **Calculation Activities** task page. Make sure that the chosen name is not already used for another **Automatic Export**.
2. Choose the **File Type** you want to export by selecting one of the following:
 - **CFD-Post** for the CFD-Post compatible format
 - **FieldView** for the FIELDVIEW format
 - **EnSight** for the EnSight format

Important

If you plan to export particle data to EnSight, you should first set up an automatic export definition so that solution data is also exported to EnSight during this calculation (see [Creating Automatic Export Definitions for Solution Data \(p. 104\)](#)). As described in the steps that follow, some of the settings will need to correspond between the two automatic export definitions.

3. Select the predefined injections that are the source of the particles from the **Injections** selection list. See [Creating and Modifying Injections \(p. 1112\)](#) for details about creating injections.
4. Select the particle variables contained in the export file by clicking the **Exported Particle Variables...** button and selecting the variables appearing in the **Reporting Variables** dialog box ([Figure 25.40 \(p. 1160\)](#)), as described in [Reporting of Current Positions for Unsteady Tracking \(p. 1161\)](#).
5. If you have added the **Color by** variable in the **Reporting Variables** dialog box, select an appropriate category and variable under **Quantity** for the particle data to be exported.
6. Set the **Frequency** at which the particle history data will be exported during the calculation. If you enter 10 in the **Frequency** text box, for example, a file will be written after every 10 time steps for transient flow cases or 10 DPM Iterations for steady flow cases.
7. If your exported particle history file is too large to postprocess because there are too many tracks or particles written to the file, you can reduce the number of particle tracks by increasing the **Skip** value.
8. If you selected **EnSight Case Gold** for the **File Type**, the **Separate Files for Each Time Step** option allows you to specify that separate files are written at the prescribed time steps. This option is enabled by default and is the recommended practice, as it ensures that all of the data is not lost if there is a disruption to the calculation (e.g., from a network failure) before it is complete. If you choose to disable this option, all of the data for the **.msc1** and **.mpg** files will be combined into a single file for each.

Important

The setting for the **Separate Files for Each Time Step** option should be the same (i.e., enabled or disabled) as that of the automatic export definition you set up to export solution data to EnSight during this calculation. For details, see [Creating Automatic Export Definitions for Solution Data \(p. 104\)](#).

9. Enter the name (and folder path, if you do not want it to be written in the current folder) for the exported particle data file in the **Particle File Name** text box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button. Make sure the file name is different from other existing **Automatic Export** definitions to avoid overwriting data.

10. If you selected **EnSight** under **File Type**, you should specify the **EnSight Encas File Name**. Enter the same name (and folder path, if necessary) that you entered in the **File Name** text box when you set up the automatic export definition for exporting solution data to EnSight during this calculation. (For details, see [Creating Automatic Export Definitions for Solution Data \(p. 104\)](#)). The .encas file created during the solution data export will be modified and renamed as a new file that contains information about all of the related particle files that are generated after every time step during the export process (including geometry, velocity, scalars, particle and particle scalar files). The name of the new file will be the root of the original .encas file with .new appended to it (e.g., if the solution data export creates test.encas, a file named test.new.encas will be written for the particle data export). It is this new file that should be read into EnSight.

Important

If you do not specify an **EnSight Encas File Name**, you will have to manually create an appropriate .encas file.

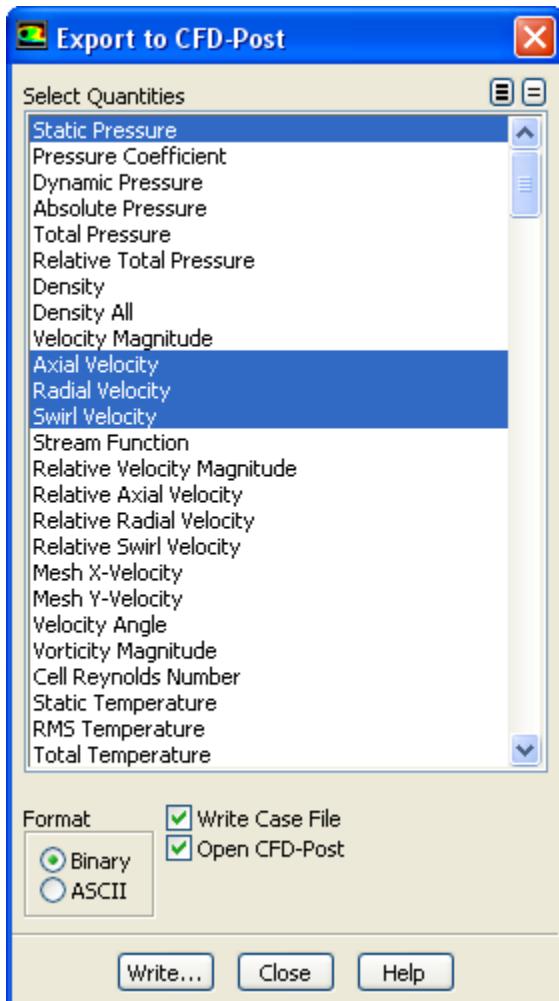

11. Click **OK** to save the settings for the automatic export definition.

The particle data will be exported as it is generated during the transient calculation. If you selected **EnSight** under **File Type**, data files will be written in both .mpg and .mscl formats.

4.17. Exporting to ANSYS CFD-Post

You can use the **Export to CFD Post** dialog box ([Figure 4.10 \(p. 109\)](#)) to export the results from all of the cell zones to files that are compatible with ANSYS CFD-Post.

File → Export to CFD-Post...

Figure 4.10 The Export to CFD-Post Dialog Box

Select the variables for which you want data saved from the **Select Quantities** selection list. When selecting the variables, be sure to include any variable that was used to create an isosurface or clipped surface (as described in [Isosurfaces \(p. 1489\)](#) and [Clipping Surfaces \(p. 1491\)](#), respectively); otherwise, the surface will not be created properly if you try to read the exported state file in CFD-Post.

Specify the format of the .cdat file by selecting either **Binary** or **ASCII** from the **Format** list. The advantage of the binary format is that it takes less time to load the exported data into ANSYS CFD-Post and requires less storage space. Note that the format for the .cst will always be ASCII.

By default, FLUENT will write a case file (i.e., .cas) along with the **CFD-Post Compatible** files. If you do not want such a case file for any reason (e.g., to improve I/O performance or save disc space), disable the **Write Case File** option. Disabling this option is only recommended if you are performing multiple export operations for a case file that is not changing.

By default, the **Open CFD-Post** option is enabled so that the following actions will occur after the files are exported:

1. A CFD-Post session opens automatically.
2. The case and .cdat files are loaded in CFD-Post.
3. CFD-Post displays the results.

If you disable the **Open CFD-Post** option, you can open CFD-Post manually and use the **Load Results** item in the **File** drop-down menu to load the results files. For more information about this feature in CFD-Post, see the separate ANSYS CFD-Post manual.

Click the **Write...** button to save the files, using the **Select File** dialog box. A **.cdat** file is written, containing the specified variable data for the specified cell zones and all of the boundary zones. A state file (i.e., **.cst**) is also written, which contains the following surfaces that you created in FLUENT for postprocessing: point surfaces, line surfaces, plane surfaces, isosurfaces, and clipped surfaces (see *Creating Surfaces for Displaying and Reporting Data (p. 1473)*).

Important

When you read the **.cdat** file into ANSYS CFD-Post, the application will attempt to read in the case file that produced the data by looking in the folder for a **.cas** file with the same prefix. If the case file is not in that folder (e.g., if you disabled the **Write Case File** option when exporting), ANSYS CFD-Post will prompt you to specify the appropriate case file.

Important

Before loading the **.cst** file into ANSYS CFD-Post, make sure that the **.cas** and **.cdat** files are already loaded for the session.

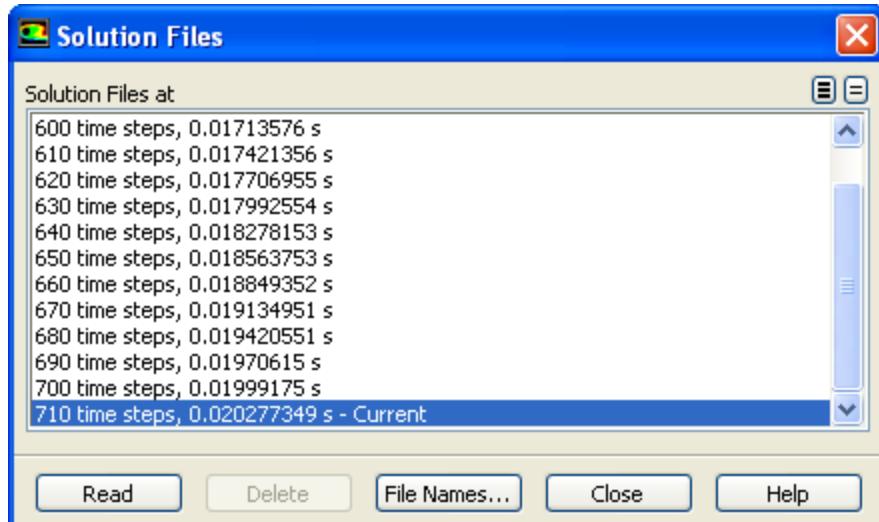

You have the option of exporting data at specified intervals during a transient calculation through the **Automatic Export** dialog box. See *Exporting Data During a Transient Calculation (p. 102)* for the complete details.

4.18. Managing Solution Files

You can manage your solution files effectively and efficiently using the **Solution Files** dialog box. Here, you can select previously saved files created using the **Autosave** dialog box and read or delete them.

File → **Solution Files...**

Figure 4.11 The Solution Files Dialog Box

The **Solution Files** dialog box (*Figure 4.11 (p. 110)*) lists all of the solution files that have been automatically saved. They are listed by iteration number or time step/flow time. For the file that is currently read in, the status of current will appear in the **Solution Files at** list. You can make any of the files in the list current by clicking the **Read** button. Note that if more than one file is selected, the **Read** button is disabled. When an earlier solution is made current, the solution files that were generated for a later iteration/time step will be removed from this list when the calculation continues.

You can delete solution files by selecting an entry in the list and clicking **Delete**. Note that a currently loaded solution file cannot be deleted, however multiple (non-current) files can be selected and deleted. If multiple files are selected and one of those files is a currently loaded solution file, clicking **Delete** will result in the current solution file being skipped.

You can click the **File Names...** button to obtain information about the solution files and the path of the associated files.

The **Solution Files** dialog box is particularly useful for reading in files that were saved during the autosave session, since case and data files may not necessarily have the same file name.

4.19. Mesh-to-Mesh Solution Interpolation

ANSYS FLUENT can interpolate solution data for a given geometry from one mesh to another, allowing you to compute a solution using one mesh (e.g., hexahedral) and then change to another mesh (e.g., hybrid) and continue the calculation using the first solution as a starting point.

Important

ANSYS FLUENT does zeroth-order interpolation for interpolating the solution data from one mesh to another.

For additional information, please see the following sections:

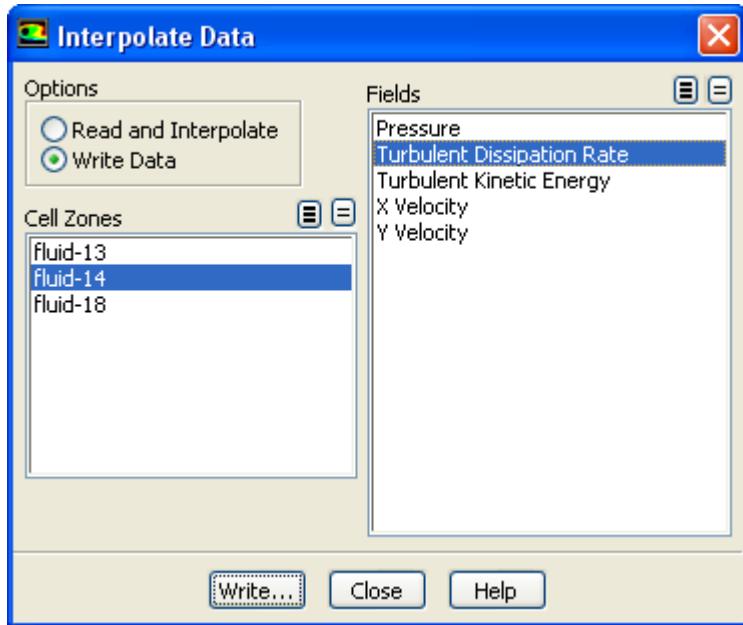

- [4.19.1. Performing Mesh-to-Mesh Solution Interpolation](#)
- [4.19.2. Format of the Interpolation File](#)

4.19.1. Performing Mesh-to-Mesh Solution Interpolation

The procedure for mesh-to-mesh solution interpolation is as follows:

1. Set up the model and calculate a solution on the initial mesh.
2. Write an interpolation file for the solution data to be interpolated onto the new mesh, using the **Interpolate Data** dialog box (*Figure 4.12 (p. 112)*).

File → Interpolate...

Figure 4.12 The Interpolate Data Dialog Box

- Under **Options**, select **Write Data**.
- In the **Cell Zones** selection list, select the cell zones for which you want to save data to be interpolated.

Note

If your case includes both fluid and solid zones, write the data for the fluid zones and the data for the solid zones to separate files.

- Select the variable(s) for which you want to interpolate data in the **Fields** selection list. All ANSYS FLUENT solution variables are available for interpolation.
 - Click **Write...** and specify the interpolation file name in the resulting **Select File** dialog box. The file format is described in *Format of the Interpolation File* (p. 113).
- Set up a new case.
 - Read in the new mesh, using the appropriate menu item in the **File/Read/** or **File/Import/** menu.
 - Define the appropriate models.

Important

Enable all of the models that were enabled in the original case. For example, if the energy equation was enabled in the original case and you forget to enable it in the new case, the temperature data in the interpolation file will not be interpolated.

- Define the boundary conditions, material properties, etc.

Important

An alternative way to set up the new case is to save the boundary conditions from the original model using the `write-settings` text command, and then read in those boundary conditions with the new mesh using the `read-settings` text command. See [Reading and Writing Boundary Conditions \(p. 74\)](#) for further details.

4. Read in the data to be interpolated.

File → Interpolate...

- a. Under **Options**, select **Read and Interpolate**.
- b. In the **Cell Zones** list, select the cell zones for which you want to read and interpolate data.
If the solution has not been initialized, computed, or read, all zones in the **Cell Zones** list are selected by default, to ensure that no zone remains without data after the interpolation. If all zones already have data (from initialization or a previously computed or read solution), select a subset of the **Cell Zones** to read and interpolate data onto a specific zone (or zones).
- c. Click the **Read...** button and specify the interpolation file name in the resulting **Select File** dialog box.

Important

If your case includes both fluid and solid zones, the two sets of data are saved to separate files. Hence perform these steps twice, once to interpolate the data for the fluid zones and once to interpolate the data for the solid zones.

5. Reduce the under-relaxation factors and calculate on the new mesh for a few iterations to avoid sudden changes due to any imbalance of fluxes after interpolation. Then increase the under-relaxation factors and compute a solution on the new mesh.

4.19.2. Format of the Interpolation File

An example of an interpolation file is shown below:

```
2
2
34800
3
x-velocity
pressure
y-velocity
-0.068062
-0.0680413
...
```

The format of the interpolation file is as follows:

- The first line is the interpolation file version. It is 1 for FLUENT 5 and 2 for FLUENT 6 and later releases.
- The second line is the dimension (2 or 3).
- The third line is the total number of points.
- The fourth line is the total number of fields (temperature, pressure, etc.) included.

- Starting at the fifth line is a list of field names. To see a complete list of the field names used by ANSYS FLUENT, enter the display/contour text command and view the available choices by pressing **Enter** at the contours of> prompt. The list depends on the models turned on.
- After the field names is a list of x , y , and (in 3D) z coordinates for all the data points.
- At the end is a list of the field values at all the points in the same order as their names. The number of coordinate and field points should match the number given in line 3.

4.20. Mapping Data for Fluid-Structure Interaction (FSI) Applications

ANSYS FLUENT allows you to map variables (e.g., temperature, pressure) from the cell or face zones of an ANSYS FLUENT simulation onto locations associated with a finite element analysis (FEA) mesh. The results are written to a file for inclusion into an FEA simulation. During this process, both the original and the new mesh can be viewed simultaneously. ANSYS FLUENT maps the data using zeroth-order interpolation, and can write the output file in a variety of formats.

This capability is useful when solving fluid-structure interaction (FSI) problems, and allows you to perform further analysis on the solid portion of your model using FEA software. Mapping the data may be preferable to simply exporting the ANSYS FLUENT data file (as described in [Exporting Solution Data \(p. 86\)](#)), since the meshes used in CFD analysis are typically finer than those used in finite element analysis.

For additional information, please see the following sections:

4.20.1. FEA File Formats

The FEA software types that are compatible with ANSYS FLUENT's FSI mapping capability include ABAQUS, I-deas, ANSYS, NASTRAN, and PATRAN. For details about the kinds of files that can be read or written during this process, see [Table 4.3: FEA File Extensions for FSI Mapping \(p. 114\)](#).

Table 4.3 FEA File Extensions for FSI Mapping

Type	Input File	Output File
ABAQUS	.inp	.inp
I-deas	.unv	.unv
ANSYS	.cdb, .neu	.cdb
NASTRAN	.bdf	.bdf
PATRAN	.neu, .out, .pat	.out

4.20.2. Using the FSI Mapping Dialog Boxes

To begin the process of mapping ANSYS FLUENT data, you must first create a mesh file that can be used as the input file in the steps that follow. The resolution of the mesh should be appropriate for your eventual finite element analysis. You are free to use the method and preprocessor of your choice in the creation of this file, but the end result must correspond to one of the entries in the Input File column of [Table 4.3: FEA File Extensions for FSI Mapping \(p. 114\)](#).

When creating the input file, note the following:

- While the input file may be scaled when it is read into ANSYS FLUENT, the volumes or surfaces on which the data is to be mapped must otherwise be spatially coincident with their counterparts in the ANSYS FLUENT simulation.
- The input file can be only a portion of the overall FEA model (i.e., you can exclude the parts of the model on which you are not mapping ANSYS FLUENT data). When this is the case, note that the numbering of the nodes and elements in the input file must match the numbering of the nodes and elements in the complete file you will use for your finite element analysis.

Next, read a case file in ANSYS FLUENT and make sure data is available for mapping, either by running the calculation or by reading a data file.

Finally, perform the following steps to generate an output file in which the ANSYS FLUENT data has been mapped to the mesh of the input file:

1. Open the ANSYS FLUENT dialog box that is appropriate for the zones from which the data is to be taken. If the data you are mapping is from a volume (e.g., the cell zone of a solid region), open the **Volume FSI Mapping** dialog box using the **File/FSI Mapping/Volume...** menu item (*Figure 4.13 (p. 115)*). If instead the data is from a surface (e.g., a face boundary zone), open the **Surface FSI Mapping** dialog box using the **File/FSI Mapping/Surface...** menu item (*Figure 4.14 (p. 116)*).

File → FSI Mapping → Volume...

or

File → FSI Mapping → Surface...

Figure 4.13 The Volume FSI Mapping Dialog Box for Cell Zone Data

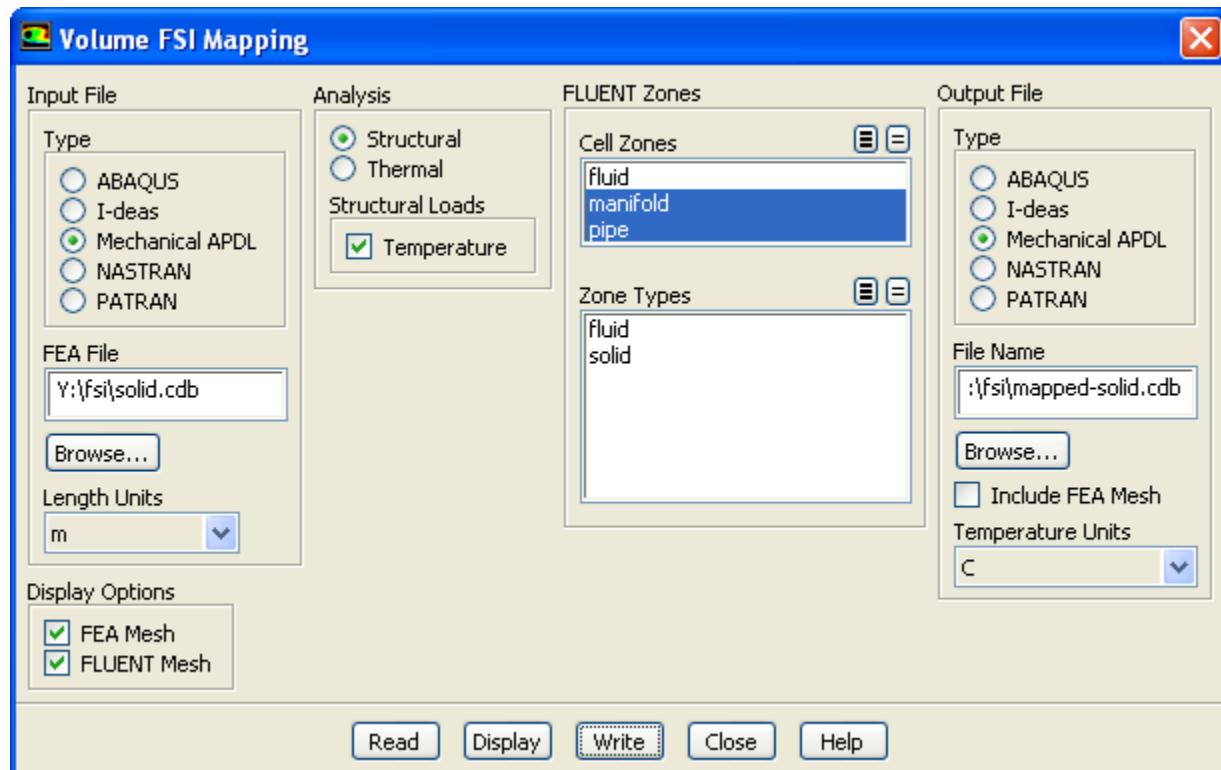

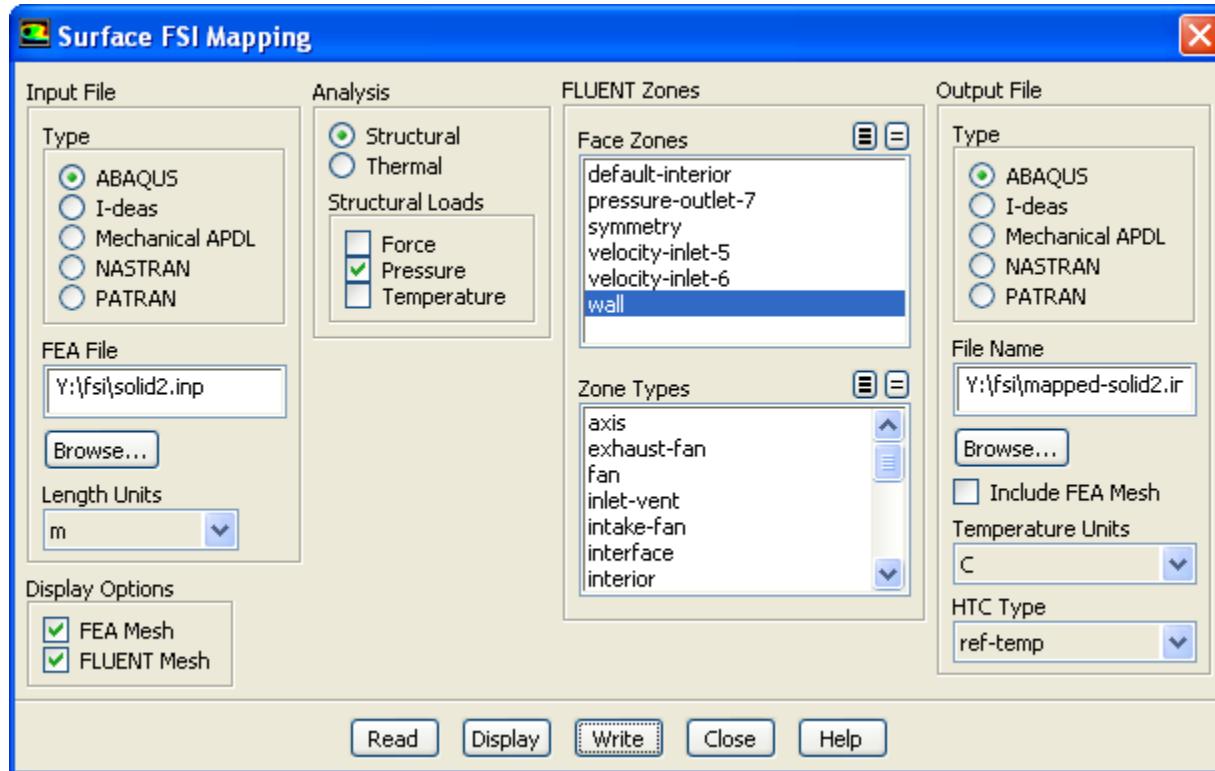

Figure 4.14 The Surface FSI Mapping Dialog Box for Face Zone Data

2. Specify the parameters of the input file and read it into ANSYS FLUENT.
 - a. Select the format of the input file from the **Type** list in the **Input File** group box, based on the FEA software with which it is associated. The choices include:
 - **ABAQUS**
 - **I-deas**
 - **Mechanical APDL**
 - **NASTRAN**
 - **PATRAN**
 For a list of the file extensions associated with these types, see the Input File column of *Table 4.3: FEA File Extensions for FSI Mapping* (p. 114).
 - b. Enter the name and extension (along with the folder path, if it is not in the current folder) of the input file in the **FEA File** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.
 - c. Specify the length units that were used in the creation of the input file by making a selection from the **Length Units** drop-down menu. This ensures that the input file is scaled appropriately relative to the ANSYS FLUENT file.
 - d. Click the **Read** button to read the input file into memory.

Important

Note that the input file will only be held in memory until the output file is written, or until the FSI mapping dialog box is closed.

3. Display the meshes so that you can visually verify that the input file is properly scaled and aligned with the ANSYS FLUENT mesh file.
 - a. Make sure that the **FEA Mesh** and **FLUENT Mesh** options are enabled in the **Display Options** group box. Note that you can disable either of these options if you want to examine one of the meshes independently.
 - b. Click the **Display** button to display the meshes in the graphics window.

Important

For the ANSYS FLUENT mesh, only the zones selected in the **FLUENT Zones** group box will be displayed—in this case, the default selections. If the default zones are not appropriate, you should redisplay the meshes after you make your zone selections in a later step.

4. Specify the type of data variables to be mapped.
 - a. Select either **Structural** or **Thermal** in the **Analysis** group box. Your selection should reflect the kind of further analysis you intend to pursue, and will determine what variables are available for mapping.
 - b. Enable the variables you want to map in the **Structural Loads** or **Thermal Loads** group box. When mapping volume data, you can enable only **Temperature**. When mapping surface data, you can enable **Force**, **Pressure**, and **Temperature** for structural analysis, or **Temperature**, **Heat Flux**, and **Heat Trans Coeff** for thermal analysis.

Important

Note that the **Energy Equation** must be enabled in the **Energy** dialog box if you want to map temperature for a structural analysis or any variable for a thermal analysis.

5. Select the zones that contain the data to be mapped in the **FLUENT Zones** group box. You can select individual zones in the **Cell Zones** or **Face Zones** selection lists, or select all zones of a particular type in the **Zone Type** selection list. If you modify the default selections, you should display the meshes again, as described previously.

Important

- Note that all wall zones in the **Face Zones** selection list are selected by default in the **Surface FSI Mapping** dialog box, and this includes the shadow walls created for two-sided walls. If your ANSYS FLUENT file contains a wall/shadow pair (e.g., separating a solid zone from a fluid zone), you should make sure that only the correct wall or shadow of the pair is selected.
- Inlet zones do not have heat transfer coefficient data, and so any attempts to map this combination will be ignored.

6. Specify the parameters of the output file and write it.
 - a. Select the format of the output file from the **Type** list in the **Output File** group box, based on the software with which you plan to perform your finite element analysis. The choices in this list

are the same as those for the input file type. Note that you can select an output file type that is different from the input file type.

For details about the file extensions associated with the various types of output files, see the Output File column of [Table 4.3: FEA File Extensions for FSI Mapping \(p. 114\)](#).

- b. Enter the name (with the folder path, if appropriate) of the output file in the **File Name** text-entry box. Alternatively, you can specify it through the **Select File** dialog box, which is opened by clicking the **Browse...** button.
- c. To include additional FEA information like node/element information in the exported output file, enable **Include FEA Mesh**. By default, this option is disabled and therefore, only the selected boundary condition values are exported.
- d. When mapping temperature for a structural analysis or any variable for a thermal analysis, make a selection in the **Temperature Units** drop-down menu. [Table 4.4: Units Associated with the Temperature Units Drop-Down List Selections \(p. 118\)](#) shows the units for the mapped variables, depending on the **Temperature Units** selection.

Table 4.4 Units Associated with the Temperature Units Drop-Down List Selections

Temperature Units Selection	Temperature	Heat Flux	Heat Transfer Coefficient
K	K	W/m ²	W/m ² -K
C	°C	W/m ²	W/m ² - °C
F	°F	BTU/ft ² -hr	BTU/ft ² -hr- °F

- e. When mapping the heat transfer coefficient for a thermal analysis, make a selection in the **HTC Type** drop-down menu to determine how the heat transfer coefficient h_{eff} is calculated.

ref-temp

calculates h_{eff} using [Equation 34-42 \(p. 1702\)](#), where T_{ref} is the reference temperature defined in the [Reference Values Task Page \(p. 2046\)](#). Note that this option has the same definition as the field variable **Surface Heat Transfer Coef.**, as described in [Alphabetical Listing of Field Variables and Their Definitions \(p. 1674\)](#).

cell-temp

calculates h_{eff} using the general form of [Equation 34-42 \(p. 1702\)](#), but defines T_{ref} as the temperature of the cell adjacent to the face.

wall-func-htc

calculates h_{eff} using [Equation 34-54 \(p. 1707\)](#). Note that this option has the same definition as the field variable **Wall Func. Heat Tran. Coef.**, as described in [Alphabetical Listing of Field Variables and Their Definitions \(p. 1674\)](#).

- f. Click **Write** to write an output file in which the ANSYS FLUENT data has been mapped to the mesh of the input file.

The input file will be released from memory when the output file is written.

4.21. Saving Picture Files

Graphic window displays can be saved in various formats (including TIFF and PostScript). There can be slight differences between pictures and the displayed graphics windows, since pictures are generated using the internal software renderer, while the graphics windows may utilize specialized graphics hardware for optimum performance.

Many systems provide a utility to “dump” the contents of a graphics window into a raster file. This is generally the fastest method of generating a picture (since the scene is already rendered in the graphics window), and guarantees that the picture is identical to the window.

For additional information, please see the following sections:

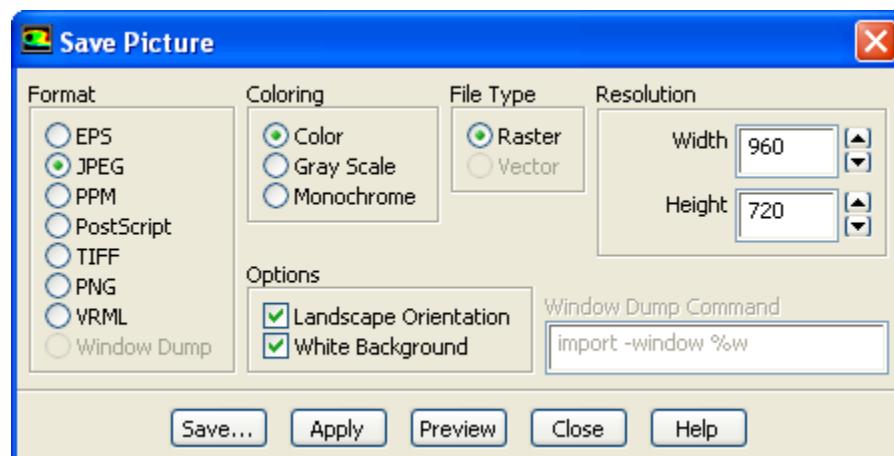

- 4.21.1. Using the Save Picture Dialog Box
- 4.21.2. Picture Options for PostScript Files

4.21.1. Using the Save Picture Dialog Box

To set picture parameters and save picture files, use the *Save Picture Dialog Box* (p. 2144) (*Figure 4.15* (p. 119)).

File → Save Picture...

Figure 4.15 The Save Picture Dialog Box

For your convenience, this dialog box may also be opened using the **Save Picture** button () in the standard toolbar.

The procedure for saving a picture file is as follows:

1. Choose the picture file **Format**.
2. Set the **Coloring**.
3. Specify the **File Type**, if applicable.
4. Define the **Resolution**, if applicable.
5. Set the appropriate **Options**.
6. If you are generating a window dump, specify the **Window Dump Command**.
7. (optional) Preview the result by clicking **Preview**.

8. Click the **Save...** button and enter the file name in the resulting **Select File** dialog box. See [Automatic Numbering of Files \(p. 63\)](#) for information on special features related to file name specification.

If you are not ready to save a picture but want to save the current picture settings, click the **Apply** button instead of the **Save...** button. The applied settings become the defaults for subsequent pictures.

4.21.1.1. Choosing the Picture File Format

To choose the picture file format, select one of the following items in the **Format** list:

EPS

(Encapsulated PostScript) output is the same as PostScript output, with the addition of Adobe Document Structuring Conventions (v2) statements. Currently, no preview bitmap is included in EPS output. Often, programs that import EPS files use the preview bitmap to display on-screen, although the actual vector PostScript information is used for printing (on a PostScript device). You can save EPS files in raster or vector format.

JPEG

is a common raster file format.

PPM

output is a common raster file format.

PostScript

is a common vector file format. You can also choose to save a PostScript file in raster format.

TIFF

is a common raster file format.

PNG

is a common raster file format.

VRML

is a graphics interchange format that allows export of 3D geometrical entities that you can display in the ANSYS FLUENT graphics window. This format can commonly be used by VR systems and the 3D geometry can be viewed and manipulated in a web-browser graphics window.

Important

Non-geometric entities such as text, titles, color bars, and orientation axis are not exported. In addition, most display or visibility characteristics set in ANSYS FLUENT, such as lighting, shading method, transparency, face and edge visibility, outer face culling, and hidden line removal, are not explicitly exported but are controlled by the software used to view the VRML file.

Window Dump

(Linux systems only) selects a window dump operation for generating the picture. With this format, you need to specify the appropriate **Window Dump Command**.

4.21.1.2. Specifying the Color Mode

For all formats except VRML and the window dump, specify the type of **Coloring** you want to use for the picture file.

- Select **Color** for a color-scale copy.
- Select **Gray Scale** for a gray-scale copy.

- Select **Monochrome** for a black-and-white copy.

Most monochrome PostScript devices render **Color** images in shades of gray, but to ensure that the color ramp is rendered as a linearly-increasing gray ramp, you should select **Gray Scale**.

4.21.1.3. Choosing the File Type

When you save an EPS (Encapsulated PostScript) or PostScript file, choose one of the following under **File Type**:

- A **Raster** file defines the color of each individual pixel in the image. Raster files have a fixed resolution. The supported raster formats are EPS, JPEG, PPM, PostScript, TIFF, and PNG.
- A **Vector** file defines the graphics image as a combination of geometric primitives like lines, polygons, and text. Vector files are usually scalable to any resolution. The supported vector formats include EPS, PostScript, and VRML.

Important

For the quickest print time, you can save vector files for simple 2D displays and raster files for complicated scenes.

4.21.1.4. Defining the Resolution

For raster picture files (i.e., JPEG, PPM, TIFF, and PNG), you can control the resolution of the picture image by specifying the size (in pixels). Set the desired **Width** and **Height** under **Resolution**. If the **Width** and **Height** are both zero, the picture is generated at the same resolution as the active graphics window. To check the size of the active window in pixels, click **Info** in the **Display Options** dialog box.

For EPS and PostScript files, specify the resolution in dots per inch (**DPI**) instead of setting the width and height.

4.21.1.5. Picture Options

For all picture formats except VRML and the window dump, you can control two additional settings under **Options**:

- Specify the orientation of the picture using the **Landscape Orientation** button. If this option is turned on, the picture is made in landscape mode; otherwise, it is made in portrait mode.
- Control the foreground/background color using the **White Background** option. If this option is enabled, the picture is saved with a white background, and (if you using the classic color scheme for the graphics window) the foreground color is changed to black.

4.21.2. Picture Options for PostScript Files

ANSYS FLUENT provides options that allow you to save PostScript files that can be printed more quickly. The following options are found in the display/set/picture/driver/post-format text menu:

fast-raster

enables a raster file that may be larger than the standard raster file, but will print much more quickly.

raster

enables the standard raster file.

rle-raster

enables a run-length encoded raster file that is about the same size as the standard raster file, but will print slightly more quickly. This is the default file type.

vector

enables the standard vector file.

4.21.2.1. Window Dumps (Linux Systems Only)

If you select the **Window Dump** format, the program uses the specified **Window Dump Command** to save the picture file. For example, if you want to use xwd to capture a window, set the **Window Dump Command** to

```
xwd -id %w >
```

When the dump occurs, ANSYS FLUENT automatically interprets %w to be the ID number of the active window.

When you click the **Save...** button, the **Select File** dialog box appears. Enter the file name for the output from the window dump (e.g., myfile.xwd).

If you are planning to make an animation, save the window dumps into numbered files, using the %n variable. To do this, use the **Window Dump Command** (xwd -id %w), but for the file name in the **Select File** dialog box enter myfile%n.xwd. Each time a new window dump is created, the value of %n increases by one. So there is no need to tack numbers onto the picture file names manually.

To use the **ImageMagick** animate program, saving the files in MIFF format (the native **ImageMagick** format) is more efficient. In such cases, use the **ImageMagick** tool **import**. Set the default **Window Dump Command** enter

```
import -window %w
```

Click **Save...** to invoke the **Select File** dialog box. Specify the output format to be MIFF by using the .miff suffix at the end of file name.

The window dump feature is both, system and graphics-driver specific. Thus the commands available for dumping windows depends on the particular configuration.

The window dump captures the window exactly as it is displayed, including resolution, colors, transparency, etc. For this reason, all of the inputs that control these characteristics are disabled in the **Save Picture** dialog box when you enable the **Window Dump** format. If you are using an 8-bit graphics display, use one of the built-in raster drivers (e.g., TIFF) to generate higher-quality 24-bit color output rather than dumping the 8-bit window.

4.21.2.2. Previewing the Picture Image

Before saving a picture file, you have the option of previewing what the saved image will look like. Click **Preview** to open a new window that will display the graphics using the current settings. This allows you to investigate the effects of different options interactively before saving the final, approved picture.

4.22. Setting Data File Quantities

By default, the information saved in a data file includes a standard set of quantities that were computed during the calculation. These quantities are specifically suitable for postprocessing and restarting solutions in ANSYS FLUENT. If, however, you plan to postprocess the data file in an application other than ANSYS

FLUENT (such as ANSYS CFD-Post) you may want to include additional quantities that are derived from the standard quantities.

Note that some standard quantities are also listed as additional quantities. If using ANSYS CFD-Post, where a standard quantity has a corresponding entry in the additional quantity list, the latter should be selected. This is because ANSYS CFD-Post requires that some standard quantities be derived into a specific form.

Note

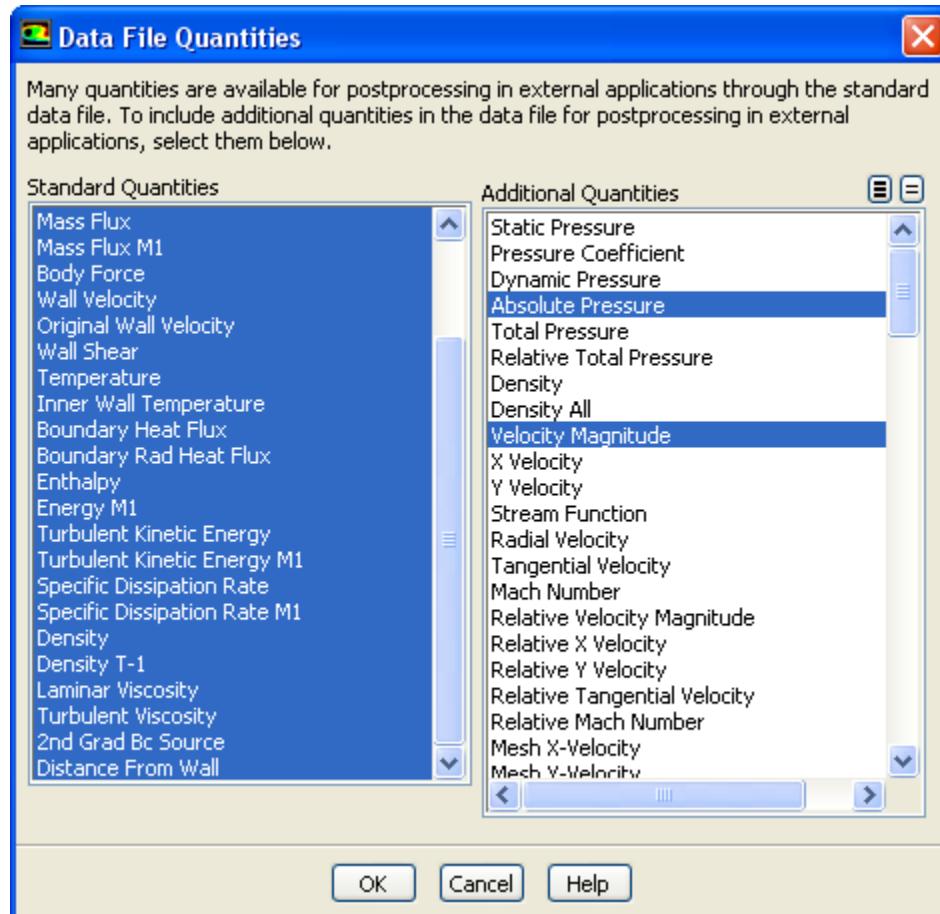

Not all standard quantities will be available in CFD-Post for post processing. An example of such a quantity is the Mach number.

The procedure for generating a data file with additional quantities is as follows:

1. Set up the case file for your simulation.
2. Initialize the solution using the *Solution Initialization Task Page* (p. 2088).
3. Specify the quantities to be written in the data file, using the **Data File Quantities** dialog box (*Figure 4.16* (p. 123)).

File → Data File Quantities...

Figure 4.16 The Data File Quantities Dialog Box

- a. View the **Standard Quantities** list to see what will be saved in the data file by default. Note that you cannot deselect any of the **Standard Quantities**.
 - b. Select the additional quantities you want saved from the **Additional Quantities** selection list.
 - c. Click **OK**.
4. Save the case file. Note that the data file quantities you specified in the previous step will be saved as part of the case file.
 5. Run the calculation and save the data file. This can be done as separate steps, or as one step if you have enabled the automatic saving of data files via the [Calculation Activities Task Page \(p. 2093\)](#).

The **Data File Quantities** dialog box can also be opened by clicking the **Data File Quantities...** button in the **Autosave Case/Data** dialog box.

4.23. The .fluent File

When starting up, ANSYS FLUENT looks in your home folder for an optional file called `.fluent`. If it finds the file, it loads it with the Scheme `load` function. This file can contain Scheme functions that customize the code's operation.

The `.fluent` file can also contain TUI commands that are executed via the Scheme function `ti-menu-load-string`. For example, if the `.fluent` file contains

```
(ti-menu-load-string "file read-case test.cas")
```

then ANSYS FLUENT will read in the case file `test.cas`. For more details about the function `ti-menu-load-string`, see [Text Menu Input from Character Strings \(p. 55\)](#).

Chapter 5: Unit Systems

This chapter describes the units used in ANSYS FLUENT and how you can control them. Information is organized into the following sections:

- [5.1. Restrictions on Units](#)
- [5.2. Units in Mesh Files](#)
- [5.3. Built-In Unit Systems in ANSYS FLUENT](#)
- [5.4. Customizing Units](#)

ANSYS FLUENT enables you to work in any unit system, including inconsistent units. Thus, for example, you may work in British units with heat input in Watts or you may work in SI units with length defined in inches. This is accomplished by providing ANSYS FLUENT with a correct set of conversion factors between the units you want to use and the standard SI unit system that is used internally by the solver. ANSYS FLUENT uses these conversion factors for input and output, internally storing all parameters and performing all calculations in SI units. Both solvers always prompt you for the units required for all dimensional inputs.

Units can be altered part-way through a problem setup and/or after you have completed your calculation. If you have input some parameters in SI units and then you switch to British, all of your previous inputs (and the default prompts) are converted to the new unit system. If you have completed a simulation in SI units but you would like to report the results in any other units, you can alter the unit system and ANSYS FLUENT will convert all of the problem data to the new unit system when results are displayed. As noted above, all problem inputs and results are stored in SI units internally. This means that the parameters stored in the case and data files are in SI units. ANSYS FLUENT simply converts these values to your unit system at the interface level.

5.1. Restrictions on Units

It is important to note that the units for some inputs in ANSYS FLUENT are different from the units used for the rest of the problem setup.

- You must always define the following in SI units, regardless of the unit system you are using:
 - Boundary profiles (see [Profiles \(p. 382\)](#))
 - Source terms (see [Defining Mass, Momentum, Energy, and Other Sources \(p. 257\)](#))
 - Custom field functions (see [Custom Field Functions \(p. 1708\)](#))
 - Data in externally-created XY plot files (see [XY Plots of File Data \(p. 1593\)](#))
 - User-defined functions (See the [UDF Manual](#) for details about user-defined functions.)
- If you define a material property by specifying a temperature-dependent polynomial or piecewise-polynomial function, remember that temperature in the function is always in units of Kelvin or Rankine. If you are using Celsius or Kelvin as your temperature unit, then polynomial coefficient values must be entered in terms of Kelvin; if you are using Fahrenheit or Rankine as the temperature unit, values must be entered in terms of Rankine. See [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#) for information about temperature-dependent material properties.

5.2. Units in Mesh Files

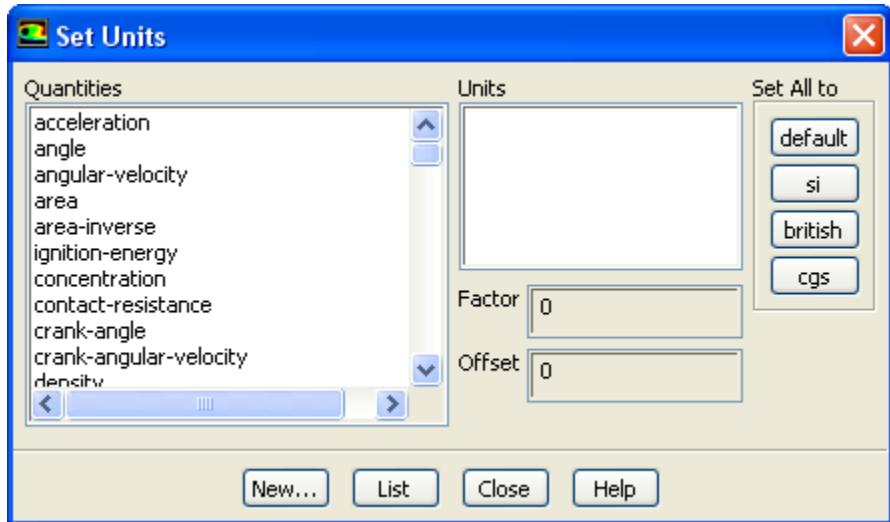

Some mesh generators allow you to define a set of units for the mesh dimensions. However, when you read the mesh into ANSYS FLUENT, it is always assumed that the unit of length is meters. If this is not true, you will need to scale the mesh, as described in [Scaling the Mesh \(p. 205\)](#).

5.3. Built-In Unit Systems in ANSYS FLUENT

ANSYS FLUENT provides four built-in unit systems: British, SI, CGS, and "default", all of which can be selected in the **Set Units** dialog box ([Figure 5.1 \(p. 126\)](#)), using the buttons under the **Set All to** heading. To display the **Set Units** dialog box, select **General** in the navigation pane and click **Units...** in the task page.

Figure 5.1 The Set Units Dialog Box

To choose the English Engineering standard for all units, click the **british** button; to select the International System of units (SI) standard for all units, click the **si** button; to choose the CGS (centimeter-gram-second) standard for all units, click the **cgs** button; and to return to the "default" system, click the **default** button. The default system of units is similar to the SI system, but uses degrees instead of radians for angles. Clicking on one of the buttons under **Set All to** will immediately change the unit system. You can then close the dialog box if you are not interested in customizing any units.

Changing the unit system in the **Set Units** dialog box causes all future inputs that have units to be based on the newly selected unit system.

5.4. Customizing Units

If you would like a mixed unit system, or any unit system different from the four supplied by ANSYS FLUENT (and described in [Built-In Unit Systems in ANSYS FLUENT \(p. 126\)](#)), you can use the **Set Units** dialog box ([Figure 5.1 \(p. 126\)](#)) to select an available unit or specify your own unit name and conversion factor for each quantity.

For additional information, see the following sections:

5.4.1. Listing Current Units

5.4.2. Changing the Units for a Quantity

5.4.3. Defining a New Unit

5.4.1. Listing Current Units

Before customizing units for one or more quantities, you may want to list the current units. You can do this by clicking the **List** button at the bottom of the **Set Units** dialog box. ANSYS FLUENT will print out a list (in the text window) containing all quantities and their current units, conversion factors, and offsets.

5.4.2. Changing the Units for a Quantity

ANSYS FLUENT will allow you to modify the units for individual quantities. This is useful for problems in which you want to use one of the built-in unit systems, but you want to change the units for one quantity (or for a few). For example, you may want to use SI units for your problem, but the dimensions of the geometry are given in inches. You can select the SI unit system, and then change the unit of length from meters to inches.

To change the units for a particular quantity, you will follow these two steps:

1. Select the quantity in the **Quantities** list (they are arranged in alphabetical order).
2. Choose a new unit from those that are available in the **Units** list.

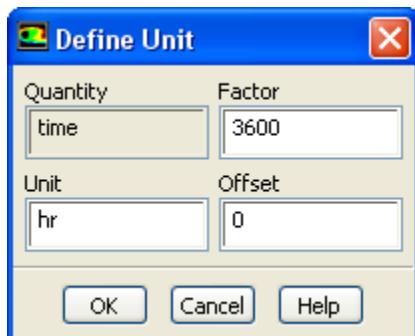

For the example cited above, you would choose **length** in the **Quantities** list, and then select **in** in the **Units** list. The **Factor** will automatically be updated to show 0.0254 meters/inch. (See [Figure 5.1 \(p. 126\)](#).) If there was a non-zero offset for the new unit, the **Offset** field would also be updated. For example, if you were using SI units but wanted to define temperature in Celsius instead of Kelvin, you would select **temperature** in the **Quantities** list and **c** in the **Units** list. The **Factor** would change to 1, and the **Offset** would change to 273.15. Once you have selected the quantity and the new unit, no further action is needed, unless you want to change the units for another quantity by following the same procedure.

5.4.3. Defining a New Unit

To create a new unit to be used for a particular quantity, you will follow the procedure below:

1. In the **Set Units** dialog box, select the quantity in the **Quantities** list.
2. Click the **New...** button and the **Define Unit** dialog box ([Figure 5.2 \(p. 127\)](#)) will open. In this dialog box, the selected quantity will be shown in the **Quantity** field.

Figure 5.2 The Define Unit Dialog Box

3. Enter the name of your new unit in the **Unit** field, the conversion factor in the **Factor** field, and the offset in the **Offset** field.
4. Click **OK** in the **Define Unit** dialog box, and the new unit will appear in the **Set Units** dialog box.

For example, if you want to use hours as the unit of time, select **time** in the **Quantities** list in the **Set Units** dialog box and click the **New...** button. In the resulting **Define Unit** dialog box, enter **hr** for the **Unit** and 3600 for the **Factor**, as in *Figure 5.2* (p. 127). Then click **OK**. The new unit **hr** will appear in the **Units** list in the **Set Units** dialog box, and it will be selected.

5.4.3.1. Determining the Conversion Factor

The conversion factor you specify (**Factor** in the **Define Unit** dialog box) tells ANSYS FLUENT the number to multiply by to obtain the SI unit value from your customized unit value. Thus the conversion factor should have the form SI units/custom units. For example, if you want the unit of length to be inches, you should input a conversion factor of 0.0254 meters/inch. If you want the unit of velocity to be feet/min, you can determine the conversion factor by using the following equation:

$$x \frac{\text{ft}}{\text{min}} \times \frac{0.3048\text{m}}{\text{ft}} \times \frac{\text{min}}{60\text{s}} = y \frac{\text{m}}{\text{s}} \quad (5-1)$$

You should input a conversion factor of 0.0051, which is equal to 0.3048/60.

Chapter 6: Reading and Manipulating Meshes

ANSYS FLUENT can import different types of meshes from various sources. You can modify the mesh by translating or scaling node coordinates, partitioning the domain for parallel processing, reordering the cells in the domain to decrease bandwidth, and merging or separating zones. You can convert all 3D meshes to polyhedral cells, except for pure hex meshes. Hexahedral cells are preserved during conversion. You can also obtain diagnostic information on the mesh, including memory usage and simplex, topological, and domain information. You can find out the number of nodes, faces, and cells in the mesh, determine the minimum and maximum cell volumes in the domain, and check for the proper numbers of nodes and faces per cell. These and other capabilities are described in the following sections.

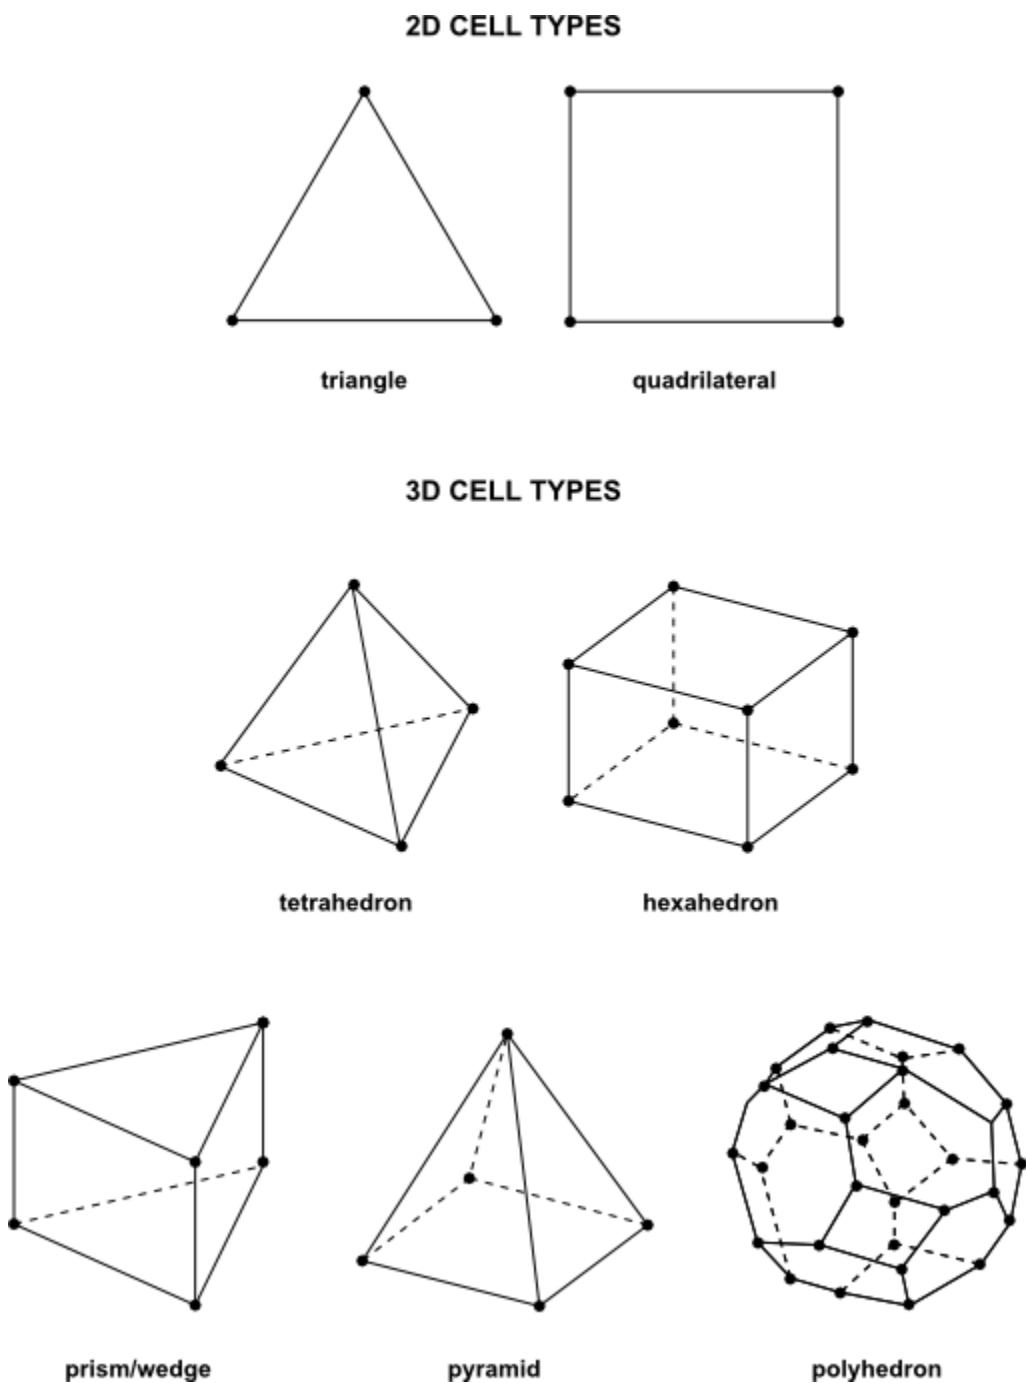

- 6.1. Mesh Topologies
- 6.2. Mesh Requirements and Considerations
- 6.3. Mesh Import
- 6.4. Non-Conformal Meshes
- 6.5. Checking the Mesh
- 6.6. Reporting Mesh Statistics
- 6.7. Converting the Mesh to a Polyhedral Mesh
- 6.8. Modifying the Mesh

See [Adapting the Mesh](#) (p. 1441) for information about adapting the mesh based on solution data and related functions, and [Mesh Partitioning and Load Balancing](#) (p. 1733) for details on partitioning the mesh for parallel processing.

6.1. Mesh Topologies

As an unstructured solver, ANSYS FLUENT uses internal data structures to assign an order to the cells, faces, and grid points in a mesh and to maintain contact between adjacent cells. Therefore, it does not require i,j,k indexing to locate neighboring cells. This gives you the flexibility to use the best mesh topology for your problem, as the solver does not force an overall structure or topology on the mesh.

For 2D meshes, quadrilateral and triangular cells are accepted, and for 3D meshes, hexahedral, tetrahedral, pyramid, wedge, and polyhedral cells can be used. [Figure 6.1](#) (p. 130) depicts each of these cell types. Both single-block and multi-block structured meshes, as well as hybrid meshes containing quadrilateral and triangular cells or hexahedral, tetrahedral, pyramid, and wedge cells are acceptable. ANSYS FLUENT also accepts meshes with hanging nodes (i.e., nodes on edges and faces that are not vertices of all the cells sharing those edges or faces) and hanging edges (i.e., edges on faces that do not act as edges for both of the cells sharing those faces), although you may need to remove the hanging nodes / edges from interior walls. See [Hanging Node Adaption](#) in the [Theory Guide](#) for information about acceptable hanging nodes, and [Using the tpo1y Filter to Remove Hanging Nodes / Edges](#) (p. 156) and [Converting Cells with Hanging Nodes / Edges to Polyhedra](#) (p. 185) for details on removing hanging nodes / edges. Meshes with non-conformal boundaries (i.e., meshes with multiple subdomains in which the mesh node locations at the internal subdomain boundaries are not identical) are also acceptable. For details, see [Non-Conformal Meshes](#) (p. 162).

Figure 6.1 Cell Types

Some examples of meshes that are valid for ANSYS FLUENT are presented in *Examples of Acceptable Mesh Topologies* (p. 130). Different cell shapes and their face-node connectivity are explained in *Face-Node Connectivity in ANSYS FLUENT* (p. 135). *Choosing the Appropriate Mesh Type* (p. 142) explains how to choose the mesh type that is best suited for your problem.

6.1.1. Examples of Acceptable Mesh Topologies

ANSYS FLUENT can solve problems on a wide variety of meshes. *Figure 6.2* (p. 131)-*Figure 6.13* (p. 135) show examples of meshes that are valid for ANSYS FLUENT.

O-type meshes, meshes with zero-thickness walls, C-type meshes, conformal block-structured meshes, multiblock structured meshes, non-conformal meshes, and unstructured triangular, tetrahedral, quadrilateral, hexahedral, and polyhedral meshes are all acceptable.

Note

Though ANSYS FLUENT does not require a cyclic branch cut in an O-type mesh, it will accept a mesh that contains one.

6.1.2. Face-Node Connectivity in ANSYS FLUENT

This section contains information about the connectivity of faces and their related nodes in terms of node number and face number.

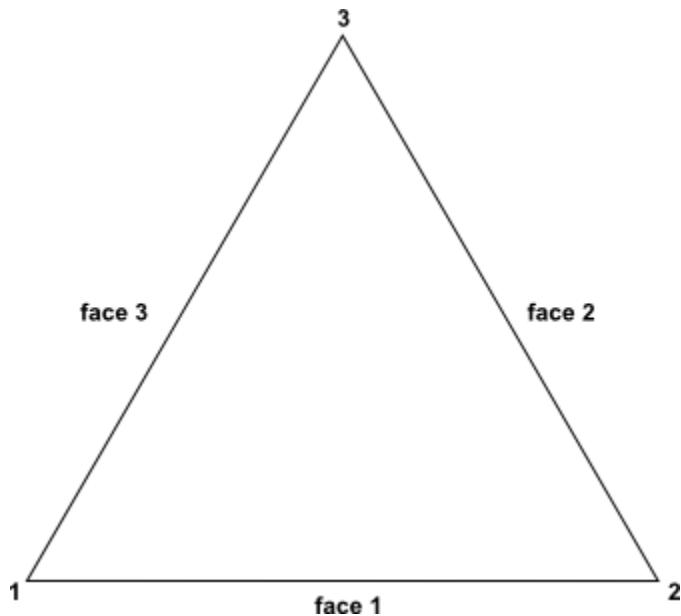

Face-node connectivity for the following cell shapes is explained here:

- triangular ([Figure 6.14 \(p. 136\)](#))
- quadrilateral ([Figure 6.15 \(p. 137\)](#))
- tetrahedral ([Figure 6.16 \(p. 138\)](#))
- wedge ([Figure 6.17 \(p. 139\)](#))
- pyramidal ([Figure 6.18 \(p. 140\)](#))
- hex ([Figure 6.19 \(p. 141\)](#))
- polyhedral ([Figure 6.20 \(p. 142\)](#))

This information is useful in interfacing with ANSYS FLUENT.

6.1.2.1. Face-Node Connectivity for Triangular Cells

6.1.2.7. Face-Node Connectivity for Polyhedral Cells

Figure 6.20 An Example of a Polyhedral Cell

For polyhedral cells, there is no explicit face and node numbering as with the other cell types.

6.1.3. Choosing the Appropriate Mesh Type

ANSYS FLUENT can use meshes comprised of triangular or quadrilateral cells (or a combination of the two) in 2D, and tetrahedral, hexahedral, polyhedral, pyramid, or wedge cells (or a combination of these) in 3D. The choice of which mesh type to use will depend on your application. When choosing mesh type, consider the following issues:

- setup time
- computational expense
- numerical diffusion

6.1.3.1. Setup Time

Many flow problems solved in engineering practice involve complex geometries. The creation of structured or block-structured meshes (consisting of quadrilateral or hexahedral elements) for such problems can be extremely time-consuming if not impossible. Therefore, setup time for complex geometries is the major motivation for using unstructured meshes employing triangular or tetrahedral cells. However, if your geometry is relatively simple, there may be no saving in setup time with either approach.

Other risks of using structured or block-structured meshes with complicated geometries include the oversimplification of the geometry, mesh quality issues, and a less efficient mesh distribution (e.g., fine resolution in areas of less importance) that results in a high cell count.

If you already have a mesh created for a structured code, it will save you time to use this mesh in ANSYS FLUENT rather than regenerate it. This can be a motivation for using quadrilateral or hexahedral cells in your ANSYS FLUENT simulation.

Note

ANSYS FLUENT has a range of filters that allow you to import structured meshes from other codes, including FLUENT 4. For details, see *Mesh Import* (p. 149).

6.1.3.2. Computational Expense

When geometries are complex or the range of length scales of the flow is large, a triangular/tetrahedral mesh can be created with far fewer cells than the equivalent mesh consisting of quadrilateral/hexahedral elements. This is because a triangular/tetrahedral mesh allows clustering of cells in selected regions of the flow domain. Structured quadrilateral/hexahedral meshes will generally force cells to be placed in regions where they are not needed. Unstructured quadrilateral/hexahedral meshes offer many of the advantages of triangular/tetrahedral meshes for moderately-complex geometries.

A characteristic of quadrilateral/hexahedral elements that might make them more economical in some situations is that they permit a much larger aspect ratio than triangular/tetrahedral cells. A large aspect ratio in a triangular/tetrahedral cell will invariably affect the skewness of the cell, which is undesirable as it may impede accuracy and convergence. Therefore, if you have a relatively simple geometry in which the flow conforms well to the shape of the geometry, such as a long thin duct, use a mesh of high-aspect-ratio quadrilateral/hexahedral cells. The mesh is likely to have far fewer cells than if you use triangular/tetrahedral cells.

Converting the entire domain of your (tetrahedral) mesh to a polyhedral mesh will result in a lower cell count than your original mesh. Although the result is a coarser mesh, convergence will generally be faster, possibly saving you some computational expense.

In summary, the following practices are generally recommended:

- For simple geometries, use quadrilateral/hexahedral meshes.
- For moderately complex geometries, use unstructured quadrilateral/hexahedral meshes.
- For relatively complex geometries, use triangular/tetrahedral meshes with prism layers.
- For extremely complex geometries, use pure triangular/tetrahedral meshes.

6.1.3.3. Numerical Diffusion

A dominant source of error in multidimensional situations is numerical diffusion (false diffusion). The term *false diffusion* is used because the diffusion is not a real phenomenon, yet its effect on a flow calculation is analogous to that of increasing the real diffusion coefficient.

The following comments can be made about numerical diffusion:

- Numerical diffusion is most noticeable when the real diffusion is small, that is, when the situation is convection-dominated.

- All practical numerical schemes for solving fluid flow contain a finite amount of numerical diffusion. This is because numerical diffusion arises from truncation errors that are a consequence of representing the fluid flow equations in discrete form.
- The second-order and the MUSCL discretization scheme used in ANSYS FLUENT can help reduce the effects of numerical diffusion on the solution.
- The amount of numerical diffusion is inversely related to the resolution of the mesh. Therefore, one way of dealing with numerical diffusion is to refine the mesh.
- Numerical diffusion is minimized when the flow is aligned with the mesh.

This is the most relevant to the choice of the mesh. If you use a triangular/tetrahedral mesh, the flow can *never* be aligned with the mesh. If you use a quadrilateral/hexahedral mesh, this situation might occur, but *not for complex flows*. It is only in a *simple* flow, such as the flow through a long duct, in which you can rely on a quadrilateral/hexahedral mesh to minimize numerical diffusion. In such situations, it is advantageous to use a quadrilateral/hexahedral mesh, since you will be able to get a better solution with fewer cells than if you were using a triangular/tetrahedral mesh.

- If you would like higher resolution for a gradient that is perpendicular to a wall, you can create prism layers with higher aspect ratios near the wall.

6.2. Mesh Requirements and Considerations

This section contains information about special geometry/mesh requirements and general comments on mesh quality.

6.2.1. Geometry/Mesh Requirements

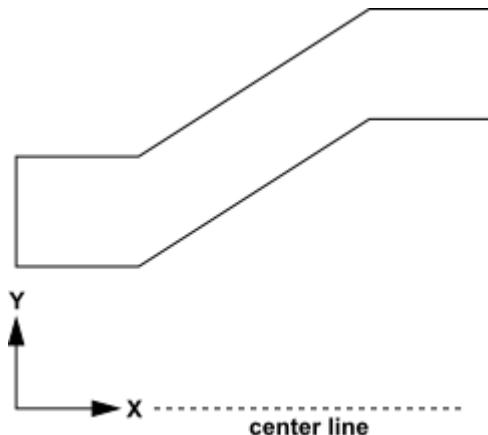

6.2.2. Mesh Quality

6.2.1. Geometry/Mesh Requirements

You should be aware of the following geometry setup and mesh construction requirements at the beginning of your problem setup:

- Axisymmetric geometries must be defined such that the axis of rotation is the x axis of the Cartesian coordinates used to define the geometry ([Figure 6.21 \(p. 144\)](#)).

Figure 6.21 Setup of Axisymmetric Geometries with the x Axis as the Centerline

- ANSYS FLUENT allows you to set up periodic boundaries using either conformal or non-conformal periodic zones. For conformal periodic boundaries, the periodic zones must have identical meshes.

The conformal periodic boundaries can be created in GAMBIT or TGrid when you are generating the volume mesh. See the GAMBIT Modeling Guide or the TGrid User's Guide for more information about creating periodic boundaries in GAMBIT or TGrid. Alternatively, you can create the conformal periodic boundaries in ANSYS FLUENT using the `mesh/modify-zones/make-periodic` text command. For details, see [Creating Conformal Periodic Zones \(p. 195\)](#).

Although GAMBIT and TGrid can produce true periodic boundaries, most CAD packages do not. If your mesh was created in such a package, set up a non-conformal interface with the periodic boundary condition option enabled in ANSYS FLUENT. For details, see [Creating Conformal Periodic Zones \(p. 195\)](#).

6.2.2. Mesh Quality

The quality of the mesh plays a significant role in the accuracy and stability of the numerical computation. Regardless of the type of mesh used in your domain, checking the quality of your mesh is essential. One important indicator of mesh quality that ANSYS FLUENT allows you to check is a quantity referred to as the orthogonal quality. In order to determine the orthogonal quality of a given cell, the following quantities are calculated for each face i :

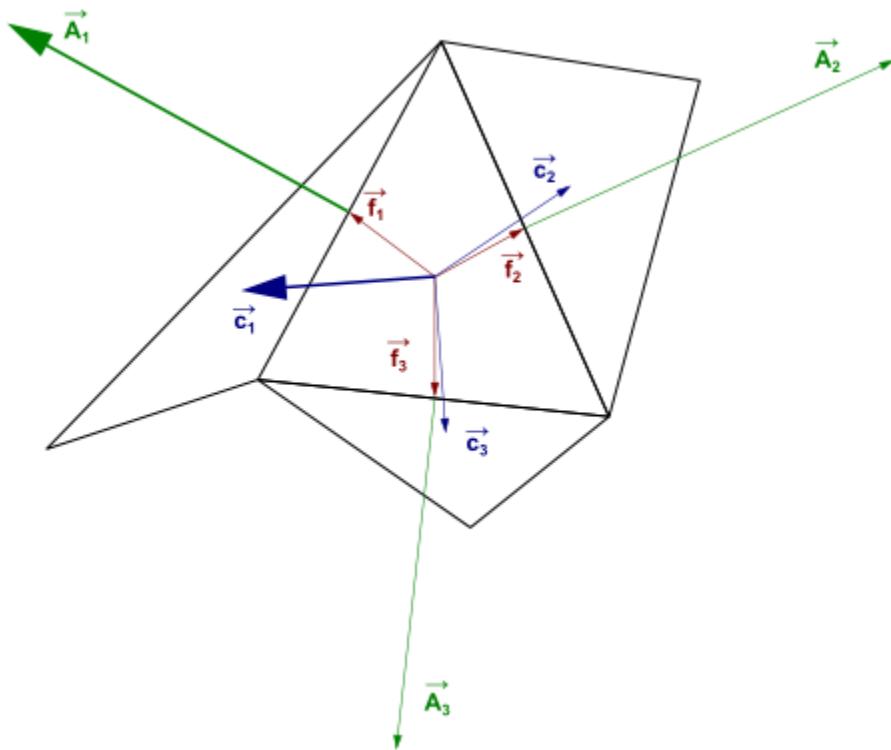

- the normalized dot product of the area vector of a face (\vec{A}_i) and a vector from the centroid of the cell to the centroid of that face (\vec{f}_i):

$$\frac{\vec{A}_i \cdot \vec{f}_i}{|\vec{A}_i| |\vec{f}_i|} \quad (6-1)$$

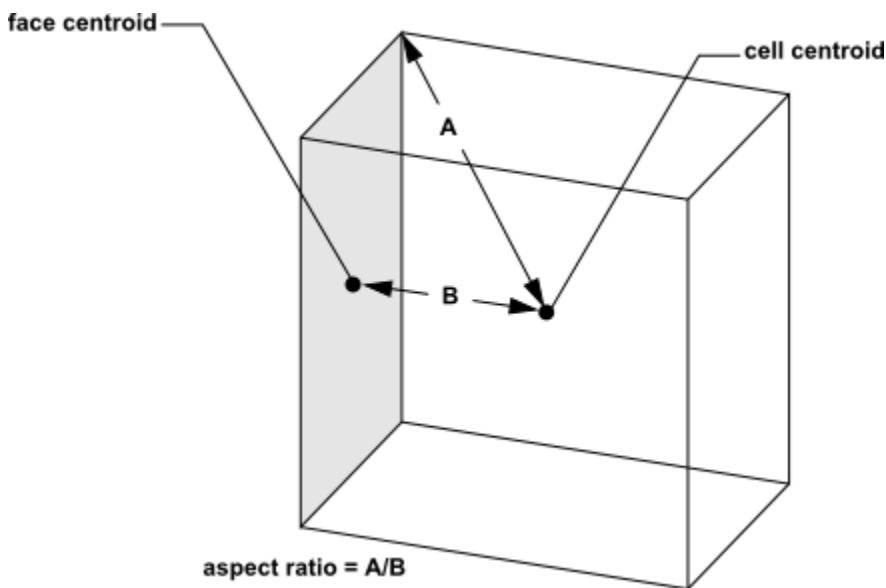

- the normalized dot product of the area vector of a face (\vec{A}_i) and a vector from the centroid of the cell to the centroid of the adjacent cell that shares that face (\vec{c}_i):

$$\frac{\vec{A}_i \cdot \vec{c}_i}{|\vec{A}_i| |\vec{c}_i|} \quad (6-2)$$

The minimum value that results from calculating [Equation 6-1 \(p. 145\)](#) and [Equation 6-2 \(p. 145\)](#) for all of the faces is then defined as the orthogonal quality for the cell. Therefore, the worst cells will have an orthogonal quality closer to 0 and the best cells will have an orthogonal quality closer to 1. [Figure 6.22 \(p. 146\)](#) illustrates the relevant vectors, and is an example where [Equation 6-2 \(p. 145\)](#) produces the minimum value and therefore determines the orthogonal quality.

Figure 6.22 The Vectors Used to Compute Orthogonal Quality

Another important indicator of the mesh quality is the aspect ratio. The aspect ratio is a measure of the stretching of a cell. It is computed as the ratio of the maximum value to the minimum value of any of the following distances: the normal distances between the cell centroid and face centroids, and the distances between the cell centroid and nodes. For a unit cube (see [Figure 6.23 \(p. 146\)](#)), the maximum distance is 0.866, and the minimum distance is 0.5, so the aspect ratio is 1.732. This type of definition can be applied on any type of mesh, including polyhedral.

Figure 6.23 Calculating the Aspect Ratio for a Unit Cube

To check the quality of your mesh, you can use the **Report Quality** button in the **General** task page:

◆ General → Report Quality

A message will be displayed in the console, such as the example that follows:

```
Mesh Quality:  
Orthogonal Quality ranges from 0 to 1, where values close to 0 correspond to low quality.  
Minimum Orthogonal Quality = 6.07960e-01  
Maximum Aspect Ratio = 5.42664e+00
```

If you would like more information about the quality displayed in the console (including additional quality metrics and the zones that have the cells with the lowest quality), set the mesh/check-verbosity text command to 2 prior to using the **Report Quality** button.

For information about how to improve poor quality cells, see [Repairing Meshes \(p. 175\)](#).

When evaluating whether the quality of your mesh is sufficient for the problem you are modeling, it is important to consider attributes such as mesh element distribution, cell shape, smoothness, and flow-field dependency. These attributes are described in the sections that follow.

6.2.2.1. Mesh Element Distribution

Since you are discretely defining a continuous domain, the degree to which the salient features of the flow (such as shear layers, separated regions, shock waves, boundary layers, and mixing zones) are resolved depends on the density and distribution of mesh elements. In many cases, poor resolution in critical regions can dramatically affect results. For example, the prediction of separation due to an adverse pressure gradient depends heavily on the resolution of the boundary layer upstream of the point of separation.

Resolution of the boundary layer (i.e., mesh spacing near walls) also plays a significant role in the accuracy of the computed wall shear stress and heat transfer coefficient. This is particularly true in laminar flows where the mesh adjacent to the wall should obey

$$y_p \sqrt{\frac{u_\infty}{v_x}} \leq 1 \quad (6-3)$$

where

y_p = distance to the wall from the adjacent cell centroid

u_∞ = free-stream velocity

v = kinematic viscosity of the fluid

x = distance along the wall from the starting point of the boundary layer

[Equation 6-3 \(p. 147\)](#) is based upon the Blasius solution for laminar flow over a flat plate at zero incidence [75] (p. 2371).

Proper resolution of the mesh for turbulent flows is also very important. Due to the strong interaction of the mean flow and turbulence, the numerical results for turbulent flows tend to be more susceptible to mesh element distribution than those for laminar flows. In the near-wall region, different mesh resolutions are required depending on the near-wall model being used. See [Model Hierarchy \(p. 695\)](#) for guidelines.

In general, no flow passage should be represented by fewer than 5 cells. Most cases will require many more cells to adequately resolve the passage. In regions of large gradients, as in shear layers or mixing zones, the mesh should be fine enough to minimize the change in the flow variables from cell to cell.

Unfortunately, it is very difficult to determine the locations of important flow features in advance. Moreover, the mesh resolution in most complicated 3D flow fields will be constrained by CPU time and computer resource limitations (i.e., memory and disk space). Although accuracy increases with larger meshes, the CPU and memory requirements to compute the solution and postprocess the results also increase. Solution-adaptive mesh refinement can be used to increase and/or decrease mesh density based on the evolving flow field, and thus provides the potential for more economical use of grid points (and hence reduced time and resource requirements). See [Adapting the Mesh \(p. 1441\)](#) for information on solution adaption.

6.2.2.2. Cell Quality

The quality of the cell (including its orthogonal quality, aspect ratio, and skewness) also has a significant impact on the accuracy of the numerical solution.

- *Orthogonal quality* is computed for cells using the vector from the cell centroid to each of its faces, the corresponding face area vector, and the vector from the cell centroid to the centroids of each of the adjacent cells (see [Equation 6–1 \(p. 145\)](#), [Equation 6–2 \(p. 145\)](#), and [Figure 6.22 \(p. 146\)](#)). The worst cells will have an orthogonal quality closer to 0, with the best cells closer to 1. The minimum orthogonal quality for all types of cells should be more than 0.01, with an average value that is significantly higher.
- *Aspect ratio* is a measure of the stretching of the cell. As discussed in [Computational Expense \(p. 143\)](#), for highly anisotropic flows, extreme aspect ratios may yield accurate results with fewer cells. Generally, it is best to avoid sudden and large changes in cell aspect ratios in areas where the flow field exhibit large changes or strong gradients.
- *Skewness* is defined as the difference between the shape of the cell and the shape of an equilateral cell of equivalent volume. Highly skewed cells can decrease accuracy and destabilize the solution. For example, optimal quadrilateral meshes will have vertex angles close to 90 degrees, while triangular meshes should preferably have angles of close to 60 degrees and have all angles less than 90 degrees. A general rule is that the maximum skewness for a triangular/tetrahedral mesh in most flows should be kept below 0.95, with an average value that is significantly lower. A maximum value above 0.95 may lead to convergence difficulties and may require changing the solver controls, such as reducing under-relaxation factors and/or switching to the pressure-based coupled solver.

Cell size change and face warp are additional quality measure that could affect stability and accuracy. See the TGrid User's Guide for more details.

6.2.2.3. Smoothness

Truncation error is the difference between the partial derivatives in the governing equations and their discrete approximations. Rapid changes in cell volume between adjacent cells translate into larger truncation errors. ANSYS FLUENT provides the capability to improve the smoothness by refining the mesh based on the change in cell volume or the gradient of cell volume. For information on refining the mesh based on change in cell volume, see [Gradient Adaption \(p. 1447\)](#) and [Volume Adaption \(p. 1453\)](#).

6.2.2.4. Flow-Field Dependency

The effect of resolution, smoothness, and cell shape on the accuracy and stability of the solution process is dependent on the flow field being simulated. For example, very skewed cells can be tolerated in benign flow regions, but can be very damaging in regions with strong flow gradients.

Since the locations of strong flow gradients generally cannot be determined a priori, you should strive to achieve a high-quality mesh over the entire flow domain.

6.3. Mesh Import

Since ANSYS FLUENT can handle a number of different mesh topologies, there are many sources from which you can obtain a mesh to be used in your simulation. You can generate a mesh using GAMBIT, TGrid, GeoMesh, PreBFC, ICEM CFD, I-deas, NASTRAN, PATRAN, ARIES, Mechanical APDL, CFX, or other preprocessors. You can also use the mesh contained in a FLUENT/UNS, RAMPANT, or FLUENT 4 case file. You can also prepare multiple mesh files and combine them to create a single mesh.

- [6.3.1. GAMBIT Mesh Files](#)
- [6.3.2. GeoMesh Mesh Files](#)
- [6.3.3. TGrid Mesh Files](#)
- [6.3.4. PreBFC Mesh Files](#)
- [6.3.5. ICEM CFD Mesh Files](#)
- [6.3.6. I-deas Universal Files](#)
- [6.3.7. NASTRAN Files](#)
- [6.3.8. PATRAN Neutral Files](#)
- [6.3.9. Mechanical APDL Files](#)
- [6.3.10. CFX Files](#)
- [6.3.11. Using the fe2ram Filter to Convert Files](#)
- [6.3.12. Using the tpoly Filter to Remove Hanging Nodes / Edges](#)
- [6.3.13. FLUENT/UNS and RAMPANT Case Files](#)
- [6.3.14. FLUENT 4 Case Files](#)
- [6.3.15. ANSYS FIDAP Neutral Files](#)
- [6.3.16. Reading Multiple Mesh/Case/Data Files](#)
- [6.3.17. Reading Surface Mesh Files](#)

6.3.1. GAMBIT Mesh Files

You can use GAMBIT to create 2D and 3D structured/unstructured/hybrid meshes. To create any of these meshes for ANSYS FLUENT, follow the procedure described in the GAMBIT Modeling Guide, and export your mesh in FLUENT 5/6 format. All such meshes can be imported directly into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

6.3.2. GeoMesh Mesh Files

You can use GeoMesh to create complete 2D quadrilateral or triangular meshes, 3D hexahedral meshes, and triangular surface meshes for 3D tetrahedral meshes. To create any of these meshes for ANSYS FLUENT, follow the procedure described in the GeoMesh User's Guide.

To complete the generation of a 3D tetrahedral mesh, read the surface mesh into TGrid and generate the volume mesh there. All other meshes can be imported directly into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

6.3.3. TGrid Mesh Files

You can use TGrid to create 2D and 3D unstructured triangular/tetrahedral meshes from boundary or surface meshes. Follow the meshing procedure described in the TGrid User's Guide, and save your mesh using the **File/Write/Mesh...** menu item. To import the mesh into ANSYS FLUENT, use the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

6.3.4. PreBFC Mesh Files

You can use PreBFC to create two different types of meshes for ANSYS FLUENT, structured quadrilateral/hexahedral and unstructured triangular/tetrahedral.

6.3.4.1. Structured Mesh Files

To generate a structured 2D or 3D mesh, follow the procedure described in the PreBFC User's Guide (Chapters 6 and 7). The resulting mesh will contain quadrilateral (2D) or hexahedral (3D) elements. Do not specify more than 70 wall zones and 35 inlet zones.

To import the mesh, use the **File/Import/PreBFC File...** menu item, as described in *PreBFC Files* (p. 86).

To manually convert a file in PreBFC format to a mesh file suitable for ANSYS FLUENT, enter the following command:

```
utility f142seg input_filename output_filename
```

The output file produced can be read into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in *Reading Mesh Files* (p. 64).

6.3.4.2. Unstructured Triangular and Tetrahedral Mesh Files

To generate an unstructured 2D mesh, follow the procedure described in the PreBFC User's Guide. Save the mesh file in the RAMPANT format using the MESH=RAMPANT/TGRID command. The current ANSYS FLUENT format is the same as the RAMPANT format. The resulting mesh will contain triangular elements. To import the mesh, use the **File/Read/Mesh...** menu item, as described in *Reading Mesh Files* (p. 64).

To generate a 3D unstructured tetrahedral mesh, follow the procedure described in Chapter 8 of the PreBFC User's Guide for generating a surface mesh. Then read the surface mesh into TGrid, and complete the mesh generation there. See *TGrid Mesh Files* (p. 149) for information about TGrid mesh files.

6.3.5. ICEM CFD Mesh Files

You can use ICEM CFD to create structured meshes in FLUENT 4 format and unstructured meshes in RAMPANT format.

- To import a FLUENT 4 mesh, follow the instructions in *FLUENT 4 Case Files* (p. 157).
- To import a RAMPANT mesh, use the **File/Read/Mesh...** menu item, as described in *Reading Mesh Files* (p. 64).

The current ANSYS FLUENT format is the same as the RAMPANT format, *not* the FLUENT 4 format. After reading a triangular or tetrahedral ICEM CFD volume mesh, perform smoothing and swapping (as described in *Improving the Mesh by Smoothing and Swapping* (p. 1466)) to improve its quality.

6.3.6. I-deas Universal Files

You can import an I-deas Universal file into ANSYS FLUENT in three different ways.

- Generate an I-deas surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge and/or hexahedral elements. Import it into TGrid using the commands described in the TGrid User's Guide. Adhere to the restrictions described in Appendix B of the TGrid User's Guide. In TGrid, complete the mesh generation (if necessary) and follow the instructions in *TGrid Mesh Files* (p. 149).

- Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Import it directly using the **File/Import/I-deas Universal...** menu item, as described in *I-deas Universal Files (p. 83)*.
- Generate an I-deas volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Use the `fe2ram` filter to convert the Universal file to the format used by ANSYS FLUENT. To convert an input file in I-deas Universal format to an output file in ANSYS FLUENT format, follow the instructions below in *Using the fe2ram Filter to Convert Files (p. 155)*. After the output file is written, read it into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in *Reading Mesh Files (p. 64)*.

6.3.6.1. Recognized I-deas Datasets

The following Universal file datasets are recognized by the ANSYS FLUENT mesh import utility:

- **Node Coordinates** dataset number 15, 781, 2411
- **Elements** dataset number 71, 780, 2412
- **Permanent Groups** dataset number 752, 2417, 2429, 2430, 2432, 2435

For 2D volume meshes, the elements must exist in a constant z plane.

Note

The mesh area or mesh volume datasets are *not* recognized. This implies that writing multiple mesh areas/volumes to a single Universal file may confuse ANSYS FLUENT.

6.3.6.2. Grouping Nodes to Create Face Zones

Nodes are grouped in I-deas using the `Group` command to create boundary face zones. In ANSYS FLUENT, boundary conditions are applied to each zone. Faces that contain the nodes in a group are gathered into a single zone. It is important not to group nodes of internal faces with nodes of boundary faces.

One technique is to generate groups automatically based on curves or mesh areas—i.e., every curve or mesh area will be a different zone in ANSYS FLUENT. You may also create the groups manually, generating groups consisting of all nodes related to a given curve (2D) or mesh area (3D).

6.3.6.3. Grouping Elements to Create Cell Zones

Elements in I-deas are grouped using the `Group` command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in ANSYS FLUENT. If the elements are not grouped, ANSYS FLUENT will place all the cells into a single zone.

6.3.6.4. Deleting Duplicate Nodes

I-deas may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in I-deas before writing the universal file for import into ANSYS FLUENT.

6.3.7. NASTRAN Files

There are three different ways in which you can import a NASTRAN file into ANSYS FLUENT:

- You can generate a NASTRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into TGrid using the commands described in the

TGrid User's Guide and adhering to the restrictions described in Appendix B of the TGrid User's Guide. In TGrid, complete the mesh generation (if necessary) and then follow the instructions in [TGrid Mesh Files \(p. 149\)](#).

- You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and import it directly using the **File/Import/NASTRAN** menu item, as described in [NASTRAN Files \(p. 84\)](#).
- You can generate a NASTRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements. Then use the `fe2ram` filter to convert the NASTRAN file to the format used by ANSYS FLUENT. To convert an input file in NASTRAN format to an output file in ANSYS FLUENT format, follow the instructions below in [Using the fe2ram Filter to Convert Files \(p. 155\)](#). After the output file has been written, you can read it into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

After reading a triangular or tetrahedral NASTRAN volume mesh using the latter methods perform smoothing and swapping (as described in [Improving the Mesh by Smoothing and Swapping \(p. 1466\)](#)) to improve its quality.

6.3.7.1. Recognized NASTRAN Bulk Data Entries

The following NASTRAN file datasets are recognized by the ANSYS FLUENT mesh import utility:

- **GRID** single-precision node coordinates
- **GRID*** double-precision node coordinates
- **CBAR** line elements
- **CTETRA, CTRIA3** tetrahedral and triangular elements
- **CHEXA, CQUAD4, CPENTA** hexahedral, quadrilateral, and wedge elements

For 2D volume meshes, the elements must exist in a constant *z* plane.

6.3.7.2. Deleting Duplicate Nodes

NASTRAN may generate duplicate or coincident nodes in the process of creating elements. These nodes must be removed in NASTRAN before writing the file for import into ANSYS FLUENT.

6.3.8. PATRAN Neutral Files

There are three different ways in which you can import a PATRAN Neutral file into ANSYS FLUENT.

- You can generate a PATRAN surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, and/or hexahedral elements, and import it into TGrid using the commands described in the TGrid User's Guide and adhering to the restrictions described in Appendix B of the TGrid User's Guide. In TGrid, complete the mesh generation (if necessary) and then follow the instructions in [TGrid Mesh Files \(p. 149\)](#).
- You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements (grouping nodes with the same component-group name) and import it directly to ANSYS FLUENT by selecting the **File/Import/PATRAN** menu item, as described in [PATRAN Neutral Files \(p. 85\)](#).
- You can generate a PATRAN volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements and then use the `fe2ram` filter to convert the Neutral file into the format used by ANSYS FLUENT. To convert an input file in PATRAN Neutral format to an output file in ANSYS FLUENT.

ENT format, follow the instructions below in [Using the fe2ram Filter to Convert Files \(p. 155\)](#). After the output file has been written, you can read it into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

After reading a triangular or tetrahedral PATRAN volume mesh using the latter methods perform smoothing and swapping (as described in [Improving the Mesh by Smoothing and Swapping \(p. 1466\)](#)) to improve its quality.

Important

To retain a zone type during PATRAN Neutral file import, please add the abbreviated form of the “zone-type” before the “zone-name”, as shown below:

Zone Type in ANSYS FLUENT	Zone Name for PATRAN export (zone-type) - (zone-name)
mass-flow-inlet	m-f-i-zone-name
pressure-outlet	p-o-zone-name
fan	fan-zone-name
velocity-inlet	v-i-zone-name
pressure-far-field	p-f-f-zone-name
solid	solid-zone-name
fluid	fluid-zone-name

6.3.8.1. Recognized PATRAN Datasets

The following PATRAN Neutral file packet types are recognized by the ANSYS FLUENT mesh import utility:

- **Node Data** Packet Type 01
- **Element Data** Packet Type 02
- **Distributed Load Data** Packet Type 06
- **Node Temperature Data** Packet Type 10
- **Name Components** Packet Type 21
- **File Header** Packet Type 25

For 2D volume meshes, the elements must exist in a constant *z* plane.

6.3.8.2. Grouping Elements to Create Cell Zones

Elements are grouped in PATRAN using the `Named Component` command to create the multiple cell zones. All elements grouped together are placed in a single cell zone in ANSYS FLUENT. If the elements are not grouped, ANSYS FLUENT will place all the cells into a single zone.

6.3.9. Mechanical APDL Files

There are three different ways in which you can import a Mechanical APDL file into ANSYS FLUENT.

- You can generate a surface or volume mesh containing triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements using Mechanical APDL or ARIES, and import it into TGrid using the commands

described in the TGrid User's Guide and adhering to the restrictions described in Appendix B of the TGrid User's Guide. In TGrid, complete the mesh generation (if necessary) and then follow the instructions in [TGrid Mesh Files \(p. 149\)](#).

- You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, as well as with higher order elements like 20 node hexahedron, SOLID92, and SOLID187. Then import it directly to ANSYS FLUENT using the **File/Import/Mechanical APDL** menu item, as described in [Mechanical APDL Files \(p. 84\)](#).

The higher order elements will be converted to their corresponding linear elements during the import in ANSYS FLUENT.

- You can generate a Mechanical APDL volume mesh with linear triangular, quadrilateral, tetrahedral, wedge, or hexahedral elements, and then use the fe2ram filter to convert the Mechanical APDL file into the format used by ANSYS FLUENT. To convert an input file in ANSYS 5.4 or 5.5 format to an output file in ANSYS FLUENT format, follow the instructions in [Using the fe2ram Filter to Convert Files \(p. 155\)](#). After the output file has been written, you can read it into ANSYS FLUENT using the **File/Read/Mesh...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

After reading a triangular or tetrahedral volume mesh using method 2 or 3 above, you should perform smoothing and swapping (as described in [Improving the Mesh by Smoothing and Swapping \(p. 1466\)](#)) to improve its quality.

6.3.9.1. Recognized ANSYS 5.4 and 5.5 Datasets

ANSYS FLUENT can import mesh files from ANSYS 5.4 and 5.5 (.cddb files), retaining original boundary names. The following ANSYS file datasets are recognized by the ANSYS FLUENT mesh import utility:

- **NBLOCK** node block data
- **EBLOCK** element block data
- **CMBLOCK** element/node grouping

The elements must be STIF63 linear shell elements. In addition, if element data without an explicit element ID is used, the filter assumes sequential numbering of the elements when creating the zones.

6.3.10. CFX Files

You can import the meshes from 3D CFX files, such as definition (.def) and result (.res) files into ANSYS FLUENT, using the **File/Import/CFX** menu item, as described in [CFX Files \(p. 80\)](#). The fe2ram utility is used as the import filter, which can be used as a stand-alone program to obtain an ANSYS FLUENT mesh file. See [Using the fe2ram Filter to Convert Files \(p. 155\)](#) for information about fe2ram.

Important

Note that you have the ability to import only the mesh from a CFX file, and not any results or data.

When importing a mesh from a CFX definition or results file, select whether you want the ANSYS FLUENT zones to be created from the physics data objects or the primitive mesh region objects. The former option is the default and is called "Zoning by CCL" and the latter option is called "Zoning by Group". This will allow you to choose the type of mesh topology you would like to preserve when importing the file:

- If you want zones to be created from the physics data objects, enable **Create Zones from CCL Physics Data** in the **Select File** dialog box.
- If you want zones to be created from the primitive mesh region objects, disable **Create Zones from CCL Physics Data** in the **Select File** dialog box. This will result in the group zoning.

Important

The primitive mesh topology may contain additional regions which do not appear in the physics definition.

The default import method is the **Create Zones from CCL Physics Data** method. This method will not import CFX subdomain regions, however, the zoning by group method can import subdomain regions.

The 3D element set corresponding to zones/domains present in these files are imported as cell zones in ANSYS FLUENT. They may contain tetrahedral, pyramidal, wedge, and hexahedral elements. The boundary zones in these files are a group of faces with a boundary condition name/type and are imported as face zones with the boundary condition name/type retained in ANSYS FLUENT. The following boundary condition types are retained:

- **inlet**
- **outlet**
- **symmetry**
- **interface**
- **wall**

The boundaries of type **Interface** may be conformal or non-conformal. If they are non-conformal, they are retained. However, conformal interfaces contain coincident nodes which are merged and changed to type **Interior**. For some cases, for the merge to work correctly, the merge tolerance may need to be adjusted. Alternatively, the [Fuse Face Zones Dialog Box \(p. 2235\)](#) in ANSYS FLUENT can be used to merge the conformal interfaces. For details, see [Fusing Face Zones \(p. 193\)](#).

6.3.11. Using the fe2ram Filter to Convert Files

The `fe2ram` filter can be used to manually convert files of certain formats into ANSYS FLUENT mesh files, which can then be read into ANSYS FLUENT. To use the `fe2ram` filter, enter the following at a command prompt in a terminal or command window:

```
utility fe2ram [dimension] format [zoning] input_file output_file
```

Note

The items enclosed in square brackets are optional. Do not type the square brackets.

- *dimension* indicates the dimension of the dataset. Replace *dimension* with `-d2` to indicate that the mesh is two dimensional. For a 3D mesh, do not enter any value for *dimension*, because 3D is the default.
- *format* indicates the format of the file you wish to convert. For example, replace *format* with `-tANSYS` for a Mechanical APDL file, `-tIDEAS` for an I-deas file, `-tNASTRAN` for a NASTRAN file, etc. To print a list of the formats which `fe2ram` can convert, type

```
utility fe2ram -cl -help.
```

- *zoning* indicates how zones were identified in the original format. Replace *zoning* by *-zID* for a mesh that was zoned by property IDs, or *-zNONE* to ignore all zone groupings. For a mesh zoned by group, do not enter anything for *zoning*, because zoning by groups is the default.
- *input_file* is the name of the original file. *output_file* is the name of the file to which you want to write the converted mesh information.

For example, if you wanted to convert the 2D I-deas volume mesh file *sample.unv* to an output file called *sample.grd*, you will enter the following command:

```
utility fe2ram -d2 -tIDEAS sample.unv sample.grd
```

6.3.12. Using the `tpoly` Filter to Remove Hanging Nodes / Edges

As noted in [Mesh Topologies](#) (p. 129), ANSYS FLUENT can accept meshes that contain hanging nodes or hanging edges. However, the creation of interior walls can yield an error if hanging nodes / edges are located on the zone that is turned into an interior wall. This problem can occur in the following cases:

- If you read a mesh file that has an interior (or two-sided) wall boundary condition setup, but the shadow wall has not been created yet.
- If you turn an interior surface into a wall.
- If you slit an interior surface (e.g., turn it into a non-conformal interface).

Such error-producing hanging nodes / edges may be present in hexcore or CutCell meshes, for example. You can remove the hanging nodes / edges by converting the associated cells to polyhedra. Each cell that is converted will retain the same overall dimensions, but the number of faces associated with the cell will increase. You can perform the conversion prior to reading the mesh into ANSYS FLUENT by using the `tpoly` filter, or during an ANSYS FLUENT session by using the `mesh/polyhedra/convert-hanging-nodes` text command (see [Converting Cells with Hanging Nodes / Edges to Polyhedra](#) (p. 185)).

When you use the `tpoly` filter, you must specify an input case file that contains a mesh with hanging nodes / edges. This file can either be in ASCII or Binary format, and the file should be unzipped. If the input file does not contain hanging nodes / edges, then none of the cells are converted to polyhedra. When you use the `tpoly` filter, you should specify an output case file name. After the input file has been processed by the `tpoly` filter, an ASCII output file is generated.

Important

The output case file resulting from a `tpoly` conversion only contains mesh information. None of the solver-related data of the input file is retained.

To convert a file using the `tpoly` filter, before starting ANSYS FLUENT, type the following:

```
utility tpoly input_filename output_filename
```

6.3.12.1. Limitations

Meshes with polyhedra have the following limitations:

- The following mesh manipulation tools are not available on polyhedral meshes:
 - `extrude-face-zone` under the `modify-zone` option
 - `fuse`

- skewness smoothing
- swapping (will not affect polyhedral cells)
- The polyhedral cells that result from the conversion are not eligible for adaption. For more information about adaption, see [Adapting the Mesh \(p. 1441\)](#).
- The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:
 - When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
 - None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see [Diffusion-Based Smoothing \(p. 581\)](#) for details).

6.3.13. FLUENT/UNS and RAMPANT Case Files

If you have a FLUENT/UNS 3 or 4 case file or a RAMPANT 2, 3, or 4 case file and you want to run an ANSYS FLUENT simulation using the same mesh, you can read it into ANSYS FLUENT using the **File/Read/Case...** menu item, as described in [Reading FLUENT/UNS and RAMPANT Case and Data Files \(p. 72\)](#).

6.3.14. FLUENT 4 Case Files

If you have a FLUENT 4 case file and you want to run an ANSYS FLUENT simulation using the same mesh, import it into ANSYS FLUENT using the **File/Import/FLUENT 4 Case File...** menu item, as described in [FLUENT 4 Case Files \(p. 86\)](#). ANSYS FLUENT will read mesh information and zone types from the FLUENT 4 case file.

Important

FLUENT 4 may interpret some pressure boundaries differently from the current release of ANSYS FLUENT. Check the conversion information printed out by ANSYS FLUENT to see if you need to modify any boundary types.

To manually convert an input file in FLUENT 4 format to an output file in the current ANSYS FLUENT format, enter the following command:

```
utility fl42seg input_filename output_filename
```

After the output file has been written, you can read it into ANSYS FLUENT using the **File/Read/Case...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

6.3.15. ANSYS FIDAP Neutral Files

If you have an ANSYS FIDAP Neutral file and you want to run an ANSYS FLUENT simulation using the same mesh, import it using the menu item, as described in [ANSYS FIDAP Neutral Files \(p. 81\)](#). ANSYS FLUENT will read mesh information and zone types from the ANSYS FIDAP file.

To manually convert an input file in ANSYS FIDAP format to an output file in ANSYS FLUENT

```
utility fe2ram [dimension] -tFIDAP7 input_file output_file
```

The item in square brackets is optional. Do not type the square brackets. For a 2D file, replace *dimension* with -d2. For a 3D file, do not enter anything for *dimension*, because 3D is the default.

After the output file has been written, read it into ANSYS FLUENT using the **File/Read/Case...** menu item, as described in [Reading Mesh Files \(p. 64\)](#).

6.3.16. Reading Multiple Mesh/Case/Data Files

There may be some cases in which you will need to read multiple mesh files (subdomains) to form your computational domain.

- To solve on a multiblock mesh, generate each block of the mesh in the mesh generator and save it to a separate mesh file.
- For very complicated geometries, it may be more efficient to save the mesh for each part as a separate mesh file.

The mesh node locations need not be identical at the boundaries where two separate meshes meet. ANSYS FLUENT can handle non-conformal mesh interfaces. See [Non-Conformal Meshes \(p. 162\)](#) for details about non-conformal mesh boundaries.

There are two ways for reading multiple mesh files in ANSYS FLUENT:

- Using ANSYS FLUENT's ability to read multiple mesh files.
- Using TGrid or tmerge.

6.3.16.1. Using ANSYS FLUENT's Ability to Read Multiple Mesh Files

ANSYS FLUENT allows you to handle more than one mesh at a time within the same solver settings. This capability of handling multiple meshes saves time, since you can directly read in the different mesh files in ANSYS FLUENT itself without using other tools like TGrid or tmerge.

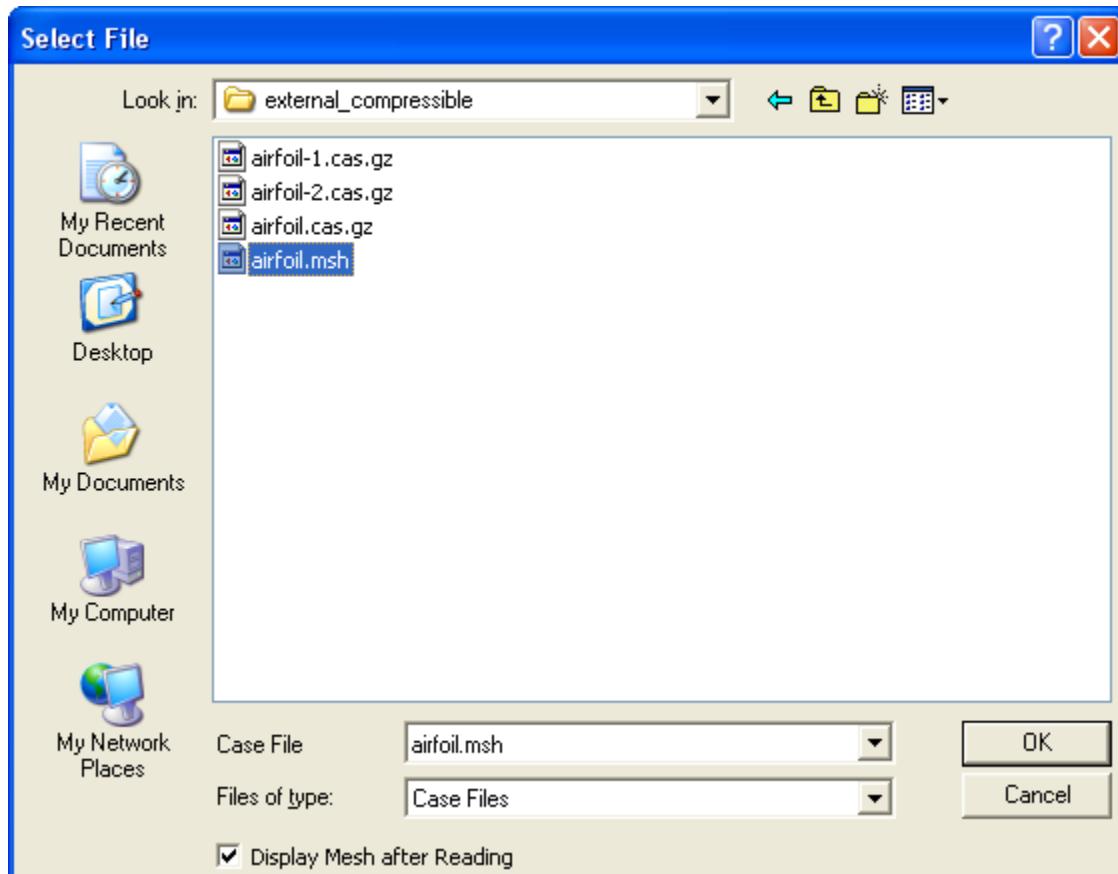

The steps to take when reading more than one mesh file are:

1. Read in your first mesh file.

File → Read → Mesh...

In [The Select File Dialog Box \(p. 33\)](#) ([Figure 6.24 \(p. 159\)](#)), select the mesh file and click **OK**.

Figure 6.24 The Select File Dialog Box

2. Read in your second mesh file and append it to the first mesh selected in the first step.

Mesh → Zone → Append Case File...

In *The Select File Dialog Box* (p. 33), select the second mesh file and click **OK**.

3. (optional). Display your meshes using the **Mesh Display** dialog box.

↳ **General → Display...**

You will find that the second mesh is appended to the first.

ANSYS FLUENT also allows you to append the data on the mesh. To do that, follow the procedure above. For the second step, use the following menu item:

Mesh → Zone → Append Case & Data Files...

Select the case file in *The Select File Dialog Box* (p. 33) (*Figure 6.24* (p. 159)), and click **OK**. Both the case and data files will be appended.

Important

Reading multiple mesh and data options are available for serial and parallel cases.

6.3.16.2. Using TGrid or tmerge

1. Generate the mesh for the whole domain in the mesh generator, and save each cell zone (or block or part) to a separate mesh file for ANSYS FLUENT.

Important

If one (or more) of the meshes you wish to import is structured (e.g., a FLUENT 4 mesh file), first convert it to ANSYS FLUENT format using the `f142seg` filter described in [FLUENT 4 Case Files \(p. 157\)](#).

2. Before starting the solver, use either TGrid or the `tmerge` filter to combine the meshes into one mesh file. The TGrid method is convenient, but the `tmerge` method allows you to rotate, scale, and/or translate the meshes before they are merged. Note that the `tmerge` filter allows you to merge large meshes with very low memory requirement.

- To use TGrid, do the following:
 - a. Read all of the mesh files into TGrid. When TGrid reads the mesh files, it will automatically merge them into a single mesh.
 - b. Save the merged mesh file.

See the TGrid User's Guide for information about reading and writing files in TGrid.

- To use the `tmerge` filter, do the following before starting ANSYS FLUENT:
 - a. For 3D problems, type `utility tmerge -3d`. For 2D problems, type `utility tmerge -2d`.
 - b. When prompted, specify the names of the input files (the separate mesh files) and the name of the output file in which to save the complete mesh. Be sure to include the `.msh` extension.
 - c. For each input file, specify scaling factors, translation distances, and rotation information.

For information about the various options available when using `tmerge`, type `utility tmerge -h`.

3. Read the combined mesh file into the solver in the usual manner (using the **File/Read/Mesh...** menu item).

For a conformal mesh, if you do not want a boundary between the adjacent cell zones, use the **Fuse Face Zones** dialog box to fuse the overlapping boundaries. For details, see [Fusing Face Zones \(p. 193\)](#). The matching faces will be moved to a new zone with a boundary type of **interior** and the original zone(s) will be discarded.

Important

If you are planning to use sliding meshes, or if you have non-conformal boundaries between adjacent cell zones, do not combine the overlapping zones. Instead, change the type of the two overlapping zones to **interface** (as described in [Non-Conformal Meshes \(p. 162\)](#)).

In this example, scaling, translation, or rotation is not requested. Hence you can simplify the inputs to the following:

```
user@mymachine:> utility tmerge -2d
```

```

Starting /ansys_inc/v140/fluent/utility/tmerge14.0/lnamd64/tmerge_2d.14.0.0

Append 2D grid files.
tmerge2D ANSYS Inc, stream, Version 14.0.0

Enter name of grid file (ENTER to continue) : my1.msh

x,y scaling factor, eg. 1 1      : 1 1

x,y translation, eg. 0 1       : 0 0

rotation angle (deg), eg. 45    : 0

Enter name of grid file (ENTER to continue) : my2.msh

x,y scaling factor, eg. 1 1      : 1 1

x,y translation, eg. 0 1       : 0 0

rotation angle (deg), eg. 45    : 0

Enter name of grid file (ENTER to continue) : Enter

Enter name of output file        : final.msh

Appending done.

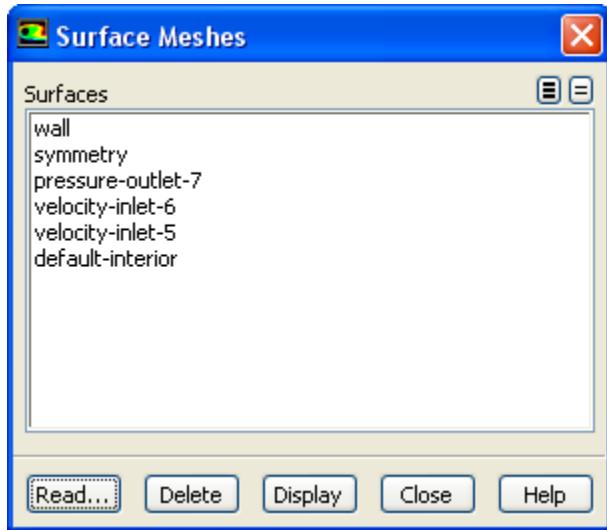

```

6.3.17. Reading Surface Mesh Files

Surface meshes are used as background meshes for geometry-based adaption. Perform the following steps to read the surface mesh file into ANSYS FLUENT:

1. Open the **Geometry Based Adaption** dialog box.
Adapt → Geometry...
2. Enable the **Reconstruct Geometry** option.
3. Click the **Surface Meshes...** button to open the **Surface Meshes** dialog box (*Figure 6.25 (p. 162)*).
4. In the *Surface Meshes Dialog Box* (p. 2290), click **Read...** and select the surface mesh file using *The Select File Dialog Box* (p. 33).

Note that you can also display and delete the surfaces using this dialog box.

Figure 6.25 The Surface Meshes Dialog Box

6.4. Non-Conformal Meshes

In ANSYS FLUENT it is possible to use a mesh that has non-conformal interfaces, that is, boundaries between cell zones in which the mesh node locations are not identical. Such non-conformal interfaces permit the cell zones to be easily connected to each other by passing fluxes from one mesh to another. The principle requirement is that the boundary zones that comprise the non-conformal interface must overlap either partially or fully. (This requirement does not apply to non-conformal periodic boundaries.)

6.4.1. Non-Conformal Mesh Calculations

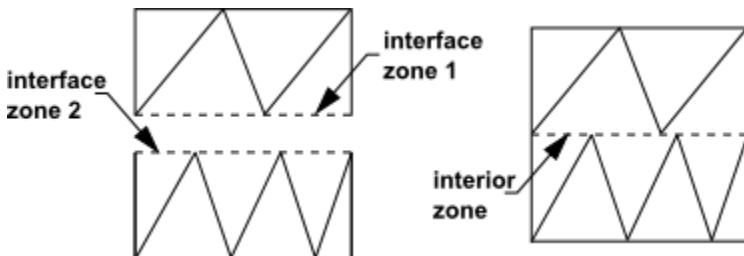

6.4.2. Non-Conformal Interface Algorithm

6.4.3. Requirements and Limitations of Non-Conformal Meshes

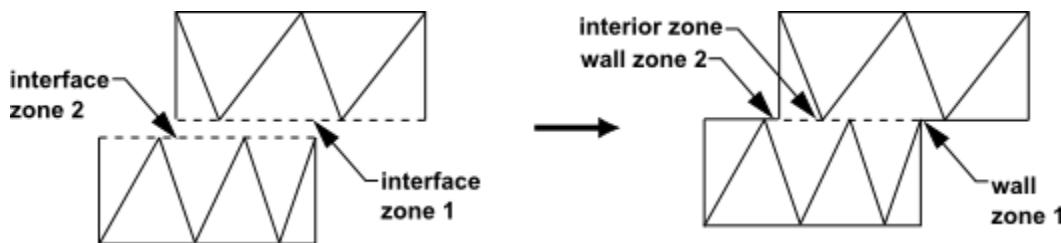

6.4.4. Using a Non-Conformal Mesh in ANSYS FLUENT

6.4.1. Non-Conformal Mesh Calculations

To compute the flux across the non-conformal boundary, ANSYS FLUENT must first compute the intersection between the interface zones that comprise the boundary. The resulting intersection produces an interior zone where the two interface zones overlap (see [Figure 6.26 \(p. 162\)](#)).

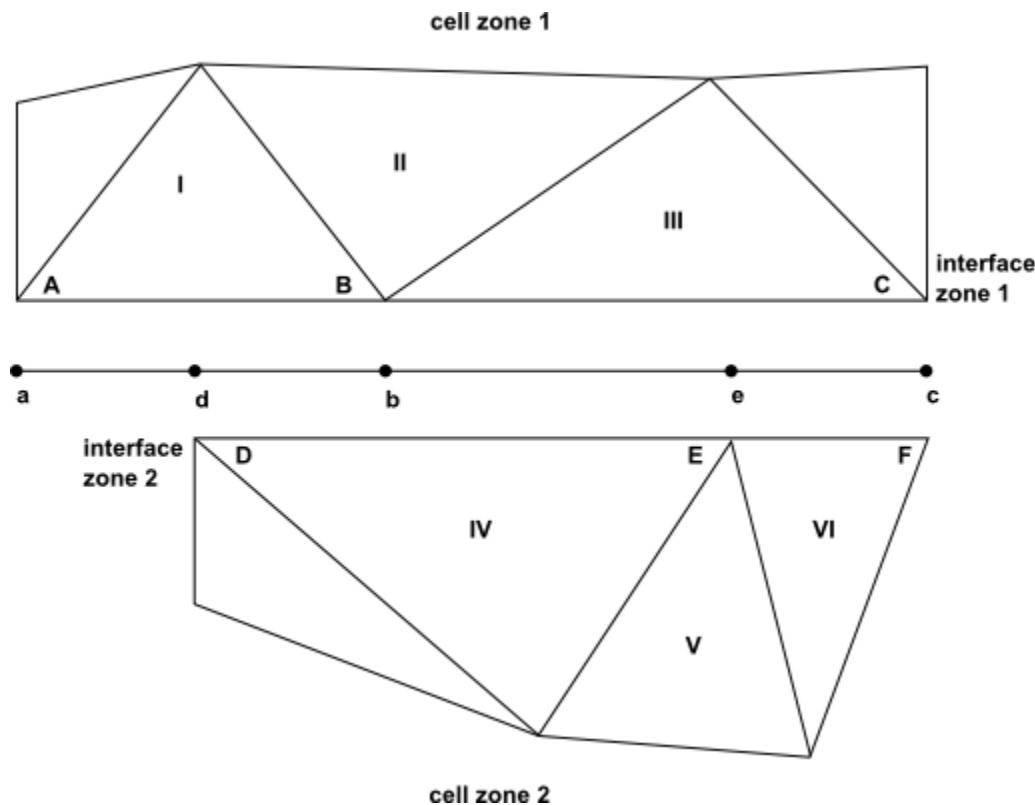

Figure 6.26 Completely Overlapping Mesh Interface Intersection

If one of the interface zones extends beyond the other ([Figure 6.27 \(p. 163\)](#)), by default ANSYS FLUENT will create additional wall zones for the portion(s) of the boundary where the two interface zones do not overlap.

Figure 6.27 Partially Overlapping Mesh Interface Intersection

Fluxes across the mesh interface are computed using the faces resulting from the intersection of the two interface zones, not from the interface zone faces.

In the example shown in [Figure 6.28 \(p. 163\)](#), the interface zones are composed of faces A-B and B-C, and faces D-E and E-F.

Figure 6.28 Two-Dimensional Non-Conformal Mesh Interface

The intersection of these zones produces the faces a-d, d-b, b-e, and e-c. Faces produced in the region where the two cell zones overlap (d-b, b-e, and e-c) are grouped to form an interior zone, while the remaining face (a-d) forms a wall zone.

To compute the flux across the interface into cell IV, face D-E is ignored and instead faces d-b and b-e are used to bring information into cell IV from cells I and III.

While the previous discussion described the default treatment of a non-conformal interface, there are several options you can enable to revise the treatment of the fluxes at the interface:

- periodic boundary condition
- periodic repeats

- coupled wall

These non-conformal interface options are described in the following sections.

- 6.4.1.1.The Periodic Boundary Condition Option
- 6.4.1.2.The Periodic Repeats Option
- 6.4.1.3.The Coupled Wall Option

6.4.1.1. The Periodic Boundary Condition Option

Non-conformal interfaces can be used to implement a periodic boundary condition like that described for conformal periodic boundaries (see *Periodic Boundary Conditions* (p. 336)). The advantage of using a mesh interface is that, unlike the standard periodic boundary condition, the nodes of the two zones do not have to match one-for-one.

The interface zones that utilize the periodic boundary condition option (*Figure 6.29* (p. 164) and *Figure 6.30* (p. 165)) are coupled in the manner described in the previous section, except that the zones do not overlap (i.e., the zones are not spatially coincident at any point). In order to generate the new faces that will be used to compute the fluxes across the interface, the nodes of the first zone are either translated or rotated (about a given axis) onto the other zone. The distance/angle that the nodes are translated/rotated is called the “periodic offset”. The new faces will be defined between all of the combined nodes, and then applied to each of the original zones.

Figure 6.29 Non-Conformal Periodic Boundary Condition (Translational)

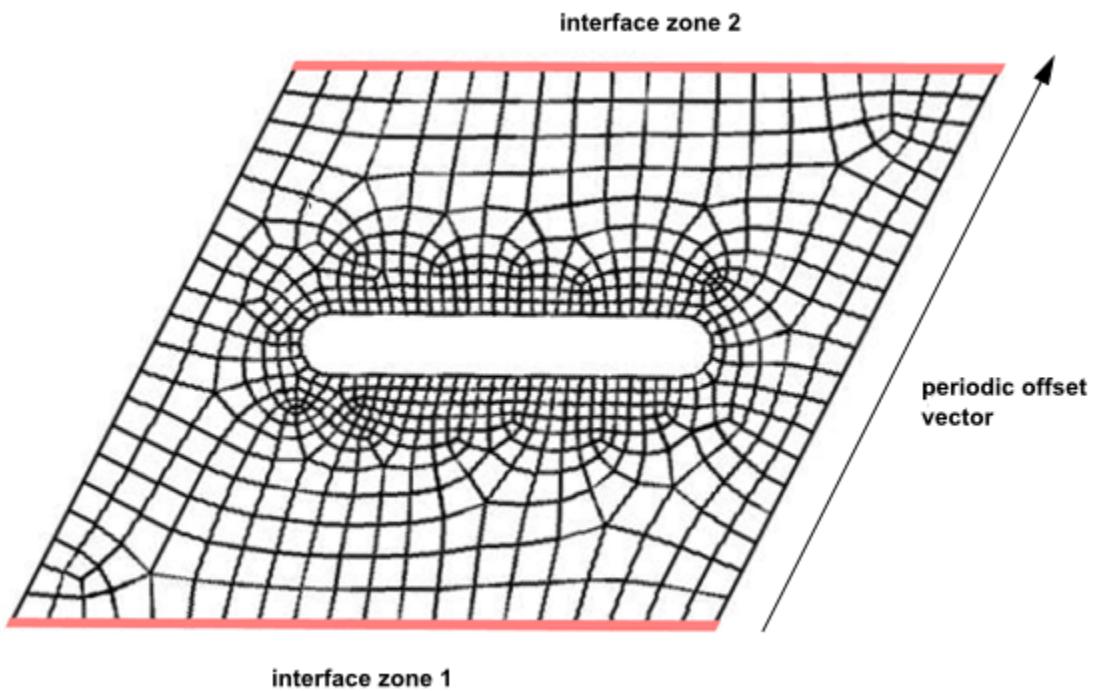

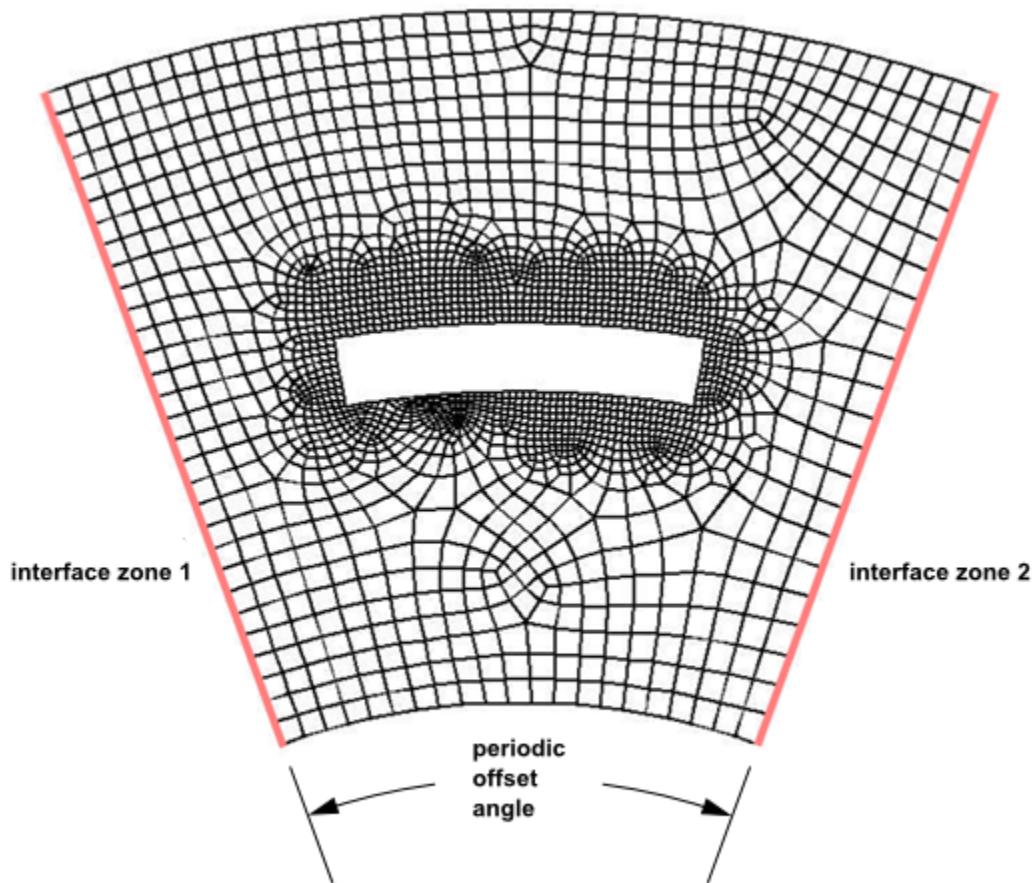

Figure 6.30 Non-Conformal Periodic Boundary Condition (Rotational)

6.4.1.2. The Periodic Repeats Option

The periodic repeats option is appropriate when each of the interface zones is adjacent to a pair of conformal periodic zones (see [Figure 6.31 \(p. 166\)](#) and [Figure 6.32 \(p. 167\)](#)). The periodic repeats option takes into account the repeating nature of the flow solutions in the two cell zones in the following manner. Wherever the interface zones overlap (i.e., wherever interface zone 1 and 2 are spatially coincident), the fluxes on either side of the interface are coupled in the usual way. The portion of interface zone 1 that does not overlap is coupled to the non-overlapping portion of interface zone 2, by translating or rotating the fluxes by the periodic offset. This is similar to the treatment of non-conformal periodic boundary conditions. The periodic repeats option is typically used in conjunction with the sliding mesh model when simulating the interface between a rotor and stator.

Figure 6.31 Translational Non-Conformal Interface with the Periodic Repeats Option

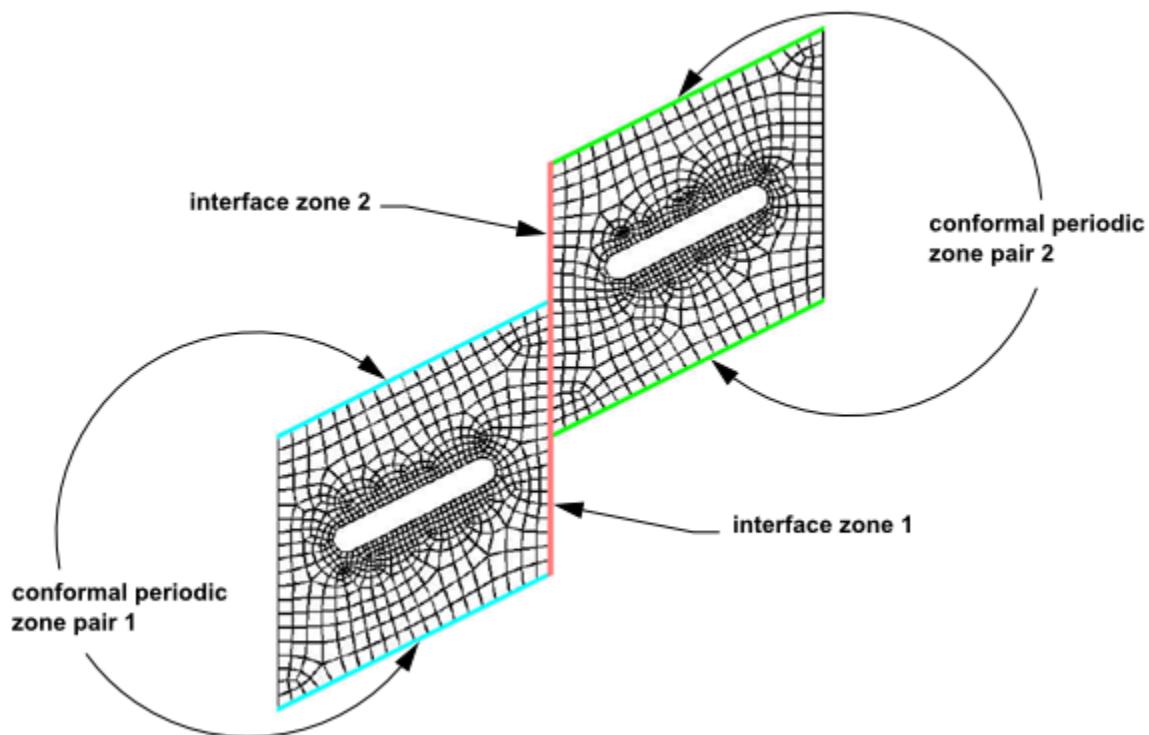

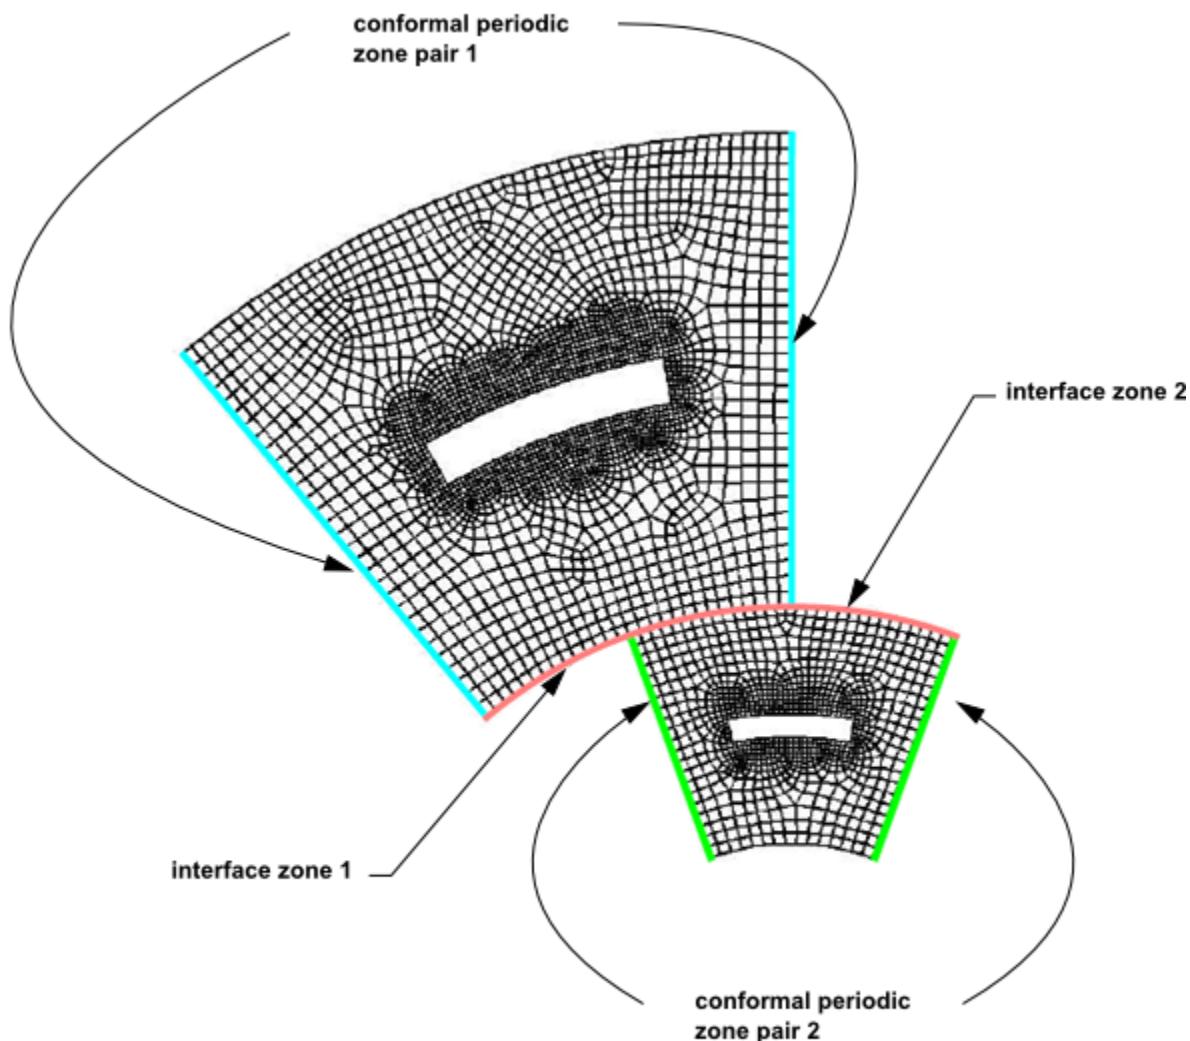

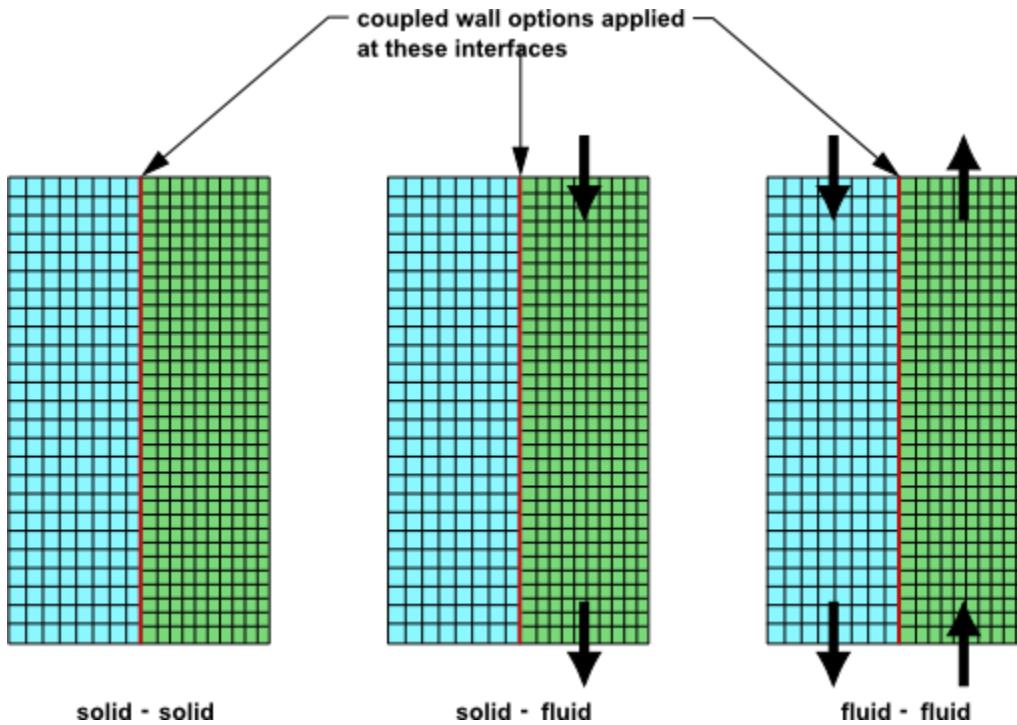

Figure 6.32 Rotational Non-Conformal Interface with the Periodic Repeats Option

6.4.1.3. The Coupled Wall Option

As described previously, the typical function of non-conformal interfaces is to couple fluid zones, so as to permit fluid flow to pass from one mesh interface to the other. Another available option is to create a coupled wall boundary at the interface. In such a case, fluid flow would not pass across the interface, as the interface is acting as a wall zone. Coupled wall heat transfer, on the other hand, would be permitted. Such an interface is required if one or both of the cell zones is a solid. It is also allowable if both of the cell zones are fluids; for example, you can model a thin wall or baffle separating the two fluid zones. [Figure 6.33 \(p. 168\)](#) illustrates coupled walls with both solid and fluid zones.

Note that coupled walls can also make use of the periodic repeats option. That is, both options can be invoked simultaneously. For details see [Using a Non-Conformal Mesh in ANSYS FLUENT \(p. 170\)](#).

Figure 6.33 Non-Conformal Coupled Wall Interfaces

6.4.2. Non-Conformal Interface Algorithm

In the current version of ANSYS FLUENT, non-conformal interface calculations are handled using a virtual polygon approach, which stores the area vector and centroid of the polygon faces. This approach does not involve node movement and cells are not necessarily water-tight cells. Hence gradients are corrected to take into account the missing face area. Note that in transient cases, the stationary non-conformal interfaces will be automatically preserved by ANSYS FLUENT during mesh update.

Previous versions of FLUENT (6.1 or earlier) used a triangular face approach, which triangulated the polygon intersection faces and stored triangular faces. This approach involved node movement and water-tight cells, and was not as stable as the current virtual polygon approach. Note that case files in which the interface was set up using FLUENT 6.1 or earlier can be read and run normally in the current version of ANSYS FLUENT, which will use the virtual polygon approach rather than the triangular face approach.

It is possible that distorted meshes may be produced during sliding mesh calculations, generating what are called "left-handed" faces. You cannot obtain a flow solution until all of the faces are "right handed," and so ANSYS FLUENT corrects the left handedness of these faces automatically. In extreme cases, the left-handed faces cannot be fully corrected and are deleted automatically, so that the solution does not diverge.

Left-handed cells can also be created for the geometries that contain sharp edges and corners, which may affect the final solution. For such geometries, it is recommended to first separate the zones and then create the interfaces separately to get the better solution.

The additional input of the angle/translation vector at the angle/translation-vector prompt in the console may be required to recreate face-periodic interfaces. Also, with the current mesh interface algorithm in parallel, there is no need for encapsulation.

6.4.3. Requirements and Limitations of Non-Conformal Meshes

This section describes the requirements and limitations of non-conformal meshes:

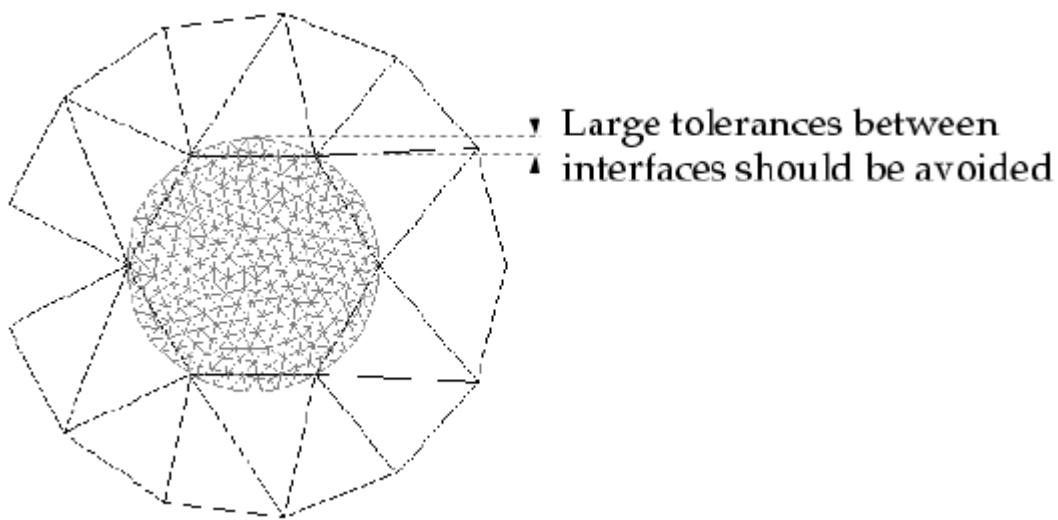

- The mesh interface can be of any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features (e.g., 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.

For example, consider the case of two concentric circles that define two fluid zones with a circular, non-conformal interface between them, as shown in [Figure 6.34 \(p. 169\)](#). Because the node spacing on the interface edge of the outer fluid zone is coarse compared to the radius of curvature, the interface does not closely follow the feature (in this case, the circular edge.)

Important

The maximum tolerance between two interfaces should not be larger than their adjacent cell size at that location. That is, no cell should be completely enclosed between two interfaces.

Figure 6.34 A Circular Non-Conformal Interface

- If you create a single mesh with multiple cell zones separated by a non-conformal boundary, you must be sure that each cell zone has a distinct face zone on the non-conformal boundary.

The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. It is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in [Reading Multiple Mesh/Case/Data Files \(p. 158\)](#).

- All periodic zones must be correctly oriented (either rotational or translational) before you create the non-conformal interface.
- You must not enable the periodic boundary condition option if the interface is adjacent to another non-conformal interface.
- In order for the periodic boundary condition option or periodic repeats option to be valid, the edges of the second interface zone must be offset from the corresponding edges of the first interface zone.

by a uniform amount (either a uniform translational displacement or a uniform rotation angle). This is not true for non-conformal interfaces in general.

The periodic boundary condition option has the additional requirement that the angle associated with a rotational periodic must be able to divide 360 without remainder.

- The periodic repeats option requires that some portion of the two interface zones must overlap (i.e., be spatially coincident).
- The periodic repeats option requires that the non-overlapping portions of the interface zones must have identical shape and dimensions. If the interface is part of a sliding mesh, you must define the mesh motion such that this criterion is met at all times.
- The periodic repeats option requires one pair of conformal periodic zones adjacent to each of the interface zones. For example, when you calculate just one channel and blade of a fan, turbine, etc., you must have conformal periodics on either side of the interface threads. This will not work with non-conformal periodics.

Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.

- You must not have a single non-conformal interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (i.e., the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See [Using a Non-Conformal Mesh in ANSYS FLUENT](#) (p. 170) for information about creating coupled interfaces.

6.4.4. Using a Non-Conformal Mesh in ANSYS FLUENT

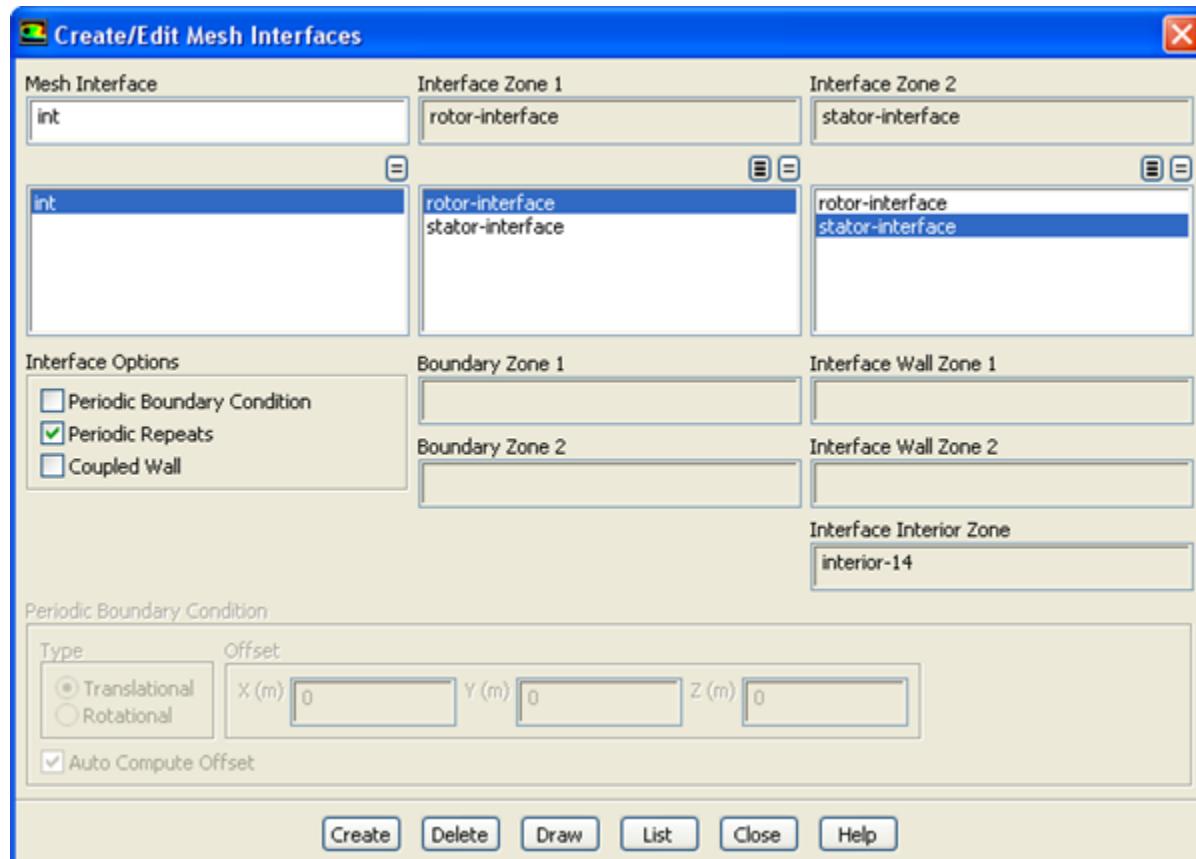

If your multiple-zone mesh includes non-conformal boundaries, check if the mesh meets all the requirements (listed in [Requirements and Limitations of Non-Conformal Meshes](#) (p. 169)). This ensures that ANSYS FLUENT can obtain a solution on the mesh. Then do the following:

1. Read the mesh into ANSYS FLUENT. If you have multiple mesh files that have not yet been merged, first follow the instructions in [Reading Multiple Mesh/Case/Data Files](#) (p. 158) to merge them into a single mesh.
2. After reading in the mesh, change the type of each pair of zones that comprises the non-conformal boundary to **interface** (as described in [Changing Cell and Boundary Zone Types](#) (p. 213)).

Boundary Conditions

3. Define the non-conformal mesh interfaces in the [Create/Edit Mesh Interfaces Dialog Box](#) (p. 2022) ([Figure 6.35](#) (p. 171)).

Mesh Interfaces → Create/Edit...

Figure 6.35 The Create/Edit Mesh Interfaces Dialog Box

- Enter a name for the interface in the **Mesh Interface** text-entry box.
- Specify the two interface zones that comprise the mesh interface by selecting one or more zones in the **Interface Zone 1** list and one or more zones in the **Interface Zone 2** list.

Important

If one of your interface zones is much smaller than the other, you should specify the smaller zone as **Interface Zone 1** to improve the accuracy of the intersection calculation.

- Enable the desired **Interface Options**, if appropriate. There are three options:
 - Enable **Periodic Boundary Condition** to create a non-conformal periodic boundary condition interface.
 - Select either **Translational** or **Rotational** as the periodic boundary condition **Type** to define the type of periodicity.
 - Retain the enabled default setting of **Auto Compute Offset** if you want ANSYS FLUENT to automatically compute the offset. After creating the interface, the offsets will be displayed in these fields. The fields will be uneditable when the **Auto Compute Offset** is enabled.
 - Disable **Auto Compute Offset** if you decide that you do not want ANSYS FLUENT to find the offset. In this case, you will have to provide the offset coordinates or angle in the required fields, depending on whether **Translational** or **Rotational** periodicity is selected.

Important

Auto computation means that the rotational angle or the translational offset will be automatically calculated and used while creating a non-conformal periodic boundary condition interface. However, it still relies on the **Rotational Axis Origin** and the **Rotational Axis Direction** that was entered for the cell zone in the cell zone condition dialog box (e.g., the **Fluid** dialog box). Therefore, before proceeding with the creation of the non-conformal periodic boundary condition interface, you have to correctly enter the rotational axis for the corresponding cell zone.

Note that auto computation of the non-conformal periodic boundary condition offset does not mean that the **Rotational Axis Origin** and **Rotational Axis Direction** are also detected automatically and updated. It is still your responsibility to set up these values correctly.

Important

The **Periodic Boundary Condition** option is only valid when a single zone is selected in each of the **Interface Zone 1** and the **Interface Zone 2** selection lists.

- Enable **Periodic Repeats** when each of the two cell zones has a single pair of conformal periodics adjacent to the interface (see *Figure 6.31 (p. 166)*). This option is typically used in conjunction with the sliding mesh model, when simulating the interface between a rotor and stator.
-

Important

The **Periodic Repeats** option is only valid when a single zone is selected in each of the **Interface Zone 1** and the **Interface Zone 2** selection lists.

- Enable **Coupled Wall** if you would like to model a thermally coupled wall between two fluid zones that share a non-conformal interface.
-

Important

Note that the following interfaces are coupled by default:

- the interface between a solid zone and fluid zone
- the interface between a solid zone and solid zone

Therefore, no action is required in the **Create/Edit Mesh Interfaces** dialog box to set up such interfaces.

- d. Click **Create** to create a new mesh interface. For all types of interfaces, ANSYS FLUENT will create boundary zones for the interface (e.g., **wall-9**, **wall-10**), which will appear under **Boundary Zone 1** and **Boundary Zone 2**. If you have enabled the **Coupled** option, ANSYS FLUENT will also create

wall interface zones (e.g., **wall-4**, **wall-4-shadow**), which will appear under **Interface Wall Zone 1** and **Interface Wall Zone 2**.

- e. If the two interface zones did not overlap entirely, check the boundary zone type of the zone(s) created for the non-overlapping portion(s) of the boundary. If the zone type is not correct, you can use the [Boundary Conditions Task Page \(p. 1958\)](#) to change it.
- f. If you have any **Coupled Wall** type interfaces, define boundary conditions (if relevant) by updating the interface wall zones using the **Boundary Conditions** task page.

Boundary Conditions

If you create an incorrect mesh interface, you can select it in the **Mesh Interface** selection list and click the **Delete** button to delete it. Any boundary zones or wall interface zones that were created when the interface was created will also be deleted. You may then proceed with the problem setup as usual.

You can click the **Draw** button to display interface zones or mesh interfaces in the graphics window. Note that you can only select and display interface zones from **Interface Zone 1** or **Interface Zone 2** prior to defining any **Mesh Interfaces**. After a **Mesh Interface** is defined, you can select the appropriate mesh interface and click the **Draw** button to display the zones under **Interface Zone 1** and **Interface Zone 2** together as defined by the **Mesh Interface**. This is particularly useful if you want to check the location of the interface zones prior to setting up a mesh interface.

6.5. Checking the Mesh

The mesh checking capability in ANSYS FLUENT examines various aspects of the mesh, including the mesh topology, periodic boundaries, simplex counters, and (for axisymmetric cases) node position with respect to the x axis, and provides a mesh check report with details about domain extents, statistics related to cell volume and face area, and information about any problems associated with the mesh. You can check the mesh by clicking the **Check** button in the **General** task page.

General → Check

Important

It is generally a good idea to check your mesh right after reading it into the solver, in order to detect any mesh trouble before you get started with the problem setup.

The mesh check examines the topological information, beginning with the number of faces and nodes per cell. A triangular cell (2D) should have 3 faces and 3 nodes, a tetrahedral cell (3D) should have 4 faces and 4 nodes, a quadrilateral cell (2D) should have 4 faces and 4 nodes, and a hexahedral cell (3D) should have 6 faces and 8 nodes. Polyhedral cells (3D) will have an arbitrary number of faces and nodes.

Next, the face handedness and face node order for each zone is checked. The zones should contain all right-handed faces, and all faces should have the correct node order.

The last topological verification is checking the element-type consistency. If a mesh does not contain mixed elements (quadrilaterals and triangles or hexahedra and tetrahedra), ANSYS FLUENT will determine that it does not need to keep track of the element types. By doing so, it can eliminate some unnecessary work.

For axisymmetric cases, the number of nodes below the x axis is listed. Nodes below the x axis are forbidden for axisymmetric cases, since the axisymmetric cell volumes are created by rotating the 2D cell volume about the x axis; thus nodes below the x axis would create negative volumes.

For solution domains with rotationally periodic boundaries, the minimum, maximum, average, and prescribed periodic angles are computed. A common mistake is to specify the angle incorrectly. For domains with translationally periodic boundaries, the boundary information is checked to ensure that the boundaries are truly periodic.

Finally, the simplex counters are verified. The actual numbers of nodes, faces, and cells the solver has constructed are compared to the values specified in the corresponding header declarations in the mesh file. Any discrepancies are reported.

6.5.1. Mesh Check Report

6.5.2. Repairing Meshes

6.5.1. Mesh Check Report

When you click the **Check** button in the **General** task page, a mesh check report will be displayed in the console. The following is a sample of a successful output :

```
Mesh Check

Domain Extents:
  x-coordinate: min (m) = -4.000000e-002, max (m) = 2.550000e-001
  y-coordinate: min (m) = 0.000000e+000, max (m) = 2.500000e-002
Volume statistics:
  minimum volume (m3): 2.463287e-009
  maximum volume (m3): 4.508038e-007
  total volume (m3): 4.190433e-004
  minimum 2d volume (m3): 3.000589e-007
  maximum 2d volume (m3): 3.019523e-006
Face area statistics:
  minimum face area (m2): 4.199967e-004
  maximum face area (m2): 2.434403e-003
Checking mesh.....
Done.
```

The mesh check report begins by listing the domain extents. The domain extents include the minimum and maximum x , y , and z coordinates in meters.

Then the volume statistics are provided, including the minimum, maximum, and total cell volume in m^3 . A negative value for the minimum volume indicates that one or more cells have improper connectivity. Cells with a negative volume can often be identified using the **Iso-Value Adaption** dialog box to mark them for adaption and view them in the graphics window. For more information on creating and viewing isovalue adaption registers, see [Isovalue Adaption \(p. 1451\)](#). You *must* eliminate these negative volumes before continuing the flow solution process.

Next, the mesh report lists the face area statistics, including the minimum and maximum areas in m^2 . A value of 0 for the minimum face area indicates that one or more cells have degenerated. As with negative volume cells, you *must* eliminate such faces. It is also recommended to correct cells that have nonzero face areas, if the values are very small.

Besides the information about the domain extents and statistics, the mesh check report will also display warnings based on the results of the checks previously described. You can specify that the mesh check report displays more detailed information about the various checks and the mesh failures, by using the following text command prior to performing the mesh check:

```
mesh → check-verbosity
```

You will then be prompted to enter the level of verbosity for the mesh check report. The possible levels include:

- 0

This is the default level, and only notifies you that checks are being performed (e.g., **Checking mesh...**). The report will look like the previous example; while warnings will be displayed below the domain extents and statistics, the names of the individual checks will not be listed as they are conducted.

- 1

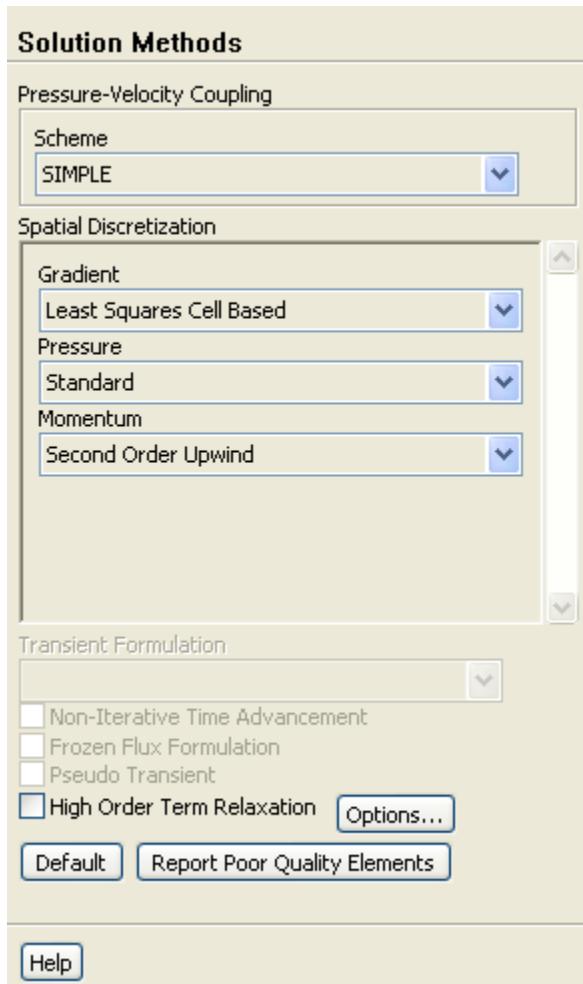

This level lists the individual checks as they are performed (e.g., **Checking right-handed cells**). Any warnings that result will be displayed immediately below the check that produced it.

- 2

This level provides the maximum information about the mesh check. The report will list the individual checks as they are performed (e.g., **Checking right-handed cells**); any warnings that result will be displayed immediately below the check that produced it. Additional details about the check failure will also be displayed, such as the location of the problem or the affected cells.

6.5.2. Repairing Meshes

If the mesh check report indicates a mesh problem or if you receive warnings, you can investigate the extent of the problem by printing the poor element statistics in the console. This can be accomplished using the **Report Poor Quality Elements** button, located at the bottom of the **Solution Methods** task page ([Figure 6.36 \(p. 176\)](#)). Note that this button is only available when the mesh has poor quality elements. For more information about the **Report Poor Quality Elements** feature, please see [Robustness on Meshes of Poor Quality \(p. 1433\)](#).

Figure 6.36 The Solution Methods Task Page

Alternatively, you can print the poor element statistics via the following text command:

```
mesh → repair-improve → report-poor-elements
```

You can also visualize the invalid and poor elements: first, mark them by using the **Mesh...** and **Mark Poor Elements** selections from the **Iso-Values of** drop-down lists of the **Iso-Value Adaption** dialog box (see [Performing Isovalue Adaption \(p. 1451\)](#) for further details). Then, display them in the graphics window using the **Manage Adaption Registers** dialog box, as described in [Manipulating Adaption Registers \(p. 1459\)](#). Similarly, you can display them using the **Contours** dialog box, by selecting **Mesh...** and **Mark Poor Elements** from the **Contours of** drop-down lists. In either case, a value of 1 is assigned to the cells that are identified as invalid or poor, as well as the cells that are adjacent to the face of an invalid or poor cell, and a value of 0 is assigned to all other cells.

The mesh check report will indicate if the mesh has problems that must be repaired, such as left-handed faces and/or faces that have the wrong node order. The simplest way to attempt to correct your mesh problems is to use the following text command:

```
mesh → repair-improve → repair
```

The `mesh/repair-improve/repair` text command will attempt to correct a number of problems identified by the mesh check, including cells that have:

- the wrong node order

- the wrong face handedness or that are not convex
- faces that are small or nonexistent
- very poor quality (see [Mesh Quality \(p. 145\)](#) for additional details)

Note that by default, the `repair` text command will only adjust the positions of interior nodes. If you want to also modify the nodes on the boundaries of the mesh, use the following text command *before* you repair the mesh:

```
mesh → repair-improve → allow-repair-at-boundaries
```

The `repair` text command may convert degenerate cells into polyhedra, based on skewness criteria (for more information on how cells are converted, see [Converting Skewed Cells to Polyhedra \(p. 184\)](#)). If you want to ensure that there are no polyhedra in the repaired mesh (e.g., if you plan on performing mesh adaption), you must disable such conversions using the following text command *before* you repair the mesh:

```
mesh → repair-improve → include-local-polyhedra-conversion-in-repair
```

If you would like to only attempt to improve the poor quality cells, you can use the following text command:

```
mesh → repair-improve → improve-quality
```

You can use the `improve-quality` text command multiple times, until the mesh is improved to your satisfaction. For greater control over the degree to which the mesh is improved, you can perform quality-based smoothing (as described in [Quality-Based Smoothing \(p. 1467\)](#)).

It should be noted that both the `repair` and the `improve-quality` text commands can be CPU intensive, if there are a large number of poor quality cells in the mesh. If you are not as concerned about cell quality, you can attempt to fix only the left-handed faces and faces with the wrong node order. Begin by repairing the node order with the following text command:

```
mesh → repair-improve → repair-face-node-order
```

Because the left-handed faces may be a result of improper face node order, the previous text command may resolve both issues at the same time. Be sure to perform another mesh check after entering the `repair-face-node-order` command, to see if the mesh has been fully repaired.

If at any point the mesh check reveals that the mesh contains left-handed faces without any node order issues, you can attempt to repair the face handedness by modifying the cell centroids with the following text command:

```
mesh → repair-improve → repair-face-handedness
```

Once again, perform a mesh check to see if the text command was successful. The `repair-face-handedness` text command is most effective for cells with high aspect ratios.

If the mesh check report includes a warning message such as

```
WARNING: node on face thread 2 has multiple shadows.
```

it indicates the existence of duplicate shadow nodes. This error occurs only in meshes with periodic-type walls. You can repair such a mesh using the following text command:

```
mesh → repair-improve → repair-periodic
```

If the interface is rotational periodic, you will be prompted for the rotation angle.

6.6. Reporting Mesh Statistics

There are several methods for reporting information about the mesh after it has been read into ANSYS FLUENT. You can report the amount of memory used by the current problem, the mesh size, and statistics about the mesh partitions. Zone-by-zone counts of cells and faces can also be reported.

Information about mesh statistics is provided in the following sections:

- 6.6.1. Mesh Size
- 6.6.2. Memory Usage
- 6.6.3. Mesh Zone Information
- 6.6.4. Partition Statistics

6.6.1. Mesh Size

You can print out the numbers of nodes, faces, cells, and partitions in the mesh by selecting the **Mesh/Info/Size** menu item.

Mesh → Info → Size

A partition is a piece of a mesh that has been segregated for parallel processing (see [Parallel Processing \(p. 1715\)](#)).

A sample of the resulting output follows:

```
Mesh Size
Level      Cells        Faces        Nodes        Partitions
  0          7917       12247       4468           1
2 cell zones, 11 face zones.
```

If you are interested in how the cells and faces are divided among the different zones, you can use the **Mesh/Info/Zones** menu item, as described in [Mesh Zone Information \(p. 179\)](#).

If you are using the density-based coupled explicit solver, the mesh information will be printed for each grid level. The grid levels result from creating coarse grid levels for the FAS multigrid convergence acceleration (see [Full-Approximation Storage \(FAS\) Multigrid](#) in the [Theory Guide](#)). A sample of the resulting output is shown below:

```
Mesh Size
Level      Cells        Faces        Nodes        Partitions
  0          7917       12247       4468           1
  1          1347       3658         0           1
  2          392        1217         0           1
  3          133        475          0           1
  4          50         197          0           1
  5          17         78          0           1
2 cell zones, 11 face zones.
```

6.6.2. Memory Usage

During an ANSYS FLUENT session you may want to check the amount of memory used and allocated in the present analysis. ANSYS FLUENT has a feature that will report the following information: the numbers of nodes, faces, cells, edges, and object pointers (generic pointers for various mesh and

graphics utilities) that are used and allocated; the amount of array memory (scratch memory used for surfaces) used and allocated; and the amount of memory used by the solver process.

You can obtain this information by selecting the **Mesh/Info/Memory Usage** menu item.

Mesh → Info → Memory Usage

The memory information will be different for Linux and Windows systems.

6.6.2.1. Linux Systems

On Linux systems, note the following definitions related to process memory information:

- Process static memory is essentially the size of the code itself.
- Process dynamic memory is the allocated heap memory used to store the mesh and solution variables.
- Process total memory is the sum of static and dynamic memory.

6.6.2.2. Windows Systems

On Windows systems, note the following definitions related to process memory information:

- Process physical memory is the allocated heap memory currently resident in RAM.
- Process virtual memory is the allocated heap memory currently swapped to the Windows system page file.
- Process total memory is the sum of physical and virtual memory.

Note the following:

- The memory information does not include the static (code) memory.
- In the serial version of ANSYS FLUENT, the heap memory value includes storage for the solver (mesh and solution variables), and Cortex (GUI and graphics memory), since Cortex and the solver are contained in the same process.
- In the parallel version, Cortex runs in its own process, so the heap memory value includes storage for the mesh and solution variables only.

On Windows systems, you can also get more information on the ANSYS FLUENT process (or processes) by using the Task Manager (see your Windows documentation for details). For the serial version, the process image name will be something like `f11400s.exe`. For the parallel version, examples of process image names are as follows: `cx1400.exe` (Cortex) and `f11400.exe` (solver host).

6.6.3. Mesh Zone Information

You can print information in the console about the nodes, faces, and cells in each zone using the **Mesh/Info/Zones** menu item.

Mesh → Info → Zones

The mesh zone information includes the total number of nodes and, for each face and cell zone, the number of faces or cells, the cell (and, in 3D, face) type (triangular, quadrilateral, etc.), the boundary condition type, and the zone ID. Sample output is shown below:

```
Zone sizes on domain 1:  
21280 hexahedral cells, zone 4.
```

```
532 quadrilateral velocity-inlet faces, zone 1.  
532 quadrilateral pressure-outlet faces, zone 2.  
1040 quadrilateral symmetry faces, zone 3.  
1040 quadrilateral symmetry faces, zone 7.  
61708 quadrilateral interior faces, zone 5.  
1120 quadrilateral wall faces, zone 6.  
23493 nodes.
```

6.6.4. Partition Statistics

You can print mesh partition statistics in the console by selecting the **Mesh/Info/Partitions** menu item.

Mesh → Info → Partitions

The statistics include the numbers of cells, faces, interfaces, and neighbors of each partition. See [Interpreting Partition Statistics \(p. 1754\)](#) for further details, including sample output.

6.7. Converting the Mesh to a Polyhedral Mesh

Since the ANSYS FLUENT solver is face based, it supports polyhedral cells. The advantages that polyhedral meshes have shown over some of the tetrahedral or hybrid meshes is the lower overall cell count, almost 3-5 times lower for unstructured meshes than the original cell count. Currently, there are three options in ANSYS FLUENT that allow you to convert your nonpolyhedral cells to a polyhedra:

- Converting the entire domain into polyhedral cells (applicable only for meshes that contain tetrahedral and/or wedge/prism cells).
- Converting skewed tetrahedral cells to polyhedral cells.
- Converting cells with hanging nodes / edges to polyhedral cells.

Information about polyhedral mesh conversion is provided in the following sections:

[6.7.1. Converting the Domain to a Polyhedra](#)

[6.7.2. Converting Skewed Cells to Polyhedra](#)

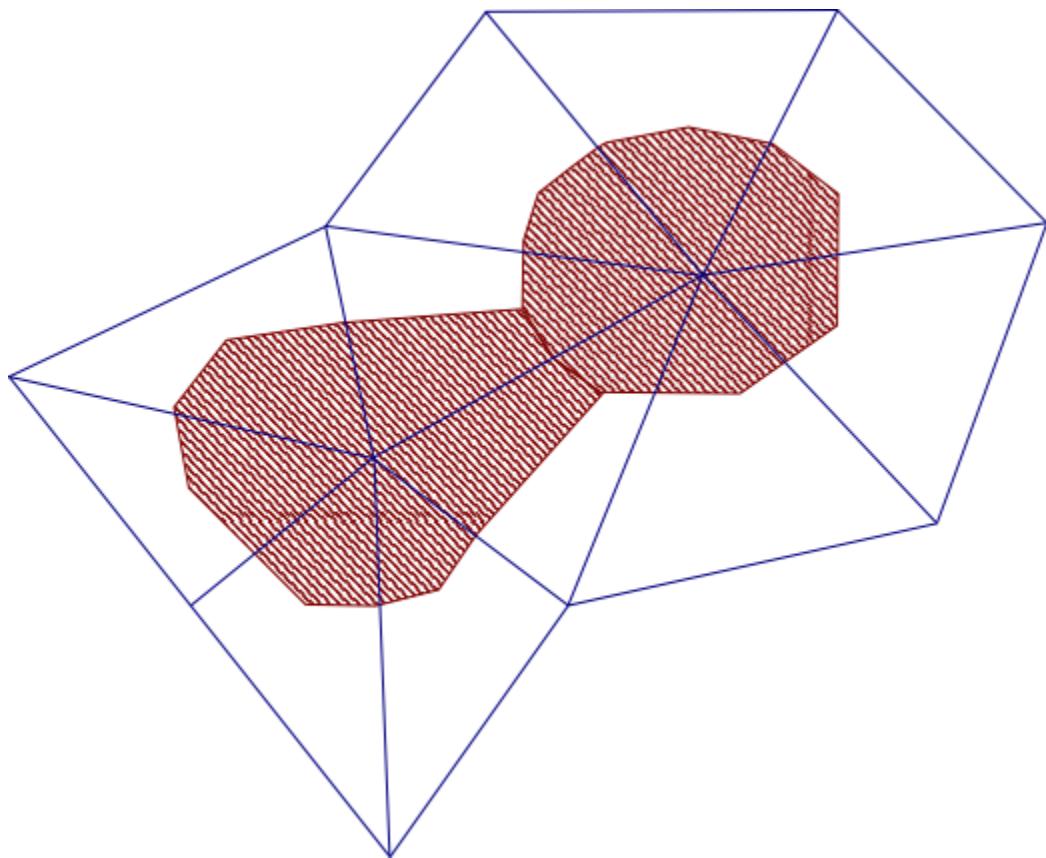

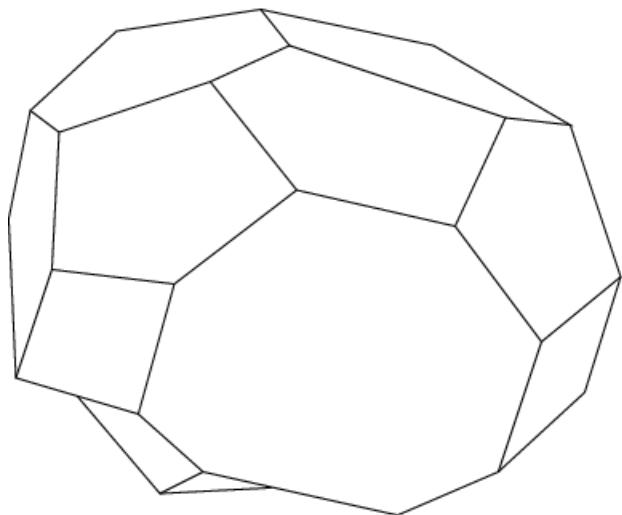

[6.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra](#)

6.7.1. Converting the Domain to a Polyhedra

Conversion of a mesh to polyhedra only applies to 3D meshes that contain tetrahedral and/or wedge/prism cells.

To begin the conversion process, ANSYS FLUENT automatically decomposes each non-hexahedral cell into multiple sub-volumes called “duals” (the shaded regions seen in the 2D example in [Figure 6.37 \(p. 181\)](#)). Each dual is associated with one of the original nodes of the cell. These duals are then agglomerated into polyhedral cells around the original nodes. Thus, the collection of duals from all cells sharing a particular node makes up each polyhedral cell (see [Figure 6.38 \(p. 181\)](#)). The node that is now within the polyhedral cell is no longer needed and is removed.

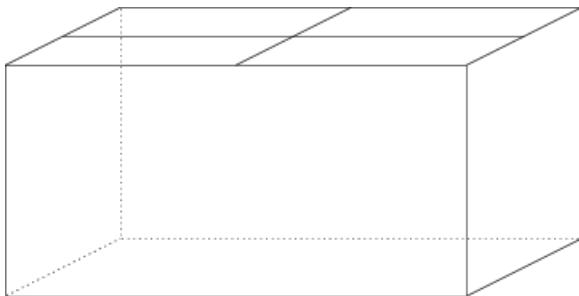

To better understand how duals are formed, you can consider the straightforward case of a tetrahedral mesh. Each of the cells are decomposed in the following manner: first, new edges are created on each face between the face centroid and the centroids of the edges of that face. Then, new faces are created within the cell by connecting the cell centroid to the new edges on each face. These interior faces establish the boundaries between the duals of a cell, and divide the cell into 4 sub-volumes. These dividing faces may be adjusted and merged with neighboring faces during the agglomeration process, in order to minimize the number of faces on the resultant polyhedral cell.

Figure 6.37 Connection of Edge Centroids with Face Centroids**Figure 6.38 A Polyhedral Cell**

Important

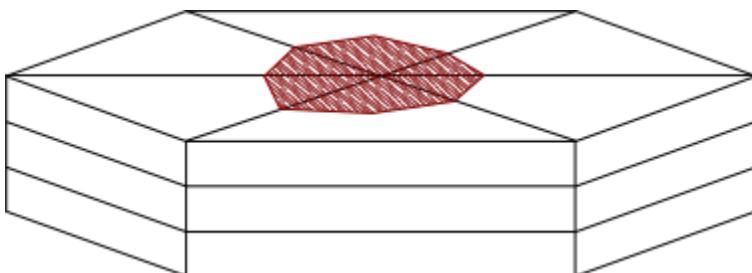

Hexahedral cells are not converted to polyhedra when the domain is converted, except when they border non-hexahedral cells. When the neighboring cell is reconfigured as polyhedra, the shared face of the hexahedral cell is decomposed into multiple faces as well, resulting in a polyhedral cell. In such a case the shape of the original hexahedral cell is preserved (i.e. the overall dimensions of the cell stay the same), but the converted cell has more than the original 6 faces (see [Figure 6.39 \(p. 182\)](#)).

Figure 6.39 A Converted Polyhedral Cell with Preserved Hexahedral Cell Shape

Conversion proceeds in a slightly different manner in boundary layers that are modeled using thin wedge/prism cells. These cells are decomposed in the plane of the boundary surface, but not in the direction normal to the surface. The resulting polyhedra will therefore preserve the thickness of the original wedge/prism cells ([Figure 6.40 \(p. 182\)](#)). In most cases, the cell count in the new polyhedral boundary layer will be lower than the original boundary layer.

Figure 6.40 Treatment of Wedge Boundary Layers

To convert the entire domain of your mesh, use the **Mesh/Polyhedra/Convert Domain** menu.

Mesh → Polyhedra → Convert Domain

The following is an example of the resulting message printed in the console:

```
Setup conversion to polyhedra.
Converting domain to polyhedra...

Creating polyhedra zones.
Processing face zones.....
Processing cell zones...
Building polyhedra mesh.....
Optimizing polyhedra mesh.....
>> Reordering domain using Reverse Cuthill-McKee method:
    zones, cells, faces, done.
Bandwidth reduction = 1796/247 = 7.27
Done.
```

Figure 6.41 (p. 183), the original tetrahedral mesh of a section of a manifold, is compared to *Figure 6.42 (p. 183)* which is the resulting mesh after the entire domain is converted to a polyhedra.

Figure 6.41 The Original Tetrahedral Mesh

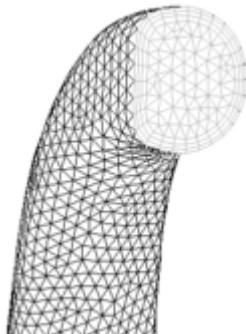

Figure 6.42 The Converted Polyhedral Mesh

Note that by default, the surfaces (i.e., manifold zones of type **interior**) will be lost during the conversion to polyhedra. If you would like to preserve any of these zones (in order to utilize them for postprocessing, for example), use the following text command prior to the conversion:

```
mesh → polyhedra → options → preserve-interior-zones
```

You will be prompted to enter a string of characters, and only those interior surfaces with a name that includes the string you specify will be preserved.

6.7.1.1. Limitations

Some limitations you will find with polyhedral meshes that you generally do not experience with other cell types include:

- Meshes that already contain polyhedral cells cannot be converted.
- Meshes with hanging nodes / edges will not be converted. This includes meshes that have undergone hanging node adaption (see [Hanging Node Adaption](#) in the [Theory Guide](#)), as well as CutCell meshes (generated by TGrid or Workbench, or resulting from the CutCell zone remeshing method in ANSYS FLUENT) and hexcore meshes (generated when using the GAMBIT **Hex Core** meshing scheme or the TGrid **Hexcore** menu option).
- The following mesh manipulation tools are not available for polyhedral meshes:
 - the `mesh/modify-zones/extrude-face-zone-delta` text command

- the `mesh/modify-zones/extrude-face-zone-para` text command
 - fuse
 - skewness smoothing
 - swapping
- Meshes in which the domain has been converted to polyhedral cells are not eligible for adaption. For more information about adaption, see [Adapting the Mesh \(p. 1441\)](#).
 - A mesh that is entirely comprised of polyhedral cells has limitations when it is to be used in a dynamic mesh problem: it cannot undergo dynamic layering, and the only remeshing method available is CutCell zone remeshing. Smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see [Diffusion-Based Smoothing \(p. 581\)](#) for details).

6.7.2. Converting Skewed Cells to Polyhedra

Another method of cell agglomeration is the skewness-based cluster approach. This type of conversion is designed to convert only part of the domain. The objective is to convert only skewed tetrahedral cells above a specified cell equivolume skewness threshold into polyhedra. By converting the highly skewed tetrahedral cells, the quality of the mesh can be improved significantly.

A different algorithm is used for local conversion. This algorithm evaluates each highly skewed tetrahedral cell and all of the surrounding cells, to select an edge on the highly skewed cell that best matches criteria for cell agglomeration. Then all of the cells which share this edge are combined into a polyhedral cell. During the process, the data is interpolated from the original cells to the resultant polyhedra.

6.7.2.1. Limitations

There are certain limitations with this type of conversion:

- The following mesh manipulation tools are not available on polyhedral meshes:
 - the `mesh/modify-zones/extrude-face-zone-delta` text command
 - the `mesh/modify-zones/extrude-face-zone-para` text command
 - fuse
 - skewness smoothing
 - swapping will not affect polyhedral cells
- The polyhedral cells that result from the conversion are not eligible for adaption. For more information about adaption, see [Adapting the Mesh \(p. 1441\)](#).
- Only tetrahedral cells are converted, as all other cells are skipped.
- Meshes with hanging nodes / edges will not be converted. This includes meshes that have undergone hanging node adaption (see [Hanging Node Adaption](#) in the [Theory Guide](#)), as well as CutCell meshes (generated by TGrid or Workbench, or resulting from the CutCell zone remeshing method in ANSYS FLUENT), as well as hexcore meshes (generated when using the GAMBIT **Hex Core** meshing scheme or the TGrid **Hexcore** menu option). Note that if the mesh is a CutCell/hexcore mesh in which the transitional cells have been converted to polyhedra, then it does not have hanging nodes / edges and can therefore be converted.
- The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:

- When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
- None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see [Diffusion-Based Smoothing \(p. 581\)](#) for details).

6.7.2.2. Using the Convert Skewed Cells Dialog Box

To convert skewed cells in your domain to polyhedral cells, go to the **Convert Skewed Cells** dialog box.

Mesh → Polyhedra → Convert Skewed Cells...

Figure 6.43 The Convert Skewed Cells Dialog Box

1. Select the zone(s) you want to consider for local polyhedra conversion from the **Cell Zones** selection list. After the zone selection is made, the **Current** value of the **Maximum Cell Skewness** and the percentage of **Cells Above Target** are displayed.
2. Specify the maximum allowable cell skewness in the **Target** text-entry box, and press <Enter> to update the **Cells Above Target**.

Important

The **Cells Above Target (%)** should be only a couple of percentage points, otherwise the conversion will be ineffective due to the high face count.

3. Click the **Convert** button.

The number of created polyhedra and the resulting maximum cell skewness will be printed in the console.

6.7.3. Converting Cells with Hanging Nodes / Edges to Polyhedra

ANSYS FLUENT provides a text command that allows you to convert cells that have hanging nodes / edges into polyhedra. Such a conversion may be done in order to prevent errors associated with interior

walls (see [Using the `tpoly` Filter to Remove Hanging Nodes / Edges \(p. 156\)](#)). Each of the converted polyhedra preserve the shape of the original cell (i.e., the overall dimensions of each cell stay the same), but the number of faces associated with each cell increases (see [Figure 6.39 \(p. 182\)](#) for an example). Such a conversion may be helpful for CutCell meshes (generated by TGrid or Workbench, or resulting from the CutCell zone remeshing method in ANSYS FLUENT), as well as hexcore meshes (generated when using the GAMBIT **Hex Core** meshing scheme or the TGrid **Hexcore** menu option). You could also convert the cells with hanging nodes in a mesh that has undergone adaption (see [Adapting the Mesh \(p. 1441\)](#)), but you would need to be sure that no further refinement/coarsening of the mesh will be necessary.

To convert the cells with hanging nodes / edges, use the following text command:

```
mesh → polyhedra → convert-hanging-nodes
```

6.7.3.1. Limitations

There are certain limitations with this type of conversion:

- The following mesh manipulation tools are not available on polyhedral meshes:
 - the `mesh/modify-zones/extrude-face-zone-delta` text command
 - the `mesh/modify-zones/extrude-face-zone-para` text command
 - `fuse`
 - skewness smoothing
 - swapping will not affect polyhedral cells
- The polyhedral cells that result from the conversion are not eligible for adaption.
- The polyhedral cells that result from this conversion have the following limitations with regard to the update methods available for dynamic mesh problems:
 - When applying dynamic layering to a cell zone, you cannot have polyhedral cells adjacent to the moving face zone.
 - None of the remeshing methods except for CutCell zone remeshing will modify polyhedral cells.

Note that smoothing is allowed for polyhedral cells, and diffusion-based smoothing is recommended over spring-based smoothing (see [Diffusion-Based Smoothing \(p. 581\)](#) for details).

6.8. Modifying the Mesh

There are several ways in which you can modify or manipulate the mesh after it has been read into ANSYS FLUENT. You can scale or translate the mesh, copy, merge, or separate zones, create or slit periodic zones, and fuse boundaries. In addition, you can reorder the cells in the domain to decrease bandwidth. Smoothing and diagonal swapping, which can be used to improve the mesh, are described in [Improving the Mesh by Smoothing and Swapping \(p. 1466\)](#). Methods for partitioning meshes to be used in a parallel solver are discussed in [Mesh Partitioning and Load Balancing \(p. 1733\)](#).

Important

Whenever you modify the mesh, you should be sure to save a new case file (and a data file, if data exists). If you have old data files that you would like to be able to read in again, be sure to retain the original case file as well, as the data in the old data files may not correspond to the new case file.

Information about mesh manipulation is provided in the following sections:

- 6.8.1. Merging Zones
- 6.8.2. Separating Zones
- 6.8.3. Fusing Face Zones
- 6.8.4. Creating Conformal Periodic Zones
- 6.8.5. Slitting Periodic Zones
- 6.8.6. Slitting Face Zones
- 6.8.7. Orienting Face Zones
- 6.8.8. Extruding Face Zones
- 6.8.9. Replacing, Deleting, Deactivating, and Activating Zones
- 6.8.10. Copying Cell Zones
- 6.8.11. Replacing the Mesh
- 6.8.12. Reordering the Domain and Zones
- 6.8.13. Scaling the Mesh
- 6.8.14. Translating the Mesh
- 6.8.15. Rotating the Mesh

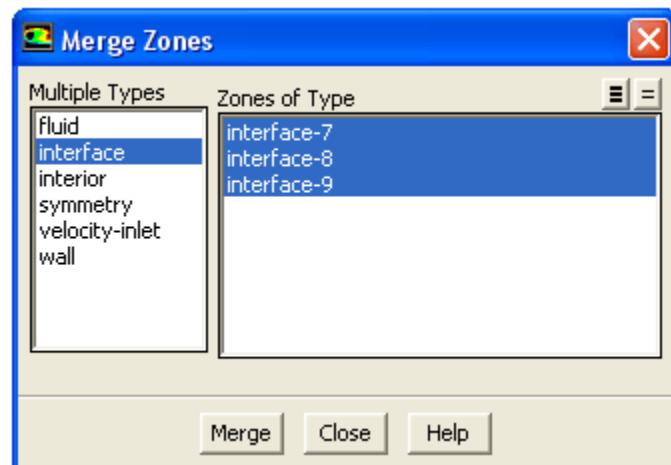

6.8.1. Merging Zones

To simplify the solution process, you may want to merge zones. Merging zones involves combining multiple zones of similar type into a single zone. Setting boundary conditions and postprocessing may be easier after you have merged similar zones.

Zone merging is performed in the *Merge Zones Dialog Box* (p. 2231) (*Figure 6.44* (p. 187)).

Mesh → Merge...

Figure 6.44 The Merge Zones Dialog Box

6.8.1.1. When to Merge Zones

ANSYS FLUENT allows you to merge zones of similar type into a single zone. This is not necessary unless the number of zones becomes prohibitive to efficient setup or postprocessing of the numerical analysis. For example, setting the same boundary condition parameters for a large number of zones can be time-consuming and may introduce inconsistencies. In addition, the postprocessing of the data often involves surfaces generated using the zones. A large number of zones often translates into a large number of surfaces that must be selected for the various display options, such as color contouring. Fortunately,

surfaces can also be merged (see [Grouping, Renaming, and Deleting Surfaces \(p. 1495\)](#)), minimizing the negative impact of a large number of zones on postprocessing efficiency.

Although merging zones can be helpful, there may be cases where you will want to retain a larger number of zones. Since the merging process is not fully reversible, a larger number of zones provides more flexibility in imposing boundary conditions. Although a large number of zones can make selection of surfaces for display tedious, it can also provide more choices for rendering the mesh and the flow-field solution. For instance, it can be difficult to render an internal flow-field solution. If the outer domain is composed of several zones, the meshes of subsets of these zones can be plotted along with the solution to provide the relationship between the geometry and solution field. Merging zones may also adversely affect dynamic zones and mesh interfaces.

6.8.1.2. Using the Merge Zones Dialog Box

The procedure for merging multiple zones of the same type into a single zone is as follows:

1. Select the zone type in the **Multiple Types** list. This list contains all the zone types for which there are multiple zones. When you choose a type from this list, the corresponding zones will appear in the **Zones of Type** list.
2. Select two or more zones in the **Zones of Type** list.
3. Click the **Merge** button to merge the selected zones. Note that if your case file has dynamic zones or mesh interfaces, the **Warning** dialog box will open before the merge is initiated, allowing you to specify whether you want to delete such zones or interfaces first (see [Warning Dialog Box \(p. 2232\)](#) for details).

Important

Remember to save a new case file (and a data file, if data exists).

6.8.2. Separating Zones

Upon reading a mesh file, ANSYS FLUENT automatically performs zone separations in two conditions. If a face zone is attached to multiple cells zones in the preprocessor, the face zone will be separated so that each one is attached to only one cell zone. Furthermore, if you have defined an internal face as a wall type, an additional shadow wall zone will be generated (e.g., for a wall named **baffle**, a shadow wall zone named **baffle-shadow** will be generated).

There are several methods available in ANSYS FLUENT that allow you to manually separate a single face or cell zone into multiple zones of the same type. If your mesh contains a zone that you want to break up into smaller portions, you can make use of these features. For example, if you created a single wall zone when generating the mesh for a duct, but you want to specify different temperatures on specific portions of the wall, you will need to break that wall zone into two or more wall zones. If you plan to solve a problem using the sliding mesh model or multiple reference frames, but you forgot to create different fluid zones for the regions moving at different speeds, you will need to separate the fluid zone into two or more fluid zones.

Important

- After performing any of these separations, you should save a new case file. If data exists, it is automatically assigned to the proper zones when separation occurs, so you should also write a new data file. The old data cannot be read on top of the case file in which the zones have changed.
- The maximum number of zones into which you can separate any one face zone or cell zone is 32.

There are four ways to separate face zones and two ways to separate cell zones. The face separation methods will be described first, followed by the cell separation tools. Slitting (decoupling) of periodic zones is discussed in [Slitting Periodic Zones \(p. 195\)](#).

Note that all of the separation methods allow you to report the result of the separation before you commit to performing it.

6.8.2.1. Separating Face Zones

For more information, see the following sections:

[6.8.2.1.1. Methods for Separating Face Zones](#)

[6.8.2.1.2. Inputs for Separating Face Zones](#)

6.8.2.1.1. Methods for Separating Face Zones

For geometries with sharp corners, it is often easy to separate face zones based on significant angle. Faces with normal vectors that differ by an angle greater than or equal to the specified significant angle will be placed in different zones. For example, if your mesh consists of a cube, and all 6 sides of the cube are in a single wall zone, you would specify a significant angle of 89° . Since the normal vector for each cube side differs by 90° from the normals of its adjacent sides, each of the 6 sides will be placed in a different wall zone.

If you have a small face zone and would like to put each face in the zone into its own zone, you can do so by separating the faces based on face. Each individual face (triangle, quad, or polygon) will be separated into different zones.

You can also separate face zones based on the marks stored in adaption registers. For example, you can mark cells for adaption based on their location in the domain (region adaption), their boundary closeness (boundary adaption), isovalue of some variable, or any of the other adaption methods discussed in [Adapting the Mesh \(p. 1441\)](#). When you specify which register is to be used for the separation of the face zone, all faces of cells that are marked will be placed into a new face zone. (Use the [Manage Adaption Registers Dialog Box \(p. 2287\)](#) to determine the ID of the register you wish to use.)

Finally, you can separate face zones based on contiguous regions. For example, when you use coupled wall boundary conditions you need the faces on the zone to have a consistent orientation. Consistent orientation can only be guaranteed on contiguous regions, so you may need to separate face zones to allow proper boundary condition specification.

6.8.2.1.2. Inputs for Separating Face Zones

To break up a face zone based on angle, face, adaption mark, or region, use the [Separate Face Zones Dialog Box \(p. 2233\)](#) ([Figure 6.45 \(p. 190\)](#)).

Mesh → Separate → Faces...

Figure 6.45 The Separate Face Zones Dialog Box

Important

If you are planning to separate face zones, you should do so before performing any adaptions using the (default) hanging node adaption method. Face zones that contain hanging nodes cannot be separated.

The steps for separating faces are as follows:

1. Select the separation method (**Angle**, **Face**, **Mark**, or **Region**) under **Options**.
2. Specify the face zone to be separated in the **Zones** list.
3. If you are separating by face or region, skip to the next step. Otherwise, do one of the following:
 - If you are separating faces by angle, specify the significant angle in the **Angle** field.
 - If you are separating faces by mark, select the adaption register to be used in the **Registers** list.
4. (optional) To check what the result of the separation will be before you actually separate the face zone, click the **Report** button. The report will look like the following example:

```
45 faces in contiguous region 0
30 faces in contiguous region 1
11 faces in contiguous region 2
14 faces in contiguous region 3
Separates zone 4 into 4 zone(s).
```

5. To separate the face zone, click the **Separate** button. A report will be printed in the console like the following example:

```
45 faces in contiguous region 0
30 faces in contiguous region 1
11 faces in contiguous region 2
14 faces in contiguous region 3
Separates zone 4 into 4 zone(s).
Updating new zone information ...
  created new zone wall-4:001 from wall-4
  created new zone wall-4:002 from wall-4
  created new zone wall-4:010 from wall-4
done.
```

Important

When you separate the face zone by adaption mark, you may sometimes find that a face of a corner cell will be placed in the wrong face zone. You can usually correct this problem by performing an additional separation, based on angle, to move the offending face to a new zone. You can then merge this new zone with the zone in which you want the face to be placed, as described in [Merging Zones](#) (p. 187).

6.8.2.2. Separating Cell Zones

For more information, see the following sections:

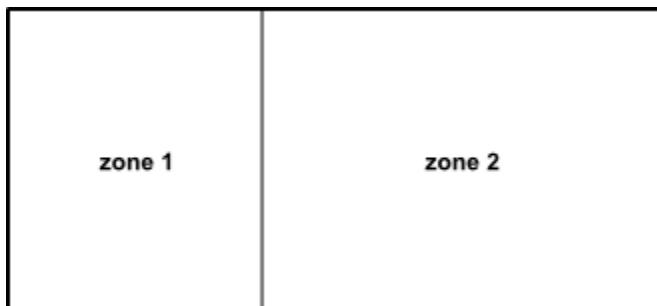

[6.8.2.2.1. Methods for Separating Cell Zones](#)

[6.8.2.2.2. Inputs for Separating Cell Zones](#)

6.8.2.2.1. Methods for Separating Cell Zones

If you have two or more enclosed cell regions sharing internal boundaries (as shown in [Figure 6.46](#) (p. 191)), but all of the cells are contained in a single cell zone, you can separate the cells into distinct zones using the separation-by-region method. Note that if the shared internal boundary is of type **interior**, you must change it to another double-sided face zone type (**fan**, **radiator**, etc.) prior to performing the separation.

Figure 6.46 Cell Zone Separation Based on Region

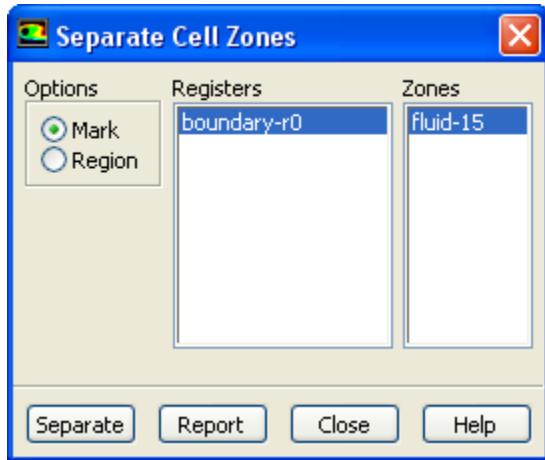

You can also separate cell zones based on the marks stored in adaption registers. You can mark cells for adaption using any of the adaption methods discussed in [Adapting the Mesh](#) (p. 1441) (e.g., you can mark cells with a certain isovalue range or cells inside or outside a specified region). When you specify which register is to be used for the separation of the cell zone, cells that are marked will be placed into a new cell zone. (Use the [Manage Adaption Registers Dialog Box](#) (p. 2287) to determine the ID of the register you wish to use.)

6.8.2.2.2. Inputs for Separating Cell Zones

To break up a cell zone based on region or adaption mark, use the [Separate Cell Zones Dialog Box](#) (p. 2234) ([Figure 6.47](#) (p. 192)).

Mesh → Separate → Cells...

Figure 6.47 The Separate Cell Zones Dialog Box**Important**

If you are planning to separate cell zones, you should do so before performing any adaptions using the (default) hanging node adaption method. Cell zones that contain hanging nodes cannot be separated.

The steps for separating cells are as follows:

1. Select the separation method (**Mark** or **Region**) under **Options**.
2. Specify the cell zone to be separated in the **Zones** list.
3. If you are separating cells by mark, select the adaption register to be used in the **Registers** list.
4. (optional) To check what the result of the separation will be before you actually separate the cell zone, click the **Report** button. The report will look like this:

```
Separates zone 14 into two zones, with 1275 and 32 cells.
```

5. To separate the cell zone, click the **Separate** button. ANSYS FLUENT will print the following information:

```
Separates zone 14 into two zones, with 1275 and 32 cells.
No faces marked on thread, 2
No faces marked on thread, 3
No faces marked on thread, 1
No faces marked on thread, 5
No faces marked on thread, 7
No faces marked on thread, 8
No faces marked on thread, 9
No faces marked on thread, 61
Separates zone 62 into two zones, with 1763 and 58 faces.
All faces marked on thread, 4
No faces marked on thread, 66
Moved 32 cells from cell zone 14 to zone 10
Updating new zone information ...
    created new zone interior-4:010 from interior-4
    created new zone interior-6:009 from interior-6
    created new zone fluid-14:008 from fluid-14
done.
```

As shown in the example above, separation of a cell zone will often result in the separation of face zones as well. When you separate by mark, faces of cells that are moved to a new zone will be placed

in a new face zone. When you separate by region, faces of cells that are moved to a new zone will not necessarily be placed in a new face zone.

If you find that any faces are placed incorrectly, see the comment above, at the end of the inputs for face zone separation.

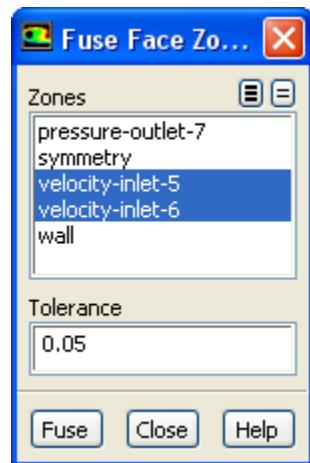

6.8.3. Fusing Face Zones

The face-fusing utility is a convenient feature that can be used to fuse boundaries (and merge duplicate nodes and faces) created by assembling multiple mesh regions. When the domain is divided into sub-domains and the mesh is generated separately for each subdomain, you will combine the subdomains into a single file before reading the mesh into the solver. For details, see [Reading Multiple Mesh/Case/Data Files \(p. 158\)](#). This situation could arise if you generate each block of a multiblock mesh separately and save it to a separate mesh file. Another possible scenario is that you decided, during mesh generation, to save the mesh for each part of a complicated geometry as a separate part file. (Note that the mesh node locations need not be identical at the boundaries where two subdomains meet; see [Non-Conformal Meshes \(p. 162\)](#) for details.)

The **Fuse Face Zones** dialog box ([Figure 6.48 \(p. 193\)](#)) allows you to merge the duplicate nodes and delete these artificial internal boundaries.

Mesh → Fuse...

Figure 6.48 The Fuse Face Zones Dialog Box

The boundaries on which the duplicate nodes lie are assigned zone ID numbers (just like any other boundary) when the mesh files are combined, as described in [Reading Multiple Mesh/Case/Data Files \(p. 158\)](#). You need to keep track of the zone ID numbers when tmerge or TGrid reports its progress or, after the complete mesh is read in, display all boundary mesh zones and use the mouse-probe button to determine the zone names (see [Controlling the Mouse Button Functions \(p. 1548\)](#) for information about the mouse button functions).

6.8.3.1. Inputs for Fusing Face Zones

The steps for fusing face zones are as follows:

1. Select the zones to be fused in the **Zones** list.

Important

When using the Fuse Face Zone utility, each of the selected face zones must be fused in its entirety with another face zone having the same connectivity. Partial fusing of face zones is not supported.

2. Click the **Fuse** button to fuse the selected zones.

If all of the appropriate faces do not get fused using the default **Tolerance**, you should increase it and attempt to fuse the zones again. (This tolerance is the same as the matching tolerance discussed in [Creating Conformal Periodic Zones \(p. 195\)](#).) The **Tolerance** should not exceed 0.5, or you may fuse the wrong nodes.

When fusing face zones using the GUI, ANSYS FLUENT automatically assigns a new name to the fused interface zone. If you would like to preserve the original name of one of the face zones being fused, you can use the `mesh/modify-zones/fuse-face-zones` text command, as shown in the following example.

```
/mesh/modify-zones > fuse-face-zones

()
Zone to fuse(1) [()] top
Zone to fuse(2) [()] bottom.1
Zone to fuse(3) [()] <Enter>

all 378 faces matched for zones 3 and 12.
    fusing created new thread, interior-18.
The fused zone name: (automatic bottom.1 top)
Enter name [automatic] top

Name of zone 18 is changed into top.

Fused list of zones.
```

Important

Remember to save a new case file (and a data file, if data exists) after fusing faces.

6.8.3.1.1. Fusing Zones on Branch Cuts

Meshes imported from structured mesh generators or solvers (such as FLUENT 4) can often be O-type or C-type meshes with a reentrant branch cut where coincident duplicate nodes lie on a periodic boundary. Since ANSYS FLUENT uses an unstructured mesh representation, there is no reason to retain this artificial internal boundary. (You can preserve these periodic boundaries and the solution algorithm will solve the problem with periodic boundary conditions.)

To fuse this periodic zone with itself, you must first slit the periodic zone, as described in [Slitting Periodic Zones \(p. 195\)](#). This will create two symmetry zones that you can fuse using the procedure above.

Note that if you need to fuse portions of a non-periodic zone with itself, you must use the `mesh/modify-zones/fuse-face-zones` text command.

`mesh → modify-zones → fuse-face-zones`

This command will prompt you for the name or ID of each zone to be fused. (You will enter the same zone twice.) To change the node tolerance, use the `mesh/modify-zones/matching-tolerance` text command.

6.8.4. Creating Conformal Periodic Zones

ANSYS FLUENT allows you to set up periodic boundaries using either conformal or non-conformal periodic zones. You can assign periodicity to your mesh by coupling a pair of face zones. If the two zones have identical node and face distributions, you can create a conformal periodic zone. If the two zones are not identical at the boundaries within a specified tolerance, then you can create a periodic zone at a non-conformal mesh interface ([Non-Conformal Meshes \(p. 162\)](#)).

Important

Remember to save a new case file (and a data file, if data exists) after creating or slitting a periodic boundary.

To create conformal periodic boundaries, you will use the `mesh/modify-zones/make-periodic` text command.

`mesh → modify-zones → make-periodic`

You will need to specify the two face zones that will comprise the periodic pair (you can enter their full names or just their IDs), and indicate whether they are rotationally or translationally periodic. The order in which you specify the periodic zone and its matching shadow zone is not significant.

```
/mesh/modify-zones> make-periodic

Periodic zone [()] 1
Shadow zone [()] 4
Rotational periodic? (if no, translational) [yes] n
Create periodic zones? [yes] yes
Auto detect translation vector? [yes] yes

computed translation deltas: -2.000000 -2.000000
all 10 faces matched for zones 1 and 4.

zone 4 deleted

created periodic zones.
```

When you create a conformal periodic boundary, the solver will check to see if the faces on the selected zones “match” (i.e., whether or not the nodes on corresponding faces are coincident). The matching tolerance for a face is a fraction of the minimum edge length of the face. If the periodic boundary creation fails, you can change the matching tolerance using the `mesh/modify-zones/matching-tolerance` text command, but it should not exceed 0.5 or you may match up the periodic zones incorrectly and corrupt the mesh.

`mesh → modify-zones → matching-tolerance`

For information about creating non-conformal periodic boundaries, see [Using a Non-Conformal Mesh in ANSYS FLUENT \(p. 170\)](#).

6.8.5. Slitting Periodic Zones

If you wish to decouple the zones in a periodic pair, you can use the `mesh/modify-zones/slit-periodic` text command.

mesh → modify-zones → slit-periodic

You will specify the periodic zone's name or ID, and the solver will decouple the two zones in the pair (the periodic zone and its shadow) and change them to two symmetry zones:

```
/mesh/modify-zones> slit-periodic  
Periodic zone [()] periodic-1  
Slit periodic zone? [yes] yes  
  
Slit periodic zone.
```

6.8.6. Slitting Face Zones

The face-zone slitting feature has two uses:

- You can slit a single boundary zone of any double-sided type (i.e., any boundary zone that has cells on both sides of it) into two distinct zones.
- You can slit a coupled wall zone into two distinct, uncoupled wall zones.

When you slit a face zone, the solver will duplicate all faces and nodes, except those nodes that are located at the ends (2D) or edges (3D) of the zone. One set of nodes and faces will belong to one of the resulting boundary zones and the other set will belong to the other zone. The only ill effect of the shared nodes at each end is that you may see some inaccuracies at those points when you graphically display solution data with a slit boundary. (Note that if you adapt the boundary after slitting, you will not be able to fuse the boundaries back together again.)

Before you can slit, you first need to select the zone in the **Boundary Condition** task page and change the **Type** to **wall**. Upon changing the **Type** to **wall**, another shadow zone will be created (i.e., if the original zone is called **rad-outlet**, another zone called **rad-outlet-shadow** will be created). Then you can apply the `mesh/modify-zones/slit-face-zone` text command on either of the walls (i.e., **rad-outlet** or **rad-outlet-shadow**) to separate them into two distinct walls.

For example, the outlet of the radiator in an underhood application is typically of **interior** type (i.e., has cells on both sides). If you know the mass flow rate through this zone (either from other CFD models or from test data) and want to apply it as a boundary condition at the radiator outlet, you first need to slit the radiator outlet. To be able to slit it, select **wall** from the **Type** drop-down list in the **Boundary Conditions** task page for this outlet. It will create a wall and a shadow. Then you can use the TUI command (`mesh/modify-zones/slit-face-zone`) to slit them. After it is slit, two additional walls will be created, one facing one side of the outlet and another facing the other. Then you can select the appropriate wall and change the **Type** to **mass-flow-inlet** and specify the mass flow rate using the *Mass-Flow Inlet Dialog Box* (p. 1978). There is no option of **mass-flow-inlet** without first slitting it.

Important

You should not confuse "slitting" a face zone with "separating" a face zone. When you slit a face zone, additional faces and nodes are created and placed in a new zone. When you separate a face zone, a new zone will be created, but no new faces or nodes are created; the existing faces and nodes are simply redistributed among the zones.

6.8.6.1. Inputs for Slitting Face Zones

If you wish to slit a face zone, you can use the mesh/modify-zones/slit-face-zone text command.

mesh → modify-zones → slit-face-zone

You will specify the face zone's name or ID, and the solver will replace the zone with two zones:

```
/mesh/modify-zones > slit-face-zone
Face zone id/name [] wall-4
zone 4 deleted
face zone 4 created
face zone 10 created
```

Important

Remember to save a new case file (and a data file, if data exists) after slitting faces.

6.8.7. Orienting Face Zones

The faces of a boundary face zone (which have cells only on one side) are oriented such that the normals are all pointing in one direction. However, for internal face zones (which have cells on both sides), the normals are allowed to point in either direction. To orient them so that they all point in one direction, you can use the following TUI command:

mesh → modify-zones → orient-face-zone

Having all of the normals oriented in one direction is needed for some boundary condition types. For example, the **fan** boundary condition type determines the flow direction based on its normals. If some of the normals are pointing in one direction and some in the other, the correct flow orientation cannot be determined, which leads to incorrect results.

6.8.8. Extruding Face Zones

The ability to extrude a boundary face zone allows you to extend the solution domain without having to exit the solver. A typical application of the extrusion capability is to extend the solution domain when recirculating flow is impinging on a flow outlet. The current extrusion capability creates prismatic or hexahedral layers based on the shape of the face and normal vectors computed by averaging the face normals to the face zone's nodes. You can define the extrusion process by specifying a list of displacements (in SI units) or by specifying a total distance (in SI units) and parametric coordinates.

Important

- Note that extrusion is not possible from boundary face zones that have hanging nodes.
- Extruding face zones is only allowed in the 3D version of ANSYS FLUENT.

6.8.8.1. Specifying Extrusion by Displacement Distances

You can specify the extrusion by entering a list of displacement distances (in SI units) using the mesh/modify-zones/extrude-face-zone-delta text command.

mesh → modify-zones → extrude-face-zone-delta

Note

This text command is not available in the parallel version of ANSYS FLUENT.

You will be prompted for the boundary face zone ID or name and a list of displacement distances.

6.8.8.2. Specifying Extrusion by Parametric Coordinates

You can specify the extrusion by specifying a distance (in SI units) and parametric coordinates using the mesh/modify-zones/extrude-face-zone-para text command.

mesh → modify-zones → extrude-face-zone-para

Note

This text command is not available in the parallel version of ANSYS FLUENT.

You will be prompted for the boundary face zone ID or name, a total distance, and a list of parametric coordinates. The list of parametric coordinates should begin with 0.0 and end with 1.0. For example, the following list of parametric coordinates would create two equally spaced extrusion layers: 0.0, 0.5, 1.0.

6.8.9. Replacing, Deleting, Deactivating, and Activating Zones

ANSYS FLUENT allows you to append or replace an existing cell zone in the mesh. You can also permanently delete a cell zone and all associated face zones, or temporarily deactivate and activate zones from your ANSYS FLUENT case.

6.8.9.1. Replacing Zones

This feature allows you to replace a small region of a computational domain with a new region of different mesh quality. This functionality will be required where you may want to make changes to the geometry or mesh quality for any part of the domain. This ability of ANSYS FLUENT will save you time, since you can modify only the required part of the domain without remeshing the whole domain every time.

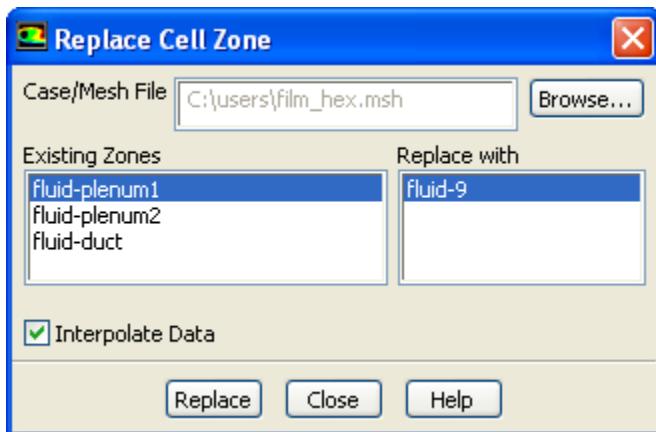

The replacement mesh must be prepared in advance, with the following considerations:

- The replacement mesh must contain a single cell zone.
- The cell zone in the replacement mesh must be of the same zone type as the zone that is being replaced.
- If the boundaries of the replacement mesh will form a non-conformal interface with existing zones (i.e., zones that are not replaced in the existing mesh), these boundaries should be based on the same geometry as the existing zones. If there are sharp features (e.g., 90-degree angles) or curvature in the mesh, it is especially important that both sides of the interface closely follow that feature.
- The replacement cell zone does not need to have the same name as the existing zone being replaced.
- When naming the boundary zones of the replacement cell zone, note that boundary conditions will be automatically transferred from the existing cell zone based on name. All boundaries of the replacement cell zone that have unique names will be assigned the default boundary condition for that zone type.

Replacing a zone is performed using the *Replace Cell Zone Dialog Box* (p. 2235) (*Figure 6.49* (p. 199)).

Mesh → Zone → Replace...

Figure 6.49 The Replace Cell Zone Dialog Box

To replace a zone, do the following:

1. Click **Browse...** and select the new or modified mesh containing the cell zone that will replace one of the cell zones in the current mesh.
*The name of the cell zone in the replacement mesh will be displayed in the **Replace with** list.*
2. Under **Existing Zones**, select the zone you want to replace.
3. Under **Replace with**, select the zone from the replacement mesh.
4. Enable/Disable **Interpolate Data**, if data already exists. If the replacement cell zone is geometrically different, then **Interpolate Data** can be turned off to prevent data interpolation over the non-matching geometries.
5. Click **Replace** to replace the selected zone.
6. Set up the boundary conditions for any of the boundaries of the replacement mesh that do not share a name with one of the existing boundaries.

6.8.9.2. Deleting Zones

To permanently delete zones, select them in the *Delete Cell Zones Dialog Box* (p. 2236) (*Figure 6.50* (p. 200)), and click **Delete**.

Mesh → Zone → Delete...

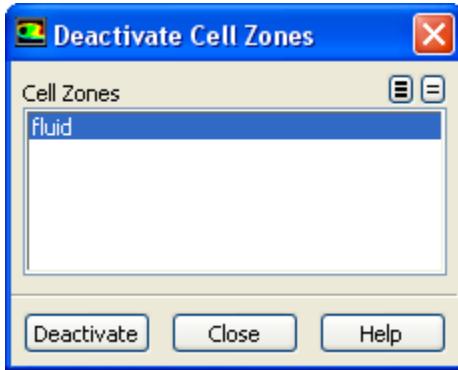

Figure 6.50 The Delete Cell Zones Dialog Box

All of the cells, faces, and nodes associated with the cell zone will be deleted. If one of the faces is of type **interior** and borders another cell zone, the face will automatically be changed to a wall and will stay attached to the remaining cell zone.

6.8.9.3. Deactivating Zones

To deactivate zones, select them in the *Deactivate Cell Zones Dialog Box* (p. 2237) (*Figure 6.51* (p. 200)), and click **Deactivate**.

Mesh → Zone → Deactivate...

Figure 6.51 The Deactivate Cell Zones Dialog Box

Deactivation will separate all relevant interior face zones (i.e., fan, interior, porous-jump, or radiator) into wall and wall-shadow pairs.

Note

When you deactivate a zone using the **Deactivate Cell Zones** dialog box, ANSYS FLUENT will remove the zone from the mesh and from all relevant solver loops.

To deactivate selected cell zones in parallel

1. Read in the data file, or initialize your solution.
2. Select the zone(s) to be deactivated under **Cell Zones**.
3. Click the **Deactivate** button.

Important

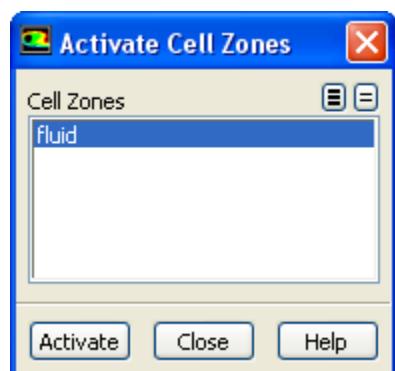

If you have neither read in the data file nor initialized the solution prior to clicking the **Deactivate** button, then the selected cell zones will only be *marked* for deactivation. The zones will not be deactivated until data is read or the solution is initialized.

6.8.9.4. Activating Zones

You can reactivate the zones and recover the last data available for them using the *Activate Cell Zones Dialog Box* (p. 2237) (*Figure 6.52 (p. 201)*).

Mesh → Zone → Activate...

Figure 6.52 The Activate Cell Zones Dialog Box

Note

The **Activate Cell Zones** dialog box will only be populated with zones that were previously deactivated.

After reactivation, you need to make sure that the boundary conditions for the wall and wall-shadow pairs are restored correctly to what you assigned before deactivating the zones. If you plan to reactivate them at a later time, make sure that the face zones that are separated during deactivation are not modified. Adaption, however, is supported.

To activate selected cell zones in parallel

1. Read in the data file, or initialize your solution.
2. Select the zone(s) to be activated under **Cell Zones**.
3. Click the **Activate** button.

Important

If you have neither read in the data file nor initialized the solution, prior to clicking the **Activate** button, then the selected cell zones will only be *marked* for activation. The zones will not be activated until data is read or the solution is initialized.

6.8.10. Copying Cell Zones

You can create a copy of a cell zone that is offset from the original either by a translational distance or a rotational angle. Note that in the copied zone, the bounding face zones are all converted to walls, any existing cell data is initialized to a constant value, and non-conformal interfaces and dynamic zones are not copied; otherwise, the model settings are the same as in the original zone.

To copy a zone, use the following text command:

```
mesh → modify-zones → copy-move-cell-zone
```

You will then be prompted to enter the ID of the zone you want to copy, and either the distance for translation in each of the axes or the rotational angle, origin, and axis.

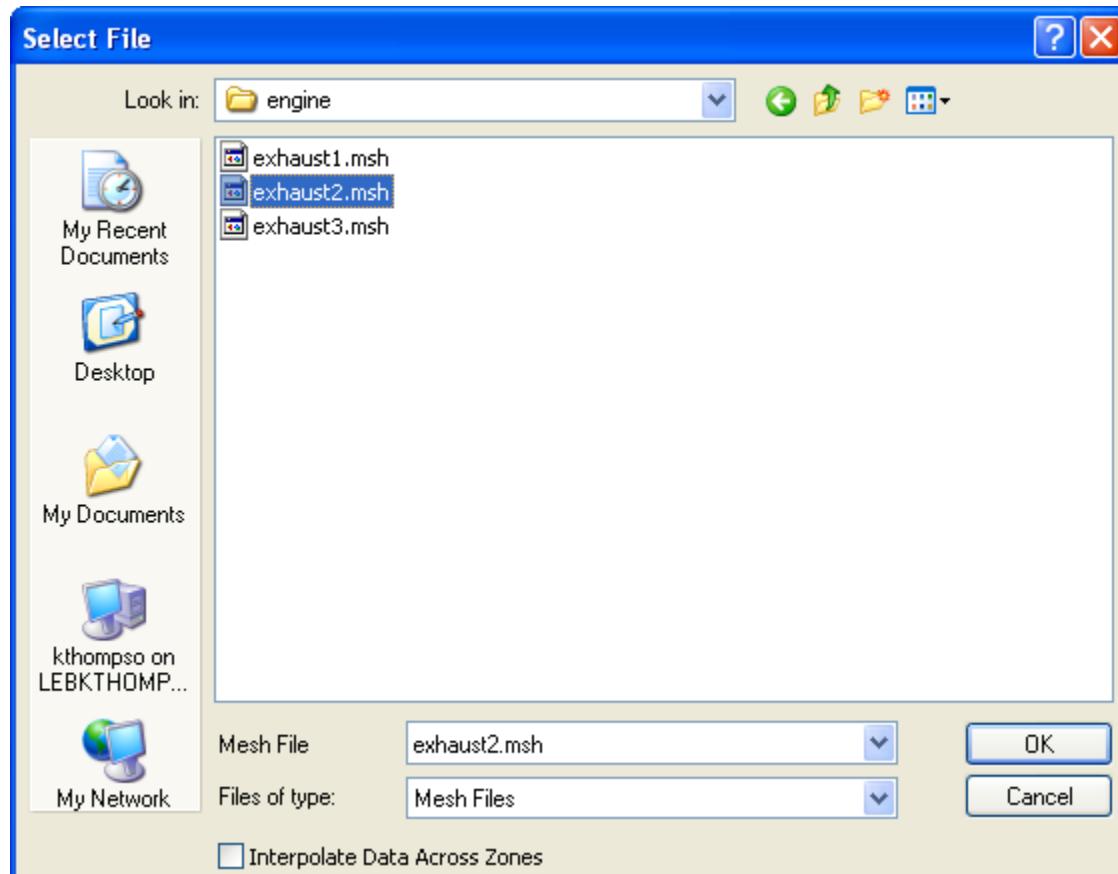

Note that if you want the copied zone to be connected to existing zones, you must either fuse the boundaries (as described in *Fusing Face Zones* (p. 193)) or set up a non-conformal interface (as described in *Using a Non-Conformal Mesh in ANSYS FLUENT* (p. 170)).

6.8.11. Replacing the Mesh

ANSYS FLUENT allows you to replace your mesh, so that you can continue to run your simulation on a new mesh without having to manually copy the case file settings or interpolate the existing data. Replacing the mesh globally may be helpful, for example, if you would like to perform a mesh refinement study with a prepared series of meshes, or if your results indicate that your current mesh is not of sufficient quality. Note that the data interpolation is done automatically during the replacement if data exists (i.e., you have initialized the flow field or run a calculation).

Global mesh replacement is performed using the **Mesh/Replace...** menu item, which opens the **Select File** dialog box (*Figure 6.53* (p. 203)).

Figure 6.53 The Select File Dialog Box

6.8.11.1. Inputs for Replacing the Mesh

The steps for replacing the mesh using the **Select File** dialog box (*Figure 6.53 (p. 203)*) are as follows:

1. Select the replacement mesh from the appropriate folder.
2. By default, data is interpolated between matching zone pairs (i.e., between the zones with the same names in both the current mesh and the replacement mesh). You can enable the **Interpolate Data Across Zones** option if you want to interpolate data across cell zones when replacing the mesh. This option is appropriate when the matching zone pairs do not have the same interior zone boundaries. Note that global conservation of data is not enforced when the **Interpolate Data Across Zones** option is enabled, so it should only be used when absolutely necessary. For best data interpolation, the zone boundaries of the replacement mesh should be coincident with those of the current mesh.
3. Click the **OK** button to replace the mesh.

6.8.11.2. Limitations

The following limitations apply when replacing meshes:

- The boundary conditions of the zones in the current mesh are mapped onto the zones with the same names in the replacement mesh, as described in *Reading and Writing Boundary Conditions* (p. 74). If your replacement mesh contains zones for which no match is found, these zones will have the default boundary conditions for that zone type.

- The replacement mesh is expected to be an ANSYS FLUENT mesh (.msh) file. You can select an ANSYS FLUENT case (.cas) file instead, but be aware that only the mesh information will be used and all of the setup information associated with that case file will be ignored.
- If you intend to select an ANSYS FLUENT case (.cas) file as the replacement mesh, you must first delete any defined non-conformal mesh interfaces in the case file (as described in [Using a Non-Conformal Mesh in ANSYS FLUENT](#) (p. 170)).
- You should ensure that the replacement mesh has the same mesh scaling as your current mesh. The data interpolation will not work properly if the meshes are scaled differently.

6.8.12. Reordering the Domain and Zones

Reordering the domain can improve the computational performance of the solver by rearranging the nodes, faces, and cells in memory. The **Mesh/Reorder** submenu contains commands for reordering the domain and zones, and also for printing the bandwidth of the present mesh partitions. The domain can be reordered to increase memory access efficiency, and the zones can be reordered for user-interface convenience. The bandwidth provides insight into the distribution of the cells in the zones and in memory.

To reorder the domain, select the **Domain** menu item.

Mesh → Reorder → Domain

To reorder the zones, select the **Zones** menu item.

Mesh → Reorder → Zones

Finally, you can print the bandwidth of the present mesh partitions by selecting the **Print Bandwidth** menu item. This command prints the semi-bandwidth and maximum cell distance for each mesh partition.

Mesh → Reorder → Print Bandwidth

Important

Remember to save a new case file (and a data file, if data exist) after reordering.

6.8.12.1. About Reordering

The Reverse Cuthill-McKee algorithm [18] (p. 2367) is used in the reordering process to construct a “level tree” initiated from a “seed cell” in the domain. First a cell (called the seed cell) is selected using the algorithm of Gibbs, Poole, and Stockmeyer [26] (p. 2368). Each cell is then assigned to a level based on its distance from the seed cell. These level assignments form the level tree. In general, the faces and cells are reordered so that neighboring cells are near each other in the zone and in memory. Since most of the computational loops are over faces, you would like the two cells in memory cache at the same time to reduce cache and/or disk swapping—i.e., you want the cells near each other in memory to reduce the cost of memory access. The present scheme reorders the faces and cells in the zone, and the nodes, faces, and cells in memory.

You may also choose to reorder the zones. The zones are reordered by first sorting on zone type and then on zone ID. Zone reordering is performed simply for user-interface convenience.

A typical output produced using the domain reordering is shown below:

```
>> Reordering domain using Reverse Cuthill-McKee method:  
      zones, cells, faces, done.  
      Bandwidth reduction = 809/21 = 38.52  
      Done.
```

If you print the bandwidth, you will see a report similar to the following:

```
Maximum cell distance = 21
```

The bandwidth is the maximum difference between neighboring cells in the zone—i.e., if you numbered each cell in the zone list sequentially and compared the differences between these indices.

6.8.13. Scaling the Mesh

Internally, ANSYS FLUENT stores the computational mesh in meters, the SI unit of length. When mesh information is read into the solver, it is assumed that the mesh was generated in units of meters. If your mesh was created using a different unit of length (inches, feet, centimeters, etc.), you must scale the mesh to meters. To do this, you can select from a list of common units to convert the mesh or you can supply your own custom scale factors. Each node coordinate will be multiplied by the corresponding scale factor.

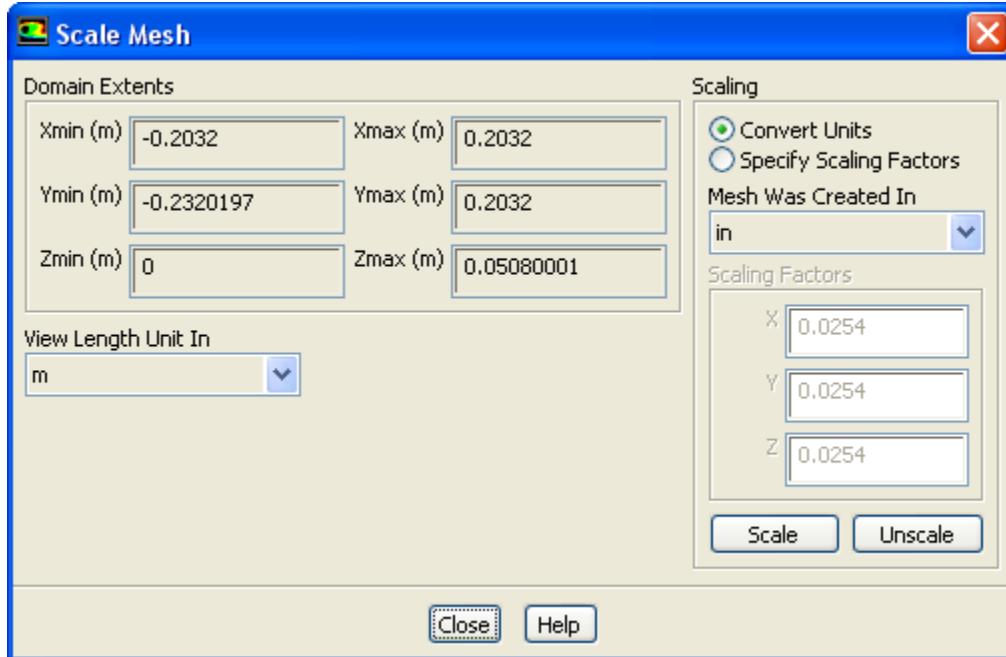

Scaling can also be used to change the physical size of the mesh. For instance, you could stretch the mesh in the x direction by assigning a scale factor of 2 in the x direction and 1 in the y and z directions. This would double the extent of the mesh in the x direction. However, you should use anisotropic scaling with caution, since it will change the aspect ratios of the cells in your mesh.

Important

- If you plan to scale the mesh in any way, you should do so before you initialize the flow or begin calculations. Any data that exists when you scale the mesh will be invalid.
- It is a good practice to scale the mesh before setting up the case, especially when you plan to create mesh interfaces or shell conduction zones.

You will use the [Scale Mesh Dialog Box \(p. 1766\)](#) ([Figure 6.54 \(p. 206\)](#)) to scale the mesh from a standard unit of measurement or to apply custom scaling factors.

 **General** → **Scale...**

Figure 6.54 The Scale Mesh Dialog Box

6.8.13.1. Using the Scale Mesh Dialog Box

The procedure for scaling the mesh is as follows:

1. Use the conversion factors provided by ANSYS FLUENT by selecting **Convert Units** in the **Scaling** group box. Then indicate the units used when creating the mesh by selecting the appropriate abbreviation for meters, centimeters, millimeters, inches, or feet from the **Mesh Was Created In** drop-down list. The **Scaling Factors** will automatically be set to the correct values (e.g., 0.0254 meters/inch).

If you created your mesh using units other than those in the **Mesh Was Created In** drop-down list, you can select **Specify Scaling Factors** and enter values for **X**, **Y**, and **Z** manually in the **Scaling Factors** group box (e.g., the number of meters per yard).

2. Click the **Scale** button. The **Domain Extents** will be updated to show the correct range in meters. If you prefer to use your original unit of length during the ANSYS FLUENT session, you can follow the procedure described below to change the unit.

6.8.13.1.1. Changing the Unit of Length

As mentioned in Step 2. of the previous section, when you scale the mesh you do not change the units; you just convert the original dimensions of your mesh points from your original units to meters by multiplying each node coordinate by the specified **Scaling Factors**. If you want to work in your original units, instead of in meters, you can make a selection from the **View Length Unit In** drop-down list. This updates the **Domain Extents** to show the range in your original units and automatically changes the length unit in the *Set Units Dialog Box* (p. 1769) (see *Customizing Units* (p. 126)). Note that this unit will be used for all future inputs of length quantities.

6.8.13.1.2. Unscaling the Mesh

If you use the wrong scale factor, accidentally click the **Scale** button twice, or wish to undo the scaling for any other reason, you can click the **Unscale** button. "Unscaling" simply divides each of the node

coordinates by the specified **Scale Factors**. (Selecting **m** in the **Mesh Was Created In** list and clicking on **Scale** will *not* unscale the mesh.)

6.8.13.1.3. Changing the Physical Size of the Mesh

You can also use the *Scale Mesh Dialog Box* (p. 1766) to change the physical size of the mesh. For example, if your 2D mesh is 5 feet by 8 feet, and you want to model the same geometry with dimensions twice as big (10 feet by 16 feet), you can enter 2 for **X** and **Y** in the **Scaling Factors** group box and click **Scale**. The **Domain Extents** will be updated to show the new range.

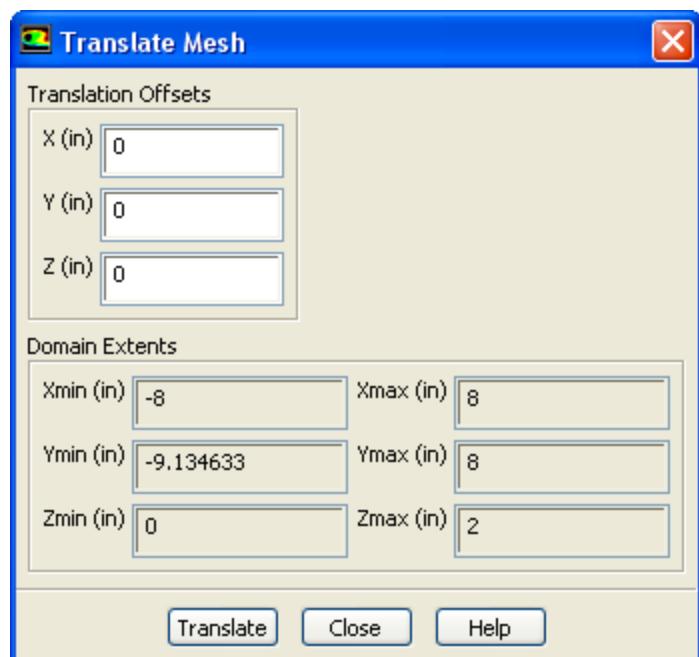

6.8.14. Translating the Mesh

You can “move” the mesh by applying prescribed offsets to the Cartesian coordinates of all the nodes in the mesh. This would be necessary for a rotating problem if the mesh were set up with the axis of rotation not passing through the origin, or for an axisymmetric problem if the mesh were set up with the axis of rotation not coinciding with the *x* axis. It is also useful if, for example, you want to move the origin to a particular point on an object (such as the leading edge of a flat plate) to make an XY plot have the desired distances on the *x* axis.

You can translate mesh points in ANSYS FLUENT using the *Translate Mesh Dialog Box* (p. 2238) (*Figure 6.55* (p. 207)).

Mesh → Translate...

Figure 6.55 The Translate Mesh Dialog Box

6.8.14.1. Using the Translate Mesh Dialog Box

The procedure for translating the mesh is as follows:

1. Enter the desired translations in the *x*, *y*, and (for 3D) *z* directions (i.e., the desired delta in the axes) in the **X**, **Y**, and **Z** text-entry boxes in the **Translation Offsets** group box. You can specify positive or negative real numbers in the current unit of length.

- Click the **Translate** button and redisplay the mesh. The **Domain Extents** will be updated to display the new extents of the translated mesh. (Note that the **Domain Extents** are purely informational; you cannot edit them manually.)

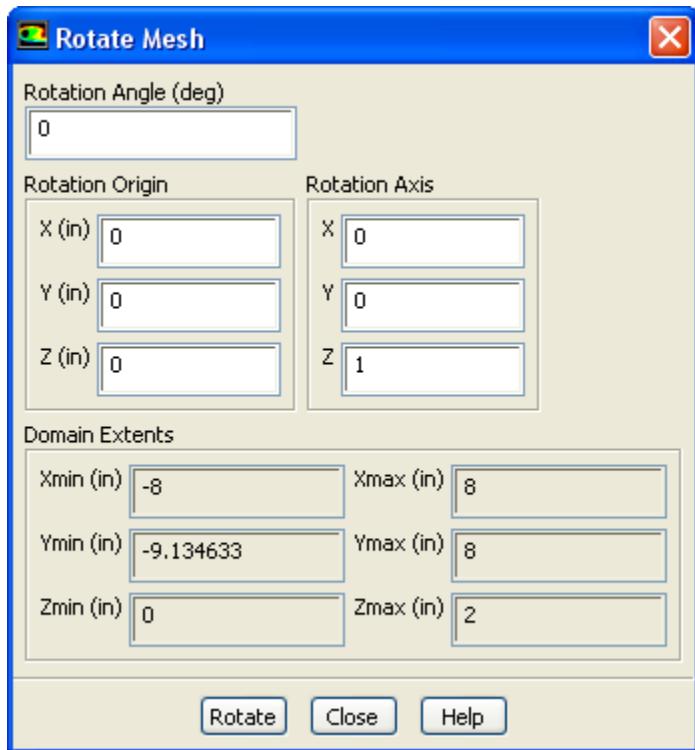

6.8.15. Rotating the Mesh

The ability to rotate the mesh is analogous to the ability to translate the mesh in ANSYS FLUENT. You can rotate the mesh about the *x*, *y*, or (for 3D) *z* axis and also specify the rotation origin. This option is useful in the cases where the structural mesh and the CFD mesh are offset by a small angle.

You can rotate the mesh in ANSYS FLUENT using the *Rotate Mesh Dialog Box* (p. 2239) (*Figure 6.56* (p. 208)).

Mesh → Rotate...

Figure 6.56 The Rotate Mesh Dialog Box

6.8.15.1. Using the Rotate Mesh Dialog Box

The procedure for rotating the mesh is as follows:

- Specify the required **Rotation Angle** for the mesh. You can specify any positive or negative real number in the correct unit of angle.
- In the **Rotation Origin** group box, enter **X**, **Y**, and (for 3D) **Z** coordinates to specify a new origin for the axis of rotation.
- In the **Rotation Axis** group box, enter values for the **X**, **Y**, and (for 3D) **Z** axes to specify the vector for the axis of rotation.
- Click the **Rotate** button and redisplay the mesh.

The Domain Extents will be updated to display the new extents of the rotated mesh. (Note that the Domain Extents are purely informational; you cannot edit them manually.)

Chapter 7: Cell Zone and Boundary Conditions

This chapter describes the cell zone and boundary condition options available in ANSYS FLUENT. Details regarding the cell zone and boundary condition inputs and the internal treatment at boundaries are provided.

The information in this chapter is divided into the following sections:

- 7.1. Overview
- 7.2. Cell Zone Conditions
- 7.3. Boundary Conditions
- 7.4. Non-Reflecting Boundary Conditions
- 7.5. User-Defined Fan Model
- 7.6. Profiles
- 7.7. Coupling Boundary Conditions with GT-Power
- 7.8. Coupling Boundary Conditions with WAVE

7.1. Overview

Cell zone and boundary conditions specify the flow and thermal variables on the boundaries of your physical model. They are, therefore, a critical component of your ANSYS FLUENT simulations and it is important that they are specified appropriately.

- 7.1.1. Available Cell Zone and Boundary Types
- 7.1.2. The Cell Zone and Boundary Conditions Task Page
- 7.1.3. Changing Cell and Boundary Zone Types
- 7.1.4. Setting Cell Zone and Boundary Conditions
- 7.1.5. Copying Cell Zone and Boundary Conditions
- 7.1.6. Changing Cell or Boundary Zone Names
- 7.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions
- 7.1.8. Defining and Viewing Parameters
- 7.1.9. Selecting Cell or Boundary Zones in the Graphics Display
- 7.1.10. Operating and Periodic Conditions
- 7.1.11. Highlighting Selected Boundary Zones
- 7.1.12. Saving and Reusing Cell Zone and Boundary Conditions

7.1.1. Available Cell Zone and Boundary Types

The boundary types available in ANSYS FLUENT are classified as follows:

- Flow inlet and exit boundaries: pressure inlet, velocity inlet, mass flow inlet, and inlet vent, intake fan, pressure outlet, pressure far-field, outflow, outlet vent, and exhaust fan.
- Wall, repeating, and pole boundaries: wall, symmetry, periodic, and axis.
- Internal face boundaries: fan, radiator, porous jump, wall, and interior.

Cell zones consist of fluids and solids, with porous media treated as a type of fluid zone.

(The internal face boundary conditions are defined on cell faces, which means that they do not have a finite thickness and they provide a means of introducing a step change in flow properties. These

boundary conditions are used to implement physical models representing fans, thin porous membranes, and radiators. The “interior” type of internal face zone does not require any input from you.)

In this chapter, the cell zones and boundary conditions listed above will be described in detail, and an explanation of how to set them and where they are most appropriately used will be provided. Note that while periodic boundaries are described in *Periodic Boundary Conditions* (p. 336), additional information about modeling fully-developed periodic flows is provided in *Periodic Flows* (p. 514).

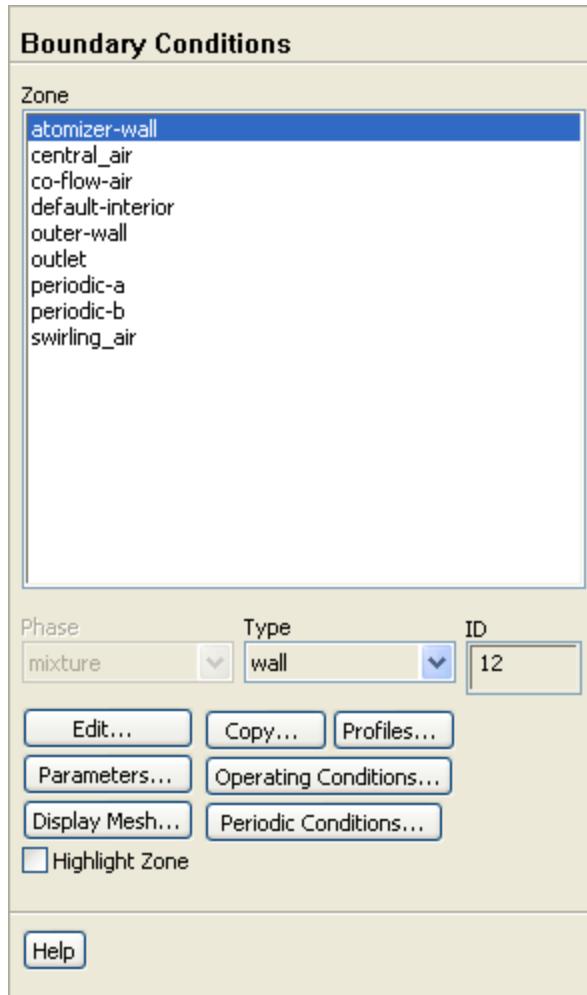

7.1.2. The Cell Zone and Boundary Conditions Task Page

The **Cell Zone Conditions** and **Boundary Conditions** task page (*Figure 7.1 (p. 212)*) allows you to change the cell zone or boundary zone type for a given zone and open other dialog boxes to set the cell zone and boundary condition parameters for each zone.

 **Cell Zone Conditions**

 **Boundary Conditions**

Figure 7.1 The Boundary Conditions Task Page

Changing Cell and Boundary Zone Types (p. 213) – *Saving and Reusing Cell Zone and Boundary Conditions* (p. 220) explain how to perform these operations with the **Cell Zone Conditions** or **Boundary**

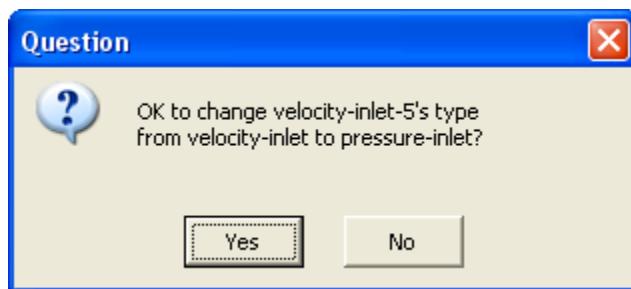

Conditions task page, and how to use the mouse and the graphics display in conjunction with the dialog box.

7.1.3. Changing Cell and Boundary Zone Types

Before you set any cell zone or boundary conditions, you should check the zone types of all boundary zones and change any if necessary. For example, if your mesh includes a pressure inlet, but you want to use a velocity inlet instead, you will need to change the pressure-inlet zone to a velocity-inlet zone.

The steps for changing a zone type are as follows:

1. In the **Cell Zone Conditions** or **Boundary Conditions** task page, select the zone to be changed in the **Zone** list.
2. Choose the correct zone type from the **Type** drop-down list.
3. Confirm the change when prompted by the *Question Dialog Box* (p. 33).

Once you have confirmed the change, the zone type will be changed, the name will change automatically (if the original name was the default name for that zone—see *Changing Cell or Boundary Zone Names* (p. 215)), and the dialog box for setting conditions for the zone will open automatically.

Important

Note that you cannot use this method to change zone types to or from the periodic type, since additional restrictions exist for this boundary type. *Creating Conformal Periodic Zones* (p. 195) explains how to create and uncouple periodic zones.

Important

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for changing types is slightly different. See *Steps for Setting Boundary Conditions* (p. 1198) for details.

7.1.3.1. Categories of Zone Types

You should be aware that you can only change zone types within each category listed in [Table 7.1: Zone Types Listed by Category \(p. 214\)](#). (Note that a double-sided face zone is a zone that separates two different cell zones or regions.)

Table 7.1 Zone Types Listed by Category

Category	Zone Types
Faces	axis, outflow, mass flow inlet, pressure far-field, pressure inlet, pressure outlet, symmetry, velocity inlet, wall, inlet vent, intake fan, outlet vent, exhaust fan
Double-Sided Faces	fan, interior, porous jump, radiator, wall
Periodic	periodic
Cells	fluid, solid (porous is a type of fluid cell)

7.1.4. Setting Cell Zone and Boundary Conditions

In ANSYS FLUENT, boundary conditions are associated with zones, not with individual faces or cells. If you want to combine two or more zones that will have the same boundary conditions, see [Merging Zones \(p. 187\)](#) for information about merging zones.

To set cell zone and boundary conditions for a particular zone, perform one of the following sequences:

1. Select the zone from the **Zone** list in the **Cell Zone Conditions** or **Boundary Conditions** task page.
2. Click the **Edit...** button.

or

1. Choose the zone in the **Zone** list.
2. Click the selected zone type from the **Type** drop-down list.

or

1. Double-click the zone in the **Zone** list.

The dialog box for the selected cell or boundary zone will open, and you can specify the appropriate conditions.

Important

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for setting conditions is slightly different from that described above. See [Steps for Setting Boundary Conditions \(p. 1198\)](#) for details.

Note that when you use the `define/boundary-conditions/zone_type` text command to define the boundary conditions (where `zone_type` is the type of zone you are defining), you can use wildcards (*) when inputting the name of the zone. This allows you to define multiple zones with similar names and compatible inputs, or a single zone with a name you are not sure of in advance. For example, if you want to define **wall-12**, **wall-15**, and **wall-17** in your current model, enter `wall-*` when prompted to enter the zone name in order to switch to multi-zone selection, and then follow the prompts.

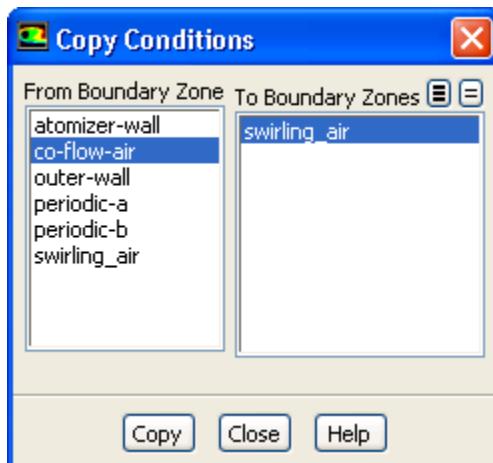

7.1.5. Copying Cell Zone and Boundary Conditions

You can copy cell zones and boundary conditions from one zone to other zones of the same type. If, for example, you have several wall zones in your model and they all have the same boundary conditions, you can set the conditions for one wall, and then simply copy them to the others.

The procedure for copying cell zone or boundary conditions is as follows:

1. In the **Cell Zone Conditions** or **Boundary Conditions** task page, click the **Copy...** button. This will open the **Copy Conditions** dialog box ([Figure 7.2 \(p. 215\)](#)).

Figure 7.2 The Copy Conditions Dialog Box

2. In the **From Cell Zone** or **From Boundary Zone** list, select the zone that has the conditions you want to copy.
3. In the **To Cell Zones** or **To Boundary Zones** list, select the zone or zones to which you want to copy the conditions.
4. Click **Copy**. ANSYS FLUENT will set *all* of the cell zones or boundary conditions for the zones selected in the **To Cell Zones** or **To Boundary Zones** list to be the same as the conditions for the zone selected in the **From Cell Zone** or **From Boundary Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

Note that you cannot copy conditions from external walls to internal (i.e., two-sided) walls, or vice versa, if the energy equation is being solved, since the thermal conditions for external and internal walls are different.

Important

If you are using one of the general multiphase models (VOF, mixture, or Eulerian), the procedure for copying boundary conditions is slightly different. See [Steps for Copying Cell Zone and Boundary Conditions \(p. 1202\)](#) for details.

7.1.6. Changing Cell or Boundary Zone Names

The default name for a zone is its type plus an ID number (e.g., **pressure-inlet-7**). In some cases, you may want to assign more descriptive names to the boundary zones. If you have two pressure-inlet zones, for example, you might want to rename them **small-inlet** and **large-inlet**. (Changing the name

of a zone will not change its type. Instructions for changing a zone's type are provided in [Changing Cell and Boundary Zone Types](#) (p. 213).)

To rename a zone, follow these steps:

1. Select the zone to be renamed in the **Zones** list in the **Cell Zone Conditions** or **Boundary Conditions** task page.
2. Click **Edit...** to open the dialog box for the selected zone.
3. Enter a new name under **Zone Name**.
4. Click the **OK** button.

Note that if you specify a new name for a zone and then change its type, the name you specified will be retained; the automatic name change that accompanies a change in type occurs only if the name of the zone is its type plus its ID.

7.1.7. Defining Non-Uniform Cell Zone and Boundary Conditions

Most conditions at each type of boundary zone can be defined as profile functions instead of constant values. You can use a profile contained in an externally generated profile file, or a function that you create using a user-defined function (UDF). Profiles are described in [Profiles](#) (p. 382), and user-defined functions are described in the separate [UDF Manual](#).

7.1.8. Defining and Viewing Parameters

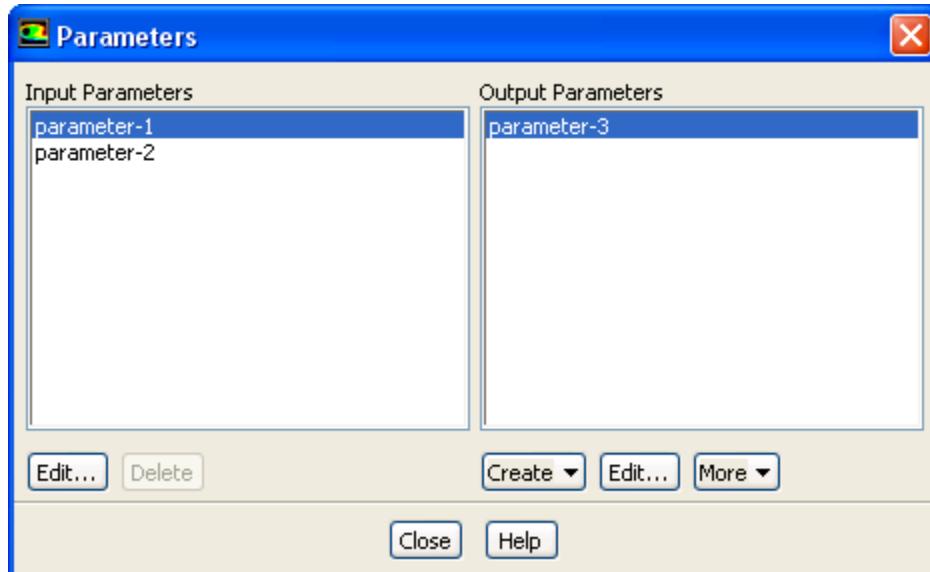

You can define a series of cases based on a set of parametric values. These parameters may be defined for numeric cell zone and boundary condition settings. This is especially useful if you are using Workbench and performing parametric studies (optimization), comparing cases with different boundary settings. Information about this feature can be found in see [Working with Parameters and Design Points](#) in the [Workbench User Guide](#). If you are not running ANSYS FLUENT through Workbench, then you can use the parameter settings to define the same boundary condition value to different boundaries having the same units.

Note

For more information about using parameters with ANSYS FLUENT in ANSYS Workbench, see [Working With Input and Output Parameters in Workbench](#) in the separate [FLUENT in Workbench User's Guide](#).

The parameters that you have defined in the various boundary condition dialog boxes are accessed by clicking the **Parameters...** button in the **Cell Zone Conditions** or **Boundary Conditions** task page. The **Parameters** dialog box will open, as shown in [Figure 7.3](#) (p. 217), listing all of the input parameters that you have created in the various boundary condition dialog boxes.

Figure 7.3 The Parameters Dialog Box

In the **Parameters** dialog box, you can

- Edit the input properties using the **Input Parameter Properties** dialog box, which is the same dialog box used to create parameters. This dialog box can also be accessed by selecting **New Input Parameter...** from the drop-down lists in the boundary conditions dialog boxes, as described later in this section.

Important

If you are using ANSYS FLUENT in ANSYS Workbench, you cannot edit the input parameters, you can only view them. For more information, see the separate [ANSYS FLUENT in ANSYS Workbench User's Guide](#).

- Delete input parameters which are not assigned to a setting.
- Create output parameters. These are single values generated by existing reports. The types of output that may be generated are **Fluxes...**, **Forces...**, **Surface Integrals...**, and **Volume Integrals....** These output parameters are discussed in greater detail in [Creating Output Parameters \(p. 1633\)](#).
- More options exist under the **More** menu:

Delete

displays a message in a dialog box, prompting you for a response to confirm the deletion of the output parameter.

Rename

allows you to edit the name of the output parameter through the **Rename** dialog box.

Print to Console

will output values to the console window. If you select multiple output parameters, then the output includes values from multiple output parameters.

Print All to Console

outputs the values from all output parameters to the console window.

Write...

allows you to store the output to a file. A dialog box is displayed allowing you to provide a file name.

Write All...

prompts you for a file name and then writes the values for all of the output parameters to a file.

Important

Changing the units for a quantity changes the value for any input parameter using that quantity.

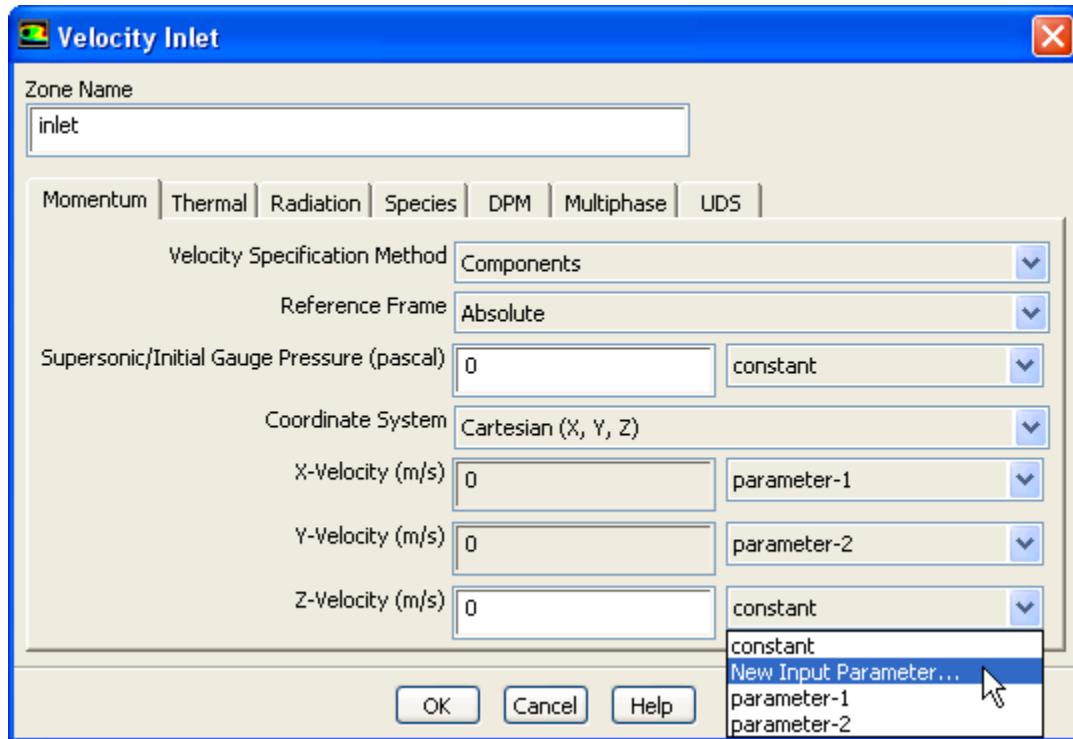

Note

Various ANSYS FLUENT setup-related input quantities (of type real and profile) can be assigned to an input parameter (indicated by the **New Input Parameter...** option in the corresponding drop-down list or by a small “p” icon next to the field). Clicking this option or icon displays the *Select Input Parameter Dialog Box* (p. 1953) where you can create and assign input parameters.

7.1.8.1. Creating a New Parameter

You can create a new cell zone or boundary condition parameter, as shown in *Figure 7.4* (p. 218).

Figure 7.4 The New Input Parameter... Selection

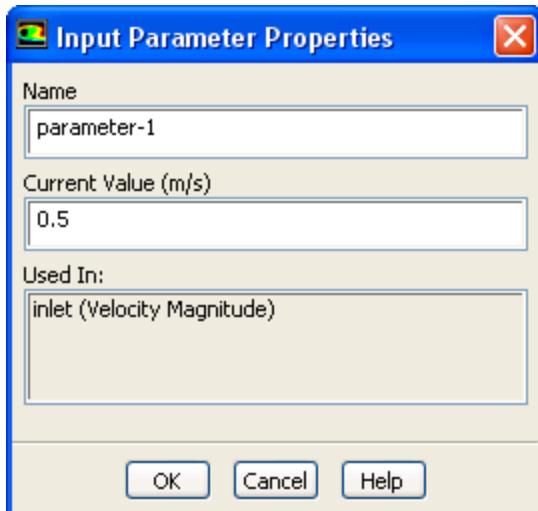

When you select **New Input Parameter...** from the drop-down list, the **Input Parameter Properties** dialog box (*Figure 7.5* (p. 219)) will open where you will

- Enter the **Name** of the parameter.

- Specify the **Current Value** as a constant.

Figure 7.5 The Input Parameter Properties Dialog Box

Once the parameters are defined in the **Input Parameter Properties** dialog box, the name of the parameter will appear in the drop-down list of the property you are defining, as seen in [Figure 7.4 \(p. 218\)](#).

Note

ANSYS FLUENT automatically creates generic default names for new input and output parameters (e.g., parameter-1, parameter-2, parameter-3, etc.) If a parameter is deleted, the default name is not reused. For example, if you have parameter-1, parameter-2, and parameter-3, then delete parameter-2 and create a new parameter, the default name for the new parameter will be parameter-4.

7.1.9. Selecting Cell or Boundary Zones in the Graphics Display

Whenever you need to select a zone in the **Cell Zone Conditions** or **Boundary Conditions** task page, you can use the mouse in the graphics window to choose the appropriate zone. This feature is particularly useful if you are setting up a problem for the first time, or if you have two or more zones of the same type and you want to determine the zone IDs (i.e., figure out which zone is which). To use this feature, do the following:

- Display the mesh using the [Mesh Display Dialog Box \(p. 1767\)](#).
- Use the mouse probe button (the right button, by default—see [Controlling the Mouse Button Functions \(p. 1548\)](#) to modify the mouse button functions) to click a cell or boundary zone in the graphics window.

The zone you select in the graphics display will automatically be selected in the **Zone** list in the **Cell Zone Conditions** or **Boundary Conditions** task page, and its name and ID will be printed in the console window.

However, if you prefer to select the surfaces to display using the **Mesh Display** dialog box, then simply click the **Display Mesh...** button in the **Cell Zone Conditions** or **Boundary Conditions** task page.

Cell Zone Conditions → Display Mesh...

 **Boundary Conditions** → **Display Mesh...**

Detailed information about the **Mesh Display** dialog box can be found in *Displaying the Mesh* (p. 1500).

7.1.10. Operating and Periodic Conditions

The **Cell Zone Conditions** and **Boundary Conditions** task pages allow you to access the **Operating Conditions** dialog box, where you can set the operating pressure, reference pressure location, include the effects of gravity, and specify other operating variables, as discussed in *Modeling Basic Fluid Flow* (p. 505).

 **Cell Zone Conditions** → **Operating Conditions...** **Boundary Conditions** → **Operating Conditions...**

The **Periodic Conditions** dialog box can be accessed from the **Boundary Conditions** task page. For a detailed description of this dialog box's inputs, refer to *Periodic Flows* (p. 514).

 **Boundary Conditions** → **Periodic Conditions...**

7.1.11. Highlighting Selected Boundary Zones

To highlight a selected boundary zone of a model which is displayed in the graphics window, enable the **Highlight Zone** option in the **Boundary Conditions** task page.

Important

Note that this is only applicable to 3D cases and is available only in the **Boundary Conditions** task page.

There are two ways in which you can highlight a boundary zone in the graphics window, after enabling the **Highlight Zone** option:

- Select the zone by highlighting it in the **Zone** list, in the **Boundary Conditions** task page.
- Use the mouse-probe button and select the zone in the graphics window.

The selected zone in the graphics window will be highlighted in a cyan color, which is the default color. You can change the color using the following text command:

```
display → set → colors → highlight-color
```

If you want to highlight a boundary zone which is not displayed in the graphics window, ANSYS FLUENT will display that boundary zone in the graphics window and then highlight it. If you disable the **Highlight Zone** option, the displayed boundary zone will be removed from the scene (graphics window) and your model will be redrawn to its original view.

7.1.12. Saving and Reusing Cell Zone and Boundary Conditions

You can save cell zone and boundary conditions to a file so that you can use them to specify the same conditions for a different case, as described in *Reading and Writing Boundary Conditions* (p. 74).

7.2. Cell Zone Conditions

Cell zones consist of fluids and solids. Porous zones in ANSYS FLUENT are treated as fluid zones. A detailed description of the various cell zones is given in the sections that follow.

- 7.2.1. Fluid Conditions
- 7.2.2. Solid Conditions
- 7.2.3. Porous Media Conditions
- 7.2.4. Fixing the Values of Variables
- 7.2.5. Defining Mass, Momentum, Energy, and Other Sources

7.2.1. Fluid Conditions

A fluid zone is a group of cells for which all active equations are solved. The only required input for a fluid zone is the type of fluid material. You must indicate which material the fluid zone contains so that the appropriate material properties will be used.

Important

If you are modeling multiphase flow, you will not specify the materials here; you will choose the phase material when you define the phases, as described in *Defining the Phases for the VOF Model* (p. 1219).

Important

If you are modeling species transport and/or combustion, you can specify the material as either a mixture or a fluid. The mixture material has to be the same as that specified in the **Species Model** dialog box when you enable the model. The fluid zones, being of different material types, must not be contiguous.

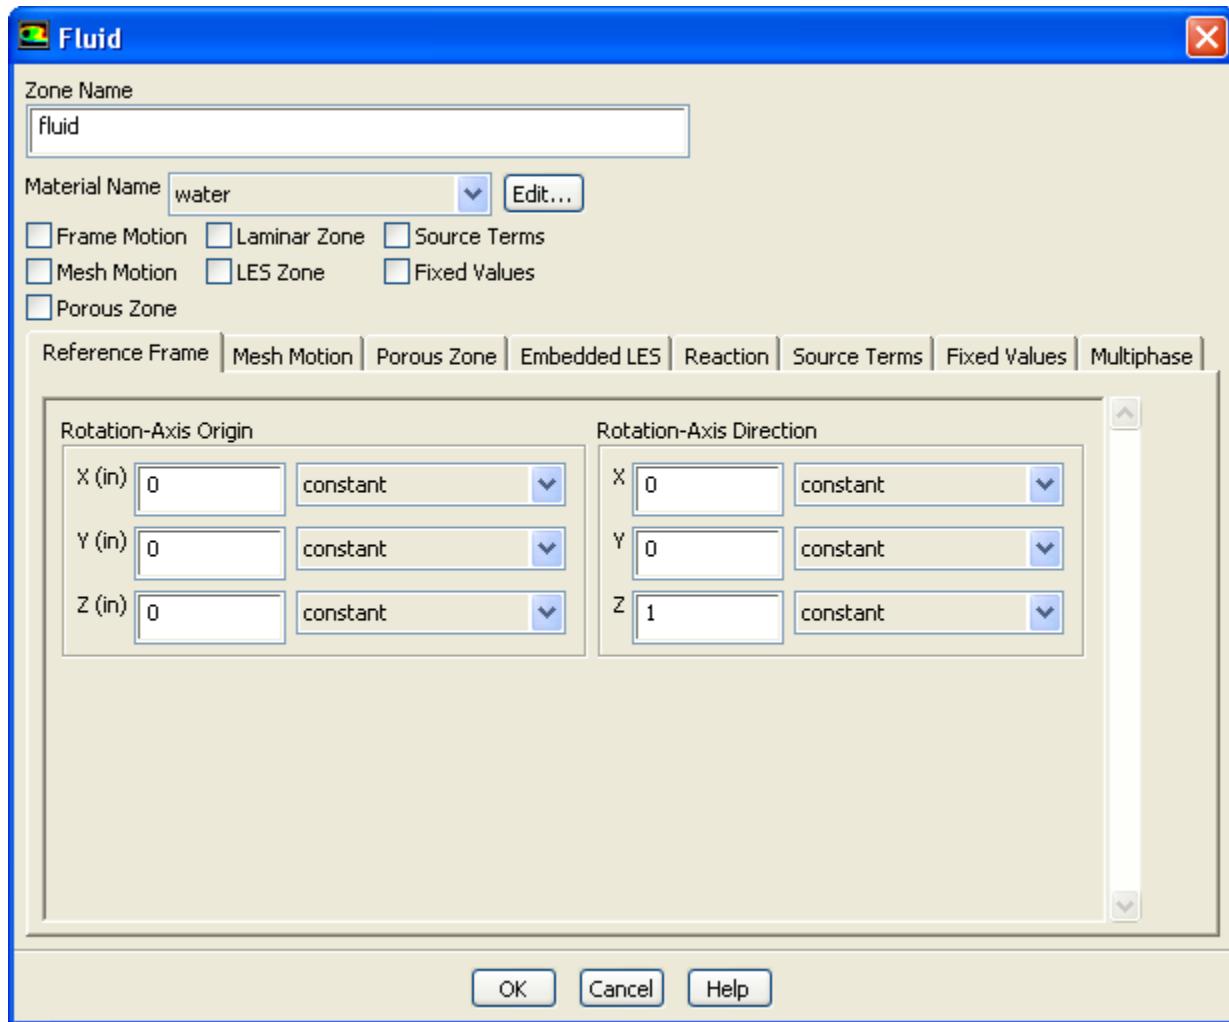

Optional inputs allow you to set sources or fixed values of mass, momentum, heat (temperature), turbulence, species, and other scalar quantities. You can also define motion for the fluid zone. If there are rotationally periodic boundaries adjacent to the fluid zone, you will need to specify the rotation axis. If you are modeling turbulence using one of the k - ε models, the k - ω model, or the Spalart-Allmaras model, you can choose to define the fluid zone as a laminar flow region. If you are modeling radiation using the DO model, you can specify whether or not the fluid participates in radiation.

Important

For information about porous zones, see *Porous Media Conditions* (p. 229).

7.2.1.1. Inputs for Fluid Zones

You will set all fluid conditions in the *Fluid Dialog Box* (p. 1942) (*Figure 7.6* (p. 222)), which is accessed from the **Cell Zone Conditions** task page (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

Figure 7.6 The Fluid Dialog Box

7.2.1.1.1. Defining the Fluid Material

To define the material contained in the fluid zone, select the appropriate item in the **Material Name** drop-down list. This list will contain all fluid materials database) in the [Create/Edit Materials Dialog Box \(p. 1882\)](#). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

Important

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid zones will be the material you specified in the [Species Model Dialog Box \(p. 1814\)](#). For multiphase flows, the materials are specified when you define the phases, as described in [Defining the Phases for the VOF Model \(p. 1219\)](#).

7.2.1.1.2. Defining Sources

If you wish to define a source of heat, mass, momentum, turbulence, species, or other scalar quantity within the fluid zone, you can do so by enabling the **Source Terms** option. See [Defining Mass, Momentum, Energy, and Other Sources \(p. 257\)](#) for details.

7.2.1.1.3. Defining Fixed Values

If you wish to fix the value of one or more variables in the fluid zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See [Fixing the Values of Variables \(p. 253\)](#) for details.

7.2.1.1.4. Specifying a Laminar Zone

When you are calculating a turbulent flow, it is possible to “turn off” turbulence modeling in a specific fluid zone. To disable turbulence modeling, turn on the **Laminar Zone** option in the **Fluid** dialog box. This is useful if you know that the flow in a certain region is laminar. For example, if you know the location of the transition point on an airfoil, you can create a laminar/turbulent transition boundary where the laminar cell zone borders the turbulent cell zone. This feature allows you to model turbulent transition on the airfoil.

By default, the **Laminar Zone** option will set the turbulent viscosity, μ_t , to zero and disable turbulence production in the fluid zone. Turbulent quantities will still be transported through the zone, but effects on fluid mixing and momentum will be ignored. If you want to keep the turbulent viscosity, you can do so using the text command `define/boundary-conditions/fluid`. You will be asked if you want to Set Turbulent Viscosity to zero within laminar zone?. If your response is no, ANSYS FLUENT will set the production term in the turbulence transport equation to zero, but will retain a non-zero μ_t .

Disabling turbulence modeling in a fluid zone can be applied to all the turbulence models except the Large Eddy Simulation (LES) model.

7.2.1.1.5. Specifying a Reaction Mechanism

If you are modeling species transport with reactions, you can enable a reaction mechanism in a fluid zone by turning on the **Reaction** option and selecting an available mechanism from the **Reaction Mechanism** drop-down list. See [Defining Zone-Based Reaction Mechanisms \(p. 872\)](#) for more information about defining reaction mechanisms.

7.2.1.1.6. Specifying the Rotation Axis

If there are rotationally periodic boundaries adjacent to the fluid zone or if the zone is rotating, either the mesh or its reference frame, you must specify the rotation axis. To define the axis for a moving reference frame problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Reference Frame** tab. To define the axis for a moving mesh problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Mesh Motion** tab.

Note

If a frame motion and a mesh motion are specified at the same zone and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

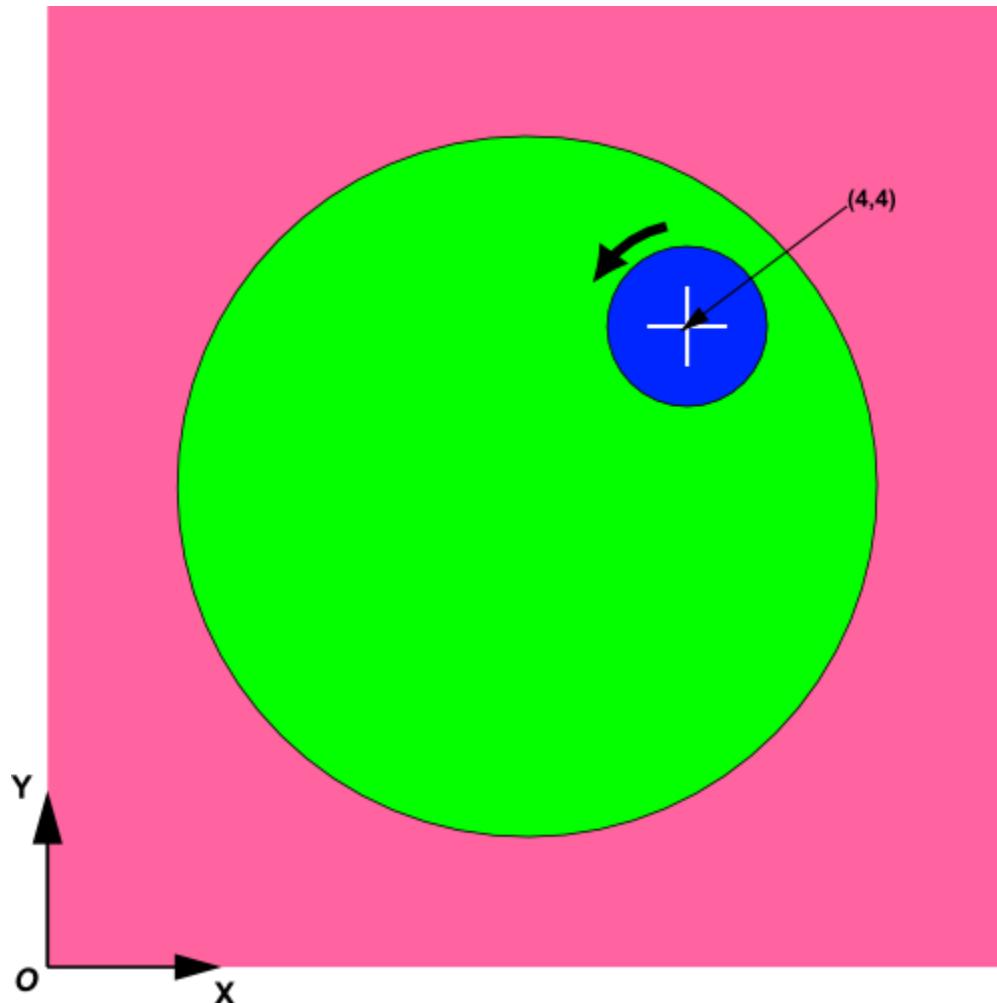

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction** inputs for the frame of reference and the mesh motion. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z-direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the *x* axis, with the origin at (0,0).

7.2.1.1.7. Defining Zone Motion

To define zone motion for a moving reference frame (MRF), enable the **Frame Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Reference Frame** tab.

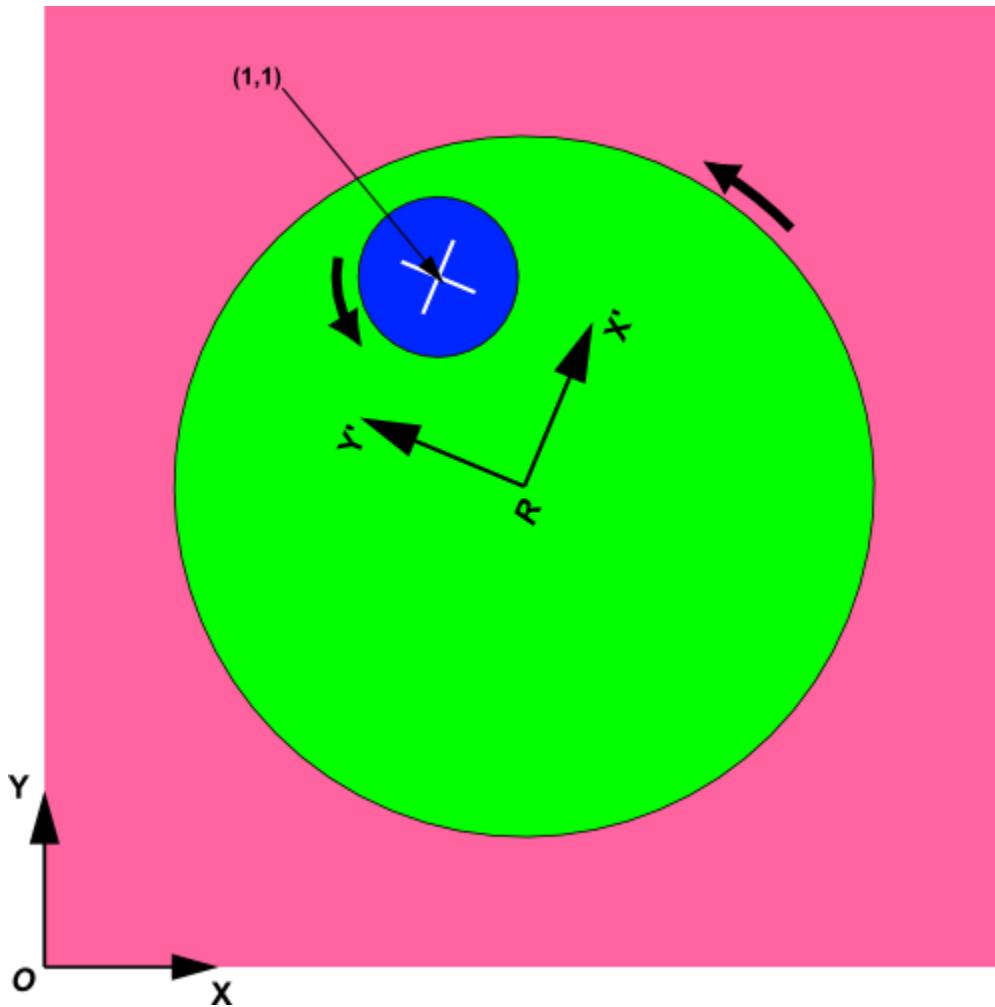

To define zone motion for a moving (sliding) mesh, enable the **Mesh Motion** option in the **Fluid** dialog box. Set the appropriate parameters in the expanded portion of the dialog box, under the **Mesh Motion** tab. See [Setting Up the Sliding Mesh Problem \(p. 566\)](#) for details.

For cases that do not contain zones with motion specified in a relative frame to another zone, select **absolute** from the **Relative To Cell Zone** drop-down list. Here, the velocity and rotation components are specified in an **absolute** reference frame, which is the default setting, as shown in [Figure 7.7 \(p. 225\)](#). If no moving zones are present in the simulation, then **absolute** will be the only available selection. See [The Multiple Reference Frame Model](#) for more information.

Figure 7.7 Rotation Specified in the Absolute Reference Frame

For cases where you have a moving zone specified relative to another moving zone, select the cell zone carrying the primary motion from the **Relative To Cell Zone** drop-down list under the **Reference Frame** tab or the **Mesh Motion** tab. Note that for such cases, **Rotation-Axis Origin (Relative)** will appear in the interface, signifying coordinates relative to the zone selected from the **Relative To Cell Zone** drop-down list.

Figure 7.8 (p. 226) illustrates that the rotational axis origin of the small rotating zone is specified relative to the cell zone carrying the primary motion (having local coordinate system R).

Figure 7.8 Rotation Specified Relative to a Moving Zone**Note**

The **Relative To Cell Zone** list will consist of all moving cell zones with an absolute motion specification (i.e. zones which are moving, but their motion is not relative to some other zone), excluding the current cell zone.

For problems that include linear, translational motion of the fluid zone, specify the **Translational Velocity** by setting the **X**, **Y**, and **Z** components under the **Mesh Motion** tab. For problems that include rotational motion, specify the rotational **Speed** under **Rotational Velocity**. The rotation axis is defined as described above. Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in *Defining Transient Cell Zone and Boundary Conditions* (p. 393), or a UDF macro (DEFINE_TRANSIENT_PROFILE). Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the frame motion individually. However, you can also specify the frame motion using a user-defined function. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Important

If you need to switch between the MRF and moving mesh models, simply click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF `DEFINE_ZONE_MOTION` will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

See [Modeling Flows with Moving Reference Frames \(p. 535\)](#) for details about modeling flows in moving reference frames. Details about the frame motion UDF can be found in [DEFINE_ZONE_MOTION](#) in the [UDF Manual](#).

7.2.1.1.8. Defining Radiation Parameters

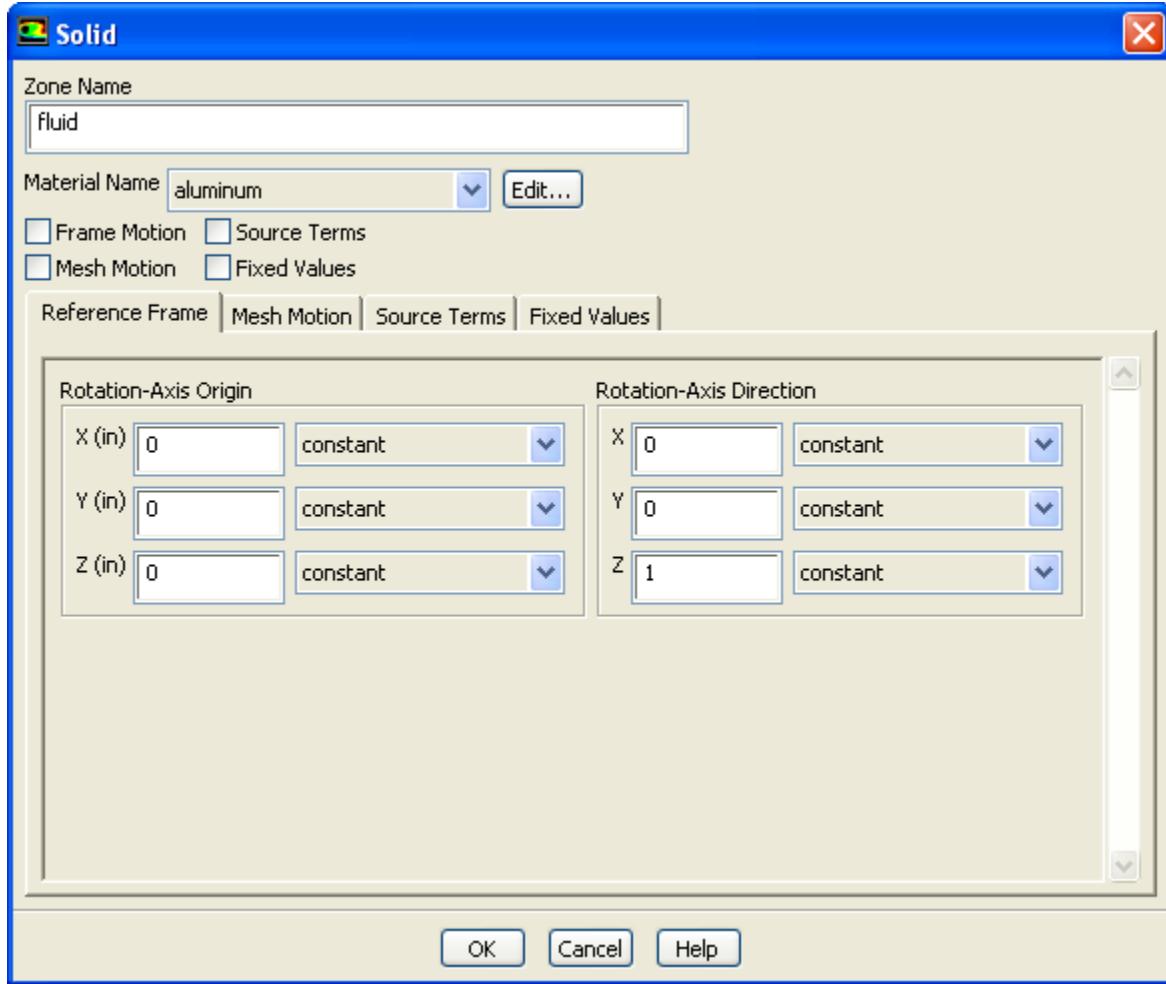

If you are using the DO radiation model, you can specify whether or not the fluid zone participates in radiation using the **Participates in Radiation** option. See [Defining Boundary Conditions for Radiation \(p. 772\)](#) for details.

7.2.2. Solid Conditions

A “solid” zone is a group of cells for which only a heat conduction problem is solved; no flow equations are solved. The material being treated as a solid may actually be a fluid, but it is assumed that no convection is taking place. The only required input for a solid zone is the type of solid material. You must indicate which material the solid zone contains so that the appropriate material properties will be used. Optional inputs allow you to set a volumetric heat generation rate (heat source) or a fixed value of temperature. You can also define motion for the solid zone. If there are rotationally periodic boundaries adjacent to the solid zone, you will need to specify the rotation axis. If you are modeling radiation using the DO model, you can specify whether or not the solid material participates in radiation.

7.2.2.1. Inputs for Solid Zones

You will set all solid conditions in the [Solid Dialog Box \(p. 1949\)](#) ([Figure 7.9 \(p. 228\)](#)), which is opened from the **Cell Zone Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.9 The Solid Dialog Box

7.2.2.1.1. Defining the Solid Material

To define the material contained in the solid zone, select the appropriate item in the **Material Name** drop-down list. This list will contain all solid materials database) in the *Create/Edit Materials Dialog Box* (p. 1882). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

7.2.2.1.2. Defining a Heat Source

If you wish to define a source of heat within the solid zone, you can do so by enabling the **Source Terms** option. See *Defining Mass, Momentum, Energy, and Other Sources* (p. 257) for details.

7.2.2.1.3. Defining a Fixed Temperature

If you wish to fix the value of temperature in the solid zone, rather than computing it during the calculation, you can do so by enabling the **Fixed Values** option. See *Fixing the Values of Variables* (p. 253) for details.

7.2.2.1.4. Specifying the Rotation Axis

If there are rotationally periodic boundaries adjacent to the solid zone or if the zone is rotating, either the mesh or its reference frame, you must specify the rotation axis. To define the axis for a moving reference frame problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Reference Frame** tab. To define the axis for a moving mesh problem, set the **Rotation-Axis Direction** and **Rotation-Axis Origin** under the **Mesh Motion** tab.

Note

If a frame motion and a mesh motion are specified at the same zone and this zone has rotationally periodic boundaries adjacent to it, then both axes have to be coaxial. Otherwise, the periodicity assumption is not valid and you will receive a warning message. In addition, the mesh check will fail.

The cell zone axis is independent of the axis of rotation used by any adjacent wall zones or any other cell zones. For 3D problems, the axis of rotation is the vector from the **Rotation-Axis Origin** in the direction of the vector given by your **Rotation-Axis Direction** inputs for the frame of reference and the mesh motion. For 2D non-axisymmetric problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z -direction vector passing through the specified point. (The z direction is normal to the plane of your geometry so that rotation occurs in the plane.) For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

7.2.2.1.5. Defining Zone Motion

Defining zone motion in solids is similar to defining them for fluids. Please refer to *Defining Zone Motion* (p. 224) for details.

7.2.2.1.6. Defining Radiation Parameters

If you are using the DO radiation model, you can specify whether or not the solid material participates in radiation using the **Participates in Radiation** option. See *Defining Boundary Conditions for Radiation* (p. 772) for details.

7.2.3. Porous Media Conditions

The porous media model can be used for a wide variety of single phase and multiphase problems, including flow through packed beds, filter papers, perforated plates, flow distributors, and tube banks. When you use this model, you define a cell zone in which the porous media model is applied and the pressure loss in the flow is determined via your inputs as described in *Momentum Equations for Porous Media* (p. 230). Heat transfer through the medium can also be represented, with or without the assumption of thermal equilibrium between the medium and the fluid flow (as described in *Treatment of the Energy Equation in Porous Media* (p. 233)).

A 1D simplification of the porous media model, termed the “porous jump,” can be used to model a thin membrane with known velocity/pressure-drop characteristics. The porous jump model is applied to a face zone, not to a cell zone, and should be used (instead of the full porous media model) whenever possible because it is more robust and yields better convergence. See *Porous Jump Boundary Conditions* (p. 353) for details.

7.2.3.1. Limitations and Assumptions of the Porous Media Model

The porous media model incorporates an empirically determined flow resistance in a region of your model defined as “porous”. In essence, the porous media model adds a momentum sink in the governing momentum equations. Consequently, the following modeling assumptions and limitations should be readily recognized:

- Since the volume blockage that is physically present is not represented in the model, by default ANSYS FLUENT uses and reports a superficial velocity inside the porous medium, based on the volumetric flow rate, to ensure continuity of the velocity vectors across the porous medium interface. This superficial velocity formulation does not take porosity into account when calculating the convection and diffusion terms of the transport equations. You can choose to use a more accurate alternative, in which the true (physical) velocity is calculated inside the porous medium and porosity is included in the differential terms of the transport equations. See [Modeling Porous Media Based on Physical Velocity](#) (p. 248) for details. In a multiphase flow system, all phases share the same porosity.
- The effect of the porous medium on the turbulence field is only approximated. See [Treatment of Turbulence in Porous Media](#) (p. 235) for details.
- In general, the ANSYS FLUENT porous medium model, for both single phase and multiphase, assumes the porosity is isotropic, and it can vary with space and time.
- The Superficial Velocity Formulation and the Physical Velocity Formulation are available for multiphase porous media. See [User Inputs for Porous Media](#) (p. 235) for details.
- The porous media momentum resistance and heat source terms are calculated separately on each phase. See [Momentum Equations for Porous Media](#) (p. 230) for details.
- The interactions between a porous medium and shock waves are not considered.
- By default, ANSYS FLUENT assumes thermal equilibrium between the porous media solids and multiphase fluid flows. The solids temperature is thus estimated by phase temperatures. However, the solids temperature can also be calculated by a UDS equation ([User-Defined Scalar \(UDS\) Transport Equations](#) (p. 505)).
- When applying the porous media model in a moving reference frame, ANSYS FLUENT will either apply the relative reference frame or the absolute reference frame when you enable the **Relative Velocity Resistance Formulation**. This allows for the correct prediction of the source terms.

7.2.3.2. Momentum Equations for Porous Media

The porous media models for single phase flows and multiphase flows use the **Superficial Velocity Porous Formulation** as the default. ANSYS FLUENT calculates the superficial phase or mixture velocities based on the volumetric flow rate in a porous region. The porous media model is described in the following sections for single phase flow, however, it is important to note the following for multiphase flow:

- In the Eulerian multiphase model ([Eulerian Model Theory](#) in the [Theory Guide](#)), the general porous media modeling approach, physical laws, and equations described below are applied to the corresponding phase for mass continuity, momentum, energy, and all the other scalar equations.
- The **Superficial Velocity Porous Formulation** generally gives good representations of the bulk pressure loss through a porous region. However, since the superficial velocity values within a porous region remain the same as those outside the porous region, it cannot predict the velocity increase in porous zones and thus limits the accuracy of the model.

Porous media are modeled by the addition of a momentum source term to the standard fluid flow equations. The source term is composed of two parts: a viscous loss term (Darcy, the first term on the

right-hand side of [Equation 7-1](#) (p. 231), and an inertial loss term (the second term on the right-hand side of [Equation 7-1](#) (p. 231))

$$S_i = - \left(\sum_{j=1}^3 D_{ij} \mu v_j + \sum_{j=1}^3 C_{ij} \frac{1}{2} \rho |v| v_j \right) \quad (7-1)$$

where S_i is the source term for the i th (x , y , or z) momentum equation, $|v|$ is the magnitude of the velocity and D and C are prescribed matrices. This momentum sink contributes to the pressure gradient in the porous cell, creating a pressure drop that is proportional to the fluid velocity (or velocity squared) in the cell.

To recover the case of simple homogeneous porous media

$$S_i = - \left(\frac{\mu}{\alpha} v_i + C_2 \frac{1}{2} \rho |v| v_i \right) \quad (7-2)$$

where α is the permeability and C_2 is the inertial resistance factor, simply specify D and C as diagonal matrices with $1/\alpha$ and C_2 , respectively, on the diagonals (and zero for the other elements).

ANSYS FLUENT also allows the source term to be modeled as a power law of the velocity magnitude:

$$S_i = - C_0 |v|^{C_l} = - C_0 |v|^{(C_l - 1)} v_i \quad (7-3)$$

where C_0 and C_l are user-defined empirical coefficients.

Important

In the power-law model, the pressure drop is isotropic and the units for C_0 are SI.

7.2.3.2.1. Darcy's Law in Porous Media

In laminar flows through porous media, the pressure drop is typically proportional to velocity and the constant C_2 can be considered to be zero. Ignoring convective acceleration and diffusion, the porous media model then reduces to Darcy's Law:

$$\nabla p = - \frac{\mu}{\alpha} \vec{v} \quad (7-4)$$

The pressure drop that ANSYS FLUENT computes in each of the three (x , y , z) coordinate directions within the porous region is then

$$\begin{aligned}\Delta p_x &= \sum_{j=1}^3 \frac{\mu}{\alpha_{xj}} v_j \Delta n_x \\ \Delta p_y &= \sum_{j=1}^3 \frac{\mu}{\alpha_{yj}} v_j \Delta n_y \\ \Delta p_z &= \sum_{j=1}^3 \frac{\mu}{\alpha_{zj}} v_j \Delta n_z\end{aligned}\tag{7-5}$$

where $1/\alpha_{ij}$ are the entries in the matrix D in [Equation 7-1 \(p. 231\)](#), v_j are the velocity components in the x , y , and z directions, and Δn_x , Δn_y , and Δn_z are the thicknesses of the medium in the x , y , and z directions.

Here, the thickness of the medium (Δn_x , Δn_y , or Δn_z) is the *actual* thickness of the porous region in your model. Thus if the thicknesses used in your model differ from the actual thicknesses, you must make the adjustments in your inputs for $1/\alpha_{ij}$.

7.2.3.2.2. Inertial Losses in Porous Media

At high flow velocities, the constant C_2 in [Equation 7-1 \(p. 231\)](#) provides a correction for inertial losses in the porous medium. This constant can be viewed as a loss coefficient per unit length along the flow direction, thereby allowing the pressure drop to be specified as a function of dynamic head.

If you are modeling a perforated plate or tube bank, you can sometimes eliminate the permeability term and use the inertial loss term alone, yielding the following simplified form of the porous media equation:

$$\nabla p = - \sum_{j=1}^3 C_{2ij} \left(\frac{1}{2} \rho v_j |v| \right) \tag{7-6}$$

or when written in terms of the pressure drop in the x , y , z directions:

$$\begin{aligned}\Delta p_x &\approx \sum_{j=1}^3 C_{2xj} \Delta n_x \frac{1}{2} \rho v_j |v| \\ \Delta p_y &\approx \sum_{j=1}^3 C_{2yj} \Delta n_y \frac{1}{2} \rho v_j |v| \\ \Delta p_z &\approx \sum_{j=1}^3 C_{2zj} \Delta n_z \frac{1}{2} \rho v_j |v|\end{aligned}\tag{7-7}$$

Again, the thickness of the medium (Δn_x , Δn_y , or Δn_z) is the thickness you have defined in your model.

7.2.3.3. Treatment of the Energy Equation in Porous Media

ANSYS FLUENT solves the standard energy transport equation (Equation 5–1 in the Theory Guide) in porous media regions with modifications to the conduction flux and the transient terms only.

7.2.3.3.1. Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are assumed to be in thermal equilibrium, the conduction flux in the porous medium uses an effective conductivity and the transient term includes the thermal inertia of the solid region on the medium:

$$\begin{aligned} \frac{\partial}{\partial t} (\gamma \rho_f E_f + (1 - \gamma) \rho_s E_s) + \nabla \cdot (\vec{v} (\rho_f E_f + p)) \\ = S_f^h + \nabla \cdot \left[k_{\text{eff}} \nabla T - \left(\sum_i h_i J_i \right) + (\bar{\tau} \cdot \vec{v}) \right] \end{aligned} \quad (7-8)$$

where

E_f = total fluid energy

E_s = total solid medium energy

ρ_f = fluid density

ρ_s = solid medium density

γ = porosity of the medium

k_{eff} = effective thermal conductivity of the medium

S_f^h = fluid enthalpy source term

The effective thermal conductivity in the porous medium, k_{eff} , is computed by ANSYS FLUENT as the volume average of the fluid conductivity and the solid conductivity:

$$k_{\text{eff}} = \gamma k_f + (1 - \gamma) k_s \quad (7-9)$$

where

k_f = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_s = solid medium thermal conductivity

The fluid thermal conductivity k_f and the solid thermal conductivity k_s can be computed via user-defined functions.

The anisotropic effective thermal conductivity can also be specified via user-defined functions. In this case, the isotropic contributions from the fluid, γk_f , are added to the diagonal elements of the solid anisotropic thermal conductivity matrix.

7.2.3.3.2. Non-Equilibrium Thermal Model Equations

For simulations in which the porous medium and fluid flow are not assumed to be in thermal equilibrium, a dual cell approach is used. In such an approach, a solid zone that is spatially coincident with the porous fluid zone is defined, and this solid zone only interacts with the fluid with regard to heat transfer. The conservation equations for energy are solved separately for the fluid and solid zones. The conservation equation solved for the fluid zone is

$$\frac{\partial}{\partial t} (\gamma \rho_f E_f) + \nabla \cdot (\bar{v} (\rho_f E_f + p)) = \nabla \cdot \left(\gamma k_f \nabla T_f - \left(\sum_i h_i J_i \right) + (\bar{\tau} \cdot \bar{v}) \right) + S_f^h + h_{fs} A_{fs} (T_f - T_s) \quad (7-10)$$

and the conservation equation solved for the solid zone is

$$\frac{\partial}{\partial t} ((1-\gamma) \rho_s E_s) = \nabla \cdot ((1-\gamma) k_s \nabla T_s) + S_s^h + h_{fs} A_{fs} (T_s - T_f) \quad (7-11)$$

where

E_f = total fluid energy

E_s = total solid medium energy

ρ_f = fluid density

ρ_s = solid medium density

γ = porosity of the medium

k_f = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_s = solid medium thermal conductivity

h_{fs} = heat transfer coefficient for the fluid / solid interface

A_{fs} = interfacial area density, i.e., the ratio of the area of the fluid / solid interface and the volume of the porous zone

T_f = temperature of the fluid

T_s = temperature of the solid medium

S_f^h = fluid enthalpy source term

S_s^h = solid enthalpy source term

The fluid thermal conductivity k_f and the solid thermal conductivity k_s can be computed via user-defined functions.

The source term due to the non-equilibrium thermal model is represented in [Equation 7-10 \(p. 234\)](#) and [Equation 7-11 \(p. 234\)](#) by $h_{fs} A_{fs} (T_f - T_s)$ and $h_{fs} A_{fs} (T_s - T_f)$, respectively.

7.2.3.4. Treatment of Turbulence in Porous Media

ANSYS FLUENT will, by default, solve the standard conservation equations for turbulence quantities in the porous medium. In this default approach, turbulence in the medium is treated as though the solid medium has no effect on the turbulence generation or dissipation rates. This assumption may be reasonable if the medium's permeability is quite large and the geometric scale of the medium does not interact with the scale of the turbulent eddies. In other instances, however, you may want to suppress the effect of turbulence in the medium.

If you are using one of the turbulence models (with the exception of the Large Eddy Simulation (LES) model), you can suppress the effect of turbulence in a porous region by enabling the **Laminar Zone** option in the *Fluid Dialog Box* (p. 1942). Refer to *Specifying a Laminar Zone* (p. 223) for details about using the **Laminar Zone** option.

7.2.3.5. Effect of Porosity on Transient Scalar Equations

For transient porous media calculations, the effect of porosity on the time-derivative terms is accounted for in all scalar transport equations and the continuity equation. When the effect of porosity is taken into account, the time-derivative term becomes $\frac{\partial}{\partial t} (\gamma p \phi)$, where ϕ is the scalar quantity (k , ε , etc.) and γ is the porosity.

The effect of porosity is enabled automatically for transient calculations, and the porosity is set to 1 by default.

7.2.3.6. User Inputs for Porous Media

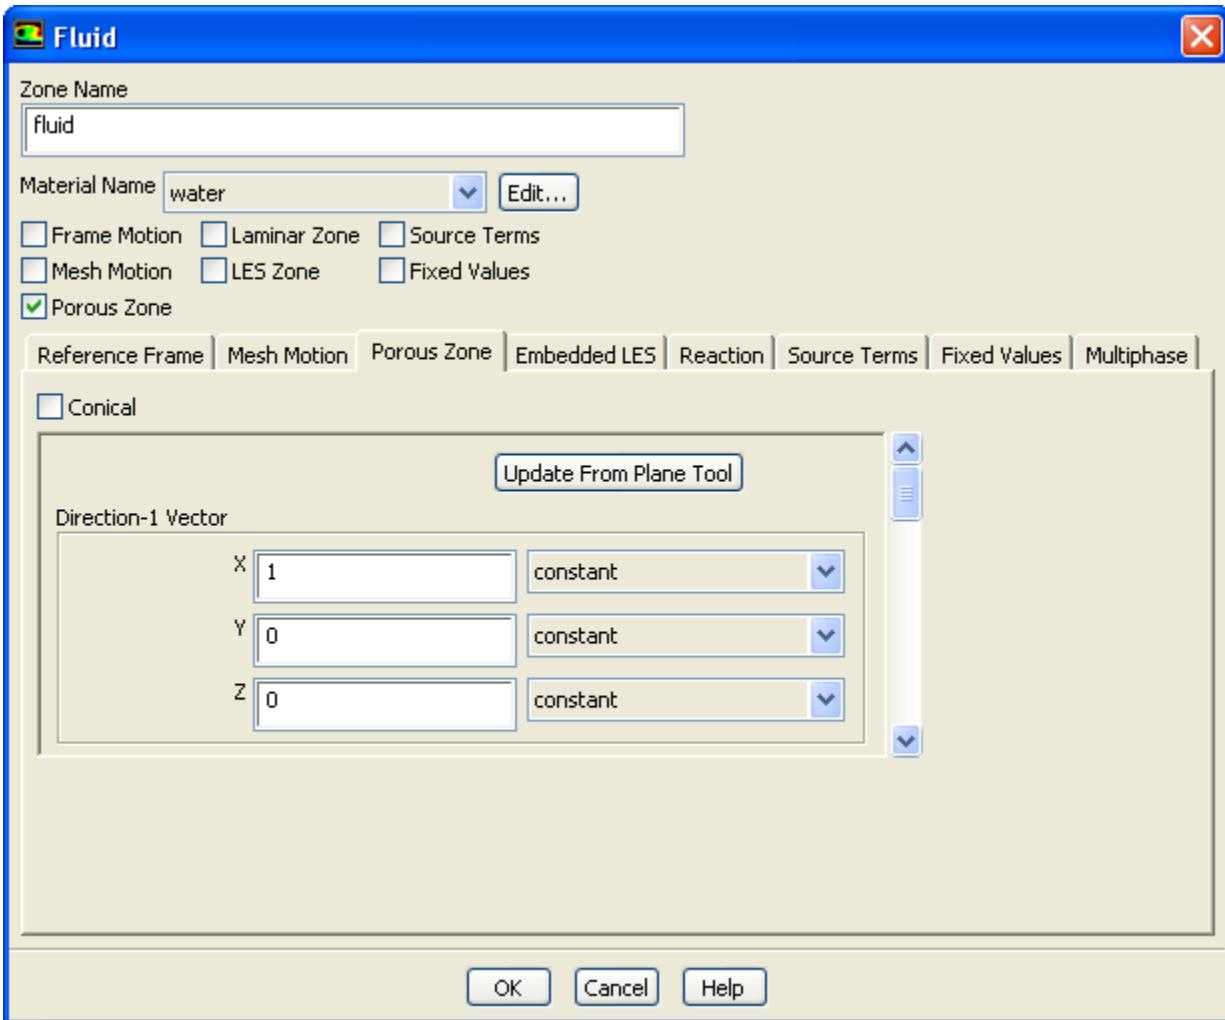

When you are modeling a porous region, the only additional inputs for the problem setup are as follows. Optional inputs are indicated as such.

1. Define the porous zone.
2. Define the porous velocity formulation in the **Cell Zone Conditions** task page. (optional)
3. Identify the fluid material flowing through the porous medium.
4. Enable reactions for the porous zone, if appropriate, and select the reaction mechanism.
5. Enable the **Relative Velocity Resistance Formulation**. By default, this option is already enabled and takes the moving porous media into consideration (as described in *Including the Relative Velocity Resistance Formulation* (p. 237)).
6. Set the viscous resistance coefficients (D_{ij} in *Equation 7-1* (p. 231), or $1/\alpha$ in *Equation 7-2* (p. 231)) and the inertial resistance coefficients (C_{ij} in *Equation 7-1* (p. 231), or C_2 in *Equation 7-2* (p. 231)), and define the direction vectors for which they apply. Alternatively, specify the coefficients for the power-law model.
7. Specify the porosity of the porous medium.
8. Specify the settings for heat transfer. (optional)
9. Set the volumetric heat generation rate in the non-solid portion of the porous medium (or any other sources, such as mass or momentum). (optional)
10. Set any fixed values for solution variables in the fluid region (optional).
11. Suppress the turbulent viscosity in the porous region, if appropriate.
12. Specify the rotation axis and/or zone motion, if relevant.

Methods for determining the resistance coefficients and/or permeability are presented below. If you choose to use the power-law approximation of the porous-media momentum source term, you will enter the coefficients C_0 and C_l in [Equation 7-3 \(p. 231\)](#) instead of the resistance coefficients and flow direction.

You will set all parameters for the porous medium in the [Fluid Dialog Box \(p. 1942\)](#) ([Figure 7.10 \(p. 236\)](#)), which is opened from the **Cell Zone Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.10 The Fluid Dialog Box for a Porous Zone

7.2.3.6.1. Defining the Porous Zone

As mentioned in [Overview \(p. 211\)](#), a porous zone is modeled as a special type of fluid zone. To indicate that the fluid zone is a porous region, enable the **Porous Zone** option in the **Fluid** dialog box. The dialog box will expand to show the porous media inputs (as shown in [Figure 7.10 \(p. 236\)](#)).

7.2.3.6.2. Defining the Porous Velocity Formulation

The **Cell Zone Conditions** task page contains a **Porous Formulation** region where you can instruct ANSYS FLUENT to use either a superficial or physical velocity in the porous medium simulation. By default,

the velocity is set to **Superficial Velocity**. For details about using the **Physical Velocity** formulation, see [Modeling Porous Media Based on Physical Velocity \(p. 248\)](#).

7.2.3.6.3. Defining the Fluid Passing Through the Porous Medium

To define the fluid that passes through the porous medium, select the appropriate fluid in the **Material Name** drop-down list in the [Fluid Dialog Box \(p. 1942\)](#). If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

Important

If you are modeling species transport or multiphase flow, the **Material Name** list will not appear in the **Fluid** dialog box. For species calculations, the mixture material for all fluid/porous zones will be the material you specified in the [Species Model Dialog Box \(p. 1814\)](#). For multiphase flows, the materials are specified when you define the phases, as described in [Defining the Phases for the VOF Model \(p. 1219\)](#).

7.2.3.6.4. Enabling Reactions in a Porous Zone

If you are modeling species transport with reactions, you can enable reactions in a porous zone by turning on the **Reaction** option in the **Fluid** dialog box and selecting a mechanism in the **Reaction Mechanism** drop-down list.

If your mechanism contains wall surface reactions, you will also need to specify a value for the **Surface-to-Volume Ratio**. This value is the surface area of the pore walls per unit volume ($\frac{A}{V}$), and can be thought of as a measure of catalyst loading. With this value, ANSYS FLUENT can calculate the total surface area on which the reaction takes place in each cell by multiplying $\frac{A}{V}$ by the volume of the cell.

See [Defining Zone-Based Reaction Mechanisms \(p. 872\)](#) for details about defining reaction mechanisms. See [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#) for details about wall surface reactions.

7.2.3.6.5. Including the Relative Velocity Resistance Formulation

Prior to ANSYS FLUENT 6.3, cases with moving reference frames used the absolute velocities in the source calculations for inertial and viscous resistance. This approach has been enhanced so that relative velocities are used for the porous source calculations ([Momentum Equations for Porous Media \(p. 230\)](#)). Using the **Relative Velocity Resistance Formulation** option (turned on by default) allows you to better predict the source terms for cases involving moving meshes or moving reference frames (MRF). This option works well in cases with non-moving and moving porous media. Note that ANSYS FLUENT will use the appropriate velocities (relative or absolute), depending on your case setup.

7.2.3.6.6. Defining the Viscous and Inertial Resistance Coefficients

The viscous and inertial resistance coefficients are both defined in the same manner. The basic approach for defining the coefficients using a Cartesian coordinate system is to define one direction vector in 2D or two direction vectors in 3D, and then specify the viscous and/or inertial resistance coefficients in each direction. In 2D, the second direction, which is not explicitly defined, is normal to the plane defined by the specified direction vector and the z direction vector. In 3D, the third direction is normal to the plane defined by the two specified direction vectors. For a 3D problem, the second direction must be

normal to the first. If you fail to specify two normal directions, the solver will ensure that they are normal by ignoring any component of the second direction that is in the first direction. You should therefore be certain that the first direction is correctly specified.

You can also define the viscous and/or inertial resistance coefficients in each direction using a user-defined function (UDF). The user-defined options become available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS FLUENT. Note that the coefficients defined in the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined function, see the [UDF Manual](#).

If you are modeling axisymmetric swirling flows, you can specify an additional direction component for the viscous and/or inertial resistance coefficients. This direction component is always tangential to the other two specified directions. This option is available for both density-based and pressure-based solvers.

In 3D, it is also possible to define the coefficients using a conical (or cylindrical) coordinate system, as described below.

Important

Note that the viscous and inertial resistance coefficients are generally based on the superficial velocity of the fluid in the porous media.

The procedure for defining resistance coefficients is as follows:

1. Define the direction vectors.
 - To use a Cartesian coordinate system, simply specify the **Direction-1 Vector** and, for 3D, the **Direction-2 Vector**. The unspecified direction will be determined as described above. These direction vectors correspond to the principle axes of the porous media.
-

Note

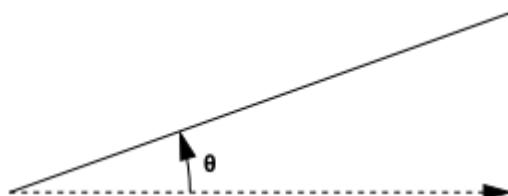

The units for the inertial resistance coefficients (**Direction-1 Vector** and **Direction-2 Vector**) is the inverse of length. Should you want to define different units, you can do so by opening the **Units** dialog box and selecting **resistance** from the **Quantities** list.

For some problems in which the principal axes of the porous medium are not aligned with the coordinate axes of the domain, you may not know a priori the direction vectors of the porous medium. In such cases, the plane tool in 3D (or the line tool in 2D) can help you to determine these direction vectors.

- a. "Snap" the plane tool (or the line tool) onto the boundary of the porous region. (Follow the instructions in [Using the Plane Tool](#) (p. 1485) or [Using the Line Tool](#) (p. 1481) for initializing the tool to a position on an existing surface.)
 - b. Rotate the axes of the tool appropriately until they are aligned with the porous medium.
 - c. Once the axes are aligned, click the **Update From Plane Tool** or **Update From Line Tool** button in the **Fluid** dialog box. ANSYS FLUENT will automatically set the **Direction-1 Vector** to the direction of the red arrow of the tool, and (in 3D) the **Direction-2 Vector** to the direction of the green arrow.
- To use a conical coordinate system (e.g., for an annular, conical filter element), follow the steps below. This option is available only in 3D cases.

- a. Turn on the **Conical** option.
- b. Set the **Cone Half Angle** (the angle between the cone's axis and its surface, shown in *Figure 7.11 (p. 239)*). To use a cylindrical coordinate system, set the **Cone Half Angle** to 0.
- c. Specify the **Cone Axis Vector** and **Point on Cone Axis**. The cone axis is specified as being in the direction of the **Cone Axis Vector** (unit vector), and passing through the **Point on Cone Axis**. The cone axis may or may not pass through the origin of the coordinate system.

Figure 7.11 Cone Half Angle

For some problems in which the axis of the conical filter element is not aligned with the coordinate axes of the domain, you may not know a priori the direction vector of the cone axis and coordinates of a point on the cone axis. In such cases, the plane tool can help you to determine the cone axis vector and point coordinates. One method is as follows:

- a. Select a boundary zone of the conical filter element that is normal to the cone axis vector in the drop-down list next to the **Snap to Zone** button.
- b. Click the **Snap to Zone** button. ANSYS FLUENT will automatically “snap” the plane tool onto the boundary. It will also set the **Cone Axis Vector** and the **Point on Cone Axis**. (Note that you will still have to set the **Cone Half Angle** yourself.)

An alternate method is as follows:

- a. “Snap” the plane tool onto the boundary of the porous region. (Follow the instructions in *Using the Plane Tool (p. 1485)* for initializing the tool to a position on an existing surface.)
- b. Rotate and translate the axes of the tool appropriately until the red arrow of the tool is pointing in the direction of the cone axis vector and the origin of the tool is on the cone axis.
- c. Once the axes and origin of the tool are aligned, click the **Update From Plane Tool** button in the **Fluid** dialog box. ANSYS FLUENT will automatically set the **Cone Axis Vector** and the **Point on Cone Axis**. (Note that you will still have to set the **Cone Half Angle** yourself.)

2. Under **Viscous Resistance**, specify the viscous resistance coefficient $1/\alpha$ in each direction.

Under **Inertial Resistance**, specify the inertial resistance coefficient C_2 in each direction. (You will need to scroll down with the scroll bar to view these inputs.)

For porous media cases containing highly anisotropic inertial resistances, enable **Alternative Formulation** under **Inertial Resistance**. The **Alternative Formulation** option provides better stability to the calculation when your porous medium is anisotropic. The pressure loss through the medium depends on the magnitude of the velocity vector of the i th component in the medium. Using the formulation of *Equation 7–6 (p. 232)* yields the expression below:

$$S_i = \frac{1}{2} \rho C_i |v_i| v_i \quad (7-12)$$

Whether or not you use the **Alternative Formulation** option depends on how well you can fit your experimentally determined pressure drop data to the ANSYS FLUENT model. For example, if the flow through the medium is aligned with the mesh in your ANSYS FLUENT model, then it will not make a difference whether or not you use the formulation.

For more information about simulations involving highly anisotropic porous media, see *Solution Strategies for Porous Media* (p. 252).

Important

Note that the alternative formulation is compatible only with the pressure-based solver.

If you are using the **Conical** specification method, **Direction-1** is the tangential direction of the cone, **Direction-2** is the normal to the cone surface (radial (r) direction for a cylinder), and **Direction-3** is the circumferential (θ) direction.

In 3D there are three possible categories of coefficients, and in 2D there are two:

- In the isotropic case, the resistance coefficients in all directions are the same (e.g., a sponge). For an isotropic case, you must explicitly set the resistance coefficients in each direction to the same value.
- When (in 3D) the coefficients in two directions are the same and those in the third direction are different or (in 2D) the coefficients in the two directions are different, you must be careful to specify the coefficients properly for each direction. For example, if you had a porous region consisting of cylindrical straws with small holes in them positioned parallel to the flow direction, the flow would pass easily through the straws, but the flow in the other two directions (through the small holes) would be very little. If you had a plane of flat plates perpendicular to the flow direction, the flow would not pass through them at all; it would instead move in the other two directions.
- In 3D the third possible case is one in which all three coefficients are different. For example, if the porous region consisted of a plane of irregularly-spaced objects (e.g., pins), the movement of flow between the blockages would be different in each direction. You would therefore need to specify different coefficients in each direction.

Methods for deriving viscous and inertial loss coefficients are described in the sections that follow.

7.2.3.6.7. Deriving Porous Media Inputs Based on Superficial Velocity, Using a Known Pressure Loss

When you use the porous media model, you must keep in mind that the porous cells in ANSYS FLUENT are *100% open*, and that the values that you specify for $1/\alpha_{ij}$ and/or $C_{2,ij}$ must be based on this assumption. Suppose, however, that you know how the pressure drop varies with the velocity through the actual device, which is only partially open to flow. The following exercise is designed to show you how to compute a value for C_2 which is appropriate for the ANSYS FLUENT model.

Consider a perforated plate which has 25% area open to flow. The pressure drop through the plate is known to be 0.5 times the dynamic head in the plate. The loss factor, K_L , defined as

$$\Delta p = K_L \left(\frac{1}{2} \rho v_{25\%open}^2 \right) \quad (7-13)$$

is therefore 0.5, based on the actual fluid velocity in the plate, i.e., the velocity through the 25% open area. To compute an appropriate value for C_2 , note that in the ANSYS FLUENT model:

1. The velocity through the perforated plate assumes that the plate is 100% open.
2. The loss coefficient must be converted into dynamic head loss per unit length of the porous region.

Noting item 1, the first step is to compute an adjusted loss factor, K'_L , which would be based on the velocity of a 100% open area:

$$\Delta p = K'_L \left(\frac{1}{2} \rho v_{100\%open}^2 \right) \quad (7-14)$$

or, noting that for the same flow rate, $v_{25\%open} = 4 \times v_{100\%open}$,

$$\begin{aligned} K'_L &= K_L \times \frac{v_{25\%open}^2}{v_{100\%open}^2} \\ &= 0.5 \times \left(\frac{4}{1} \right)^2 \\ &= 8 \end{aligned} \quad (7-15)$$

The adjusted loss factor has a value of 8. Noting item 2, you must now convert this into a loss coefficient per unit thickness of the perforated plate. Assume that the plate has a thickness of 1.0 mm (10^{-3} m). The inertial loss factor would then be

$$C_2 = \frac{K'_L}{thickness} = \frac{8}{10^{-3}} = 8000 m^{-1} \quad (7-16)$$

Note that, for anisotropic media, this information must be computed for each of the 2 (or 3) coordinate directions.

7.2.3.6.8. Using the Ergun Equation to Derive Porous Media Inputs for a Packed Bed

As a second example, consider the modeling of a packed bed. In turbulent flows, packed beds are modeled using both a permeability and an inertial loss coefficient. One technique for deriving the appropriate constants involves the use of the Ergun equation [21] (p. 2368), a semi-empirical correlation applicable over a wide range of Reynolds numbers and for many types of packing:

$$\frac{|\Delta p|}{L} = \frac{150\mu}{D_p^2} \frac{(1-\varepsilon)^2}{\varepsilon^3} v_\infty + \frac{1.75\rho}{D_p} \frac{(1-\varepsilon)}{\varepsilon^3} v_\infty^2 \quad (7-17)$$

When modeling laminar flow through a packed bed, the second term in the above equation may be dropped, resulting in the Blake-Kozeny equation [21] (p. 2368):

$$\frac{|\Delta p|}{L} = \frac{150\mu}{D_p^2} \frac{(1-\varepsilon)^2}{\varepsilon^3} v_\infty \quad (7-18)$$

In these equations, μ is the viscosity, D_p is the mean particle diameter, L is the bed depth, and ε is the void fraction, defined as the volume of voids divided by the volume of the packed bed region. Comparing [Equation 7-4 \(p. 231\)](#) and [Equation 7-6 \(p. 232\)](#) with [Equation 7-17 \(p. 242\)](#), the permeability and inertial loss coefficient in each component direction may be identified as

$$\alpha = \frac{D_p^2}{150} \frac{\varepsilon^3}{(1-\varepsilon)^2} \quad (7-19)$$

and

$$C_2 = \frac{3.5}{D_p} \frac{(1-\varepsilon)}{\varepsilon^3} \quad (7-20)$$

7.2.3.6.9. Using an Empirical Equation to Derive Porous Media Inputs for Turbulent Flow Through a Perforated Plate

As a third example we will take the equation of Van Winkle et al. [63] (p. 2370) [83] (p. 2371) and show how porous media inputs can be calculated for pressure loss through a perforated plate with square-edged holes.

The expression, which is claimed by the authors to apply for turbulent flow through square-edged holes on an equilateral triangular spacing, is

$$\dot{m} = CA_f \sqrt{(2\rho \Delta p) / \left(1 - \left(A_f/A_p\right)^2\right)} \quad (7-21)$$

where

\dot{m} = mass flow rate through the plate

A_f = the free area or total area of the holes

A_p = the area of the plate (solid and holes)

C = a coefficient that has been tabulated for various Reynolds-number ranges and for various D/t

D/t = the ratio of hole diameter to plate thickness

for $t/D > 1.6$ and for $Re > 4000$ the coefficient C takes a value of approximately 0.98, where the Reynolds number is based on hole diameter and velocity in the holes.

Rearranging [Equation 7-21 \(p. 242\)](#), making use of the relationship

$$\dot{m} = \rho v A_p \quad (7-22)$$

and dividing by the plate thickness, $\Delta x = t$, we obtain

$$\frac{\Delta p}{\Delta x} = \left(\frac{1}{2} \rho v^2 \right) \frac{1}{C^2} \frac{\left(A_p/A_f \right)^2 - 1}{t} \quad (7-23)$$

where v is the superficial velocity (not the velocity in the holes). Comparing with [Equation 7-6 \(p. 232\)](#) is seen that, for the direction normal to the plate, the constant C_2 can be calculated from

$$C_2 = \frac{1}{C^2} \frac{\left(A_p/A_f \right)^2 - 1}{t} \quad (7-24)$$

7.2.3.6.10. Using Tabulated Data to Derive Porous Media Inputs for Laminar Flow Through a Fibrous Mat

Consider the problem of laminar flow through a mat or filter pad which is made up of randomly-oriented fibers of glass wool. As an alternative to the Blake-Kozeny equation ([Equation 7-18 \(p. 242\)](#)) we might choose to employ tabulated experimental data. Such data is available for many types of fiber [36] (p. 2369).

volume fraction of solid material	dimensionless permeability B of glass wool
0.262	0.25
0.258	0.26
0.221	0.40
0.218	0.41
0.172	0.80

where $B = \alpha/a^2$ and a is the fiber diameter. α , for use in [Equation 7-4 \(p. 231\)](#), is easily computed for a given fiber diameter and volume fraction.

7.2.3.6.11. Deriving the Porous Coefficients Based on Experimental Pressure and Velocity Data

Experimental data that is available in the form of pressure drop against velocity through the porous component, can be extrapolated to determine the coefficients for the porous media. To effect a pressure drop across a porous medium of thickness, Δn , the coefficients of the porous media are determined in the manner described below.

If the experimental data is:

Velocity (m/s)	Pressure Drop (Pa)
20.0	197.8
50.0	948.1
80.0	2102.5
110.0	3832.9

then an xy curve can be plotted to create a trendline through these points yielding the following equation

$$\Delta p = 0.27394v^2 + 4.68816v \quad (7-25)$$

where Δp is the pressure drop and v is the velocity.

Important

Although the best fit curve may yield negative coefficients, it should be avoided when using the porous media model in ANSYS FLUENT.

Note that a simplified version of the momentum equation, relating the pressure drop to the source term, can be expressed as

$$\nabla p = S_i \quad (7-26)$$

or

$$\Delta p = -S_i \Delta n \quad (7-27)$$

Hence, comparing [Equation 7-25 \(p. 244\)](#) to [Equation 7-2 \(p. 231\)](#), yields the following curve coefficients:

$$0.27394 = C_2 \frac{1}{2} \rho \Delta n \quad (7-28)$$

with $\rho = 1.225 \text{ kg/m}^3$, and a porous media thickness, Δn , assumed to be 1m in this example, the inertial resistance factor, $C_2 = 0.447$.

Likewise,

$$4.68816 = \frac{\mu}{\alpha} \Delta n \quad (7-29)$$

with $\mu = 1.7894 \times 10^{-5}$, the viscous inertial resistance factor, $\frac{1}{\alpha} = 261996$.

Important

Note that this same technique can be applied to the porous jump boundary condition. Similar to the case of the porous media, you have to take into account the thickness of the medium Δn . Your experimental data can be plotted in an xy curve, yielding an equation that is equivalent to [Equation 7-114 \(p. 353\)](#). From there, you can determine the permeability α and the pressure jump coefficient C_2 .

7.2.3.6.12. Using the Power-Law Model

If you choose to use the power-law approximation of the porous-media momentum source term ([Equation 7-3 \(p. 231\)](#)), the only inputs required are the coefficients C_0 and C_1 . Under **Power Law Model** in the **Fluid** dialog box, enter the values for **C0** and **C1**. Note that the power-law model can be used in conjunction with the Darcy and inertia models.

C0 must be in SI units, consistent with the value of **C1**.

7.2.3.6.13. Defining Porosity

To define the porosity, scroll down below the resistance inputs in the **Fluid** dialog box, and set the **Porosity** under **Fluid Porosity**. Note that the value of the **Porosity** must be in the range of 0–1; furthermore, the lower and upper limits (i.e., 0 and 1, respectively) are not allowed for the non-equilibrium thermal model.

You can also define the porosity using a user-defined function (UDF). The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS FLUENT. Note that the porosity defined in the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined functions, see the separate [UDF Manual](#).

The porosity, γ , is the volume fraction of fluid within the porous region (i.e., the open volume fraction of the medium). The porosity is used in the prediction of heat transfer in the medium, as described in [Treatment of the Energy Equation in Porous Media \(p. 233\)](#), and in the time-derivative term in the scalar transport equations for unsteady flow, as described in [Effect of Porosity on Transient Scalar Equations \(p. 235\)](#). It also impacts the calculation of reaction source terms and body forces in the medium. These sources will be proportional to the fluid volume in the medium. If you want to represent the medium as completely open (no effect of the solid medium), you should set the porosity equal to 1.0 (the default). When the porosity is equal to 1.0, the solid portion of the medium will have no impact on heat transfer or thermal/reaction source terms in the medium.

7.2.3.6.14. Specifying the Heat Transfer Settings

You can model heat transfer in the porous material, with or without the assumption of thermal equilibrium between the medium and the fluid flow. Note that heat transfer is not available for inviscid flow.

7.2.3.6.14.1. Equilibrium Thermal Model

To specify that the porous medium and the fluid flow are in thermal equilibrium, scroll down below the resistance inputs in the **Fluid** dialog box to the **Heat Transfer Settings** group box and select **Equilibrium** from the **Thermal Model** list (this is the default selection). Then you must specify the material contained in the porous medium by selecting the appropriate solid in the **Solid Material Name** drop-down list.

If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box. You can define the **Thermal Conductivity** of the porous material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS FLUENT. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the `DEFINE_PROPERTY` macro. For more information on creating and using user-defined function, see the separate [UDF Manual](#).

7.2.3.6.14.2. Non-Equilibrium Thermal Model

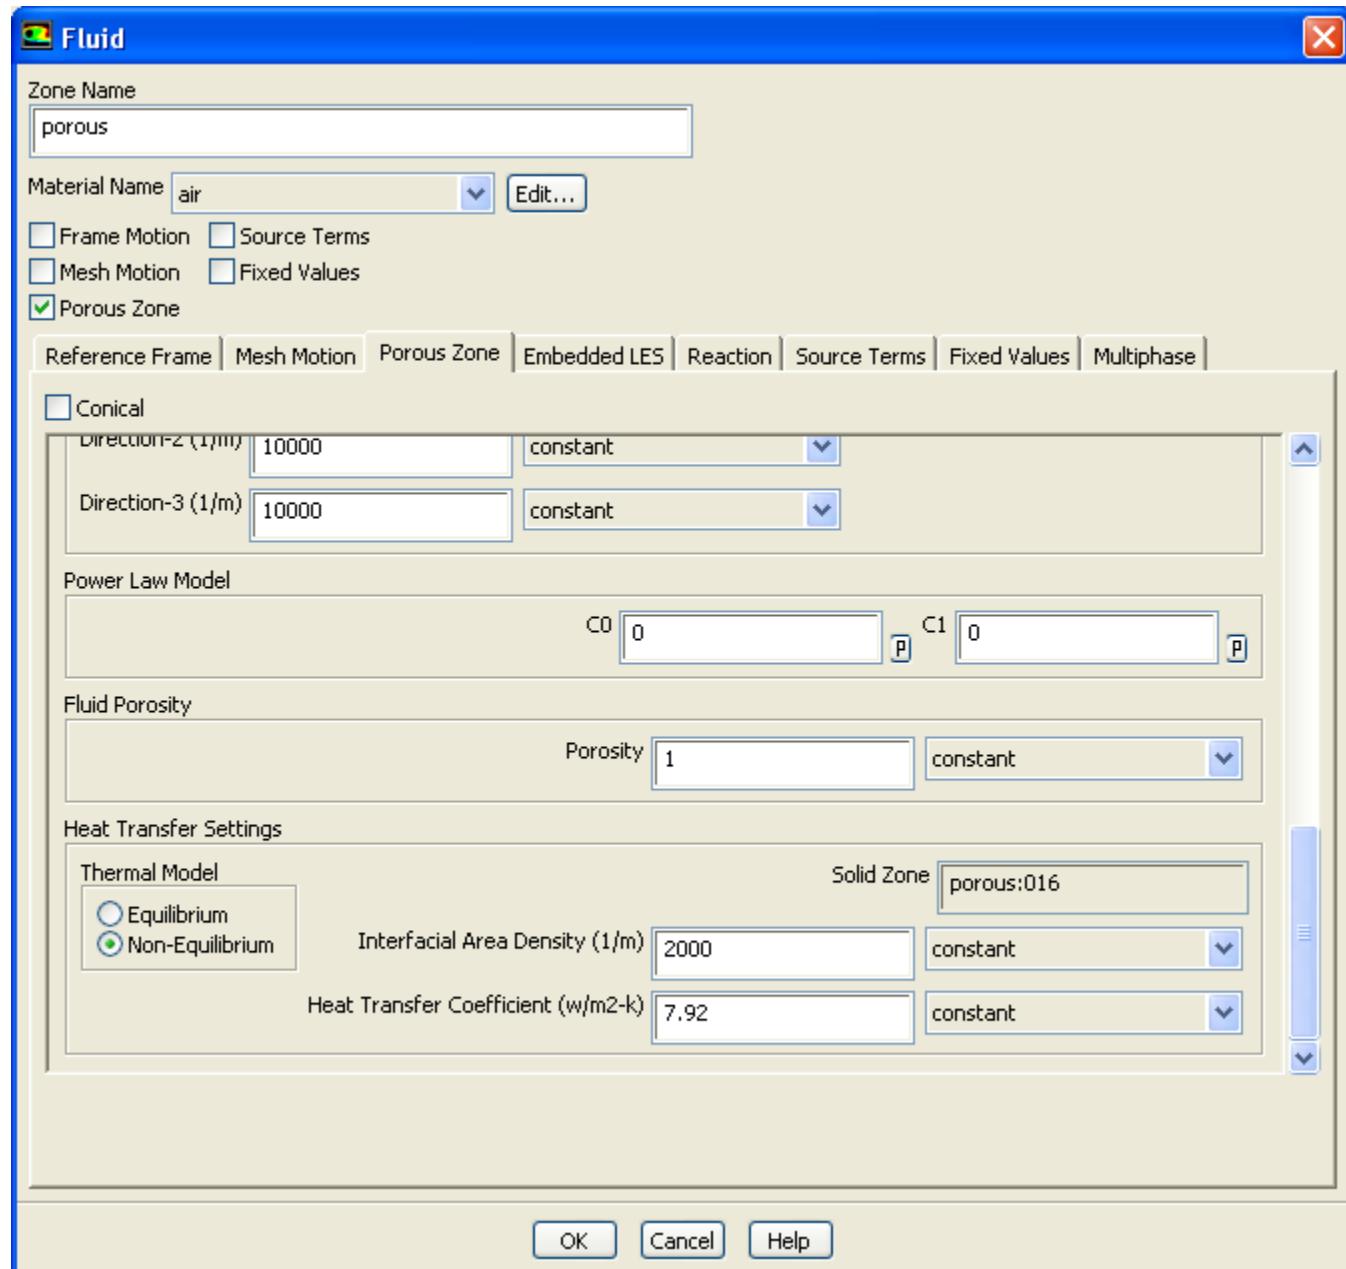

The assumption of thermal equilibrium between the solid medium and the fluid flow is not appropriate for all simulations, as the presence of different geometric length scales (e.g., pore sizes) and physical properties of solid and liquid phases may result in local temperature differences between the phases. Examples of when a non-equilibrium thermal model may be suitable include the simulation of light-off for exhaust after-treatment, fuel cells, catalytic converters, etc.

The non-equilibrium thermal model available for porous media in ANSYS FLUENT is based on a dual cell approach. This approach is referred to as “dual cell” because it involves a second solid cell zone that overlaps (i.e., is spatially coincident with) the porous fluid zone; the two zones are solved simultaneously and are coupled only through heat transfer. ANSYS FLUENT can automatically create a solid zone for you that is a duplicate of the porous fluid zone. Alternatively, you could create a duplicate cell zone manually using the `mesh/modify-zones/copy-move-cell-zone` text command, or make sure that the mesh you read contains two cell zones in the region where the porous medium will be defined. Note that you should ensure that the duplicate zone is defined as a solid zone, and that the two zones have similar levels of mesh refinement (as one-to-one mapping will be employed between the cell centroids of the fluid zone and the solid zone).

The instructions that follow assume you have already performed steps 1–7. in [User Inputs for Porous Media \(p. 235\)](#). Before you enable the non-equilibrium thermal model, click **OK** in the **Fluid** dialog box, in order to save your settings in the **Porous Zone** tab; note that if you do not save your settings, they will be reset to the default values when you enable the non-equilibrium thermal model. Then reopen the **Fluid** dialog box and scroll down below the resistance inputs in the **Porous Zone** tab. Select **Non-Equilibrium** from the **Thermal Model** list in the **Heat Transfer Settings** group box (see [Figure 7.12 \(p. 247\)](#)); this will enable the dual cell approach and display the associated GUI input controls. If a solid zone that is spatially coincident with the porous fluid zone does not already exist, use the **Question** dialog box that opens to automatically create one. The name of the newly created solid cell zone will then be displayed in the **Solid Zone** text box of the **Fluid** dialog box.

Important

Note that the **Non-Equilibrium** radio button is not available if a radiation and/or multiphase model is enabled, as such a combination is not supported.

Figure 7.12 The Heat Transfer Settings Group Box of the Fluid Dialog Box

Next, define A_{fs} and h_{fs} (as described in [Non-Equilibrium Thermal Model Equations \(p. 234\)](#)) for **Interfacial Area Density** and **Heat Transfer Coefficient**, respectively; you can define these settings as a **Constant**, a **New Input Parameter...**, or as a user-defined function. The **user-defined** option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS FLUENT. Note that the UDF must utilize the `DEFINE_PROFILE` macro. For more information on creating and using user-defined functions, see the separate [UDF Manual](#).

When you are finished setting up the porous fluid zone, you should verify that the solid zone created in the previous step has the appropriate settings. Note the name of the zone displayed in the **Solid Zone** text box of the **Heat Transfer Settings** group box (see [Figure 7.12 \(p. 247\)](#)), and then double-click that zone in the **Zone** list of the **Cell Zone Conditions** task page to open the **Solid** dialog box. Then, verify that an appropriate selection is made for **Material Name**. If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog

box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box. You can define the **Thermal Conductivity** of the solid material using a user-defined function (UDF), in order to define a non-isotropic thermal conductivity. The user-defined option becomes available in the corresponding drop-down list when the UDF has been created and loaded into ANSYS FLUENT. Note that the non-isotropic thermal conductivity defined in the UDF must utilize the `DEFINE_PROPERTY` macro. For more information on creating and using user-defined functions, see the separate [UDF Manual](#).

Note that when postprocessing simulations that utilize the non-equilibrium thermal model, attention must be paid to the fact that there are overlapping cell zones (i.e., a fluid and a solid zone) in the porous region. For example:

- When creating an isosurface and making selections from the **From Zones** selection list of the **Iso-Surface** dialog box, you should never select both the porous fluid zone and the overlapping solid zone at the same time. Note that if no selections are made in this list, then all the cell zones are selected.
- When making selections from the **Surfaces** list of the **Contours** dialog box, you should not select a surface that is associated with the porous fluid zone and a surface associated with the overlapping solid zone at the same time, if those surfaces are spatially coincident.

7.2.3.6.15. Defining Sources

If you want to include effects of the heat generated by the porous medium in the energy equation, enable the **Source Terms** option and set a non-zero **Energy** source. The solver will compute the heat generated by the porous region by multiplying this value by the total volume of the cells comprising the porous zone. You may also define sources of mass, momentum, turbulence, species, or other scalar quantities, as described in [Defining Mass, Momentum, Energy, and Other Sources \(p. 257\)](#).

7.2.3.6.16. Defining Fixed Values

If you want to fix the value of one or more variables in the fluid region of the zone, rather than computing them during the calculation, you can do so by enabling the **Fixed Values** option. See [Fixing the Values of Variables \(p. 253\)](#) for details.

7.2.3.6.17. Suppressing the Turbulent Viscosity in the Porous Region

As discussed in [Treatment of Turbulence in Porous Media \(p. 235\)](#), turbulence will be computed in the porous region just as in the bulk fluid flow. If you are using one of the turbulence models (other than the Large Eddy Simulation model) and you want the turbulence generation to be zero in the porous zone, turn on the **Laminar Zone** option in the **Fluid** dialog box. Refer to [Specifying a Laminar Zone \(p. 223\)](#) for more information about suppressing turbulence generation.

7.2.3.6.18. Specifying the Rotation Axis and Defining Zone Motion

Inputs for the rotation axis and zone motion are the same as for a standard fluid zone. See [Inputs for Fluid Zones \(p. 221\)](#) for details.

7.2.3.7. Modeling Porous Media Based on Physical Velocity

As stated in [Limitations and Assumptions of the Porous Media Model \(p. 230\)](#), by default ANSYS FLUENT calculates the superficial velocity based on volumetric flow rate. The superficial velocity in the governing equations can be represented as

$$\bar{v}_{superficial} = \gamma \bar{v}_{physical} \quad (7-30)$$

where γ is the porosity of the media defined as the ratio of the volume occupied by the fluid to the total volume.

The superficial velocity values within the porous region remain the same as those outside of the porous region, and porosity is not taken into account in the differential terms of the transport equations. This limits the accuracy of the porous model in cases where there should be an increase in velocity throughout the porous region, and does not yield accurate results when velocity values and gradients are important. For more accurate simulations of porous media flows, it becomes necessary to solve for the true, or physical, velocity throughout the flowfield rather than the superficial velocity, as well as to include porosity in all terms of the transport equations.

ANSYS FLUENT allows the calculation of the physical velocity using the **Porous Formulation**, available in the **Cell Zone Conditions** task page. By default, the **Superficial Velocity** option is turned on.

7.2.3.7.1. Single Phase Porous Media

Using the physical velocity formulation, and assuming a general scalar ϕ , the governing equation in an isotropic porous media has the following form:

$$\frac{\partial (\gamma \rho \phi)}{\partial t} + \nabla \cdot (\gamma \rho \bar{v} \phi) = \nabla \cdot (\gamma \Gamma \nabla \phi) + \gamma S_\phi \quad (7-31)$$

Assuming isotropic porosity and single phase flow, the volume-averaged mass and momentum conservation equations are as follows:

$$\frac{\partial (\gamma \rho)}{\partial t} + \nabla \cdot (\gamma \rho \bar{v}) = 0 \quad (7-32)$$

$$\frac{\partial (\gamma \rho \bar{v})}{\partial t} + \nabla \cdot (\gamma \rho \bar{v} \bar{v}) = -\gamma \nabla p + \nabla \cdot (\gamma \bar{v}) + \gamma \bar{B}_f - \left(\frac{\gamma^2 \mu}{K} \bar{v} + \frac{\gamma^3 C_2}{2} \rho |\bar{v}| \bar{v} \right) \quad (7-33)$$

The last term in [Equation 7-33 \(p. 249\)](#) represents the viscous and inertial drag forces imposed by the pore walls on the fluid.

Important

Note that even when you solve for the physical velocity in [Equation 7-33 \(p. 249\)](#), the two resistance coefficients can still be derived using the superficial velocity as given in [Defining the Viscous and Inertial Resistance Coefficients \(p. 237\)](#). ANSYS FLUENT assumes that the inputs for these resistance coefficients are based upon well-established empirical correlations that are usually based on superficial velocity. Therefore, ANSYS FLUENT automatically converts the inputs for the resistance coefficients into those that are compatible with the physical velocity formulation.

Important

Note that the inlet mass flow is also calculated from the superficial velocity. Therefore, for the same mass flow rate at the inlet and the same resistance coefficients, for either the physical or superficial velocity formulation you should obtain the same pressure drop across the porous media zone.

7.2.3.7.2. Multiphase Porous Media

You can simulate porous media multiphase flows using the **Physical Velocity Porous Formulation** to solve the true or physical velocity field throughout the entire flow field, including both porous and non-porous regions. In this approach, assuming a general scalar in the q^{th} phase, ϕ_q , the governing equation in an isotropic porous medium takes on the following form:

$$\frac{\partial (\gamma \alpha_q \rho_q \phi_q)}{\partial t} + \nabla \cdot (\gamma \alpha_q \rho_q \vec{v}_q \phi_q) = \nabla \cdot (\gamma \Gamma_q \nabla \phi_q) + \gamma S_{\phi,q} \quad (7-34)$$

Here γ is the porosity, which may vary with time and space; ρ_q is the phase density; α_q is the volume fraction; \vec{v}_q is the phase velocity vector; $S_{\phi,q}$ is the source term; and Γ_q is the diffusion coefficient.

The general scalar equation [Equation 7-34 \(p. 250\)](#) applies to all other transport equations in the Eulerian multiphase model, such as the granular phase momentum and energy equations, turbulence modeling equations, and the species transport equations.

Assuming isotropic porosity and multiphase flows, the governing equations in the q^{th} phase, [Equation 17-133](#), [Equation 17-134](#), and [Equation 17-140](#) in the [Theory Guide](#) take the general forms described below.

7.2.3.7.2.1. The Continuity Equation

$$\frac{\partial}{\partial t} \left(\gamma \alpha_q \rho_q \right) + \nabla \cdot \left(\gamma \alpha_q \rho_q \vec{v}_q \right) = \gamma \sum_{p=1}^n \left(\dot{m}_{pq} - \dot{m}_{qp} \right) + \gamma S_q \quad (7-35)$$

7.2.3.7.2.2. The Momentum Equation

$$\begin{aligned} \frac{\partial}{\partial t} \left(\gamma \alpha_q \rho_q \vec{v}_q \right) + \nabla \cdot \left(\gamma \alpha_q \rho_q \vec{v}_q \vec{v}_q \right) = & -\gamma \alpha_q \nabla p + \nabla \cdot \left(\gamma \bar{\tau}_q \right) + \gamma \alpha_q \rho_q \vec{g} \\ & + \gamma \sum_{p=1}^n \left(\bar{R}_{pq} + \dot{m}_{pq} \vec{v}_{pq} - \dot{m}_{qp} \vec{v}_{qp} \right) \\ & + \gamma \left(\vec{F}_q + \vec{F}_{lift,q} + \vec{F}_{vm,q} \right) \\ & - \alpha_q \left(\frac{\gamma^2 \mu}{K_q} \vec{v}_q + \frac{\gamma^3 C_{2,q}}{2} \rho_q \left| \vec{v}_q \right| \vec{v}_q \right) \end{aligned} \quad (7-36)$$

where the last term in [Equation 7-36 \(p. 251\)](#) is the momentum resistance (sink) source in a porous medium. It consists of two parts: a viscous loss term, and an inertial loss term. The parameter K is the permeability, and C_2 is the inertial resistance factor. Both K and C_2 are functions of $(1 - \gamma)$. When $\gamma = 1$, the flow is non-porous and the two loss terms disappear. Details about the user inputs related to the momentum resistance sources can be found in [User Inputs for Porous Media \(p. 235\)](#).

7.2.3.7.2.3. The Energy Equation

$$\begin{aligned} \frac{\partial}{\partial t} \left(\gamma \alpha_q \rho_q h_q \right) + \nabla \cdot \left(\gamma \alpha_q \rho_q \vec{v}_q h_q \right) = & -\gamma \alpha_q \frac{\partial p_q}{\partial t} + \gamma \bar{\tau}_q : \nabla \vec{v}_q - \nabla \cdot \left(\gamma \bar{q}_q \right) + \gamma S_q \\ & + \gamma \sum_{p=1}^n \left(Q_{pq} + \dot{m}_{pq} h_{pq} - \dot{m}_{qp} h_{qp} \right) + Q_{sp} \end{aligned} \quad (7-37)$$

where Q_{sp} is the heat transfer between the solids surface and the phase q in a porous medium. Assuming only convective heat transfer, we then have

$$Q_{sp} = (1 - \gamma) \alpha_q h_{q,eff} (T_s - T_q) \quad (7-38)$$

where $h_{q,eff}$ is the effective convective heat transfer coefficient, and T_s is the solids surface temperature in the porous medium. It is governed by the heat conduction equation:

$$\frac{\partial}{\partial t} \left(\rho_s h_s \right) + \nabla \cdot \left(\vec{v}_s \rho_s h_s \right) = \nabla \cdot (k_s \nabla T) - \sum_{p=1}^n Q_{sp} \quad (7-39)$$

Equation 7-39 (p. 252) can be solved as a user-defined scalar (UDS) equation, as described in *User-Defined Scalar (UDS) Transport Equations* (p. 505). By default, ANSYS FLUENT assumes that the overall heat transfer between the multiphase fluid and the solids is in equilibrium. Therefore, instead of solving *Equation 7-39* (p. 252) to obtain the solids surface temperature, we have

$$\sum_{p=1}^n Q_{sp} = 0 \quad (7-40)$$

and then

$$T_s = \frac{\sum_{p=1}^n \alpha_p h_{p,eff} T_p}{\sum_{p=1}^n \alpha_p h_{p,eff}} \quad (7-41)$$

7.2.3.8. Solution Strategies for Porous Media

In general, you can use the standard solution procedures and solution parameter settings when your ANSYS FLUENT model includes porous media. You may find, however, that the rate of convergence slows when you define a porous region through which the pressure drop is relatively large in the flow direction (e.g., the permeability, α , is low or the inertial factor, C_2 , is large). This slow convergence can occur because the porous media pressure drop appears as a momentum source term—yielding a loss of diagonal dominance—in the matrix of equations solved. The best remedy for poor convergence of a problem involving a porous medium is to supply a good initial guess for the pressure drop across the medium. You can supply this guess by patching a value for the pressure in the fluid cells upstream and/or downstream of the medium, as described in *Patching Values in Selected Cells* (p. 1351). It is important to recall, when patching the pressure, that the pressures you input should be defined as the gauge pressures used by the solver (i.e., relative to the operating pressure defined in the *Operating Conditions Dialog Box* (p. 1952)).

Another possible way to deal with poor convergence is to temporarily disable the porous media model (by turning off the **Porous Zone** option in the *Fluid Dialog Box* (p. 1942)) and obtain an initial flow field without the effect of the porous region. With the porous media model turned off, ANSYS FLUENT will treat the porous zone as a fluid zone and calculate the flow field accordingly. Once an initial solution is obtained, or the calculation is proceeding steadily to convergence, you can enable the porous media model and continue the calculation with the porous region included. (This method is not recommended for porous media with high resistance.)

Simulations involving highly anisotropic porous media may, at times, pose convergence troubles. You can address these issues by limiting the anisotropy of the porous media coefficients ($1/\alpha_{ij}$ and $C_{2_{ij}}$) to two or three orders of magnitude. Even if the medium's resistance in one direction is infinite, you do not need to set the resistance in that direction to be greater than 1000 times the resistance in the primary flow direction.

7.2.3.9. Postprocessing for Porous Media

The impact of a porous region on the flow field can be determined by examining either velocity components or pressure values. Graphical plots (including XY plots and contour or vector plots) or alphanumeric reports of the following variables/functions may be of interest:

- **X, Y, Z Velocity** (in the **Velocity...** category)
- **Static Pressure** (in the **Pressure...** category)

These variables are contained in the specified categories of the variable selection drop-down list that appears in postprocessing dialog boxes.

Note that thermal reporting in the porous region is defined as follows:

$$k_{eff} = \gamma k_f + (1 - \gamma) k_s \quad (7-42)$$

where

γ = porosity of the medium

k_f = fluid phase thermal conductivity (including the turbulent contribution, k_t)

k_s = solid medium thermal conductivity

Important

For porous media involving surface reactions, you can display/report the surface reaction rates using the **Arrhenius Rate of Reaction-n** in the **Reactions...** category of the variable selection drop-down list.

Important

Special care must be taken when postprocessing a porous media simulation that utilizes the non-equilibrium thermal model. See [Non-Equilibrium Thermal Model \(p. 246\)](#) for details.

7.2.4. Fixing the Values of Variables

The option to fix values of variables in ANSYS FLUENT allows you to set the value of one or more variables in a fluid or solid zone, essentially setting a boundary condition for the variables within the cells of the zone. When a variable is fixed in a given cell, the transport equation for that variable is not solved in the cell (and the cell is not included when the residual sum is computed for that variable). The fixed value is used for the calculation of face fluxes between the cell and its neighbors. The result is a smooth transition between the fixed value of a variable and the values at the neighboring cells.

Important

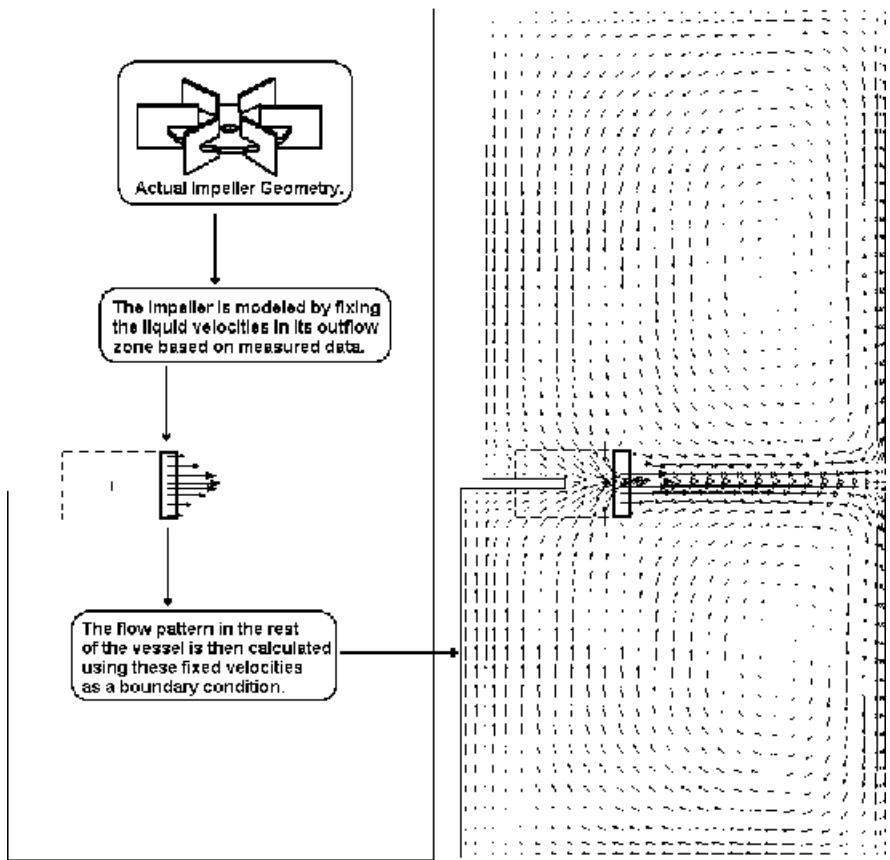

You can fix values for temperature and species mass fractions only if you are using the pressure-based solver. You can fix values for velocity components only if you are using the pressure-based segregated solver. (Refer to [Pressure-Based Solver](#) in the [Theory Guide](#) for information about the pressure-based segregated solver.)

7.2.4.1. Overview of Fixing the Value of a Variable

The ability to fix the value of a variable has a wide range of applications. The velocity fixing method is often used to model the flow in stirred tanks. This approach provides an alternative to the use of a moving reference frame (solution in the reference frame of the blade) and can be used to model baffled tanks. In both 2D and 3D geometries, a fluid cell zone may be used in the impeller regions, and velocity components can be fixed based on measured data.

Although the actual impeller geometry can be modeled and the flow pattern calculated using the sliding mesh model, experimental data for the velocity profile in the outflow region are available for many impeller types. If you do not need to know the details of the flow around the blades for your problem, you can model the impeller by fixing the experimentally-obtained liquid velocities in its outflow zone. The velocities in the rest of the vessel can then be calculated using this fixed velocity profile as a boundary condition. [Figure 7.13 \(p. 254\)](#) shows an example of how this method is used to model the flow pattern created by a disk-turbine in an axisymmetric stirred vessel.

Figure 7.13 Fixing Values for the Flow in a Stirred Tank

7.2.4.1.1. Variables That Can Be Fixed

The variables that can be fixed include velocity components (pressure-based segregated solver only), turbulence quantities, temperature (pressure-based solver only), enthalpy, species mass fractions (pressure-based solver only), and user-defined scalars. For turbulence quantities, different values can be set depending on your choice of turbulence model. You can fix the value of the temperature in a fluid or solid zone if you are solving the energy equation. If you are using the non-premixed combustion model, you can fix the enthalpy in a fluid zone. If you have more than one species in your model, you

can specify fixed values for the species mass fractions for each individual species except the last one you defined. See the [UDF Manual](#) for details about defining user-defined scalars.

If you are using the Eulerian multiphase model, you can fix the values of velocity components and (depending on which multiphase turbulence model you are using) turbulence quantities on a per-phase basis. See [Eulerian Model \(p. 1193\)](#) for details about setting boundary conditions for Eulerian multiphase calculations.

7.2.4.2. Procedure for Fixing Values of Variables in a Zone

To fix the values of one or more variables in a cell zone, follow these steps (remembering to use only SI units):

1. In the [Fluid Dialog Box \(p. 1942\)](#) or [Solid Dialog Box \(p. 1949\)](#), turn on the **Fixed Values** option.
2. Fix the values for the appropriate variables, noting the comments below.
 - To specify a constant value for a variable, choose **constant** in the drop-down list next to the relevant field and then enter the constant value in the field.
 - To specify a non-constant value for a variable, you can use a profile (see [Profiles \(p. 382\)](#)) or a user-defined function for a profile (see the [UDF Manual](#)). Select the appropriate profile or UDF in the drop-down list next to the relevant field.

If you specify a radial-type profile (see [Profile Specification Types \(p. 382\)](#)) for temperature, enthalpy, species mass/mole fractions, or turbulence quantities for the k - ε , Spalart-Allmaras, or k - ω model, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See [Specifying the Rotation Axis \(p. 223\)](#) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

- If you do not want to fix the value for a variable, choose (or keep) **none** in the drop-down list next to the relevant field. This is the default for all variables.

7.2.4.2.1. Fixing Velocity Components

To fix the velocity components, you can specify **X**, **Y**, and (in 3D) **Z Velocity** values, or, for axisymmetric cases, **Axial**, **Radial**, and (for axisymmetric swirl) **Swirl Velocity** values. The units for a fixed velocity are m/s.

For 3D cases, you can choose to specify cylindrical velocity components instead of Cartesian components. Turn on the **Local Coordinate System For Fixed Velocities** option, and then specify the **Axial**, **Radial**, and/or **Tangential Velocity** values. The local coordinate system is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See [Specifying the Rotation Axis \(p. 223\)](#) for information about setting these parameters. (Note that it is acceptable to specify the rotation axis and direction for a non-rotating zone. This will not cause the zone to rotate; it will not rotate unless it has been explicitly defined as a moving zone.)

Important

You can fix values for velocity components only if you are using the pressure-based segregated solver. (Refer to [Pressure-Based Solver](#) in the [Theory Guide](#) for information about the pressure-based segregated solver.)

7.2.4.2.2. Fixing Temperature and Enthalpy

If you are solving the energy equation, you can fix the temperature in a zone by specifying the value of the **Temperature**. The units for a fixed temperature are K.

If you are using the non-premixed combustion model, you can fix the enthalpy in a zone by specifying the value of the **Enthalpy**. The units for a fixed enthalpy are J/kg.

If you specify a radial-type profile (see [Profile Specification Types \(p. 382\)](#)) for temperature or enthalpy, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See above for details.

Important

You can fix the value of temperature only if you are using the pressure-based solver.

7.2.4.2.3. Fixing Species Mass Fractions

If you are using the species transport model, you can fix the values of the species mass fractions for individual species. ANSYS FLUENT allows you to fix the species mass fraction for each species (e.g., **h2**, **o2**) except the last one you defined.

If you specify a radial-type profile (see [Profile Specification Types \(p. 382\)](#)) for a species mass fraction, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See above for details.

Important

You can fix values for species mass fractions only if you are using the pressure-based solver.

7.2.4.2.4. Fixing Turbulence Quantities

To fix the values of k and ε in the k - ε equations, specify the **Turbulence Kinetic Energy** and **Turbulence Dissipation Rate** values. The units for k are m^2/s^2 and those for ε are m^2/s^3 .

To fix the value of the modified turbulent viscosity ($\tilde{\nu}$) for the Spalart-Allmaras model, specify the **Modified Turbulent Viscosity** value. The units for the modified turbulent viscosity are m^2/s .

To fix the values of k and ω in the k - ω equations, specify the **Turbulence Kinetic Energy** and **Specific Dissipation Rate** values. The units for k are m^2/s^2 and those for ω are 1/s.

To fix the value of k , ε , or the Reynolds stresses in the RSM transport equations, specify the **Turbulence Kinetic Energy**, **Turbulence Dissipation Rate**, **UU Reynolds Stress**, **VV Reynolds Stress**, **WW Reynolds Stress**, **UV Reynolds Stress**, **VW Reynolds Stress**, and/or **UW Reynolds Stress**. The units for k and the Reynolds stresses are m^2/s^2 , and those for ε are m^2/s^3 .

If you specify a radial-type profile (see [Profile Specification Types \(p. 382\)](#)) for k , ε , ω , or $\tilde{\nu}$, the local coordinate system upon which the radial profile is based is defined by the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the fluid zone. See above for details. Note that you cannot specify radial-type profiles for the Reynolds stresses.

7.2.4.2.5. Fixing User-Defined Scalars

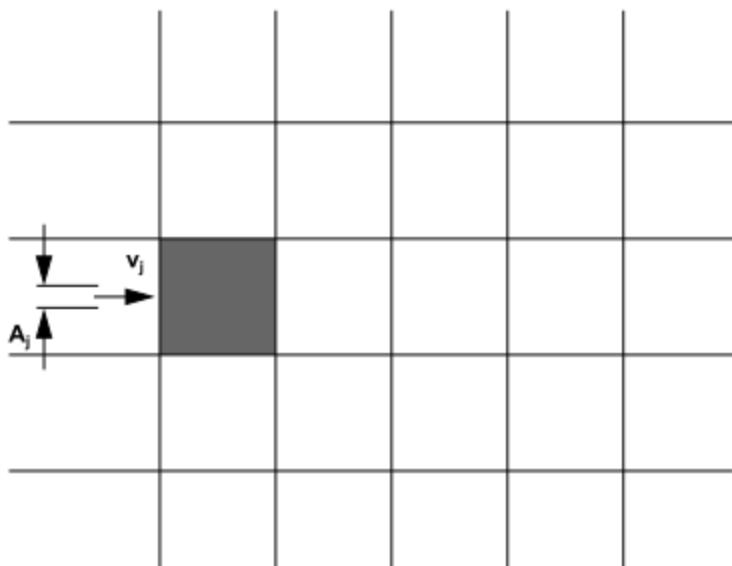

To fix the value of a user-defined scalar, specify the **User defined scalar-n** value. (There will be one for each user-defined scalar you have defined.) The units for a user-defined scalar will be the appropriate SI units for the scalar quantity. See the [UDF Manual](#) for information on user-defined scalars.

7.2.5. Defining Mass, Momentum, Energy, and Other Sources

You can define volumetric sources of mass (for single or multiple species), momentum, energy, turbulence, and other scalar quantities in a fluid zone, or a source of energy for a solid zone. This feature is useful when you want to input a known value for these sources. (For more complicated sources with functional dependency, you can create a user-defined function as described in the separate [UDF Manual](#).) To add source terms to a cell or group of cells, you must place the cell(s) in a separate zone. The sources are then applied to that cell zone. Typical uses for this feature are listed below:

- A flow source that cannot be represented by an inlet, e.g., due to an issue of scale. If you need to model an inlet that is smaller than a cell, you can place the cell where the tiny “inlet” is located in its own fluid zone and then define the mass, momentum, and energy sources in that cell zone. For the example shown in [Figure 7.14 \(p. 257\)](#), you should set a mass source of $\frac{\dot{m}}{V} = \frac{\rho_j A_j v_j}{V}$ and a momentum source of $\frac{\dot{mv}}{V} = \frac{\dot{m}v_j}{V}$, where V is the cell volume.
- Heat release due to a source (e.g., fire) that is not explicitly defined in your model. For this case, you can place the cell(s) into which the heat is originally released in its own fluid zone and then define the energy source in that cell zone.
- An energy source in a solid zone, for conjugate heat transfer applications. For this case, you can place the cell(s) into which the heat is originally released in its own solid zone and then define the energy source in that cell zone.
- A species source due to a reaction that is not explicitly included in the model. In the above example of simulating a fire, you might need to define a source for a species representing smoke generation.

Figure 7.14 Defining a Source for a Tiny Inlet

Important

Note that if you define a mass source for a cell zone, you should also define a momentum source and, if appropriate for your model, energy and turbulence sources. If you define only a mass source, that mass enters the domain with no momentum or thermal heat. The mass will therefore have to be accelerated and heated by the flow and, consequently, there may be a drop in velocity or temperature. This drop may or may not be perceptible, depending on the size of the source. (Note that defining only a momentum, energy, or turbulence source is acceptable.)

7.2.5.1. Sign Conventions and Units

All positive source terms indicate sources, and all negative source terms indicate sinks. All sources must be specified in SI units.

7.2.5.2. Procedure for Defining Sources

To define one or more source terms for a zone, follow these steps (remembering to use only SI units):

1. In the *Fluid Dialog Box* (p. 1942) or *Solid Dialog Box* (p. 1949), turn on the **Source Terms** option.
2. Set the appropriate source terms under the **Source Terms** tab, noting the comments below.
 - To specify a source, click the **Edit...** button next to the mass, momentum, energy, or other source. The sources dialog box will open where you will define the number of sources. For each source, choose **constant**, **user-defined**, or **none** in the drop-down list.
 - To specify a constant source, choose **constant** in the drop-down list and then enter the constant value in the field.
 - To specify a temperature-dependent or other functional source, you can use a user-defined function (see the *UDF Manual*).
 - If you do not want to specify a source term for a variable, choose (or keep) **none** in the drop-down list next to the relevant field. This is the default for all variables.
 - Remember that you should not define just a mass source without defining the other sources, as described in *Defining Mass, Momentum, Energy, and Other Sources* (p. 257). above.
 - Since the sources you specify are defined per unit volume, to determine the appropriate value of your source term you will often need to first determine the volume of the cell(s) in the zone for which you are defining the source. To do this, you can use the *Volume Integrals Dialog Box* (p. 2192).

7.2.5.2.1. Mass Sources

If you have only one species in your problem, you can simply define a **Mass** source for that species.

The units for the mass source are $kg/m^3 - s$. In the continuity equation (Equation 1–1 in the *Theory Guide*), the defined mass source will appear in the S_m term.

If you have more than one species, you can specify mass sources for each individual species. There will be a total **Mass** source term as well as a source term listed explicitly for each species (e.g., **h2**, **o2**) except the last one you defined. If the total of all species mass sources (including the last one) is 0, then you should specify a value of 0 for the **Mass** source, and also specify the values of the non-zero individual species mass sources. Since you cannot specify the mass source for the last species explicitly, ANSYS FLUENT will compute it by subtracting the sum of all other species mass sources from the specified total **Mass** source.

For example, if the mass source for hydrogen in a hydrogen-air mixture is 0.01, the mass source for oxygen is 0.02, and the mass source for nitrogen (the last species) is 0.015, you will specify a value of 0.01 in the **h2** field, a value of 0.02 in the **o2** field, and a value of 0.045 in the **Mass** field. This concept also applies within each cell if you use user-defined functions for species mass sources.

The units for the species mass sources are $\text{kg}/\text{m}^3 \cdot \text{s}$. In the conservation equation for a chemical species (Equation 7–1 in the Theory Guide), the defined mass source will appear in the S_i term.

7.2.5.2.2. Momentum Sources

To define a source of momentum, specify the **X Momentum**, **Y Momentum**, and/or **Z Momentum** term. The units for the momentum source are N/m^3 . In the momentum equation (Equation 1–3 in the Theory Guide), the defined momentum source will appear in the \vec{F} term.

7.2.5.2.3. Energy Sources

To define a source of energy, specify an **Energy** term. The units for the energy source are W/m^3 . In the energy equation (Equation 5–1 in the Theory Guide), the defined energy source will appear in the S_h term.

7.2.5.2.4. Turbulence Sources

7.2.5.2.4.1. Turbulence Sources for the k - ε Model

To define a source of k or ε in the k - ε equations, specify the **Turbulent Kinetic Energy** or **Turbulent Dissipation Rate** term. The units for the k source are $\text{kg}/\text{m}\cdot\text{s}^3$ and those for ε are $\text{kg}/\text{m}\cdot\text{s}^4$.

The defined k source will appear in the S_k term on the right-hand side of the turbulent kinetic energy equation (e.g., Equation 4–33 in the Theory Guide).

The defined ε source will appear in the S_ε term on the right-hand side of the turbulent dissipation rate equation (e.g., Equation 4–34 in the Theory Guide).

7.2.5.2.4.2. Turbulence Sources for the Spalart-Allmaras Model

To define a source of modified turbulent viscosity, specify the **Modified Turbulent Viscosity** term. The units for the modified turbulent viscosity source are $\text{kg}/\text{m}\cdot\text{s}^2$. In the transport equation for the Spalart-Allmaras model (Equation 4–15 in the Theory Guide), the defined modified turbulent viscosity source will appear in the $S_{\tilde{\nu}}$ term.

7.2.5.2.4.3. Turbulence Sources for the k - ω Model

To define a source of k or ω in the k - ω equations, specify the **Turbulent Kinetic Energy** or **Specific Dissipation Rate** term. The units for the k source are $\text{kg}/\text{m}\cdot\text{s}^3$ and those for ω are $\text{kg}/\text{m}^3\cdot\text{s}^2$.

The defined k source will appear in the S_k term on the right-hand side of the turbulent kinetic energy equation (Equation 4–64 in the Theory Guide).

The defined ω source will appear in the S_ω term on the right-hand side of the specific turbulent dissipation rate equation (Equation 4–65 in the Theory Guide).

7.2.5.2.4.4. Turbulence Sources for the Reynolds Stress Model

To define a source of k , ε , or the Reynolds stresses in the RSM transport equations, specify the **Turbulence Kinetic Energy**, **Turbulence Dissipation Rate**, **UU Reynolds Stress**, **VV Reynolds Stress**, **WW Reynolds Stress**, **UV Reynolds Stress**, **VW Reynolds Stress**, and/or **UW Reynolds Stress** terms. The units for the k source and the sources of Reynolds stress are $\text{kg}/\text{m}\cdot\text{s}^3$, and those for ε are $\text{kg}/\text{m}\cdot\text{s}^4$.

The defined Reynolds stress sources will appear in the S_{user} term on the right-hand side of the Reynolds stress transport equation ([Equation 4–182](#) in the [Theory Guide](#)).

The defined k source will appear in the S_k term on the right-hand side of [Equation 4–209](#) in the [Theory Guide](#).

The defined ε will appear in the S_ε term on the right-hand side of [Equation 4–212](#) in the [Theory Guide](#).

7.2.5.2.5. Mean Mixture Fraction and Variance Sources

To define a source of the mean mixture fraction or its variance for the non-premixed combustion model, specify the **Mean Mixture Fraction** or **Mixture Fraction Variance** term. The units for the mean mixture fraction source are $\text{kg}/\text{m}^3 - s$, and those for the mixture fraction variance source are $\text{kg}/\text{m}^3 - s$.

The defined mean mixture fraction source will appear in the S_{user} term in the transport equation for the mixture fraction ([Equation 8–4](#) in the [Theory Guide](#)).

The defined mixture fraction variance source will appear in the S_{user} term in the transport equation for the mixture fraction variance ([Equation 8–5](#) in the [Theory Guide](#)).

If you are using the two-mixture-fraction approach, you can also specify sources of the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**.

7.2.5.2.6. P-1 Radiation Sources

To define a source for the P-1 radiation model, specify the **P1** term. The units for the radiation source are W/m^3 , and the defined source will appear in the S_G term in [Equation 5–18](#) in the [Theory Guide](#).

Note that, if the source term you are defining represents a transfer from internal energy to radiative energy (e.g., absorption or emission), you will need to specify an **Energy** source of the same magnitude as the **P1** source, but with the opposite sign, in order to ensure overall energy conservation.

7.2.5.2.7. Progress Variable Sources

To define a source of the progress variable for the premixed combustion model, specify the **Progress Variable** term. The units for the progress variable source are $\text{kg}/\text{m}^3 \cdot \text{s}$, and the defined source will appear in the ρS_c term in [Equation 9–1](#) in the [Theory Guide](#).

7.2.5.2.8. NO, HCN, and NH₃ Sources for the NOx Model

To define a source of NO, HCN, or NH₃ for the NOx model, specify the **no**, **hcn**, or **nh3** term. The units for these sources are $\text{kg}/\text{m}^3 \cdot \text{s}$, and the defined sources will appear in the S_{NO} , S_{HCN} , and S_{NH3} terms of [Equation 14–1](#), [Equation 14–2](#), and [Equation 14–3](#) in the [Theory Guide](#).

7.2.5.2.9. User-Defined Scalar (UDS) Sources

You can specify source term(s) for each UDS transport equation you have defined in your model. See *Setting Up UDS Equations in ANSYS FLUENT* (p. 508) for details.

7.3. Boundary Conditions

Boundary conditions consist of flow inlets and exit boundaries, wall, repeating, and pole boundaries, and internal face boundaries. All the various types of boundary conditions are discussed in the sections that follow.

- [7.3.1. Flow Inlet and Exit Boundary Conditions](#)
- [7.3.2. Using Flow Boundary Conditions](#)
- [7.3.3. Pressure Inlet Boundary Conditions](#)
- [7.3.4. Velocity Inlet Boundary Conditions](#)
- [7.3.5. Mass Flow Inlet Boundary Conditions](#)
- [7.3.6. Inlet Vent Boundary Conditions](#)
- [7.3.7. Intake Fan Boundary Conditions](#)
- [7.3.8. Pressure Outlet Boundary Conditions](#)
- [7.3.9. Pressure Far-Field Boundary Conditions](#)
- [7.3.10. Outflow Boundary Conditions](#)
- [7.3.11. Outlet Vent Boundary Conditions](#)
- [7.3.12. Exhaust Fan Boundary Conditions](#)
- [7.3.13. Wall Boundary Conditions](#)
- [7.3.14. Symmetry Boundary Conditions](#)
- [7.3.15. Periodic Boundary Conditions](#)
- [7.3.16. Axis Boundary Conditions](#)
- [7.3.17. Fan Boundary Conditions](#)
- [7.3.18. Radiator Boundary Conditions](#)
- [7.3.19. Porous Jump Boundary Conditions](#)

7.3.1. Flow Inlet and Exit Boundary Conditions

ANSYS FLUENT has a wide range of boundary conditions that permit flow to enter and exit the solution domain. To help you select the most appropriate boundary condition for your application, this section includes descriptions of how each type of condition is used, and what information is needed for each one. Recommendations for determining inlet values of the turbulence parameters are also provided.

7.3.2. Using Flow Boundary Conditions

This section provides an overview of flow boundaries in ANSYS FLUENT and how to use them.

ANSYS FLUENT provides 10 types of boundary zone types for the specification of flow inlets and exits: velocity inlet, pressure inlet, mass flow inlet, pressure outlet, pressure far-field, outflow, inlet vent, intake fan, outlet vent, and exhaust fan.

The inlet and exit boundary condition options in ANSYS FLUENT are as follows:

- Velocity inlet boundary conditions are used to define the velocity and scalar properties of the flow at inlet boundaries.
- Pressure inlet boundary conditions are used to define the total pressure and other scalar quantities at flow inlets.

- Mass flow inlet boundary conditions are used in compressible flows to prescribe a mass flow rate at an inlet. It is not necessary to use mass flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow. Like pressure and velocity inlets, other inlet scalars are also prescribed.
- Pressure outlet boundary conditions are used to define the static pressure at flow outlets (and also other scalar variables, in case of backflow). The use of a pressure outlet boundary condition instead of an outflow condition often results in a better rate of convergence when backflow occurs during iteration.
- Pressure far-field boundary conditions are used to model a free-stream compressible flow at infinity, with free-stream Mach number and static conditions specified. This boundary type is available only for compressible flows.
- Outflow boundary conditions are used to model flow exits where the details of the flow velocity and pressure are not known prior to solution of the flow problem. They are appropriate where the exit flow is close to a fully developed condition, as the outflow boundary condition assumes a zero streamwise gradient for all flow variables except pressure. They are not appropriate for compressible flow calculations.
- Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) total pressure and temperature.
- Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) total pressure and temperature.
- Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) static pressure and temperature.
- Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) static pressure.

7.3.2.1. Determining Turbulence Parameters

When the flow enters the domain at an inlet, outlet, or far-field boundary, ANSYS FLUENT requires specification of transported turbulence quantities. This section describes which quantities are needed for specific turbulence models and how they must be specified. It also provides guidelines for the most appropriate way of determining the inflow boundary values.

7.3.2.1.1. Specification of Turbulence Quantities Using Profiles

If it is important to accurately represent a boundary layer or fully-developed turbulent flow at the inlet, you should ideally set the turbulence quantities by creating a profile file (see [Profiles \(p. 382\)](#)) from experimental data or empirical formulas. If you have an analytical description of the profile, rather than data points, you can either use this analytical description to create a profile file, or create a user-defined function to provide the inlet boundary information. (See the [UDF Manual](#) for information on user-defined functions.)

Once you have created the profile function, you can use it as described below:

- Spalart-Allmaras model: Choose **Turbulent Viscosity** or **Turbulent Viscosity Ratio** in the **Turbulence Specification Method** drop-down list and select the appropriate profile name in the drop-down list next to **Turbulent Viscosity** or **Turbulent Viscosity Ratio**. ANSYS FLUENT computes the boundary value for the modified turbulent viscosity, $\tilde{\nu}$, by combining $\frac{\mu_t}{\mu}$ with the appropriate values of density and molecular viscosity.

- k - ε models: Choose **K and Epsilon** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Turbulent Dissipation Rate**.
- k - ω models: Choose **K and Omega** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Specific Dissipation Rate**.
- Reynolds stress model: Choose **K and Epsilon** in the **Turbulence Specification Method** drop-down list and select the appropriate profile names in the drop-down lists next to **Turbulent Kinetic Energy** and **Turbulent Dissipation Rate**. Choose **Reynolds-Stress Components** in the **Reynolds-Stress Specification Method** drop-down list and select the appropriate profile name in the drop-down list next to each of the individual Reynolds-stress components.

7.3.2.1.2. Uniform Specification of Turbulence Quantities

In some situations, it is appropriate to specify a uniform value of the turbulence quantity at the boundary where inflow occurs. Examples are fluid entering a duct, far-field boundaries, or even fully-developed duct flows where accurate profiles of turbulence quantities are unknown.

In most turbulent flows, higher levels of turbulence are generated within shear layers than enter the domain at flow boundaries, making the result of the calculation relatively insensitive to the inflow boundary values. Nevertheless, caution must be used to ensure that boundary values are not so unphysical as to contaminate your solution or impede convergence. This is particularly true of external flows where unphysically large values of effective viscosity in the free stream can “swamp” the boundary layers.

You can use the turbulence specification methods described above to enter uniform constant values instead of profiles. Alternatively, you can specify the turbulence quantities in terms of more convenient quantities such as turbulence intensity, turbulent viscosity ratio, hydraulic diameter, and turbulence length scale. These quantities are discussed further in the following sections.

7.3.2.1.3. Turbulence Intensity

The turbulence intensity, I , is defined as the ratio of the root-mean-square of the velocity fluctuations, u' , to the mean flow velocity, u_{avg} .

A turbulence intensity of 1% or less is generally considered low and turbulence intensities greater than 10% are considered high. Ideally, you will have a good estimate of the turbulence intensity at the inlet boundary from external, measured data. For example, if you are simulating a wind-tunnel experiment, the turbulence intensity in the free stream is usually available from the tunnel characteristics. In modern low-turbulence wind tunnels, the free-stream turbulence intensity may be as low as 0.05%.

For internal flows, the turbulence intensity at the inlets is totally dependent on the upstream history of the flow. If the flow upstream is under-developed and undisturbed, you can use a low turbulence intensity. If the flow is fully developed, the turbulence intensity may be as high as a few percent. The turbulence intensity at the core of a fully-developed duct flow can be estimated from the following formula derived from an empirical correlation for pipe flows:

$$I \equiv \frac{u'}{u_{avg}} = 0.16 \left(Re_{D_H} \right)^{-1/8} \quad (7-43)$$

At a Reynolds number of 50,000, for example, the turbulence intensity will be 4%, according to this formula.

7.3.2.1.4. Turbulence Length Scale and Hydraulic Diameter

The turbulence length scale, ℓ , is a physical quantity related to the size of the large eddies that contain the energy in turbulent flows.

In fully-developed duct flows, ℓ is restricted by the size of the duct, since the turbulent eddies cannot be larger than the duct. An approximate relationship between ℓ and the physical size of the duct is

$$\ell = 0.07L \quad (7-44)$$

where L is the relevant dimension of the duct. The factor of 0.07 is based on the maximum value of the mixing length in fully-developed turbulent pipe flow, where L is the diameter of the pipe. In a channel of non-circular cross-section, you can base L on the hydraulic diameter.

If the turbulence derives its characteristic length from an obstacle in the flow, such as a perforated plate, it is more appropriate to base the turbulence length scale on the characteristic length of the obstacle rather than on the duct size.

It should be noted that the relationship of [Equation 7-44 \(p. 264\)](#), which relates a physical dimension (L) to the turbulence length scale (ℓ), is not necessarily applicable to all situations. For most cases, however, it is a suitable approximation.

Guidelines for choosing the characteristic length L or the turbulence length scale ℓ for selected flow types are listed below:

- For fully-developed internal flows, choose the **Intensity and Hydraulic Diameter** specification method and specify the hydraulic diameter $L = D_H$ in the **Hydraulic Diameter** field.
- For flows downstream of turning vanes, perforated plates, etc., choose the **Intensity and Length Scale** method and specify the characteristic length of the flow opening for L in the **Turbulent Length Scale** field.
- For wall-bounded flows in which the inlets involve a turbulent boundary layer, choose the **Intensity and Length Scale** method and use the boundary-layer thickness, δ_{99} , to compute the turbulence length scale, ℓ , from $\ell = 0.4\delta_{99}$. Enter this value for ℓ in the **Turbulence Length Scale** field.

7.3.2.1.5. Turbulent Viscosity Ratio

The turbulent viscosity ratio, $\frac{\mu_t}{\mu}$, is directly proportional to the turbulent Reynolds number

$(Re_t \equiv k^2 / (\varepsilon v))$. Re_t is large (on the order of 100 to 1000) in high-Reynolds-number boundary layers, shear layers, and fully-developed duct flows. However, at the free-stream boundaries of most external flows, $\frac{\mu_t}{\mu}$ is fairly small. Typically, the turbulence parameters are set so that $1 < \frac{\mu_t}{\mu} < 10$.

To specify quantities in terms of the turbulent viscosity ratio, you can choose **Turbulent Viscosity Ratio** (for the Spalart-Allmaras model) or **Intensity and Viscosity Ratio** (for the k - ε models, the k - ω models, or the RSM).

7.3.2.1.6. Relationships for Deriving Turbulence Quantities

To obtain the values of transported turbulence quantities from more convenient quantities such as I , L , or $\frac{\mu_t}{\mu}$, you must typically resort to an empirical relation. Several useful relations, most of which are used within ANSYS FLUENT, are presented below.

7.3.2.1.7. Estimating Modified Turbulent Viscosity from Turbulence Intensity and Length Scale

To obtain the modified turbulent viscosity, $\tilde{\nu}$, for the Spalart-Allmaras model from the turbulence intensity, I , and length scale, ℓ , the following equation can be used:

$$\tilde{\nu} = \sqrt{\frac{3}{2}} u_{avg} I \ell \quad (7-45)$$

This formula is used in ANSYS FLUENT if you select the **Intensity and Hydraulic Diameter** specification method with the Spalart-Allmaras model. ℓ is obtained from [Equation 7-44 \(p. 264\)](#).

7.3.2.1.8. Estimating Turbulent Kinetic Energy from Turbulence Intensity

The relationship between the turbulent kinetic energy, k , and turbulence intensity, I , is

$$k = \frac{3}{2} (u_{avg} I)^2 \quad (7-46)$$

where u_{avg} is the mean flow velocity.

This relationship is used in ANSYS FLUENT whenever the **Intensity and Hydraulic Diameter**, **Intensity and Length Scale**, or **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ε .

7.3.2.1.9. Estimating Turbulent Dissipation Rate from a Length Scale

If you know the turbulence length scale, ℓ , you can determine ε from the relationship

$$\varepsilon = C_\mu^{3/4} \frac{k^{3/2}}{\ell} \quad (7-47)$$

where C_μ is an empirical constant specified in the turbulence model (approximately 0.09). The determination of ℓ was discussed previously.

This relationship is used in ANSYS FLUENT whenever the **Intensity and Hydraulic Diameter** or **Intensity and Length Scale** method is used instead of specifying explicit values for k and ε .

7.3.2.1.10. Estimating Turbulent Dissipation Rate from Turbulent Viscosity Ratio

The value of ε can be obtained from the turbulent viscosity ratio $\frac{\mu_t}{\mu}$ and k using the following relationship:

$$\varepsilon = \rho C_\mu \frac{k^2}{\mu} \left(\frac{\mu_t}{\mu} \right)^{-1} \quad (7-48)$$

where C_μ is an empirical constant specified in the turbulence model (approximately 0.09).

This relationship is used in ANSYS FLUENT whenever the **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ε .

7.3.2.1.11. Estimating Turbulent Dissipation Rate for Decaying Turbulence

If you are simulating a wind-tunnel situation in which the model is mounted in the test section downstream of a mesh and/or wire mesh screens, you can choose a value of ε such that

$$\varepsilon \approx \frac{\Delta k U_\infty}{L_\infty} \quad (7-49)$$

where Δk is the approximate decay of k you wish to have across the flow domain (say, 10% of the inlet value of k), U_∞ is the free-stream velocity, and L_∞ is the streamwise length of the flow domain. [Equation 7-49 \(p. 266\)](#) is a linear approximation to the power-law decay observed in high-Reynolds-number isotropic turbulence. Its basis is the exact equation for k in decaying turbulence, $U \partial k / \partial x = -\varepsilon$.

If you use this method to estimate ε , you should also check the resulting turbulent viscosity ratio $\frac{\mu_t}{\mu}$ to make sure that it is not too large, using [Equation 7-48 \(p. 266\)](#).

Although this method is not used internally by ANSYS FLUENT, you can use it to derive a constant free-stream value of ε that you can then specify directly by choosing **K and Epsilon** in the **Turbulence Specification Method** drop-down list. In this situation, you will typically determine k from I using [Equation 7-46 \(p. 265\)](#).

7.3.2.1.12. Estimating Specific Dissipation Rate from a Length Scale

If you know the turbulence length scale, ℓ , you can determine ω from the relationship

$$\omega = \frac{k^{1/2}}{C_\mu^{1/4} \ell} \quad (7-50)$$

where C_μ is an empirical constant specified in the turbulence model (approximately 0.09). The determination of ℓ was discussed previously.

This relationship is used in ANSYS FLUENT whenever the **Intensity and Hydraulic Diameter** or **Intensity and Length Scale** method is used instead of specifying explicit values for k and ω .

7.3.2.1.13. Estimating Specific Dissipation Rate from Turbulent Viscosity Ratio

The value of ω can be obtained from the turbulent viscosity ratio $\frac{\mu_t}{\mu}$ and k using the following relationship:

$$\omega = \rho \frac{k}{\mu} \left(\frac{\mu_t}{\mu} \right)^{-1} \quad (7-51)$$

This relationship is used in ANSYS FLUENT whenever the **Intensity and Viscosity Ratio** method is used instead of specifying explicit values for k and ω .

7.3.2.1.14. Estimating Reynolds Stress Components from Turbulent Kinetic Energy

When the RSM is used, if you do not specify the values of the Reynolds stresses explicitly at the inlet using the **Reynolds-Stress Components** option in the **Reynolds-Stress Specification Method** drop-down list, they are approximately determined from the specified values of k . The turbulence is assumed to be isotropic such that

$$\overline{u'_i u'_j} = 0 \quad (7-52)$$

and

$$\overline{u'_\alpha u'_\alpha} = \frac{2}{3} k \quad (7-53)$$

(no summation over the index α).

ANSYS FLUENT will use this method if you select **K or Turbulence Intensity** in the **Reynolds-Stress Specification Method** drop-down list.

7.3.2.1.15. Specifying Inlet Turbulence for LES

The turbulence intensity value specified at a velocity inlet for LES, as described in [Large Eddy Simulation Model \(p. 724\)](#), is used to randomly perturb the instantaneous velocity field at the inlet. It does not specify a modeled turbulence quantity. Instead, the stochastic components of the flow at the inlet boundary are accounted for by superposing random perturbations on individual velocity components as described in [Inlet Boundary Conditions for the LES Model](#) in the [Theory Guide](#).

7.3.3. Pressure Inlet Boundary Conditions

Pressure inlet boundary conditions are used to define the fluid pressure at flow inlets, along with all other scalar properties of the flow. They are suitable for both incompressible and compressible flow calculations. Pressure inlet boundary conditions can be used when the inlet pressure is known but the flow rate and/or velocity is not known. This situation may arise in many practical situations, including

buoyancy-driven flows. Pressure inlet boundary conditions can also be used to define a “free” boundary in an external or unconfined flow.

For an overview of flow boundaries, see [Flow Inlet and Exit Boundary Conditions \(p. 261\)](#).

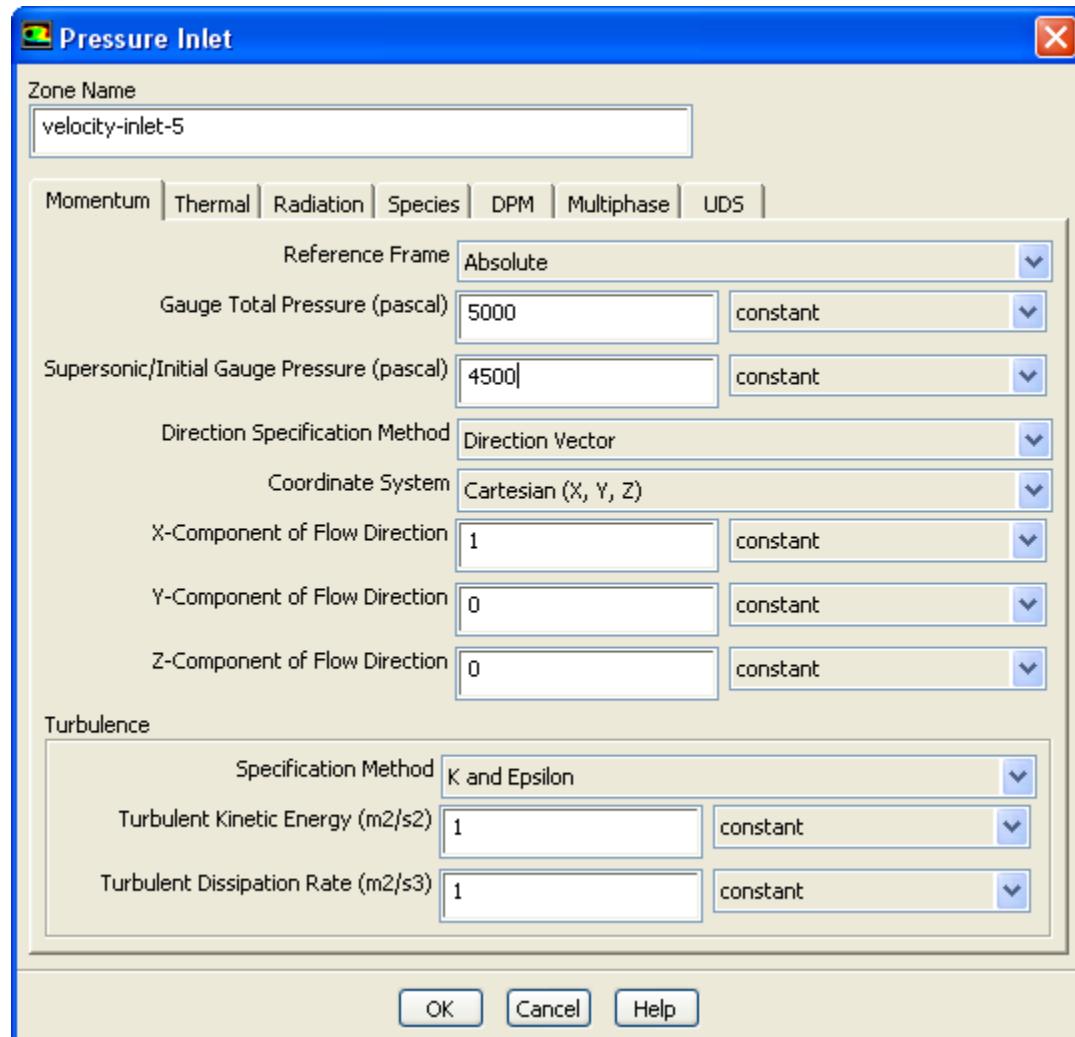

7.3.3.1. Inputs at Pressure Inlet Boundaries

7.3.3.1.1. Summary

You will enter the following information for a pressure inlet boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the [Pressure Inlet Dialog Box \(p. 1994\)](#) ([Figure 7.15 \(p. 269\)](#)), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)). Note that open channel boundary condition inputs are described in [Modeling Open Channel Flows \(p. 1204\)](#).

Figure 7.15 The Pressure Inlet Dialog Box

7.3.3.1.1. Pressure Inputs and Hydrostatic Head

When gravitational acceleration is activated in the **Operating Conditions** dialog box (accessed from the **Boundary Conditions** task page), the pressure field (including all pressure inputs) will include the hydrostatic head. This is accomplished by redefining the pressure in terms of a modified pressure which includes the hydrostatic head (denoted p') as follows:

$$p' = p - \rho_0 \vec{g} \cdot \vec{r} \quad (7-54)$$

where ρ_0 is a constant reference density, \vec{g} is the gravity vector (also a constant), and

$$\vec{r} = x\hat{i} + y\hat{j} + z\hat{k} \quad (7-55)$$

is the position vector. Noting that

$$\nabla \left(\rho_0 \vec{g} \cdot \vec{r} \right) = \rho_0 \vec{g} \quad (7-56)$$

it follows that

$$\nabla p' = \nabla \left(p - \rho_0 \vec{g} \cdot \vec{r} \right) = \nabla p - \rho_0 \vec{g} \quad (7-57)$$

The substitution of this relation in the momentum equation gives pressure gradient and gravitational body force terms of the form

$$-\nabla p' + (\rho - \rho_0) \vec{g} \quad (7-58)$$

where ρ is the fluid density. Therefore, if the fluid density is constant, we can set the reference density ρ_0 equal to the fluid density, thereby eliminating the body force term. If the fluid density is not constant (for example, density is given by the ideal gas law), then the reference density should be chosen to be representative of the average or mean density in the fluid domain, so that the body force term is small.

An important consequence of this treatment of the gravitational body force is that your inputs of pressure (now defined as p') should not include hydrostatic pressure differences. Moreover, reports of static and total pressure will not show any influence of the hydrostatic pressure. See [Natural Convection and Buoyancy-Driven Flows \(p. 743\)](#) for additional information.

7.3.3.1.1.2. Defining Total Pressure and Temperature

Enter the value for total pressure in the **Gauge Total Pressure** field in the **Pressure Inlet** dialog box. Total temperature is set in the **Thermal** tab, in the **Total Temperature** field.

Remember that the total pressure value is the gauge pressure with respect to the operating pressure defined in the [Operating Conditions Dialog Box \(p. 1952\)](#). Total pressure for an incompressible fluid is defined as

$$p_0 = p_s + \frac{1}{2} \rho |\vec{v}|^2 \quad (7-59)$$

and for a compressible fluid of constant c_p as

$$p_0 = p_s \left(1 + \frac{\gamma - 1}{2} M^2 \right)^{\gamma / (\gamma - 1)} \quad (7-60)$$

where

p_0 = total pressure

p_s = static pressure

M = Mach number

γ = ratio of specific heats (c_p/c_v)

If you are modeling axisymmetric swirl, \vec{v} in [Equation 7-59 \(p. 270\)](#) will include the swirl component.

If the cell zone adjacent to a pressure inlet is defined as a moving reference frame zone, and you are using the pressure-based solver, the velocity in [Equation 7-59 \(p. 270\)](#) (or the Mach number in [Equation 7-60 \(p. 270\)](#)) will be absolute or relative to the mesh velocity, depending on whether or not the **Absolute** velocity formulation is enabled in the **General** task page. For the density-based solver, the **Absolute** velocity formulation is always used; hence, the velocity in [Equation 7-59 \(p. 270\)](#) (or the Mach number in [Equation 7-60 \(p. 270\)](#)) is always the **Absolute** velocity.

- If **Reference Frame** is set to **Absolute** in the **Pressure Inlet** dialog box, then the total temperature, total pressure, and flow direction are also in the absolute reference frame, and therefore, the ANSYS FLUENT solver will convert it to the relative reference frame.
- If **Reference Frame** is set to **Relative to Adjacent Cell Zone** in the **Pressure Inlet** dialog box, then the total temperature, total pressure, and velocity components are also relative to the adjacent cell zone and no change is needed.

For the Eulerian multiphase model, the total temperature, and velocity components need to be specified for the individual phases. The **Reference Frame (Relative to Adjacent Cell Zone or Absolute)** for each of the phases is the same as the reference frame selected for the mixture phase. Note that the total pressure values need to be specified in the mixture phase.

Important

- If the flow is incompressible, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the static temperature.
- For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the static temperature at that boundary. If a boundary allows *only a compressible* phase to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be taken as the total temperature (relative/absolute) at that boundary. The total temperature will depend on the **Reference Frame** option selected in the **Pressure Inlet** dialog box.
- For the VOF multiphase model, if a boundary allows a *compressible phase* to enter the domain, then the temperature assigned in the **Pressure Inlet** dialog box will be considered the total temperature at that boundary. The total temperature (relative/absolute) will depend on the **Reference Frame** option chosen in the dialog box. Otherwise, the temperature assigned to the boundary will be considered the static temperature at the boundary.
- For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases will be the total or static temperature, depending on whether the phase is compressible or incompressible.
- Total temperature (relative/absolute) will depend on the **Reference Frame** option chosen in the **Pressure Inlet** dialog box.

7.3.3.1.1.3. Defining the Flow Direction

The flow direction is defined as a unit vector (\vec{d}) which is aligned with the local velocity vector, \vec{v} . This can be expressed simply as

$$\vec{d} = \frac{\vec{v}}{|\vec{v}|} \quad (7-61)$$

Important

For the inputs in ANSYS FLUENT, the flow direction \vec{d} need not be a unit vector, as it will be automatically normalized before it is applied.

Important

For a moving reference frame, the relative flow direction \vec{d}_r is defined in terms of the relative velocity, \vec{v}_r . Thus,

$$\vec{d}_r = \frac{\vec{v}_r}{|\vec{v}_r|} \quad (7-62)$$

You can define the flow direction at a pressure inlet explicitly, or you can define the flow to be normal to the boundary. If you choose to specify the direction vector, you can set either the (Cartesian) x , y , and z components, or the (cylindrical) radial, tangential, and axial components.

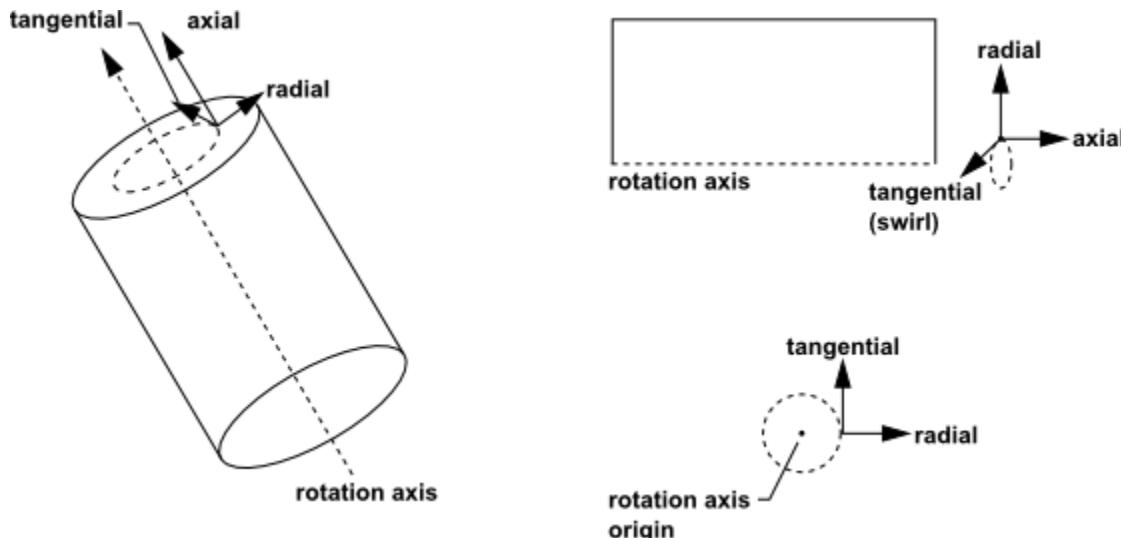

For moving zone problems calculated using the pressure-based solver, the flow direction will be absolute or relative to the mesh velocity, depending on whether or not the **Absolute** velocity formulation is enabled in the **General** task page. For the density-based solver, the flow direction will always be in the absolute frame.

The procedure for defining the flow direction is as follows (refer to [Figure 7.15 \(p. 269\)](#)):

1. Specify the flow direction by selecting **Direction Vector** or **Normal to Boundary** in the **Direction Specification Method** drop-down list.
2. If you selected **Normal to Boundary** in step 1 and you are modeling axisymmetric swirl, enter the appropriate value for the **Tangential-Component of Flow Direction**. If you chose **Normal to Boundary** and your geometry is 3D or 2D without axisymmetric swirl, there are no additional inputs for flow direction.
3. If you selected **Direction Vector** in step 1, and your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical(Radial, Tangential, Axial)**, **Local Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical Swirl** from the **Coordinate System** drop-down list. Some notes on these selections are provided below:
 - The **Cartesian** coordinate option is based on the Cartesian coordinate system used by the geometry. Enter appropriate values for the **X**, **Y**, and **Z-Component of Flow Direction**.
 - The **Cylindrical** coordinate system uses the axial, radial, and tangential components based on the following coordinate systems:
 - For problems involving a single cell zone, the coordinate system is defined by the rotation axis and origin specified in the [Fluid Dialog Box \(p. 1942\)](#).
 - For problems involving multiple zones (e.g., multiple reference frames or sliding meshes), the coordinate system is defined by the rotation axis specified in the **Fluid** (or **Solid**) dialog box for the fluid (or solid) zone that is adjacent to the inlet.

For all of the above definitions of the cylindrical coordinate system, positive radial velocities point radially outward from the rotation axis, positive axial velocities are in the direction of the rotation axis vector, and positive tangential velocities are based on the right-hand rule using the positive rotation axis (see [Figure 7.16 \(p. 273\)](#)).

Figure 7.16 Cylindrical Velocity Components in 3D, 2D, and Axisymmetric Domains

- The **Local Cylindrical** coordinate system allows you to define a coordinate system specifically for the inlet. When you use the local cylindrical option, you will define the coordinate system right here in the **Pressure Inlet** dialog box. The local cylindrical coordinate system is useful if you have several inlets with different rotation axes. Enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction.
- The **Local Cylindrical Swirl** coordinate system option allows you to define a coordinate system specifically for the inlet where the total pressure, swirl velocity, and the components of the velocity in the axial and radial planes are specified. Enter appropriate values for the **Axial** and **Radial-Component of Flow Direction**, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the Axis Origin and Axis Direction. It is recommended that you start your simulation with a smaller swirl velocity and then progressively increase the velocity to obtain a stable solution.

Important

Local Cylindrical Swirl should not be used for open channel boundary conditions and on the mixing plane boundaries while using the mixing plane model.

- If you selected **Direction Vector** in step 1, and your geometry is 2D, define the vector components as follows:
 - For a 2D planar geometry, enter appropriate values for the **X**, **Y**, and **Z-Component of Flow Direction**.
 - For a 2D axisymmetric geometry, enter appropriate values for the **Axial**, **Radial-Component of Flow Direction**.
 - For a 2D axisymmetric swirl geometry, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**.

[Figure 7.16](#) (p. 273) shows the vector components for these different coordinate systems.

7.3.3.1.1.4. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in [Initializing the Solution](#) (p. 1348).

Remember that the static pressure value you enter is relative to the operating pressure set in the [Operating Conditions Dialog Box](#) (p. 1952). Note the comments in [Pressure Inputs and Hydrostatic Head](#) (p. 269) regarding hydrostatic pressure.

The **Supersonic/Initial Gauge Pressure** is ignored by ANSYS FLUENT whenever the flow is subsonic, in which case it is calculated from the specified stagnation quantities. If you choose to initialize the solution based on the pressure-inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation pressure to compute initial values according to the isentropic relations (for compressible flow) or Bernoulli's equation (for incompressible flow). Therefore, for a sub-sonic inlet it should generally be set based on a reasonable estimate of the inlet Mach number (for compressible flow) or inlet velocity (for incompressible flow).

7.3.3.1.1.5. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in [Determining Turbulence Parameters](#) (p. 262). Turbulence modeling in general is described in [Modeling Turbulence](#) (p. 683).

7.3.3.1.1.6. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature**. See [Defining Boundary Conditions for Radiation](#) (p. 772) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

7.3.3.1.1.7. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see [Defining Cell Zone and Boundary Conditions for Species](#) (p. 878).

7.3.3.1.1.8. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in [Defining Non-Premixed Boundary Conditions](#) (p. 946).

7.3.3.1.1.9. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in [Setting Boundary Conditions for the Progress Variable](#) (p. 963).

7.3.3.1.10. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure inlet. See [Setting Boundary Conditions for the Discrete Phase](#) (p. 1124) for details.

7.3.3.1.11. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See [Defining Multiphase Cell Zone and Boundary Conditions](#) (p. 1189) for details.

7.3.3.1.12. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See [Modeling Open Channel Flows](#) (p. 1204) for details.

7.3.3.2. Default Settings at Pressure Inlet Boundaries

Default settings (in SI) for pressure inlet boundary conditions are as follows:

Gauge Total Pressure	0
Supersonic/Initial Gauge Pressure	0
Total Temperature	300
X-Component of Flow Direction	1
Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
Turbulent Kinetic Energy	1
Turbulent Dissipation Rate	1

7.3.3.3. Calculation Procedure at Pressure Inlet Boundaries

The treatment of pressure inlet boundary conditions by ANSYS FLUENT can be described as a loss-free transition from stagnation conditions to the inlet conditions. For incompressible flows, this is accomplished by application of the Bernoulli equation at the inlet boundary. In compressible flows, the equivalent isentropic flow relations for an ideal gas are used.

7.3.3.3.1. Incompressible Flow Calculations at Pressure Inlet Boundaries

When flow enters through a pressure inlet boundary, ANSYS FLUENT uses the boundary condition pressure you input as the total pressure of the fluid at the inlet plane, p_0 . In incompressible flow, the inlet total pressure and the static pressure, p_s , are related to the inlet velocity via Bernoulli's equation:

$$p_0 = p_s + \frac{1}{2} \rho v^2 \quad (7-63)$$

With the resulting velocity magnitude and the flow direction vector you assigned at the inlet, the velocity components can be computed. The inlet mass flow rate and fluxes of momentum, energy, and species can then be computed as outlined in [Calculation Procedure at Velocity Inlet Boundaries](#) (p. 281).

For incompressible flows, density at the inlet plane is either constant or calculated as a function of temperature and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

If flow exits through a pressure inlet, the total pressure specified is used as the static pressure. For incompressible flows, total temperature is equal to static temperature.

7.3.3.3.2. Compressible Flow Calculations at Pressure Inlet Boundaries

In compressible flows, isentropic relations for an ideal gas are applied to relate total pressure, static pressure, and velocity at a pressure inlet boundary. Your input of total pressure, p'_0 at the inlet and the static pressure, p'_s in the adjacent fluid cell are thus related as

$$\frac{p'_0 + p_{op}}{p'_s + p_{op}} = \left(1 + \frac{\gamma - 1}{2} M^2\right)^{\gamma / (\gamma - 1)} \quad (7-64)$$

where

$$M \equiv \frac{v}{c} = \frac{v}{\sqrt{\gamma R T_s}} \quad (7-65)$$

c = the speed of sound, and $\gamma = c_p/c_v$. Note that the operating pressure, p_{op} , appears in [Equation 7-64 \(p. 276\)](#) because your boundary condition inputs are in terms of pressure relative to the operating pressure. Given p'_0 and p'_s , [Equation 7-64 \(p. 276\)](#) and [Equation 7-65 \(p. 276\)](#) are used to compute the velocity magnitude of the fluid at the inlet plane. Individual velocity components at the inlet are then derived using the direction vector components.

For compressible flow, the density at the inlet plane is defined by the ideal gas law in the form

$$\rho = \frac{p'_s + p_{op}}{R T_s} \quad (7-66)$$

For multi-species gas mixtures, the specific gas constant, R , is computed from the species mass or mole fractions, Y_i that you defined as boundary conditions at the pressure inlet boundary. The static temperature at the inlet, T_s , is computed from your input of total temperature, T_0 , as

$$\frac{T_0}{T_s} = 1 + \frac{\gamma - 1}{2} M^2 \quad (7-67)$$

7.3.4. Velocity Inlet Boundary Conditions

Velocity inlet boundary conditions are used to define the flow velocity, along with all relevant scalar properties of the flow, at flow inlets. In this case, the total (or stagnation) pressure is not fixed but will rise (in response to the computed static pressure) to whatever value is necessary to provide the prescribed

velocity distribution. This boundary condition is equally applicable to incompressible and compressible flows.

In special instances, a velocity inlet may be used in ANSYS FLUENT to define the flow velocity at flow exits. (The scalar inputs are not used in such cases.) In such cases you must ensure that overall continuity is maintained in the domain.

For an overview of flow boundaries, see [Flow Inlet and Exit Boundary Conditions \(p. 261\)](#).

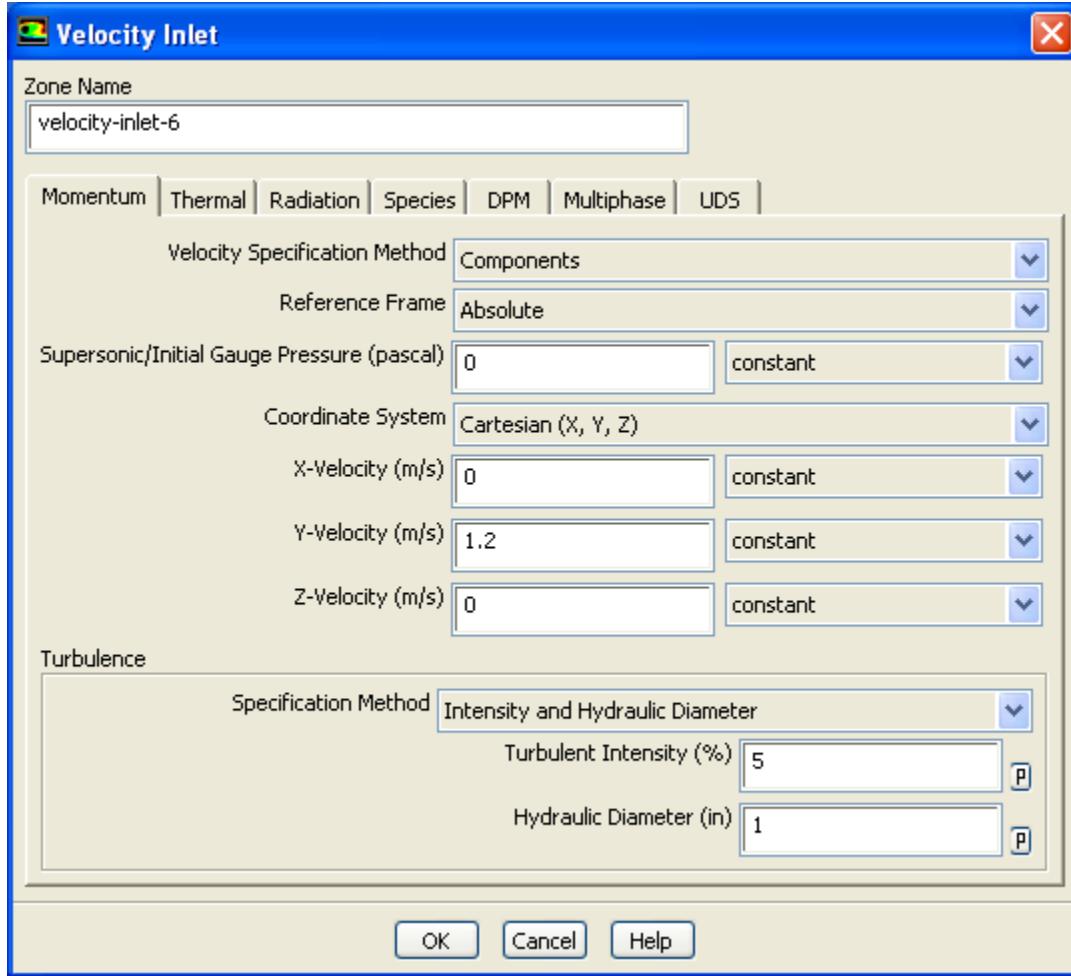

7.3.4.1. Inputs at Velocity Inlet Boundaries

7.3.4.1.1. Summary

You will enter the following information for a velocity inlet boundary:

- type of reference frame
- velocity magnitude and direction or velocity components
- swirl velocity (for 2D axisymmetric problems with swirl)
- static pressure
- temperature (for energy calculations)
- outflow gauge pressure (for calculations with the density-based solver)
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)

All values are entered in the [Velocity Inlet Dialog Box \(p. 2006\)](#) ([Figure 7.17 \(p. 278\)](#)), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.17 The Velocity Inlet Dialog Box

7.3.4.1.2. Defining the Velocity

You can define the inflow velocity by specifying the velocity magnitude and direction, the velocity components, or the velocity magnitude normal to the boundary. If the cell zone adjacent to the velocity inlet is moving (i.e., if you are using a moving reference frame, multiple reference frames, or sliding meshes), you can specify either relative or absolute velocities. For axisymmetric problems with swirl in ANSYS FLUENT, you will also specify the swirl velocity.

The procedure for defining the inflow velocity is as follows:

1. Specify the flow direction by selecting **Magnitude and Direction, Components**, or **Magnitude, Normal to Boundary** in the **Velocity Specification Method** drop-down list.
2. If the cell zone adjacent to the velocity inlet is moving, you can choose to specify relative or absolute velocities by selecting **Relative to Adjacent Cell Zone** or **Absolute** in the **Reference Frame** drop-down list. If the adjacent cell zone is not moving, **Absolute** and **Relative to Adjacent Cell Zone** will be equivalent, so you need not visit the list.
3. If you are going to set the velocity magnitude and direction or the velocity components, and your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical (Radial, Tangential, Axial)** from the **Coordinate System** drop-down list. See *Defining the Flow Direction* (p. 271) for information about Cartesian, cylindrical, and local cylindrical coordinate systems.
4. Set the appropriate velocity parameters, as described below for each specification method.

7.3.4.1.3. Setting the Velocity Magnitude and Direction

If you selected **Magnitude and Direction** as the **Velocity Specification Method** in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the **Velocity Magnitude**) and the direction of the vector:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the **Cartesian** coordinate system, you will define the **X**, **Y**, and (in 3D) **Z-Component of Flow Direction**.
- If your geometry is 2D axisymmetric, or you chose in step 3 to use a **Cylindrical** coordinate system, enter the appropriate values of **Radial**, **Axial**, and (if you are modeling axisymmetric swirl or using cylindrical coordinates) **Tangential-Component of Flow Direction**.
- If you chose in step 3 to use a **Local Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of the **Axis Origin** and the **Axis Direction**.

Figure 7.16 (p. 273) shows the vector components for these different coordinate systems.

7.3.4.1.4. Setting the Velocity Magnitude Normal to the Boundary

If you selected **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in step 1 above, you will enter the magnitude of the velocity vector at the inflow boundary (the **Velocity Magnitude**).

7.3.4.1.5. Setting the Velocity Components

If you selected **Components** as the **Velocity Specification Method** in step 1 above, you will enter the components of the velocity vector at the inflow boundary as follows:

- If your geometry is 2D non-axisymmetric, or you chose in step 3 to use the Cartesian coordinate system, you will define the **X**, **Y**, and (in 3D) **Z-Velocity**.
- If your geometry is 2D axisymmetric without swirl, you will set the **Radial** and **Axial-Velocity**.
- If your model is 2D axisymmetric with swirl, you will set the **Axial**, **Radial**, and **Swirl-Velocity**, and (optionally) the **Angular Velocity**, as described below.
- If you chose in step 3 to use a **Cylindrical** coordinate system, you will set the **Radial**, **Tangential**, and **Axial-Velocity**, and (optionally) the **Angular Velocity**, as described below.
- If you chose in step 3 to use a **Local Cylindrical** coordinate system, you will set the **Radial**, **Tangential**, and **Axial-Velocity**, and (optionally) the **Angular Velocity**, as described below, and then specify the **X**, **Y**, and **Z** component of the **Axis Origin** and the **Axis Direction**.

Important

Remember that positive values for x , y , and z velocities indicate flow in the positive x , y , and z directions. If flow enters the domain in the negative x direction, for example, you will need to specify a negative value for the x velocity. The same holds true for the radial, tangential, and axial velocities. Positive radial velocities point radially out from the axis, positive axial velocities are in the direction of the axis vector, and positive tangential velocities are based on the right-hand rule using the positive axis.

7.3.4.1.6. Setting the Angular Velocity

If you chose **Components** as the **Velocity Specification Method** in step 1 above, and you are modeling axisymmetric swirl, you can specify the inlet **Angular Velocity** Ω in addition to the **Swirl-Velocity**. Similarly, if you chose **Components** as the **Velocity Specification Method** and you chose in step 3 to use a **Cylindrical** or **Local Cylindrical** coordinate system, you can specify the inlet **Angular Velocity** Ω in addition to the **Tangential-Velocity**.

If you specify Ω , v_θ is computed for each face as Ωr , where r is the radial coordinate in the coordinate system defined by the rotation axis and origin. If you specify both the **Swirl-Velocity** and the **Angular Velocity**, or the **Tangential-Velocity** and the **Angular Velocity**, ANSYS FLUENT will add v_θ and Ωr to get the swirl or tangential velocity at each face.

7.3.4.1.7. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the velocity inlet boundary conditions. Solution initialization is discussed in *Initializing the Solution* (p. 1348).

The **Supersonic/Initial Gauge Pressure** is ignored by ANSYS FLUENT whenever the flow is subsonic. If you choose to initialize the flow based on the velocity inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Remember that the static pressure value you enter is relative to the operating pressure set in the *Operating Conditions Dialog Box* (p. 1952). Note the comments in *Pressure Inputs and Hydrostatic Head* (p. 269)

7.3.4.1.8. Defining the Temperature

For calculations in which the energy equation is being solved, you will set the static temperature of the flow at the velocity inlet boundary in the **Thermal** tab in the **Temperature** field.

7.3.4.1.9. Defining Outflow Gauge Pressure

If you are using the density-based solver, you can specify an **Outflow Gauge Pressure** for a velocity inlet boundary. If the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the **Outflow Gauge Pressure** field.

7.3.4.1.10. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in *Determining Turbulence Parameters* (p. 262). Turbulence modeling in general is described in *Modeling Turbulence* (p. 683).

7.3.4.1.11. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature**. See *Defining Boundary Conditions for Radiation* (p. 772) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

7.3.4.1.12. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see *Defining Cell Zone and Boundary Conditions for Species* (p. 878).

7.3.4.1.13. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in *Defining Non-Premixed Boundary Conditions* (p. 946).

7.3.4.1.14. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in *Setting Boundary Conditions for the Progress Variable* (p. 963).

7.3.4.1.15. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the velocity inlet. See *Setting Boundary Conditions for the Discrete Phase* (p. 1124) for details.

7.3.4.1.16. Defining Multiphase Boundary Conditions

If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See *Defining Multiphase Cell Zone and Boundary Conditions* (p. 1189) for details.

7.3.4.2. Default Settings at Velocity Inlet Boundaries

Default settings (in SI) for velocity inlet boundary conditions are as follows:

Temperature	300
Velocity Magnitude	0
X-Component of Flow Direction	1
Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
X-Velocity	0
Y-Velocity	0
Z-Velocity	0
Turbulent Kinetic Energy	1
Turbulent Dissipation Rate	1
Outflow Gauge Pressure	0

7.3.4.3. Calculation Procedure at Velocity Inlet Boundaries

ANSYS FLUENT uses your boundary condition inputs at velocity inlets to compute the mass flow into the domain through the inlet and to compute the fluxes of momentum, energy, and species through the inlet. This section describes these calculations for the case of flow entering the domain through

the velocity inlet boundary and for the less common case of flow exiting the domain through the velocity inlet boundary.

7.3.4.3.1. Treatment of Velocity Inlet Conditions at Flow Inlets

When your velocity inlet boundary condition defines flow entering the physical domain of the model, ANSYS FLUENT uses both the velocity components and the scalar quantities that you defined as boundary conditions to compute the inlet mass flow rate, momentum fluxes, and fluxes of energy and chemical species.

The mass flow rate entering a fluid cell adjacent to a velocity inlet boundary is computed as

$$\dot{m} = \int \rho \vec{V} \cdot d\vec{A} \quad (7-68)$$

Note that only the velocity component normal to the control volume face contributes to the inlet mass flow rate.

7.3.4.3.2. Treatment of Velocity Inlet Conditions at Flow Exits

Sometimes a velocity inlet boundary is used where flow exits the physical domain. This approach might be used, for example, when the flow rate through one exit of the domain is known or is to be imposed on the model.

Important

In such cases you must ensure that overall continuity is maintained in the domain.

In the pressure-based solver, when flow exits the domain through a velocity inlet boundary ANSYS FLUENT uses the boundary condition value for the velocity component normal to the exit flow area. It does not use any other boundary conditions that you have input. Instead, all flow conditions except the normal velocity component are assumed to be those of the upstream cell.

In the density-based solver, if the flow exits the domain at any face on the boundary, that face will be treated as a pressure outlet with the pressure prescribed in the **Outflow Gauge Pressure** field.

7.3.4.3.3. Density Calculation

Density at the inlet plane is either constant or calculated as a function of temperature, pressure, and/or species mass/mole fractions, where the mass or mole fractions are the values you entered as an inlet condition.

7.3.5. Mass Flow Inlet Boundary Conditions

Mass flow boundary conditions can be used in ANSYS FLUENT to provide a prescribed mass flow rate or mass flux distribution at an inlet. As with a velocity inlet, specifying the mass flux permits the total pressure to vary in response to the interior solution. This is in contrast to the pressure inlet boundary condition (see [Pressure Inlet Boundary Conditions \(p. 267\)](#)), where the total pressure is fixed while the mass flux varies. However, unlike a velocity inlet, the mass flow inlet is equally applicable to incompressible and compressible flows.

A mass flow inlet is often used when it is more important to match a prescribed mass flow rate than to match the total pressure of the inflow stream. An example is the case of a small cooling jet that is bled into the main flow at a fixed mass flow rate, while the velocity of the main flow is governed primarily by a (different) pressure inlet/outlet boundary condition pair. A mass flow inlet boundary condition can also be used as an outflow by specifying the flow direction away from the solution domain.

7.3.5.1. Limitations and Special Considerations

- The adjustment of inlet total pressure might result in a slower convergence, so if both the pressure inlet boundary condition and the mass flow inlet boundary condition are acceptable choices, you should choose the former.
- It is not necessary to use mass flow inlets in incompressible flows because when density is constant, velocity inlet boundary conditions will fix the mass flow.
- A mass flow boundary operating as an outflow has the following limitations:
 - It is available for single-phase flow only.
 - It is not available with the VOF, mixture, and Eulerian multiphase models in the pressure-based solver.
 - It is not available with the Wet Steam model in the density-based solver.

For an overview of flow boundaries, see [Flow Inlet and Exit Boundary Conditions](#) (p. 261).

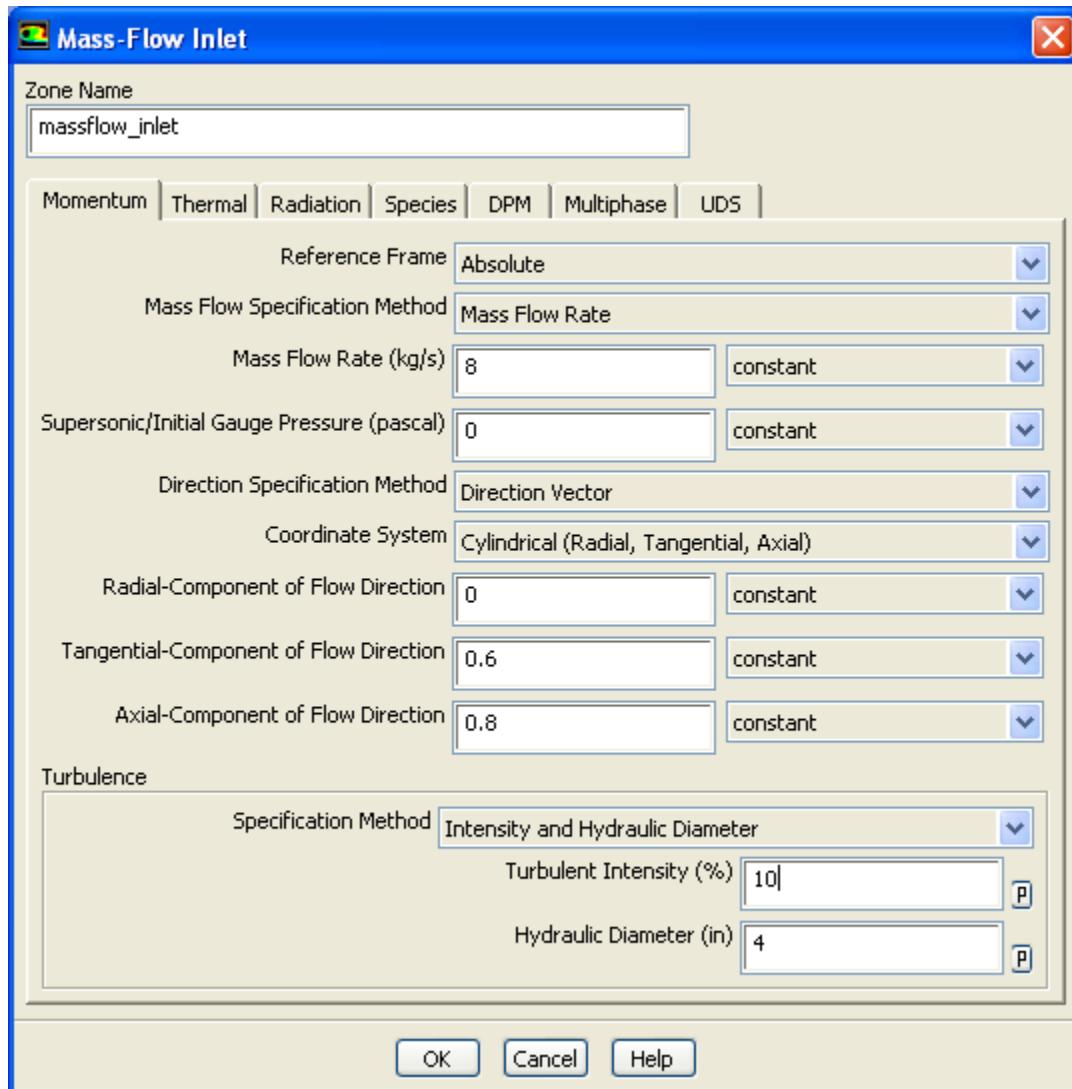

7.3.5.2. Inputs at Mass Flow Inlet Boundaries

7.3.5.2.1. Summary

You will enter the following information for a mass flow inlet boundary:

- type of reference frame
- mass flow rate, mass flux, or (primarily for the mixing plane model) mass flux with average mass flux
- total (stagnation) temperature
- static pressure
- flow direction
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the [Mass-Flow Inlet Dialog Box](#) (p. 1978) ([Figure 7.18](#) (p. 284)), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions](#) (p. 214)). Note that open channel boundary condition inputs are described in [Modeling Open Channel Flows](#) (p. 1204).

Figure 7.18 The Mass-Flow Inlet Dialog Box

7.3.5.2.2. Selecting the Reference Frame

You will have the option to specify the mass flow boundary conditions either in the absolute or relative reference frame, when the cell zone adjacent to the mass flow inlet is moving. For such a case, choose **Absolute** (the default) or **Relative to Adjacent Cell Zone** in the **Reference Frame** drop-down list. If the cell zone adjacent to the mass flow inlet is not moving, both formulations are equivalent.

7.3.5.2.3. Defining the Mass Flow Rate or Mass Flux

You can specify the mass flow rate through the inlet zone and have ANSYS FLUENT convert this value to mass flux, or specify the mass flux directly. For cases where the mass flux varies across the boundary, you can also specify an average mass flux; see below for more information about this specification method.

You can define the mass flux or mass flow rate using a profile or a user-defined function.

The inputs for mass flow rate or flux are as follows:

1. Specify the mass flow by selecting **Mass Flow Rate**, **Mass Flux**, or **Mass Flux with Average Mass Flux** in the **Mass Flow Specification Method** drop-down list.
2. If you selected **Mass Flow Rate** (the default), set the prescribed mass flow rate in the **Mass Flow Rate** field when **constant** is selected from the drop-down list. Otherwise, select your hooked UDF or transient profile.

Important

The hooked UDF or transient profile can only be used to provide time-varying specification of mass flow rate. Therefore, the transient solver must be used to run the simulation. Note that the variation of profile with position in space is not applicable with this hookup.

See [DEFINE_PROFILE](#) in the **UDF Manual** for an example of a mass flow inlet UDF.

Important

Note that for axisymmetric problems, this mass flow rate is the flow rate through the entire (2π -radian) domain, not through a 1-radian slice.

3. If you selected **Mass Flux**, set the prescribed mass flux in the **Mass Flux** field, or select your hooked UDF or profile.
4. If you selected **Mass Flux with Average Mass Flux**, set the prescribed mass flux and average mass flux in the **Mass Flux** and **Average Mass Flux** fields.

7.3.5.2.4. More About Mass Flux and Average Mass Flux

As noted above, you can specify an average mass flux with the mass flux. If, for example, you specify a mass flux profile such that the average mass flux integrated over the zone area is 4.7, but you actually want to have a total mass flux of 5, you can keep the profile unchanged, and specify an average mass flux of 5. ANSYS FLUENT will maintain the profile shape but adjust the values so that the resulting mass flux across the boundary is 5.

The mass flux with average mass flux specification method is also used by the mixing plane model described in [The Mixing Plane Model \(p. 547\)](#). If the mass flow inlet boundary is going to represent one of the mixing planes, then you do *not* need to specify the mass flux or flow rate; you can keep the default **Mass Flow Rate** of 1. When you create the mixing plane later on in the problem setup, ANSYS FLUENT will automatically select the **Mass Flux with Average Mass Flux** method in the **Mass-Flow Inlet** dialog box and set the **Average Mass Flux** to the value obtained by integrating the mass flux profile for the upstream zone. This will ensure that mass is conserved between the upstream zone and the downstream (mass flow inlet) zone.

7.3.5.2.5. Defining the Total Temperature

Enter the value for the total (stagnation) temperature of the inflow stream in the **Total Temperature** field in the **Thermal** tab.

The total temperature is specified either in the absolute reference frame or relative to the adjacent cell zone, depending on your setting for the **Reference Frame**.

For the Eulerian multiphase model, the total temperature, and mass flux components need to be specified for the individual phases. The **Reference Frame (Relative to Adjacent Cell Zone or Absolute)** for each of the phases is the same as the reference frame selected for the mixture phase.

Important

Note that you can only set the reference frame for the mixture, however, the total temperature can only be set for the individual phases.

Important

- If the flow is incompressible, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature.
- For the mixture multiphase model, if a boundary allows a combination of compressible and incompressible phases to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the static temperature at that boundary. If a boundary allows *only a compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is the total temperature (relative/absolute) at that boundary. The total temperature depends on the **Reference Frame** option selected in the **Mass-Flow Inlet** dialog box.
- For the VOF multiphase model, if a boundary allows a *compressible phase* to enter the domain, then the temperature assigned in the **Mass-Flow Inlet** dialog box is considered to be the total temperature at that boundary. The total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the dialog box. Otherwise, the temperature assigned to the boundary is considered to be the static temperature at the boundary.
- For the Eulerian multiphase model, if a boundary allows a mixture of compressible and incompressible phases in the domain, then the temperature of each of the phases is the total or static temperature, depending on whether the phase is compressible or incompressible. Total temperature (relative/absolute) depends on the **Reference Frame** option chosen in the **Mass-Flow Inlet** dialog box.

7.3.5.2.6. Defining Static Pressure

The static pressure (termed the **Supersonic/Initial Gauge Pressure**) must be specified if the inlet flow is supersonic or if you plan to initialize the solution based on the pressure inlet boundary conditions. Solution initialization is discussed in *Initializing the Solution* (p. 1348).

The **Supersonic/Initial Gauge Pressure** is ignored by ANSYS FLUENT whenever the flow is subsonic. If you choose to initialize the flow based on the mass flow inlet conditions, the **Supersonic/Initial Gauge Pressure** will be used in conjunction with the specified stagnation quantities to compute initial values according to isentropic relations.

Remember that the static pressure value you enter is relative to the operating pressure set in the *Operating Conditions Dialog Box* (p. 1952). Note the comments in *Pressure Inputs and Hydrostatic Head* (p. 269) regarding hydrostatic pressure.

7.3.5.2.7. Defining the Flow Direction

You can define the flow direction at a mass flow inlet explicitly, or you can define the flow to be normal to the boundary.

The procedure for defining the flow direction is as follows, referring to [Figure 7.18 \(p. 284\)](#) :

1. Specify the flow direction by selecting **Direction Vector**, **Normal to Boundary**, or **Outward Normals** in the **Direction Specification Method** drop-down list.
2. If you selected **Direction Vector** and your geometry is 2D, go to the next step. If your geometry is 3D, choose **Cartesian (X, Y, Z)**, **Cylindrical (Radial, Tangential, Axial)**, **Local Cylindrical (Radial, Tangential, Axial)**, or **Local Cylindrical Swirl** in the **Coordinate System** drop-down list. See [Defining the Flow Direction \(p. 271\)](#) for information about Cartesian, cylindrical, local cylindrical, and local cylindrical swirl coordinate systems.
3. If you selected **Direction Vector**, set the vector components as follows:
 - If your geometry is 2D non-axisymmetric, or you chose to use a 3D **Cartesian** coordinate system, enter appropriate values for the **X**, **Y**, and (in 3D) **Z-Component of Flow Direction**.
 - If your geometry is 2D axisymmetric, or you chose to use a 3D **Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and (if you are modeling swirl or using cylindrical coordinates) **Tangential-Component of Flow Direction**.
 - If you chose to use a 3D **Local Cylindrical** coordinate system, enter appropriate values for the **Axial**, **Radial**, and **Tangential-Component of Flow Direction**, and then specify the **X**, **Y**, and **Z** components of **Axis Origin** and the **Axis Direction**.
 - If you chose to use a 3D **Local Cylindrical Swirl** coordinate system, enter appropriate values for the **Axial** and **Radial-Component of Flow Direction** in the axial and radial planes, and the **Tangential-Velocity**. Specify the **X**, **Y**, and **Z** components of the **Axis Origin** and the **Axis Direction**.

Important

Local Cylindrical Swirl should not be used for open channel boundary conditions and on the mixing plane boundaries, while using the mixing plane model.

4. If you selected **Normal to Boundary**, there are no additional inputs for flow direction.
-

Important

Note that if you are modeling axisymmetric swirl, the flow direction will be normal to the boundary; i.e., there will be no swirl component at the boundary for axisymmetric swirl.

5. If **Outward Normals** is selected, then the mass flow boundary will operate as an outflow, pumping flow out of the domain with the rate specified in the **Mass Flow Specification Method**. If the mass flow rate is specified, then by default, the fluxes on the boundary will be allowed to vary to preserve the flow profile out of the domain. At convergence, the total mass flow rate should match the specified value. If constant mass flux is needed rather than the default variable fluxes to preserve the profiles, then you can do so via the text command `define/boundary-conditions/bc-settings/mass-flow`. Answer no when asked to preserve profile while flow leaves.
-

Important

The mass flow boundary can also operate as an outflow using the **Direction Vector** flow specification method if the flow components are pointing away from the boundary.

7.3.5.2.8. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in [Determining Turbulence Parameters \(p. 262\)](#). Turbulence modeling is described in [Modeling Turbulence \(p. 683\)](#).

7.3.5.2.9. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature**. See [Defining Boundary Conditions for Radiation \(p. 772\)](#) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

7.3.5.2.10. Defining Species Mass or Mole Fractions

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mole Fractions** or **Species Mass Fractions**. For details, see [Defining Cell Zone and Boundary Conditions for Species \(p. 878\)](#).

7.3.5.2.11. Defining Non-Premixed Combustion Parameters

If you are using the non-premixed or partially premixed combustion model, you will set the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions), as described in [Defining Non-Premixed Boundary Conditions \(p. 946\)](#).

7.3.5.2.12. Defining Premixed Combustion Boundary Conditions

If you are using the premixed or partially premixed combustion model, you will set the **Progress Variable**, as described in [Setting Boundary Conditions for the Progress Variable \(p. 963\)](#).

7.3.5.2.13. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the mass flow inlet. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.5.2.14. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See [Modeling Open Channel Flows \(p. 1204\)](#) for details.

7.3.5.3. Default Settings at Mass Flow Inlet Boundaries

Default settings (in SI) for mass flow inlet boundary conditions are as follows:

Mass Flow-Rate	1
Total Temperature	300
Supersonic/Initial Gauge Pressure	0
X-Component of Flow Direction	1
Y-Component of Flow Direction	0

Z-Component of Flow Direction	0
Turbulent Kinetic Energy	1
Turbulent Dissipation Rate	1

7.3.5.4. Calculation Procedure at Mass Flow Inlet Boundaries

When mass flow boundary conditions are used for an inlet zone, a velocity is computed for each face in that zone, and this velocity is used to compute the fluxes of all relevant solution variables into the domain. With each iteration, the computed velocity is adjusted so that the correct mass flow value is maintained.

To compute this velocity, your inputs for mass flow rate, flow direction, static pressure, and total temperature are used.

There are two ways to specify the mass flow rate. The first is to specify the total mass flow rate, \dot{m} , for the inlet. The second is to specify the mass flux, ρv_n (mass flow rate per unit area). If a total mass flow rate is specified, ANSYS FLUENT converts it internally to a uniform mass flux by dividing the mass flow rate by the total inlet area:

$$\rho v_n = \frac{\dot{m}}{A} \quad (7-69)$$

If the direct mass flux specification option is used, the mass flux can be varied over the boundary by using profile files or user-defined functions. If the average mass flux is also specified (either explicitly by you or automatically by ANSYS FLUENT), it is used to correct the specified mass flux profile, as described earlier in this section.

Once the value of ρv_n at a given face has been determined, the density, ρ , at the face must be determined in order to find the normal velocity, v_n . The manner in which the density is obtained depends upon whether the fluid is modeled as an ideal gas or not. Each of these cases is examined below.

7.3.5.4.1. Flow Calculations at Mass Flow Boundaries for Ideal Gases

If the fluid is an ideal gas, the static temperature and static pressure are required to compute the density:

$$p = \rho R T \quad (7-70)$$

If the inlet is supersonic, the static pressure used is the value that has been set as a boundary condition. If the inlet is subsonic, the static pressure is extrapolated from the cells inside the inlet face.

The static temperature at the inlet is computed from the total enthalpy, which is determined from the total temperature that has been set as a boundary condition. The total enthalpy is given by

$$h_0(T_0) = h(T) + \frac{1}{2}v^2 \quad (7-71)$$

where the velocity magnitude is related to the mass flow rate given by [Equation 7-69](#) (p. 289) and the known user-specified flow direction vector. Using [Equation 7-70](#) (p. 289) to relate density to the (known)

static pressure and (unknown) temperature, [Equation 7–71 \(p. 289\)](#) can be solved to obtain the static temperature.

When the mass flow is used as an outflow with the profile preserving feature, a scaling factor of the specified mass flow rate over the computed mass flow rate at the boundary is used to scale the normal face velocities at the boundary. The other velocity components will be extrapolated from the interior. Flow variables such as pressure, temperature, species, or other scalar quantities will be also extrapolated from adjacent cell centers.

7.3.5.4.2. Flow Calculations at Mass Flow Boundaries for Incompressible Flows

When you are modeling incompressible flows, the static temperature is equal to the total temperature. The density at the inlet is either constant or readily computed as a function of the temperature and (optionally) the species mass or mole fractions. The velocity is then computed using [Equation 7–69 \(p. 289\)](#).

7.3.5.4.3. Flux Calculations at Mass Flow Boundaries

To compute the fluxes of all variables at the inlet, the flux velocity, v_n , is used along with the inlet value of the variable in question. For example, the flux of mass is ρv_n , and the flux of turbulence kinetic energy is $\rho k v_n$. These fluxes are used as boundary conditions for the corresponding conservation equations during the course of the solution.

7.3.6. Inlet Vent Boundary Conditions

Inlet vent boundary conditions are used to model an inlet vent with a specified loss coefficient, flow direction, and ambient (inlet) pressure and temperature.

7.3.6.1. Inputs at Inlet Vent Boundaries

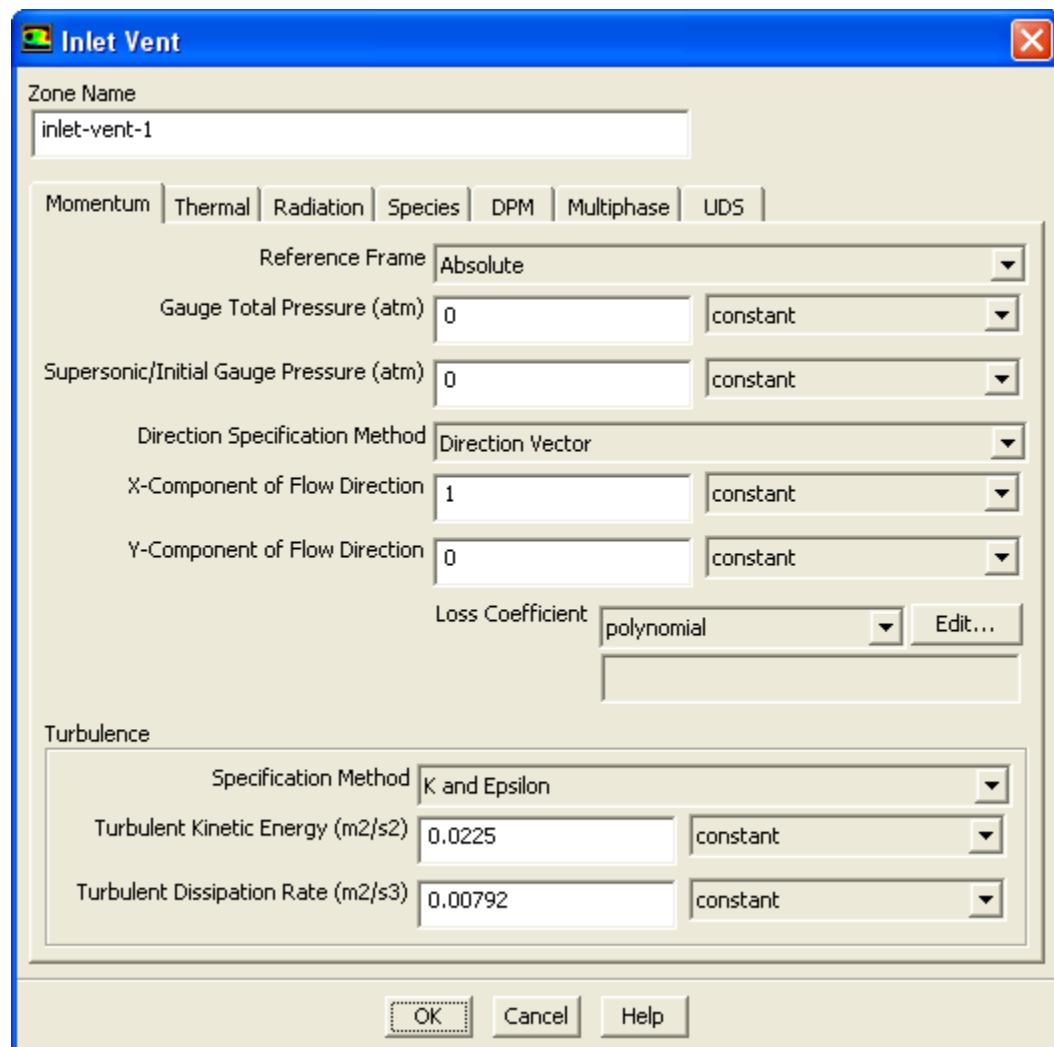

You will enter the following information for an inlet vent boundary:

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- loss coefficient
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the *Inlet Vent Dialog Box* (p. 1967) (Figure 7.19 (p. 291)), which is opened from the **Boundary Conditions** task page (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See *Inputs at Pressure Inlet Boundaries* (p. 268) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in *Modeling Open Channel Flows* (p. 1204).

Figure 7.19 The Inlet Vent Dialog Box

7.3.6.1.1. Specifying the Loss Coefficient

An inlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient that you supply. That is, the pressure drop, Δp , varies with the normal component of velocity through the vent, v , as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \quad (7-72)$$

where ρ is the fluid density, and k_L is the non-dimensional loss coefficient.

Important

Δp is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define the **Loss-Coefficient** across the vent as a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function of the normal velocity. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See *Defining Properties Using Temperature-Dependent Functions* (p. 417) for details.

7.3.7. Intake Fan Boundary Conditions

Intake fan boundary conditions are used to model an external intake fan with a specified pressure jump, flow direction, and ambient (intake) pressure and temperature.

7.3.7.1. Inputs at Intake Fan Boundaries

You will enter the following information for an intake fan boundary:

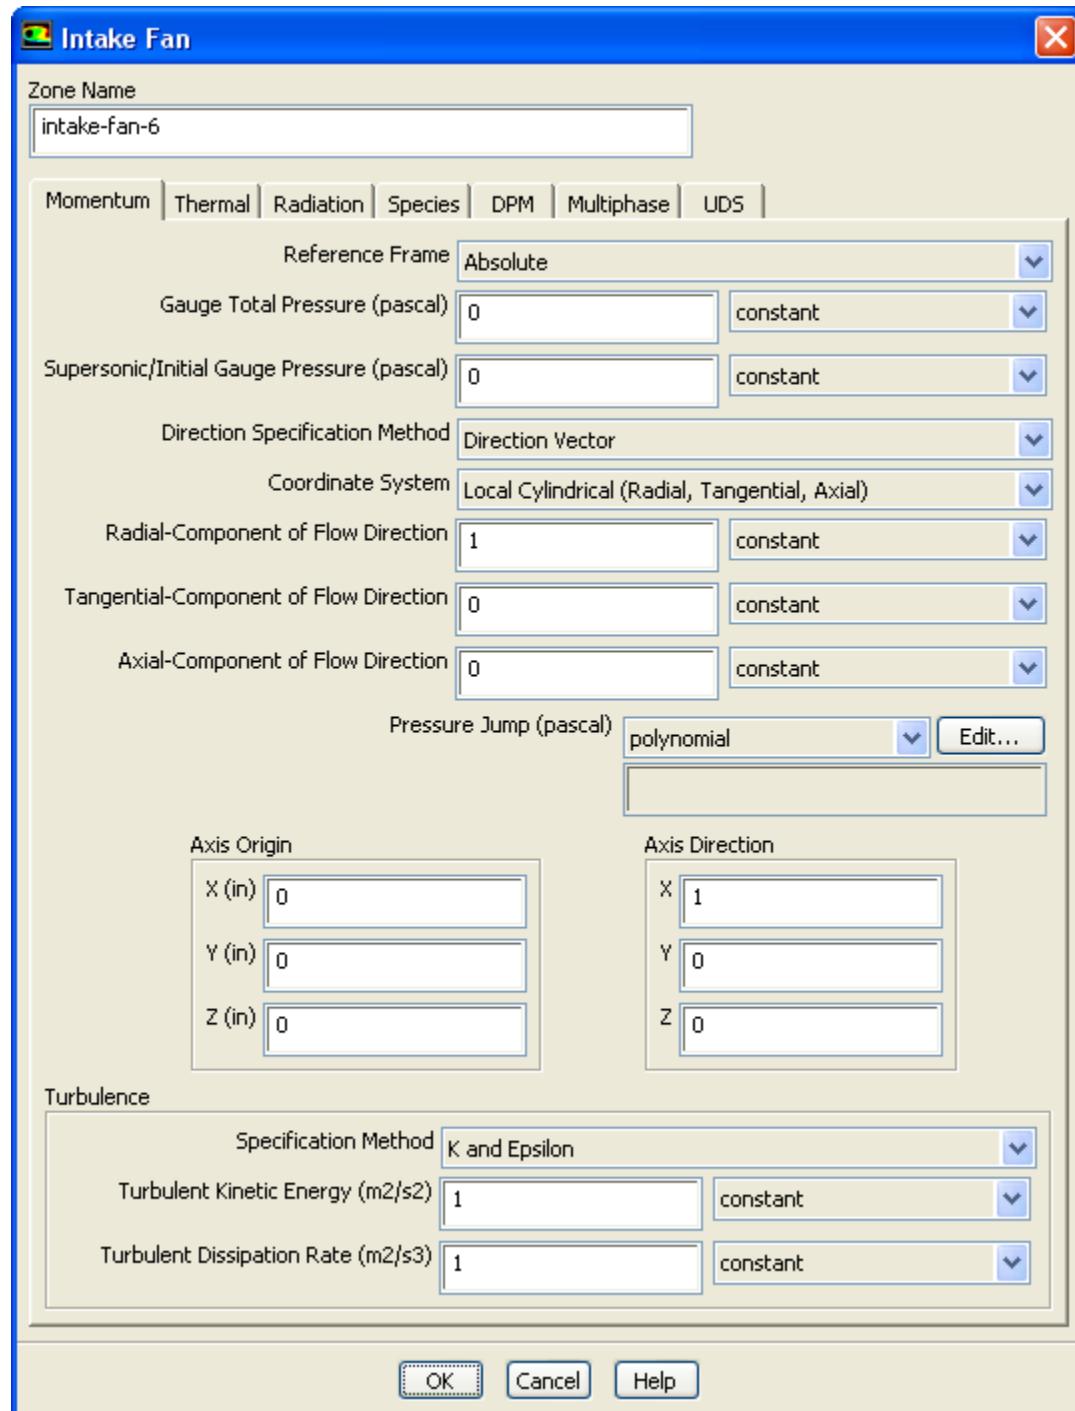

- type of reference frame
- total (stagnation) pressure
- total (stagnation) temperature
- flow direction
- static pressure
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- discrete phase boundary conditions (for discrete phase calculations)
- multiphase boundary conditions (for general multiphase calculations)
- pressure jump
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the *Intake Fan Dialog Box* (p. 1972) (shown in *Figure 7.20* (p. 293)), which is opened from the **Boundary Conditions** task page (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

The first 12 items listed above are specified in the same way that they are specified at pressure inlet boundaries. See *Inputs at Pressure Inlet Boundaries* (p. 268) for details. Specification of the pressure jump

is described here. Open channel boundary condition inputs are described in [Modeling Open Channel Flows \(p. 1204\)](#).

Figure 7.20 The Intake Fan Dialog Box

7.3.7.1.1. Specifying the Pressure Jump

An intake fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the velocity through the fan. In the case of reversed flow, the fan is treated like an outlet vent with a loss coefficient of unity.

You can define the **Pressure-Jump** across the fan as a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function of the normal velocity. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See *Defining Properties Using Temperature-Dependent Functions* (p. 417) for details.

7.3.8. Pressure Outlet Boundary Conditions

Pressure outlet boundary conditions require the specification of a static (gauge) pressure at the outlet boundary. The value of the specified static pressure is used only while the flow is subsonic. Should the flow become locally supersonic, the specified pressure will no longer be used; pressure will be extrapolated from the flow in the interior. All other flow quantities are extrapolated from the interior.

A set of “backflow” conditions is also specified should the flow reverse direction at the pressure outlet boundary during the solution process. Convergence difficulties will be minimized if you specify realistic values for the backflow quantities.

Several options in ANSYS FLUENT exist, where a radial equilibrium outlet boundary condition can be used (see *Defining Static Pressure* (p. 295) and a target mass flow rate for pressure outlets (see *Target Mass Flow Rate Option* (p. 300) for details) can be specified.

For an overview of flow boundaries, see *Flow Inlet and Exit Boundary Conditions* (p. 261).

7.3.8.1. Inputs at Pressure Outlet Boundaries

7.3.8.1.1. Summary

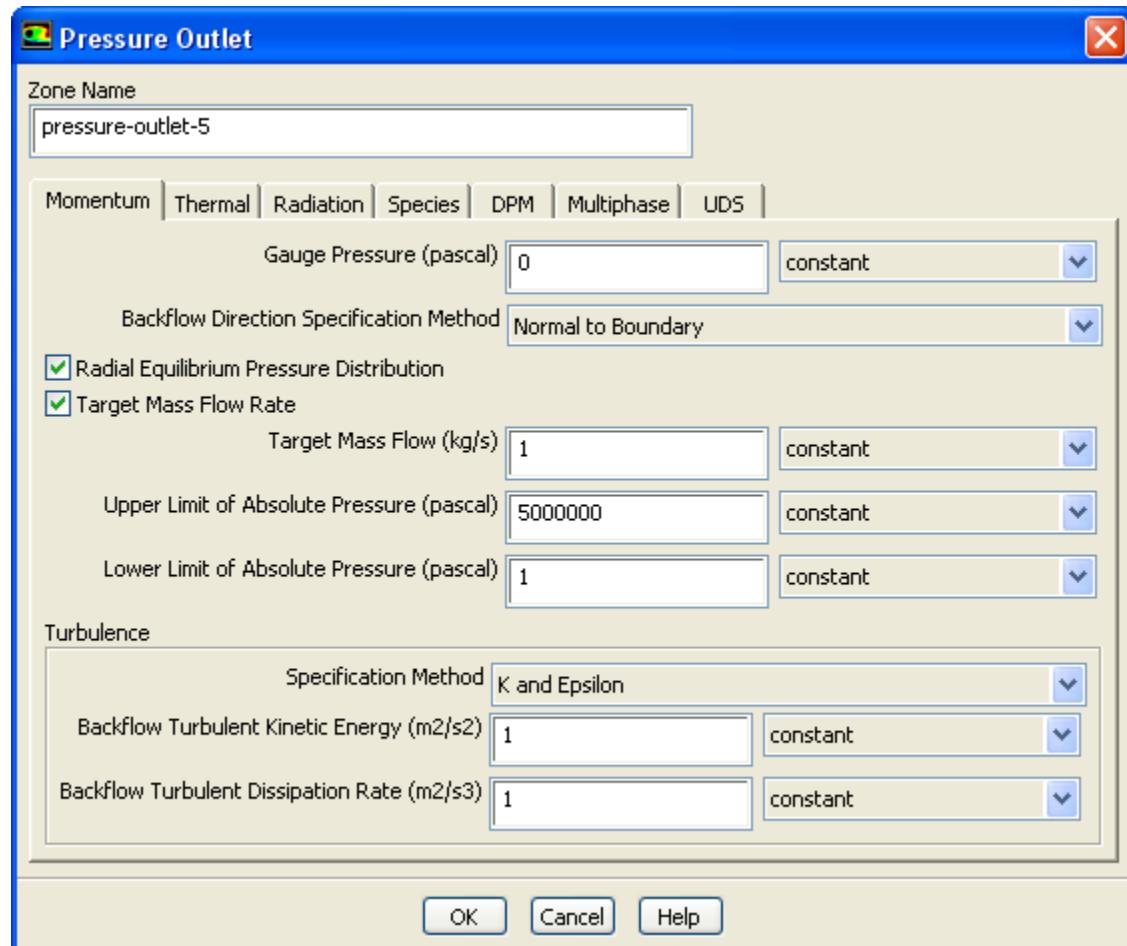

You will enter the following information for a pressure outlet boundary:

- static pressure
- backflow conditions
 - total (stagnation) temperature (for energy calculations)
 - backflow direction specification method
 - turbulence parameters (for turbulent calculations)
 - chemical species mass or mole fractions (for species calculations)
 - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
 - progress variable (for premixed or partially premixed combustion calculations)
 - multiphase boundary conditions (for general multiphase calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)
- non-reflecting boundary (for compressible density-based solver, see *General Non-Reflecting Boundary Conditions* (p. 368) for details)
- target mass flow rate (not available for multiphase flows)

All values are entered in the *Pressure Outlet Dialog Box* (p. 1999) (Figure 7.21 (p. 295)), which is opened from the **Boundary Conditions** task page (as described in *Setting Cell Zone and Boundary Condi-*

tions (p. 214)). Note that open channel boundary condition inputs are described in *Modeling Open Channel Flows* (p. 1204).

Figure 7.21 The Pressure Outlet Dialog Box

7.3.8.1.2. Defining Static Pressure

To set the static pressure at the pressure outlet boundary, enter the appropriate value for **Gauge Pressure** in the **Pressure Outlet** dialog box. This value will be used for subsonic flow only. Should the flow become locally supersonic, the pressure will be extrapolated from the upstream conditions.

Remember that the static pressure value you enter is relative to the operating pressure set in the *Operating Conditions Dialog Box* (p. 1952). Refer to *Pressure Inputs and Hydrostatic Head* (p. 269) regarding hydrostatic pressure.

ANSYS FLUENT also provides an option to use a radial equilibrium outlet boundary condition. To enable this option, turn on **Radial Equilibrium Pressure Distribution**. When this feature is active, the specified gauge pressure applies only to the position of minimum radius (relative to the axis of rotation) at the boundary. The static pressure on the rest of the zone is calculated from the assumption that radial velocity is negligible, so that the pressure gradient is given by

$$\frac{\partial p}{\partial r} = \frac{\rho v_\theta^2}{r} \quad (7-73)$$

where r is the distance from the axis of rotation and v_θ is the tangential velocity. Note that this boundary condition can be used even if the rotational velocity is zero. For example, it could be applied to the calculation of the flow through an annulus containing guide vanes.

Important

Note that the radial equilibrium outlet condition is available only for 3D and axisymmetric swirl calculations.

ANSYS FLUENT also provides an option to use an **Average Pressure Specification** method at the pressure outlet when using the pressure-based solver. This option allows the pressure along the outlet boundary to vary, but maintain an average equivalent to the specified value in the **Gauge Pressure** input field. The pressure variation allowed in this boundary implementation slightly diminishes the reflectivity of the boundary as compared with the default uniform pressure specification. For more details, see [Calculation Procedure at Pressure Outlet Boundaries \(p. 298\)](#).

Note

The **Average Pressure Specification** option is not available if the **Radial Equilibrium Pressure Distribution** option is enabled.

7.3.8.1.3. Defining Backflow Conditions

Backflow properties consistent with the models you are using will appear in the **Pressure Outlet** dialog box. The specified values will be used only if flow is pulled in through the outlet.

- The **Backflow Total Temperature** (in the **Thermal** tab) should be set for problems involving energy calculation.
- When the direction of the backflow re-entering the computational domain is known, and deemed to be relevant to the flow field solution, you can specify it choosing one of the options available in the **Backflow Direction Specification Method** drop-down list. The default value for this field is **Normal to Boundary**, and requires no further input. If you choose **Direction Vector**, the dialog box will expand to show the inputs for the components of the direction vector for the backflow, and if you are running the 3D version of ANSYS FLUENT, the dialog box will display a **Coordinate System** drop-down list. If you choose **From Neighboring Cell**, ANSYS FLUENT will determine the direction of the backflow using the direction of the flow in the cell layer adjacent to the pressure outlet.
- For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use in determining appropriate values for these inputs are provided in [Determining Turbulence Parameters \(p. 262\)](#). Turbulence modeling in general is described in [Modeling Turbulence \(p. 683\)](#).
- If you are modeling species transport, you will set the backflow species mass or mole fractions under **Species Mass Fractions** or **Species Mole Fractions**. For details, see [Defining Cell Zone and Boundary Conditions for Species \(p. 878\)](#).

- If you are modeling combustion using the non-premixed or partially premixed combustion model, you will set the backflow mixture fraction and variance values. See [Defining Non-Premixed Boundary Conditions \(p. 946\)](#) for details.
- If you are modeling combustion using the premixed or partially premixed combustion model, you will set the backflow **Progress Variable** value. See [Setting Boundary Conditions for the Progress Variable \(p. 963\)](#) for details.
- If you are using the VOF, mixture, or Eulerian model for multiphase flow, you will need to specify volume fractions for secondary phases and (for some models) additional parameters. See [Defining Multiphase Cell Zone and Boundary Conditions \(p. 1189\)](#) for details.
- If backflow occurs, the pressure you specified as the **Gauge Pressure** will be used as total pressure, so you need not specify a backflow pressure value explicitly. The flow direction will be based on your specification of the direction vector.

If the cell zone adjacent to the pressure outlet is moving (i.e., if you are using a moving reference frame, multiple reference frames, mixing planes, or sliding meshes) and you are using the pressure-based solver, the velocity in the dynamic contribution to total pressure (see [Equation 7–59 \(p. 270\)](#)) will be absolute or relative to the motion of the cell zone, depending on whether or not the **Absolute** velocity formulation is enabled in the **General** task page. For the density-based solver, the velocity in [Equation 7–59 \(p. 270\)](#) (or the Mach number in [Equation 7–60 \(p. 270\)](#)) is always in the absolute frame.

Important

Even if no backflow is expected in the converged solution, you should always set realistic values to minimize convergence difficulties in the event that backflow does occur during the calculation.

7.3.8.1.4. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optional) **External Black Body Temperature Method**. See [Defining Boundary Conditions for Radiation \(p. 772\)](#) for details. (The Rosseland radiation model does not require any boundary condition inputs.)

7.3.8.1.5. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure outlet. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.8.1.6. Defining Open Channel Boundary Conditions

If you are using the VOF model for multiphase flow and modeling open channel flows, you will need to specify the **Free Surface Level**, **Bottom Level**, and additional parameters. See [Modeling Open Channel Flows \(p. 1204\)](#) for details.

7.3.8.2. Default Settings at Pressure Outlet Boundaries

Default settings (in SI) for pressure outlet boundary conditions are as follows:

Gauge Pressure	0
Backflow Total Temperature	300

Backflow Turbulent Kinetic Energy	1
Backflow Turbulent Dissipation Rate	1

7.3.8.3. Calculation Procedure at Pressure Outlet Boundaries

At pressure outlets, ANSYS FLUENT uses the boundary condition pressure you input as the static pressure of the fluid at the outlet plane, P_s , and extrapolates all other conditions from the interior of the domain.

7.3.8.3.1. Pressure-Based Solver Implementation

In the pressure-based solver, by default, the face pressure at the boundary is the same as the value specified in the **Pressure Outlet** dialog box. When the **Average Pressure Specification** option is enabled, the face pressure value P_f for subsonic flows at the outlet boundary is computed using the following expressions:

$$P_f = 0.5 (P_c + P_e) + dp \quad (7-74)$$

where

P_c = interior cell pressure at neighboring exit face, f

P_e = specified exit pressure

dp = difference in the pressure value between the specified pressure P_e and the latest average pressure for the boundary defined by [Equation 7-75 \(p. 298\)](#)

$$dp = \left(P_e - \frac{\sum_{i=1}^{i=n_face} 0.5 (P_c + P_e) (Area)}{\sum_{i=1}^{i=n_face} Area} \right) \quad (7-75)$$

Typically, this averaging option should be used when the flow at the boundary exit is subsonic. If the flow is fully supersonic, then the **Average Pressure Specification** has no effect. If the flow at the exit is partially supersonic, then the face pressure value at the supersonic flow location will be extrapolated from the interior cells and will be included in the averaging procedure.

Note

If a geometric opening was modeled as a multiple pressure-outlet boundary condition with the average pressure specification, then the averaging is applied on each individual boundary condition and not over the entire geometric opening.

The limitations that exist when using the **Average Pressure Specification** option are listed below:

- The **Average Pressure Specification** option is not available when **Radial Equilibrium Pressure Distribution** is enabled.
- If the pressure outlet boundary is part of the mixing plane model pair, then the **Average Pressure Specification** option will not be available for that particular boundary zone.

- The **Average Pressure Specification** option is not available with multiphase flows.
- If a profile is specified for the **Gauge Pressure** field instead of a constant value, then the **Average Pressure Specification** will not be applied.

7.3.8.3.2. Density-Based Solver Implementation

In the density-based solver, there are three pressure specification methods available:

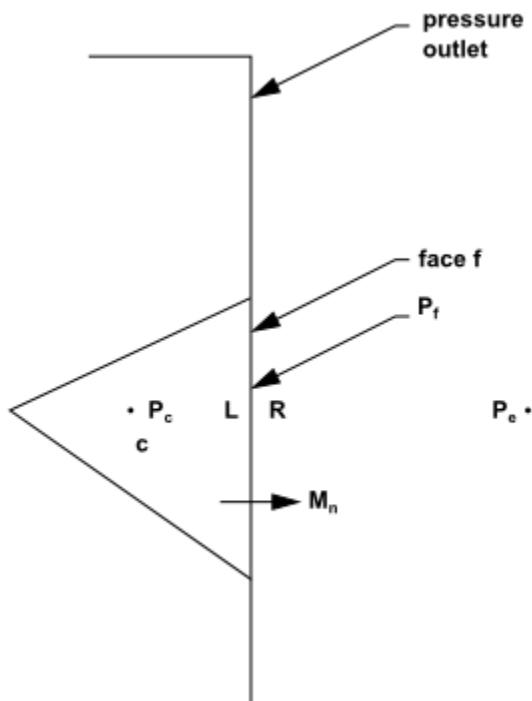

1. Weak enforcement of average pressure (default)
2. Strong enforcement of average pressure
3. Direct pressure specification

The specification methods can be changed from the text user interface:

```
define/boundary-conditions/bc-settings/pressure-outlet
```

In the direct pressure specifications, the face pressure at the boundary is same as the value specified in the **Pressure Outlet** dialog box. The implementation is similar to that in the pressure-based solver. However, the default specification method in the density-based solver is the weak enforcement of average pressure. In this implementation for subsonic flow, the pressure at the faces of the outlet boundary is computed using a weighted average of the left and right state of the face boundary. This weighting is a blend of fifth-order polynomials based on the exit face normal Mach number [46] ([p. 2369](#)). Therefore, the face pressure P_f is a function of (P_c, P_e, M_n) , where P_c is the interior cell pressure neighboring the exit face f , P_e is the specified exit pressure, and M_n is the face normal Mach number.

Figure 7.22 Pressures at the Face of a Pressure Outlet Boundary

For incompressible flows, the face pressure is computed as an average between the specified pressure and the interior pressure.

$$P_f = 0.5 (P_c + P_e) \quad (7-76)$$

In this boundary implementation, the exit pressure is not constant along the pressure outlet boundary. However, upon flow convergence, the average boundary pressure will be close to the specified static exit pressure.

In general the weak average pressure enforcement works well in most flow situations. However, for cases where the computed average pressure value does not match the specified pressure value at the boundary (typically this happens when we have a coarse mesh and stretched cells near the pressure-outlet boundary) then the strong average pressure enforcement can be used to guarantee the specified pressure equal to the boundary average pressure. The strong enforcement is achieved by adding locally the difference in pressure value between the latest average pressure for the boundary and the face pressure obtained from weak enforcement. The strong enforcement is applicable when the flow is fully subsonic throughout the boundary.

For all of the three pressure specification methods, if the flow becomes locally supersonic, then the face pressure values P_f are extrapolated from the interior cell pressure.

Important

When one of the NRBC model, none of the above specification methods are relevant since face pressure will be obtained from special NRBC procedures.

Important

If you are specifying a profile rather than a constant value for exit pressure, then you should not use this weak or strong enforcement of average pressure boundary. Instead, you should use the direct pressure specification method.

7.3.8.4. Other Optional Inputs at Pressure Outlet Boundaries

7.3.8.4.1. Non-Reflecting Boundary Conditions Option

One of the options that may be used at pressure outlets is non-reflecting boundary conditions (NRBC option) is used when waves are made to pass through the boundaries while avoiding false reflections. Details of non-reflecting boundary conditions can be found in [General Non-Reflecting Boundary Conditions \(p. 368\)](#) of this chapter.

7.3.8.4.2. Target Mass Flow Rate Option

The simple Bernoulli's equation is used to adjust the pressure at every iteration on a pressure outlet zone in order to meet the desired mass flow rate. The change in pressure, based on Bernoulli's equation is given by the following equation:

$$dP = 0.5 \rho_{ave} \left(\dot{m}^2 - \dot{m}_{req}^2 \right) / \left(\rho_{ave} A \right)^2 \quad (7-77)$$

where dP is the change in pressure, \dot{m} is the current computed mass flow rate at the pressure-outlet boundary, \dot{m}_{req} is the required mass flow rate, ρ_{ave} is the computed average density at the pressure-outlet boundary, and A is the area of the pressure-outlet boundary.

7.3.8.4.3. Limitations

- The target mass flow rate option is not available with multiphase flows or when any of the non-reflecting boundary conditions models are used.
- If the pressure-outlet zone is used in the mixing-plane model, the target mass flow rate option will not be available for that particular zone.
- The pressure outlet will not achieve the target mass flow rate if the flow becomes choked (i.e., the Mach number of the fluid in the pressure-outlet zone becomes equal to 1).

7.3.8.4.4. Target Mass Flow Rate Settings

To use the target mass flow rate option

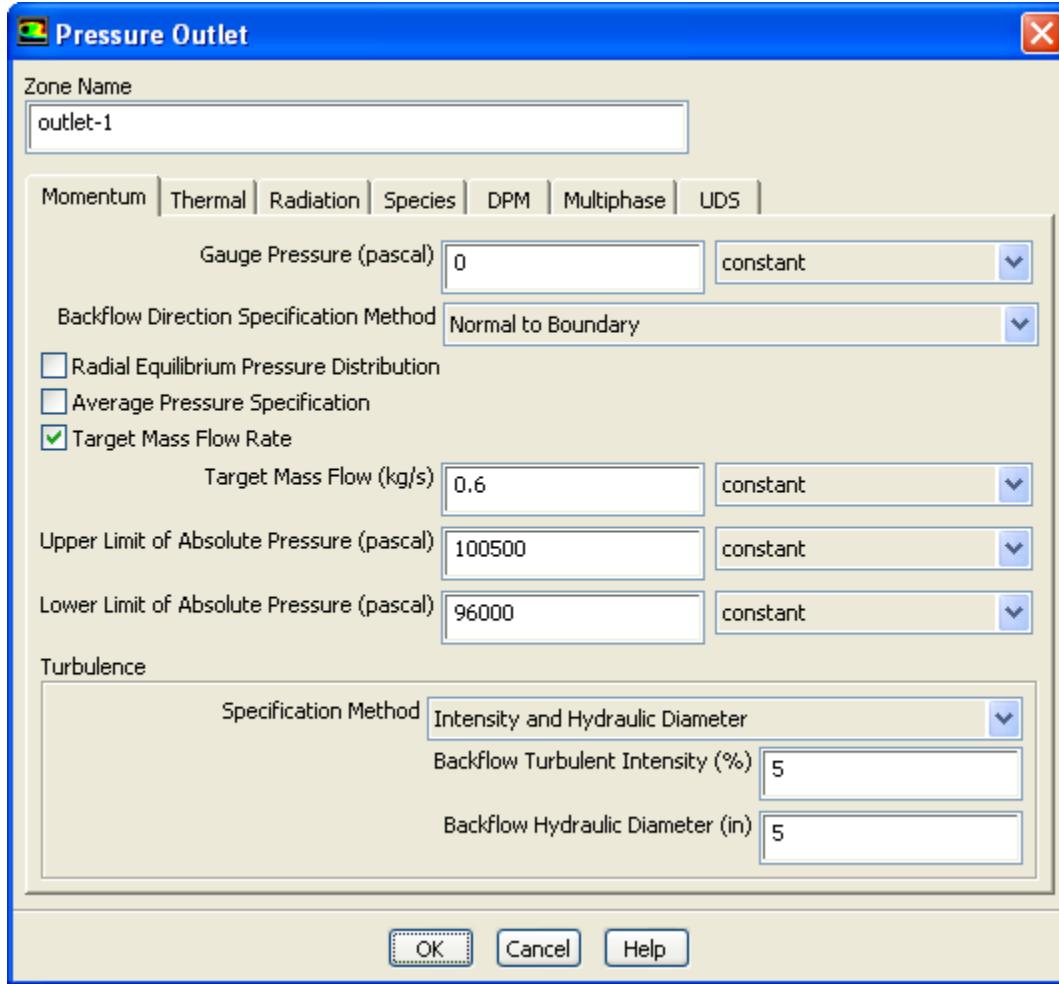

1. Enable **Target Mass Flow Rate** in the **Pressure Outlet** dialog box.
2. Specify the **Target Mass Flow** as either a constant value or hook a UDF to set the target mass flow rate.

The settings for the target mass flow rate option can be accessed from the target-mass-flow-rate-settings text command:

```
define → boundary-conditions → target-mass-flow-rate-settings
```

You will be prompted to

- a. Set the under-relaxation factor (the default setting is 0.05).
 - b. Enable the targeted mass flow rate verbosity (the default is no). If enabled, it prints to the console window the required mass flow rate, computed mass flow rate, mean pressure, the new pressure imposed on the outlet, and the change in pressure in SI units.
3. In the **Pressure Outlet** dialog box, specify the **Upper Limit of Absolute Pressure** and **Lower Limit of Absolute Pressure**. Specifying the range of the pressure limits improves convergence in cases with a large number of outlet boundaries, which have different pressure variations on different boundaries. You can also use the define/boundary-conditions/pressure-outlet text command to specify these limits.

Figure 7.23 The Pressure Outlet Dialog Box with the Target Mass Flow Rate Option Enabled

7.3.8.4.5. Solution Strategies When Using the Target Mass Flow Rate Option

If convergence difficulties are encountered or if the solution is not converging at the desired mass flow rate, then try to lower the under-relaxation factor from the default value. Otherwise, you can use the alternate method to converge at the required mass flow rate.

In some cases, you may want to switch off the target mass flow rate option initially, then guess an exit pressure that will bring the solution closer to the target mass flow rate. After the solution stabilizes, you can turn on the target mass flow rate option and iterate to convergence. For many complex flow problems, this strategy is usually very successful.

The use of Full Multigrid Initialization is also very helpful in obtaining a good starting solution and in general will reduce the time required to get a converged solution on a target mass flow rate. For further information on Full Multigrid Initialization, see [Full Multigrid \(FMG\) Initialization \(p. 1353\)](#).

7.3.8.4.6. Setting Target Mass Flow Rates Using UDFs

For some unsteady problems it is desirable that the target mass flow rate be a function of the physical flow time. This enforcement of boundary condition can be done by attaching a UDF with `DEFINE_PROFILE` functions to the target mass flow rate field.

Important

Note that the mass flow rate profile is a function of time and only one constant value should be applied to all zone faces at a given time.

An example of a simple UDF using a `DEFINE_PROFILE` that will adjust the mass flow rate can be found in `DEFINE_PROFILE` in the [UDF Manual](#).

7.3.9. Pressure Far-Field Boundary Conditions

Pressure far-field conditions are used in ANSYS FLUENT to model a free-stream condition at infinity, with free-stream Mach number and static conditions being specified. The pressure far-field boundary condition is often called a characteristic boundary condition, since it uses characteristic information (Riemann invariants) to determine the flow variables at the boundaries.

7.3.9.1. Limitations

Note the following limitations and restrictions when using pressure far-field boundary conditions:

- This boundary condition is applicable only when the density is calculated using the ideal-gas law (see [Density \(p. 421\)](#)). Using it for other flows is not permitted. To effectively approximate true infinite-extent conditions, you must place the far-field boundary far enough from the object of interest. For example, in lifting airfoil calculations, it is not uncommon for the far-field boundary to be a circle with a radius of 20 chord lengths.
- It is incompatible with the multiphase models (VOF, mixture, and Eulerian) that are available with the pressure-based solver.
- It cannot be applied to flows that employ constant density, the real gas model, and the wet steam model, which are available in the density-based solver.

For an overview of flow boundaries, see [Flow Inlet and Exit Boundary Conditions \(p. 261\)](#).

7.3.9.2. Inputs at Pressure Far-Field Boundaries

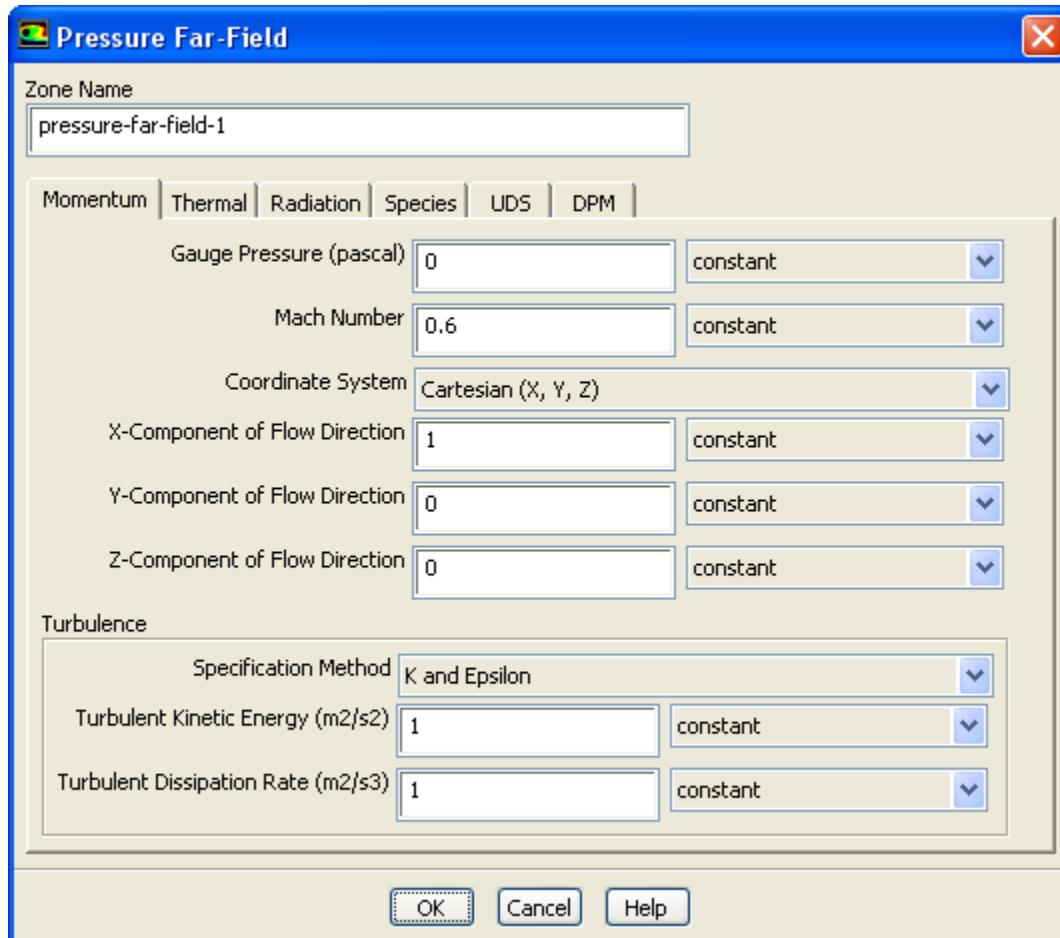

7.3.9.2.1. Summary

You will enter the following information for a pressure far-field boundary:

- static pressure
- Mach number
- temperature
- flow direction
- turbulence parameters (for turbulent calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- chemical species mass or mole fractions (for species calculations)
- discrete phase boundary conditions (for discrete phase calculations)

All values are entered in the *Pressure Far-Field Dialog Box* (p. 1990) (*Figure 7.24* (p. 304)), which is opened from the **Boundary Conditions** task page (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

Figure 7.24 The Pressure Far-Field Dialog Box

7.3.9.2.2. Defining Static Pressure, Mach Number, and Static Temperature

To set the static pressure and temperature at the far-field boundary in the **Pressure Far-Field** dialog box, enter the appropriate values for **Gauge Pressure** and **Mach Number** in the **Momentum** tab. The Mach number can be subsonic, sonic, or supersonic. Set the **Temperature** in the **Thermal** tab.

7.3.9.2.3. Defining the Flow Direction

You can define the flow direction at a pressure far-field boundary by setting the components of the direction vector. If your geometry is 2D non-axisymmetric enter appropriate values for **X** and **Y** in the **Pressure Far-Field** dialog box (*Figure 7.24* (p. 304)). If your geometry is 2D axisymmetric, enter the appropriate values for **Axial**, **Radial**, and (if you are modeling axisymmetric swirl) **Tangential-Component of Flow Direction**.

If your geometry is 3D, you can choose a **Coordinate System** that is **Cartesian**, **Cylindrical**, or **Local Cylindrical**. In the Cartesian coordinate system, enter the appropriate values for **X**, **Y**, and **Z-Component of Flow Direction**. If the direction cosine data on the boundary is available, then use the cylindrical or local cylindrical coordinate system and specify the **Axial**, **Radial**, **Tangential-Component of Flow Dir-**

ection. For **Cylindrical**, axis parameters need to be specified on the adjacent cell zone of the boundary face. For **Local Cylindrical Swirl**, specify the **Axis Origin** and **Axis Direction**.

7.3.9.2.4. Defining Turbulence Parameters

For turbulent calculations, there are several ways in which you can define the turbulence parameters. Instructions for deciding which method to use and determining appropriate values for these inputs are provided in *Determining Turbulence Parameters* (p. 262). Turbulence modeling is described in *Modeling Turbulence* (p. 683).

7.3.9.2.5. Defining Radiation Parameters

If you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature Method**. See *Defining Boundary Conditions for Radiation* (p. 772) for details.

7.3.9.2.6. Defining Species Transport Parameters

If you are modeling species transport, you will set the species mass or mole fractions under **Species Mass Fractions** or **Species Mole Fractions**. See *Defining Cell Zone and Boundary Conditions for Species* (p. 878) for details.

7.3.9.3. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the pressure far-field boundary. See *Setting Boundary Conditions for the Discrete Phase* (p. 1124) for details.

7.3.9.4. Default Settings at Pressure Far-Field Boundaries

Default settings (in SI) for pressure far-field boundary conditions are as follows:

Gauge Pressure	0
Mach Number	0.6
Temperature	300
X-Component of Flow Direction	1
Y-Component of Flow Direction	0
Z-Component of Flow Direction	0
Turbulent Kinetic Energy	1
Turbulent Dissipation Rate	1

7.3.9.5. Calculation Procedure at Pressure Far-Field Boundaries

The pressure far-field boundary condition is a non-reflecting boundary condition based on the introduction of Riemann invariants (i.e., characteristic variables) for a one-dimensional flow normal to the boundary. For flow that is subsonic there are two Riemann invariants, corresponding to incoming and outgoing waves:

$$R_{\infty} = v_{n_{\infty}} - \frac{2c_{\infty}}{\gamma - 1} \quad (7-78)$$

$$R_i = v_{n_i} + \frac{2c_i}{\gamma - 1} \quad (7-79)$$

where v_n is the velocity magnitude normal to the boundary, c is the local speed of sound and γ is the ratio of specific heats (ideal gas). The subscript ∞ refers to conditions being applied at infinity (the boundary conditions), and the subscript i refers to conditions in the interior of the domain (i.e., in the cell adjacent to the boundary face). These two invariants can be added and subtracted to give the following two equations:

$$v_n = \frac{1}{2} (R_i + R_{\infty}) \quad (7-80)$$

$$c = \frac{\gamma - 1}{4} (R_i - R_{\infty}) \quad (7-81)$$

where v_n and c become the values of normal velocity and sound speed applied on the boundary. At a face through which flow exits, the tangential velocity components and entropy are extrapolated from the interior; at an inflow face, these are specified as having free-stream values. Using the values for v_n , c , tangential velocity components, and entropy the values of density, velocity, temperature, and pressure at the boundary face can be calculated.

7.3.10. Outflow Boundary Conditions

Outflow boundary conditions in ANSYS FLUENT are used to model flow exits where the details of the flow velocity and pressure are not known prior to solving the flow problem. You do not define any conditions at outflow boundaries (unless you are modeling radiative heat transfer, a discrete phase of particles, or split mass flow): ANSYS FLUENT extrapolates the required information from the interior. It is important, however, to understand the limitations of this boundary type.

Important

Note that outflow boundaries cannot be used in the following cases:

- If a problem includes pressure inlet boundaries; use pressure outlet boundary conditions (see [Pressure Outlet Boundary Conditions \(p. 294\)](#)) instead.
- If you are modeling compressible flow.
- If you are modeling unsteady flows with varying density, even if the flow is incompressible.
- With the multiphase models (Eulerian, mixture, and VOF (except when modeling open channel flow, as described in [Open Channel Flow](#) in the [Theory Guide](#)).

For an overview of flow boundaries, see [Flow Inlet and Exit Boundary Conditions \(p. 261\)](#).

7.3.10.1. ANSYS FLUENT's Treatment at Outflow Boundaries

The boundary conditions used by ANSYS FLUENT at outflow boundaries are as follows:

- A zero diffusion flux for all flow variables.
- An overall mass balance correction.

The zero diffusion flux condition applied at outflow cells means that the conditions of the outflow plane are extrapolated from within the domain and have no impact on the upstream flow. The extrapolation procedure used by ANSYS FLUENT updates the outflow velocity and pressure in a manner that is consistent with a fully-developed flow assumption, as noted below, when there is no area change at the outflow boundary.

The zero diffusion flux condition applied by ANSYS FLUENT at outflow boundaries is approached physically in fully-developed flows. Fully-developed flows are flows in which the flow velocity profile (and/or profiles of other properties such as temperature) is unchanging in the flow direction.

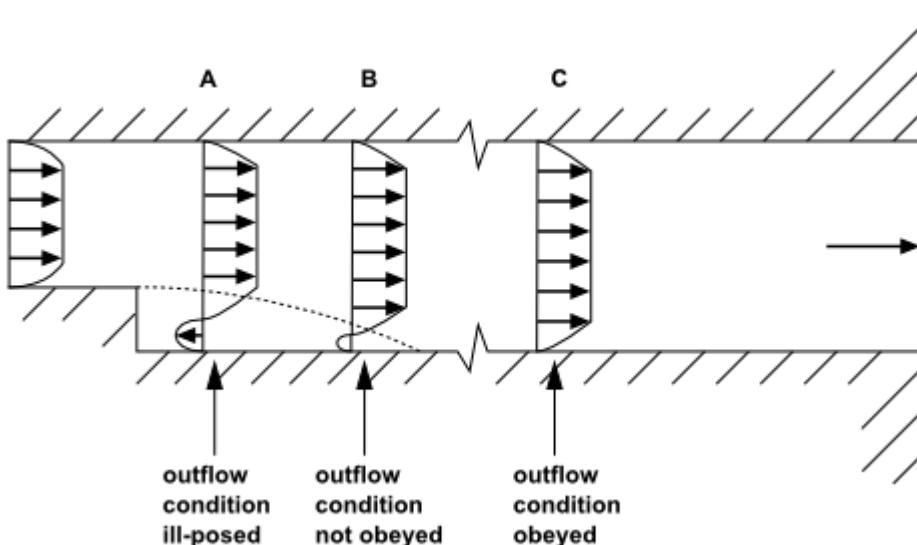

It is important to note that gradients in the cross-stream direction may exist at an outflow boundary. Only the diffusion fluxes in the direction normal to the exit plane are assumed to be zero.

7.3.10.2. Using Outflow Boundaries

As noted in [ANSYS FLUENT's Treatment at Outflow Boundaries \(p. 307\)](#), the outflow boundary condition is obeyed in fully-developed flows where the diffusion flux for all flow variables in the exit direction are zero. However, you may also define outflow boundaries at physical boundaries where the flow is not fully developed—and you can do so with confidence if the assumption of a zero diffusion flux at the exit is expected to have a small impact on your flow solution. The appropriate placement of an outflow boundary is described by example below.

- Outflow boundaries where normal gradients are negligible: [Figure 7.25 \(p. 307\)](#) shows a simple two-dimensional flow problem and several possible outflow boundary location choices. Location C shows the outflow boundary located upstream of the plenum exit but in a region of the duct where the flow is fully-developed. At this location, the outflow boundary condition is exactly obeyed.

Figure 7.25 Choice of the Outflow Boundary Condition Location

- Ill-posed outflow boundaries: Location B in [Figure 7.25 \(p. 307\)](#) shows the outflow boundary near the reattachment point of the recirculation in the wake of the backward-facing step. This choice of outflow boundary condition is ill-posed as the gradients normal to the exit plane are quite large at this point and can be expected to have a significant impact on the flow field upstream. Because the outflow boundary condition ignores these axial gradients in the flow, location B is a poor choice for an outflow boundary. The exit location should be moved downstream from the reattachment point.

[Figure 7.25 \(p. 307\)](#) shows a second ill-posed outflow boundary at location A. Here, the outflow is located where flow is pulled into the ANSYS FLUENT domain through the outflow boundary. In situations like this the ANSYS FLUENT calculation typically does not converge and the results of the calculation have no validity. This is because when flow is pulled into the domain through an outflow, the mass flow rate through the domain is “floating” or undefined. In addition, when flow enters the domain through an outflow boundary, the scalar properties of the flow are not defined. For example, the temperature of the flow pulled in through the outflow is not defined. (ANSYS FLUENT chooses the temperature using the temperature of the fluid adjacent to the outflow, inside the domain.) Thus you should view all calculations that involve flow entering the domain through an outflow boundary with skepticism. For such calculations, pressure outlet boundary conditions (see [Pressure Outlet Boundary Conditions \(p. 294\)](#)) are recommended.

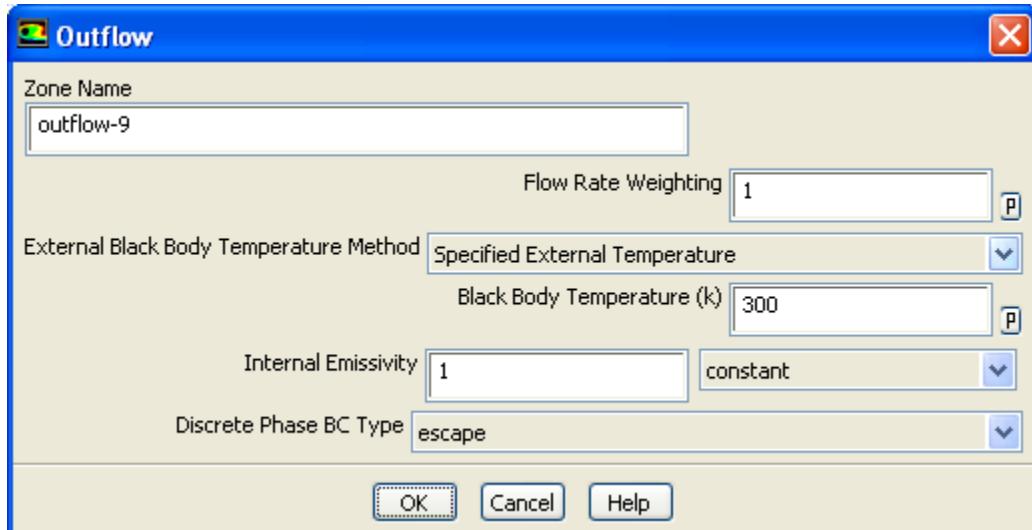

Important

Note that convergence may be affected if there is recirculation through the outflow boundary at any point during the calculation, even if the final solution is not expected to have any flow reentering the domain. This is particularly true of turbulent flow simulations.

7.3.10.3. Mass Flow Split Boundary Conditions

In ANSYS FLUENT, it is possible to use multiple outflow boundaries and specify the fractional flow rate through each boundary. In the [Outflow Dialog Box \(p. 1982\)](#), set the **Flow Rate Weighting** to indicate what portion of the outflow is through the boundary.

Figure 7.26 The Outflow Dialog Box

The **Flow Rate Weighting** is a weighting factor:

$$\text{percentage flow} = \frac{\text{Flow Rate Weighting specified on boundary}}{\text{sum of all Flow Rate Weightings}} \quad (7-82)$$

By default, the **Flow Rate Weighting** for all outflow boundaries is set to 1. If the flow is divided equally among all of your outflow boundaries (or if you have just one outflow boundary), you need not change the settings from the default; ANSYS FLUENT will scale the flow rate fractions to obtain equal fractions through all outflow boundaries. Thus, if you have two outflow boundaries and you want half of the flow to exit through each one, no inputs are required from you. If, however, you want 75% of the flow to exit through one, and 25% through the other, you will need to explicitly specify both **Flow Rate Weighting** values, i.e., 0.75 for one boundary and 0.25 for the other.

Important

If you specify a **Flow Rate Weighting** of 0.75 at the first exit and leave the default **Flow Rate Weighting** (1.0) at the second exit, then the flow through each boundary will be

$$\text{Boundary 1} = \frac{0.75}{0.75 + 1.0} = 0.429 \text{ or } 42.9\%$$

$$\text{Boundary 2} = \frac{1.0}{0.75 + 1.0} = 0.571 \text{ or } 57.1\%$$

7.3.10.4. Other Inputs at Outflow Boundaries

7.3.10.4.1. Radiation Inputs at Outflow Boundaries

In general, there are no boundary conditions for you to set at an outflow boundary. If, however, you are using the P-1 radiation model, the DTRM, the DO model, or the surface-to-surface model, you will set the **Internal Emissivity** and (optionally) **External Black Body Temperature Method** in the **Outflow** dialog box. These parameters are described in [Defining Boundary Conditions for Radiation \(p. 772\)](#). The default value for **Internal Emissivity** is 1 and the default value for **Black Body Temperature** is 300.

7.3.10.4.2. Defining Discrete Phase Boundary Conditions

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the outflow boundary. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.11. Outlet Vent Boundary Conditions

Outlet vent boundary conditions are used to model an outlet vent with a specified loss coefficient and ambient (discharge) pressure and temperature.

7.3.11.1. Inputs at Outlet Vent Boundaries

You will enter the following information for an outlet vent boundary:

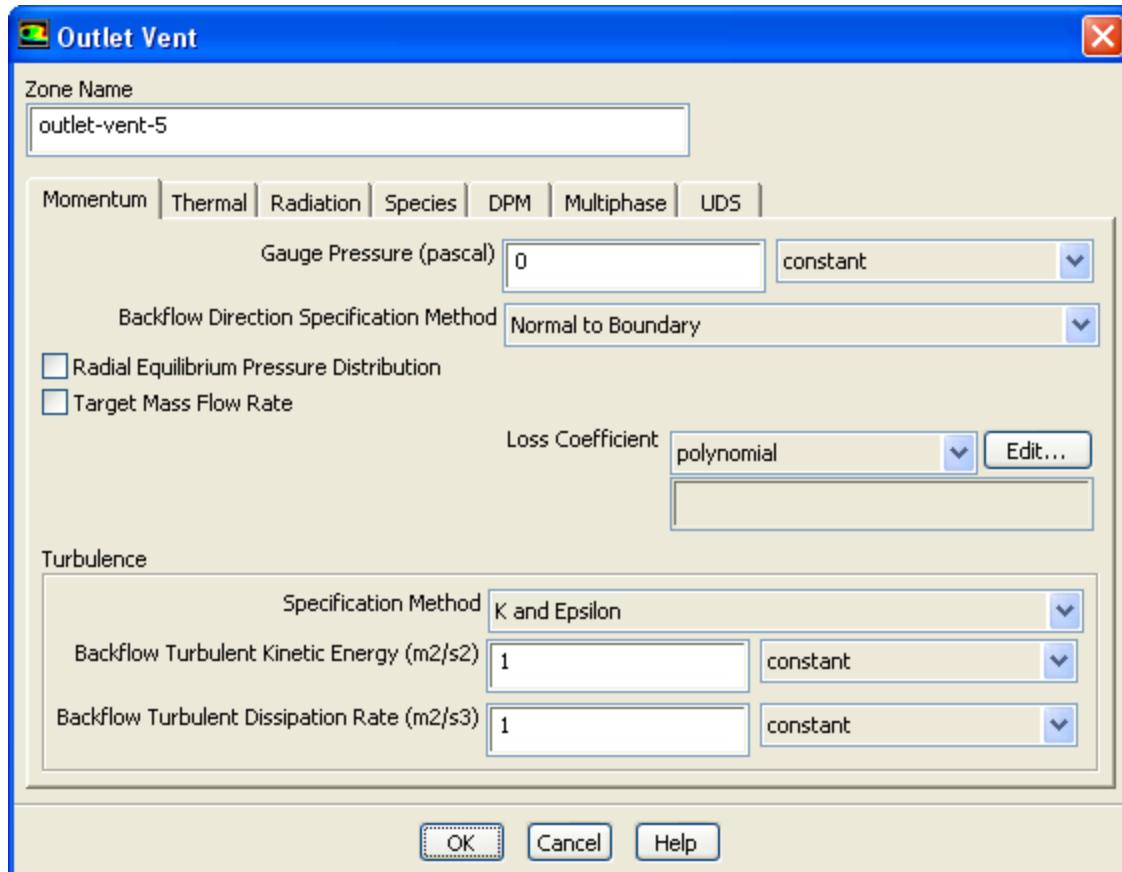

- static pressure
- backflow conditions
 - total (stagnation) temperature (for energy calculations)

- turbulence parameters (for turbulent calculations)
- chemical species mass or mole fractions (for species calculations)
- mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
- progress variable (for premixed or partially premixed combustion calculations)
- multiphase boundary conditions (for general multiphase calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
- loss coefficient
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

All values are entered in the [Outlet Vent Dialog Box \(p. 1984\)](#) (*Figure 7.27 (p. 310)*), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See [Inputs at Pressure Outlet Boundaries \(p. 294\)](#) for details. Specification of the loss coefficient is described here. Open channel boundary condition inputs are described in [Modeling Open Channel Flows \(p. 1204\)](#).

Figure 7.27 The Outlet Vent Dialog Box

7.3.11.1.1. Specifying the Loss Coefficient

An outlet vent is considered to be infinitely thin, and the pressure drop through the vent is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient which you supply. That is, the pressure drop, Δp , varies with the normal component of velocity through the vent, v , as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \quad (7-83)$$

where ρ is the fluid density, and k_L is the nondimensional loss coefficient.

Important

Δp is the pressure drop in the direction of the flow; therefore the vent will appear as a resistance even in the case of backflow.

You can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Loss Coefficient** across the vent. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See *Defining Properties Using Temperature-Dependent Functions* (p. 417) for details.

7.3.12. Exhaust Fan Boundary Conditions

Exhaust fan boundary conditions are used to model an external exhaust fan with a specified pressure jump and ambient (discharge) pressure.

7.3.12.1. Inputs at Exhaust Fan Boundaries

You will enter the following information for an exhaust fan boundary:

- static pressure
- backflow conditions
 - total (stagnation) temperature (for energy calculations)
 - turbulence parameters (for turbulent calculations)
 - chemical species mass or mole fractions (for species calculations)
 - mixture fraction and variance (for non-premixed or partially premixed combustion calculations)
 - progress variable (for premixed or partially premixed combustion calculations)
 - multiphase boundary conditions (for general multiphase calculations)
 - user-defined scalar boundary conditions (for user-defined scalar calculations)
- radiation parameters (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
- pressure jump
- open channel flow parameters (for open channel flow calculations using the VOF multiphase model)

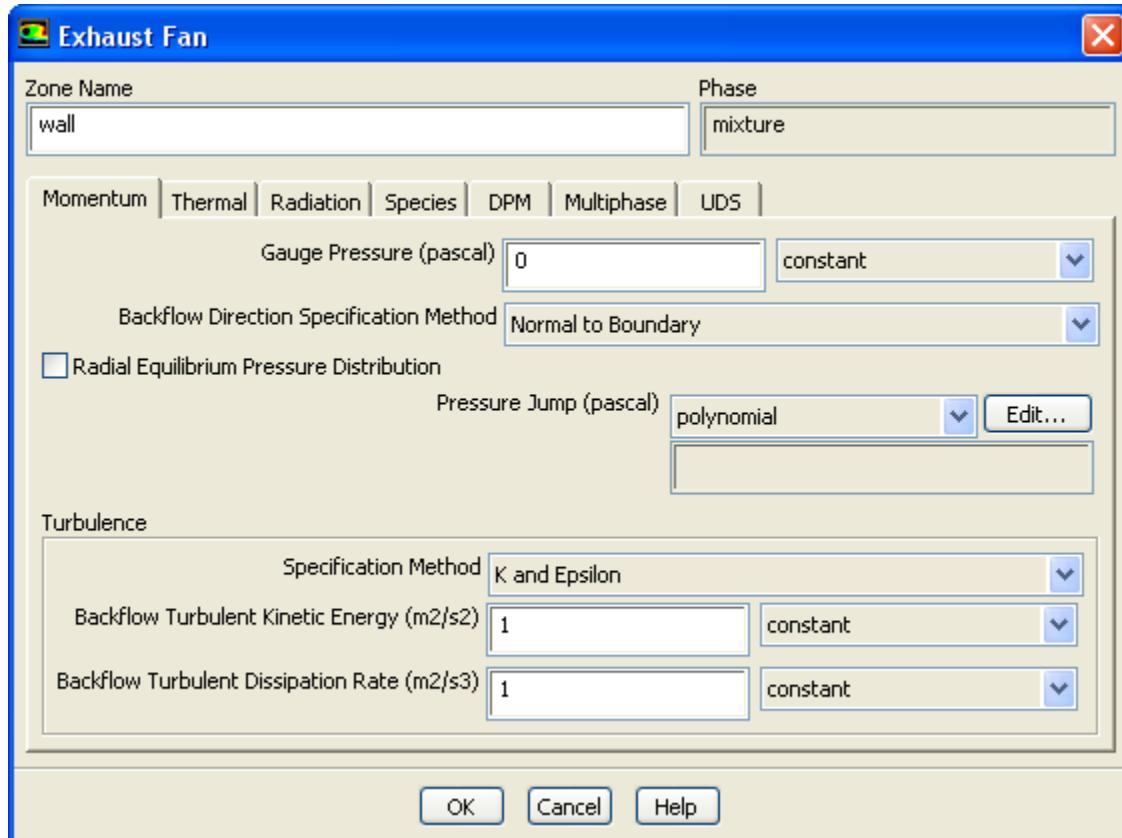

All values are entered in the *Exhaust Fan Dialog Box* (p. 1961) (*Figure 7.28* (p. 312)), which is opened from the **Boundary Conditions** task page (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

The first 4 items listed above are specified in the same way that they are specified at pressure outlet boundaries. See *Inputs at Pressure Outlet Boundaries* (p. 294) for details. Specification of the pressure jump is described here. Open channel boundary condition inputs are described in *Modeling Open Channel Flows* (p. 1204).

7.3.12.1.1. Specifying the Pressure Jump

An exhaust fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the local fluid velocity normal to the fan. You can define a **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial** function for the **Pressure Jump** across the fan. The dialog boxes for defining these functions are the same as those used for defining temperature-dependent properties. See *Defining Properties Using Temperature-Dependent Functions* (p. 417) for details.

Figure 7.28 The Exhaust Fan Dialog Box

Important

You must be careful to model the exhaust fan so that a pressure rise occurs for forward flow through the fan. In the case of reversed flow, the fan is treated like an inlet vent with a loss coefficient of unity.

7.3.13. Wall Boundary Conditions

Wall boundary conditions are used to bound fluid and solid regions. In viscous flows, the no-slip boundary condition is enforced at walls by default, but you can specify a tangential velocity component in terms of the translational or rotational motion of the wall boundary, or model a “slip” wall by specifying shear. (You can also model a slip wall with zero shear using the symmetry boundary type, but using a symmetry boundary will apply symmetry conditions for *all* equations. See *Symmetry Boundary Conditions* (p. 334) for details.)

The shear stress and heat transfer between the fluid and wall are computed based on the flow details in the local flow field.

7.3.13.1. Inputs at Wall Boundaries

7.3.13.1.1. Summary

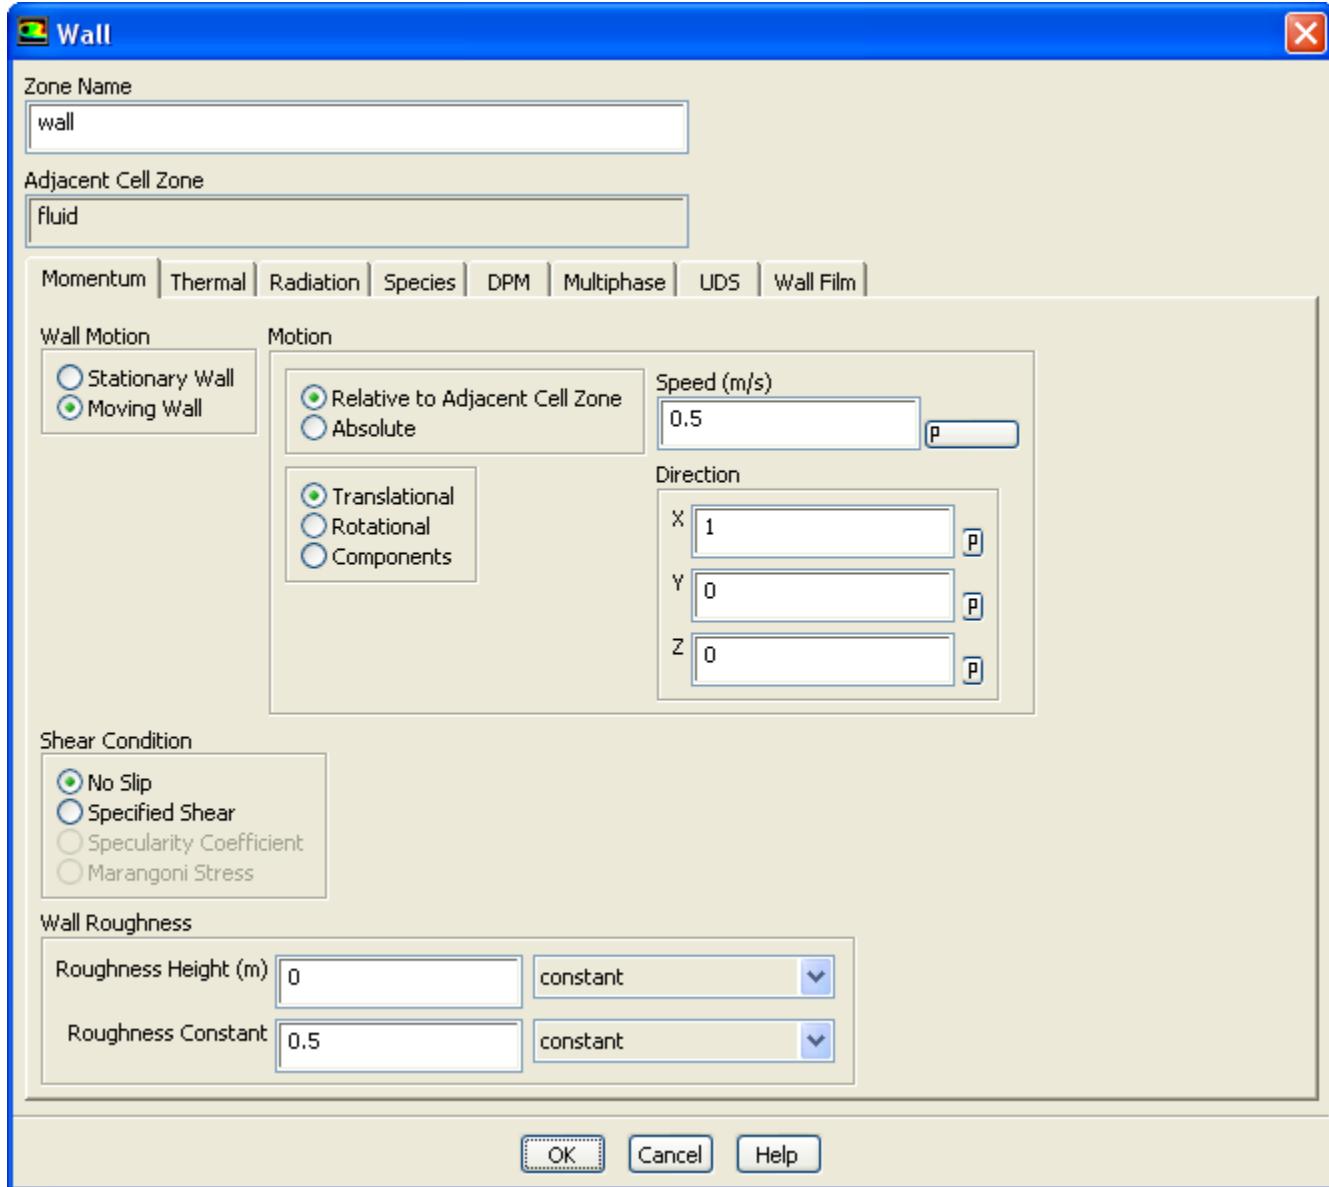

You will enter the following information for a wall boundary:

- wall motion conditions (for moving or rotating walls)
- shear conditions (for slip walls, optional)
- wall roughness (for turbulent flows, optional)
- thermal boundary conditions (for heat transfer calculations)
- species boundary conditions (for species calculations)
- chemical reaction boundary conditions (for surface reactions)
- radiation boundary conditions (for calculations using the P-1 model, the DTRM, the DO model, or the surface-to-surface model)
- discrete phase boundary conditions (for discrete phase calculations)
- wall adhesion contact angle (for VOF calculations, optional)

7.3.13.2. Wall Motion

Wall boundaries can be either stationary or moving. The stationary boundary condition specifies a fixed wall, whereas the moving boundary condition can be used to specify the translational or rotational velocity of the wall, or the velocity components.

Wall motion conditions are entered in the **Momentum** tab of the *Wall Dialog Box* (p. 2011) (*Figure 7.29* (p. 314)), which is opened from the *Boundary Conditions Task Page* (p. 1958) (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)). To view the wall motion conditions, click the **Momentum** tab.

Figure 7.29 The Wall Dialog Box for a Moving Wall

7.3.13.2.1. Defining a Stationary Wall

For a stationary wall, choose the **Stationary Wall** option under **Wall Motion**.

7.3.13.2.2. Velocity Conditions for Moving Walls

If you wish to include tangential motion of the wall in your calculation, you need to define the translational or rotational velocity, or the velocity components. Select the **Moving Wall** option under **Wall Motion**. The **Wall** dialog box will expand, as shown in *Figure 7.29* (p. 314), to show the wall velocity conditions.

Note that you cannot use the moving wall condition to model problems where the wall motion with respect to the adjacent cell zone has a component that is normal to the wall itself. For such problems, consider using a Sliding or Dynamic Mesh approach as discussed in *Modeling Flows Using Sliding and Dynamic Meshes* (p. 559). ANSYS FLUENT will neglect any normal component of wall motion that you specify using the methods below.

- **Specifying Relative or Absolute Velocity**

If the cell zone adjacent to the wall is moving (e.g., if you are using a moving reference frame or a sliding mesh), you can choose to specify velocities relative to the zone motion by enabling the **Relative to Adjacent Cell Zone** option. If you choose to specify relative velocities, a velocity of zero means that the wall is stationary in the relative frame, and therefore moving at the speed of the adjacent cell zone in the absolute frame. If you choose to specify absolute velocities (by enabling the **Absolute** option), a velocity of zero means that the wall is stationary in the absolute frame, and therefore moving at the speed of the adjacent cell zone—but in the opposite direction—in the relative reference frame.

Important

If you are using one or more moving reference frames, sliding meshes, or mixing planes, and you want the wall to be fixed in the moving frame, it is recommended that you specify relative velocities (the default) rather than absolute velocities. Then, if you modify the speed of the adjacent cell zone, you will not need to make any changes to the wall velocities, as you would if you specified absolute velocities.

Note that if the adjacent cell zone is not moving, the absolute and relative options are equivalent.

- **Translational Wall Motion**

For problems that include linear translational motion of the wall boundary (e.g., a rectangular duct with a moving belt as one wall) you can enable the **Translational** option and specify the wall's **Speed** and **Direction (X,Y,Z vector)**. By default, wall motion is "disabled" by the specification of **Translational** velocity with a **Speed** of zero.

If you need to define non-linear translational motion, you will need to use the **Components** option, described below.

- **Rotational Wall Motion**

For problems that include rotational wall motion you can enable the **Rotational** option and define the rotational **Speed** about a specified axis. To define the axis, set the **Rotation-Axis Direction** and **Rotation-Axis Origin**. This axis is independent of the axis of rotation used by the adjacent cell zone, and independent of any other wall rotation axis. For 3D problems, the axis of rotation is the vector passing through the specified **Rotation-Axis Origin** and parallel to the vector from (0,0,0) to the (X,Y,Z) point specified under **Rotation-Axis Direction**. For 2D problems, you will specify only the **Rotation-Axis Origin**; the axis of rotation is the z-direction vector passing through the specified point. For 2D axisymmetric problems, you will not define the axis: the rotation will always be about the x axis, with the origin at (0,0).

Note that the modeling of tangential rotational motion will be correct only if the wall bounds a surface of revolution about the prescribed axis of rotation (e.g., a circle or cylinder). Note also that rotational motion can be specified for a wall in a stationary reference frame.

- **Wall Motion Based on Velocity Components**

For problems that include linear or non-linear translational motion of the wall boundary you can enable the **Components** option and specify the **X-Velocity**, **Y-Velocity**, and **Z-Velocity** of the wall. You can define non-linear translational motion using a profile or a user-defined function for the **X-Velocity**, **Y-Velocity**, and/or **Z-Velocity** of the wall.

- **Wall Motion for Two-Sided Walls**

As discussed earlier in this section, when you read a mesh with a two-sided wall zone (which forms the interface between fluid/solid regions) into ANSYS FLUENT, a “shadow” zone will automatically be created so that each side of the wall is a distinct wall zone. For two-sided walls, it is possible to specify different motions for the wall and shadow zones, whether or not they are coupled. Note, however, that you cannot specify motion for a wall (or shadow) that is adjacent to a solid zone.

7.3.13.2.3. Shear Conditions at Walls

Four types of shear conditions are available:

- no-slip
- specified shear
- specularity coefficient
- Marangoni stress

The no-slip condition is the default, and it indicates that the fluid sticks to the wall and moves with the same velocity as the wall, if it is moving. The specified shear and Marangoni stress boundary conditions are useful in modeling situations in which the shear stress (rather than the motion of the fluid) is known. Examples of such situations are applied shear stress, slip wall (zero shear stress), and free surface conditions (zero shear stress or shear stress dependent on surface tension gradient). The specified shear boundary condition allows you to specify the x , y , and z components of the shear stress as constant values or profiles. The Marangoni stress boundary condition allows you to specify the gradient of the surface tension with respect to the temperature at this surface. The shear stress is calculated based on the surface gradient of the temperature and the specified surface tension gradient. The Marangoni stress option is available only for calculations in which the energy equation is being solved.

The specularity coefficient shear condition is specifically used in multiphase with granular flows. The specularity coefficient is a measure of the fraction of collisions which transfer momentum to the wall and its value ranges between zero and unity. This implementation is based on the Johnson and Jackson [38] (p. 2369) boundary conditions for granular flows.

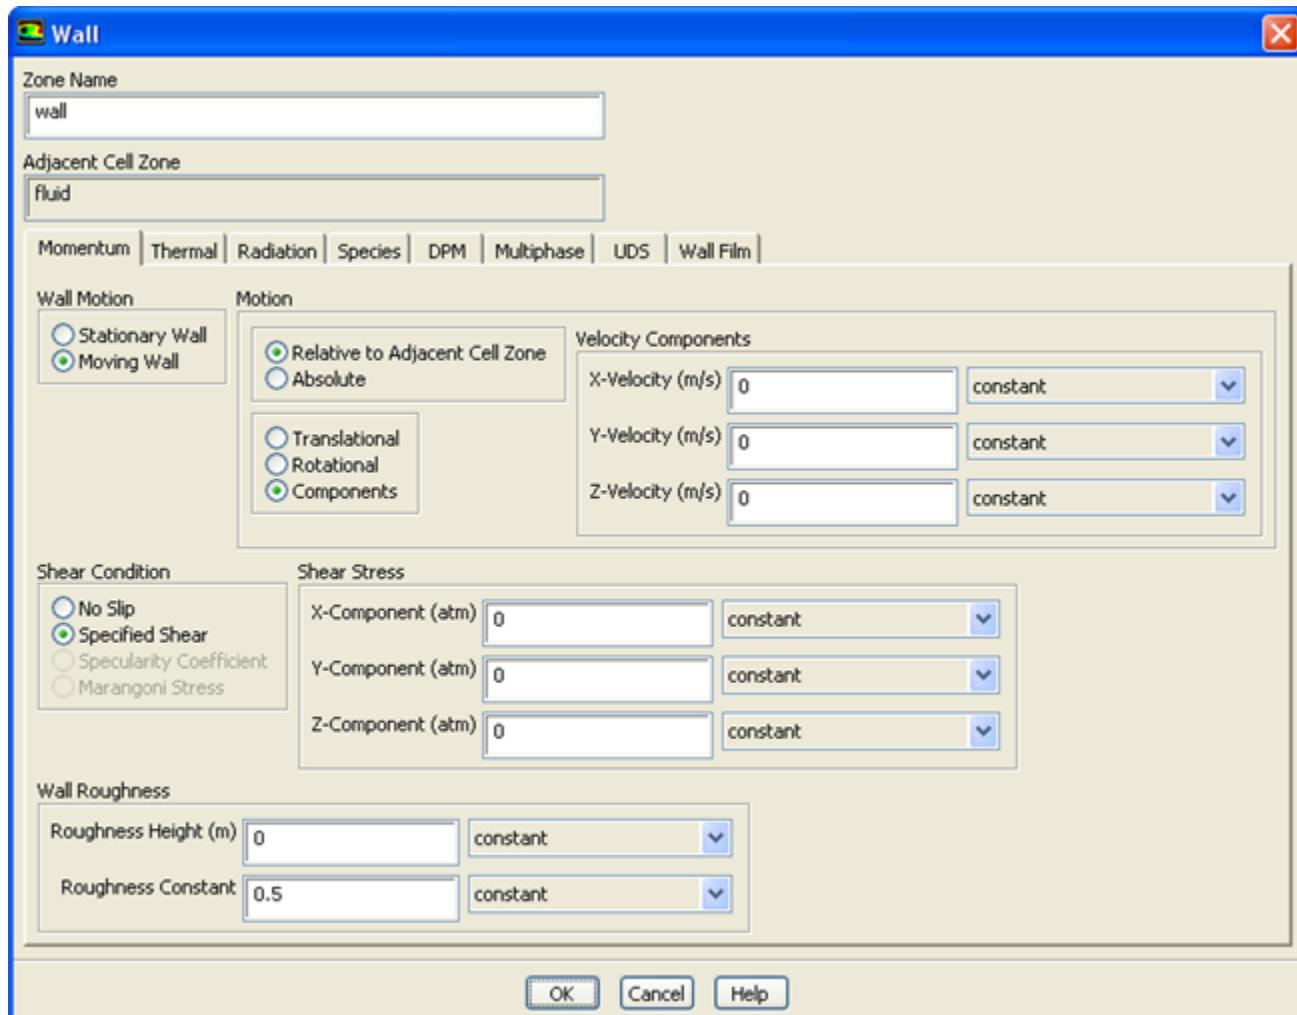

Shear conditions are entered in the **Momentum** tab of the [Wall Dialog Box](#) (p. 2011), which is opened from the [Boundary Conditions Task Page](#) (p. 1958) (as described in [Setting Cell Zone and Boundary Conditions](#) (p. 214)).

7.3.13.2.4. No-Slip Walls

You can model a no-slip wall by selecting the **No Slip** option under **Shear Condition**. This is the default for all walls in viscous flows.

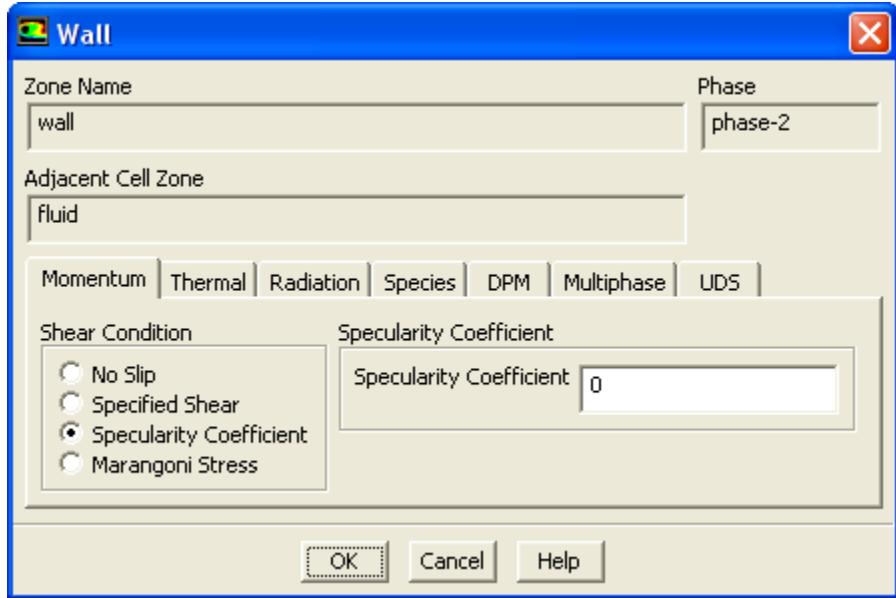

7.3.13.2.5. Specified Shear

In addition to the no-slip wall that is the default for viscous flows, you can model a slip wall by specifying zero or non-zero shear. For non-zero shear, the shear to be specified is the shear at the wall by the fluid. To specify the shear, select the **Specified Shear** option under **Shear Condition** (see [Figure 7.30](#) (p. 317)). You can then enter x , y , and z components of shear under **Shear Stress**. Wall functions for turbulence are not used with the **Specified Shear** option.

Figure 7.30 The Wall Dialog Box for Specified Shear

7.3.13.2.6. Specularity Coefficient

For multiphase granular flow, you can specify the specularity coefficient such that when the value is zero, this condition is equivalent to zero shear at the wall, but when the value is near unity, there is a significant amount of lateral momentum transfer. To specify the specularity coefficient, select the **Specularity Coefficient** option under **Shear Condition** (see *Figure 7.31* (p. 318)) and enter the desired value in the text-entry box under **Specularity Coefficient**.

Figure 7.31 The Wall Dialog Box for the Specularity Coefficient

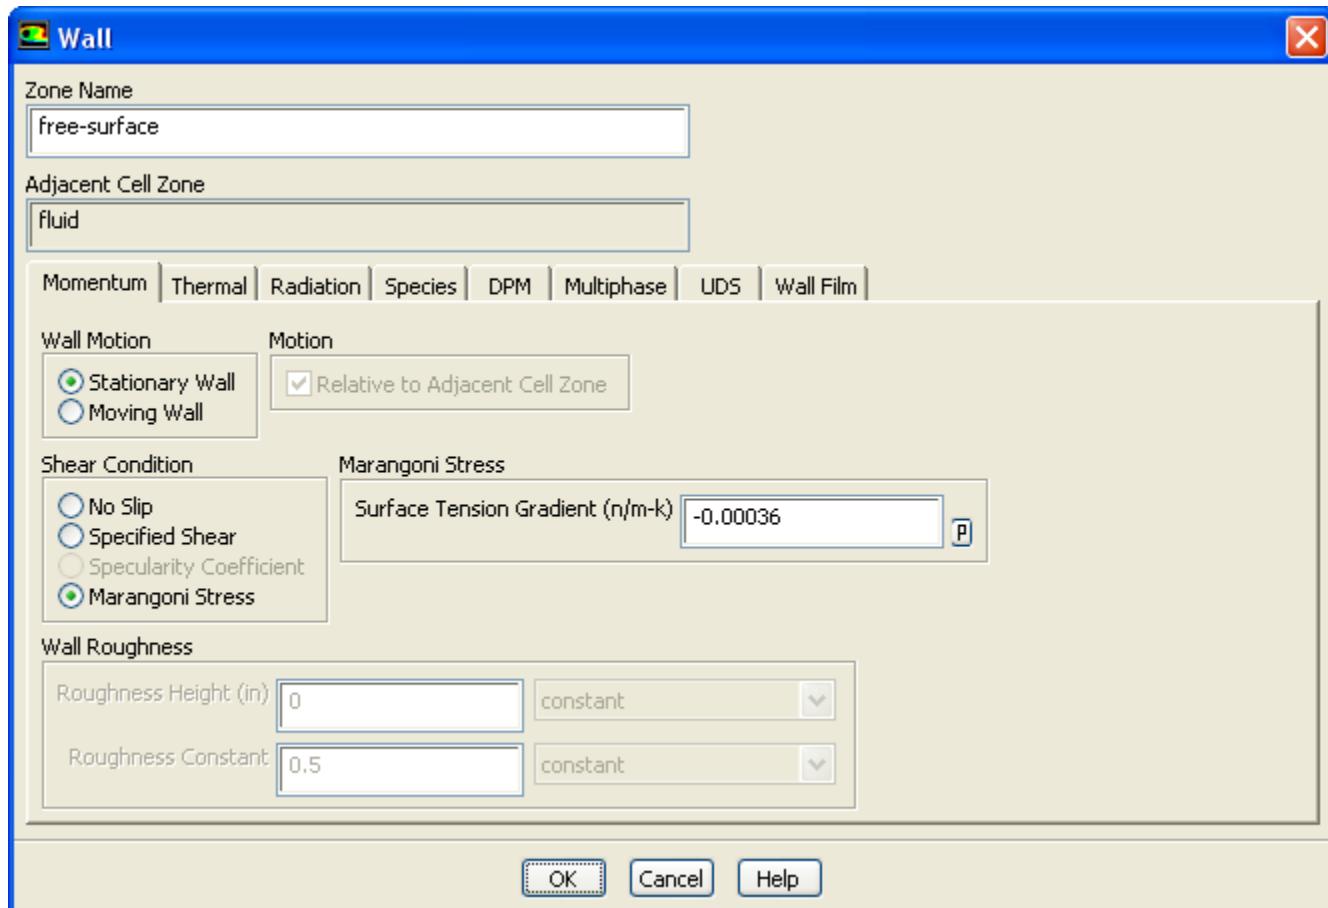

7.3.13.2.7. Marangoni Stress

ANSYS FLUENT can also model shear stresses caused by the variation of surface tension due to temperature. The shear stress applied at the wall is given by

$$\tau = \frac{d\sigma}{dT} \nabla_s T \quad (7-84)$$

where $d\sigma/dT$ is the surface tension gradient with respect to temperature, and $\nabla_s T$ is the surface gradient. This shear stress is then applied to the momentum equation.

To model Marangoni stress for the wall, select the **Marangoni Stress** option under **Shear Condition** (see [Figure 7.32 \(p. 319\)](#)). This option is available only for calculations in which the energy equation is being solved. You can then enter the surface tension gradient ($d\sigma/dT$ in [Equation 7-84 \(p. 318\)](#)) in the **Surface Tension Gradient** field. Wall functions for turbulence are not used with the **Marangoni Stress** option.

Figure 7.32 The Wall Dialog Box for Marangoni Stress

7.3.13.2.8. Wall Roughness Effects in Turbulent Wall-Bounded Flows

Fluid flows over rough surfaces are encountered in diverse situations. Examples are, among many others, flows over the surfaces of airplanes, ships, turbomachinery, heat exchangers, and piping systems, and atmospheric boundary layers over terrain of varying roughness. Wall roughness affects drag (resistance) and heat and mass transfer on the walls.

If you are modeling a turbulent wall-bounded flow in which the wall roughness effects are considered to be significant, you can include the wall roughness effects through the law-of-the-wall modified for roughness.

7.3.13.2.9. Law-of-the-Wall Modified for Roughness

Experiments in roughened pipes and channels indicate that the mean velocity distribution near rough walls, when plotted in the usual semi-logarithmic scale, has the same slope ($1/\kappa$) but a different intercept (additive constant B in the log-law). Thus, the law-of-the-wall for mean velocity modified for roughness has the form

$$\frac{u_p u^*}{\tau_w / \rho} = \frac{1}{\kappa} \ln \left(E \frac{\rho u^* y_p}{\mu} \right) - \Delta B \quad (7-85)$$

where $u^* = C_\mu^{1/4} k^{1/2}$ and

$$\Delta B = \frac{1}{\kappa} \ln f_r \quad (7-86)$$

where f_r is a roughness function that quantifies the shift of the intercept due to roughness effects.

ΔB depends, in general, on the type (uniform sand, rivets, threads, ribs, mesh-wire, etc.) and size of the roughness. There is no universal roughness function valid for all types of roughness. For a sand-grain roughness and similar types of uniform roughness elements, however, ΔB has been found to be well-correlated with the nondimensional roughness height, $K_s^+ = \rho K_s u^* / \mu$, where K_s is the physical roughness height and $u^* = C_\mu^{1/4} k^{1/2}$. Analyses of experimental data show that the roughness function is not a single function of K_s^+ , but takes different forms depending on the K_s^+ value. It has been observed that there are three distinct regimes:

- hydrodynamically smooth ($K_s^+ \leq 2.25$)
- transitional ($2.25 < K_s^+ \leq 90$)
- fully rough ($K_s^+ > 90$)

According to the data, roughness effects are negligible in the hydrodynamically smooth regime, but become increasingly important in the transitional regime, and take full effect in the fully rough regime.

In ANSYS FLUENT, the whole roughness regime is subdivided into the three regimes, and the formulas proposed by Cebeci and Bradshaw based on Nikuradse's data [14] (p. 2367) are adopted to compute ΔB for each regime.

For the hydrodynamically smooth regime ($K_s^+ \leq 2.25$):

$$\Delta B = 0 \quad (7-87)$$

For the transitional regime ($2.25 < K_s^+ \leq 90$):

$$\Delta B = \frac{1}{\kappa} \ln \left[\frac{K_s^+ - 2.25}{87.75} + C_s K_s^+ \right] \times \sin \{0.4258 (\ln K_s^+ - 0.811)\} \quad (7-88)$$

where C_s is a roughness constant, and depends on the type of the roughness.

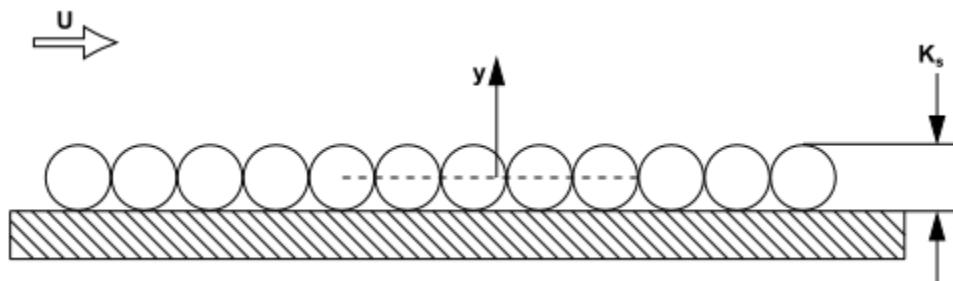

In the fully rough regime ($K_s^+ > 90$):

$$\Delta B = \frac{1}{\kappa} \ln (1 + C_s K_s^+) \quad (7-89)$$

In the solver, given the roughness parameters, $\Delta B (K_s^+)$ is evaluated using the corresponding formula ([Equation 7-87 \(p. 320\)](#), [Equation 7-88 \(p. 320\)](#), or [Equation 7-89 \(p. 321\)](#)). The modified law-of-the-wall in [Equation 7-85 \(p. 320\)](#) is then used to evaluate the shear stress at the wall and other wall functions for the mean temperature and turbulent quantities.

Besides the shift in the law-of-the-wall, an additional modification has been made to account for the displacement caused by the surface roughness. The viscous sublayer is fully established only near hydraulically smooth walls. In the transitional roughness regime, the roughness elements are slightly thicker than the viscous sublayer and start to disturb it, so that in fully rough flows, the sublayer is destroyed and viscous effects become negligible. The following figure illustrates the equivalent sand-grain roughness using a wall with a layer of closely packed spheres, which have an average roughness height (see for example, Schlichting and Gersten [76] (p. 2371)):

Figure 7.33 Illustration of Equivalent Sand-Grain Roughness

It can be assumed that the roughness has a blockage effect, which is about 50% of its height (note that the figure above shows a two-dimensional cut of a three-dimensional arrangement). This leads to the idea to shift the wall physically to 50% of the height of the roughness elements:

$$y^+ = y^+ + K_s^+ / 2 \quad (7-90)$$

which gives about the correct displacement caused by the surface roughness.

This shift is the default treatment for rough walls for all turbulence models based on the ω -equation and for the following turbulence models based on the ε -equation, when they are used with standard and scalable wall functions. The use of scalable wall functions is recommended:

- Standard, RNG and realizable K- ε model
- Reynolds stress models

Note

Rough walls cannot be used together with the ε -equation and enhanced wall treatment.

Important

Prior to ANSYS FLUENT 14, the shift described by [Equation 7–90 \(p. 321\)](#) was not applied when using turbulence models based on the ε -equation. You can recover the previous code behavior by using the following scheme command:

```
(rpsetvar 'ke-rough-wall-treatment-r14? #f)
```

7.3.13.2.10. Setting the Roughness Parameters

The roughness parameters are in the **Momentum** tab of the [Wall Dialog Box \(p. 2011\)](#) (see [Figure 7.32 \(p. 319\)](#)), which is opened from the [Boundary Conditions Task Page \(p. 1958\)](#) (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

To model the wall roughness effects, you must specify two roughness parameters: the **Roughness Height**, K_s , and the **Roughness Constant**, C_s . The default roughness height (K_s) is zero, which corresponds to smooth walls. For the roughness to take effect, you must specify a non-zero value for K_s . For a uniform sand-grain roughness, the height of the sand-grain can simply be taken for K_s . For a non-uniform sand-grain, however, the mean diameter (D_{50}) would be a more meaningful roughness height. For other types of roughness, an “equivalent” sand-grain roughness height could be used for K_s . The above approaches are only relevant if the height is considered constant per surface. However, if the roughness constant or roughness height is not constant, then you can specify a profile (see [Profile files \(p. 382\)](#)). Similarly, user-defined functions may be used to define a wall roughness height that is not constant. For details on the format of user-defined functions, refer to the [UDF Manual](#).

Choosing a proper roughness constant (C_s) is dictated mainly by the type of the given roughness. The default roughness constant ($C_s = 0.5$) was determined so that, when used with k - ε turbulence models, it reproduces Nikuradse’s resistance data for pipes roughened with tightly-packed, uniform sand-grain roughness. You may need to adjust the roughness constant when the roughness you want to model departs much from uniform sand-grain. For instance, there is some experimental evidence that, for non-uniform sand-grains, ribs, and wire-mesh roughness, a higher value ($C_s = 0.5 \sim 1.0$) is more appropriate. Unfortunately, a clear guideline for choosing C_s for arbitrary types of roughness is not available.

Note

The rough wall formulation using the shift introduced in [Equation 7–90 \(p. 321\)](#) eliminates all restrictions with respect to mesh resolution near the wall and can therefore be run on arbitrary fine meshes.

7.3.13.3. Thermal Boundary Conditions at Walls

When you are solving the energy equation, you need to define thermal boundary conditions at wall boundaries. Five types of thermal conditions are available:

- fixed heat flux
- fixed temperature
- convective heat transfer
- external radiation heat transfer

- combined external radiation and convection heat transfer

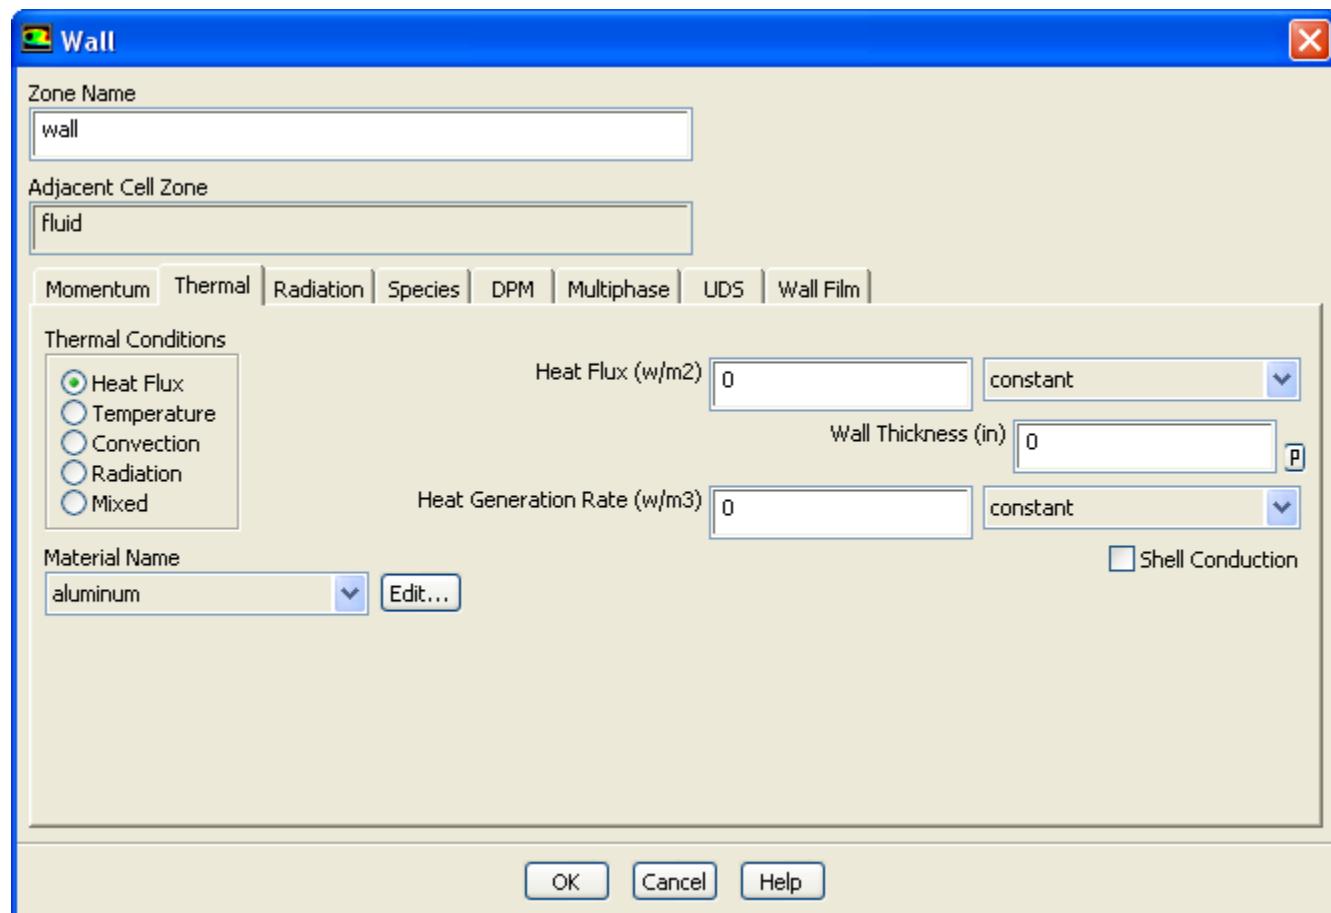

If the wall zone is a “two-sided wall” (a wall that forms the interface between two regions, such as the fluid/solid interface for a conjugate heat transfer problem) a subset of these thermal conditions will be available, but you will also be able to choose whether or not the two sides of the wall are “coupled”. See below for details.

The inputs for each type of thermal condition are described below. If the wall has a non-zero thickness, you should also set parameters for calculating thin-wall thermal resistance and heat generation in the wall, as described below.

You can model conduction within boundary walls and internal (i.e., two-sided) walls of your model. This type of conduction, called shell conduction, allows you to more conveniently model heat conduction on walls where the wall thickness is small with respect to the overall geometry (e.g., finned heat exchangers or sheet metal in automobile underhoods). Meshing these walls with solid cells would lead to high-aspect-ratio meshes and a significant increase in the total number of cells. See below for details about shell conduction.

Thermal conditions are entered in the **Thermal** tab of the [Wall Dialog Box \(p. 2011\)](#) ([Figure 7.34 \(p. 323\)](#)), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.34 The Wall Dialog Box (Thermal Tab)

7.3.13.3.1. Heat Flux Boundary Conditions

For a fixed heat flux condition, choose the **Heat Flux** option under **Thermal Conditions**. You will then need to set the appropriate value for the heat flux at the wall surface in the **Heat Flux** field. You can define an adiabatic wall by setting a zero heat flux condition. This is the default condition for all walls.

7.3.13.3.2. Temperature Boundary Conditions

To select the fixed temperature condition, choose the **Temperature** option under **Thermal Conditions** in the **Wall** dialog box. You will need to specify the temperature at the wall surface (**Temperature**). The heat transfer to the wall is computed using [Equation 7–92 \(p. 331\)](#) or [Equation 7–93 \(p. 332\)](#).

7.3.13.3.3. Convective Heat Transfer Boundary Conditions

For a convective heat transfer wall boundary, select **Convection** under **Thermal Conditions**. Your inputs of **Heat Transfer Coefficient** and **Free Stream Temperature** will allow ANSYS FLUENT to compute the heat transfer to the wall using [Equation 7–96 \(p. 332\)](#).

7.3.13.3.4. External Radiation Boundary Conditions

If radiation heat transfer from the exterior of your model is of interest, you can enable the **Radiation** option in the **Wall** dialog box and set the **External Emissivity** and **External Radiation Temperature**.

7.3.13.3.5. Combined Convection and External Radiation Boundary Conditions

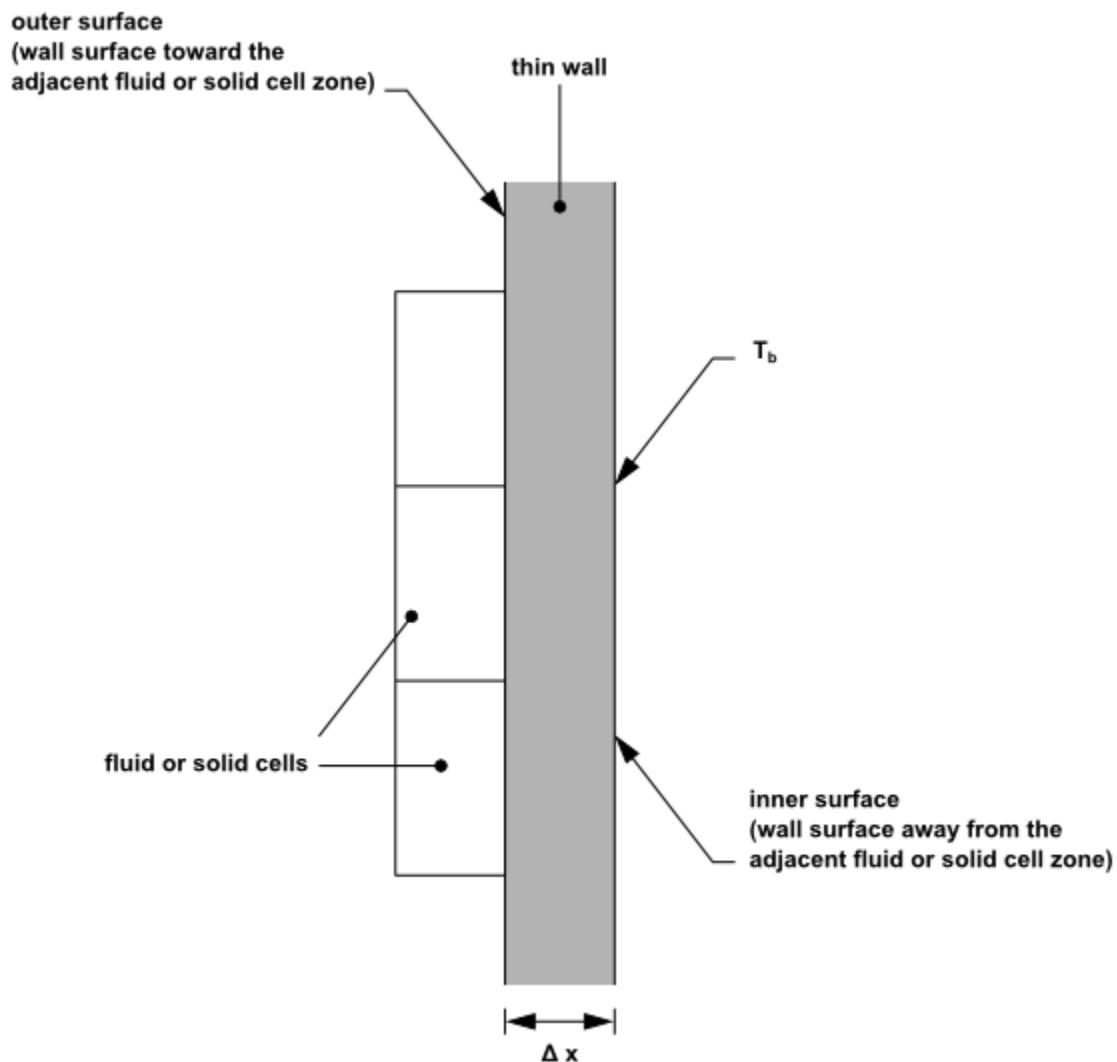

You can choose a thermal condition that combines the convection and radiation boundary conditions by selecting the **Mixed** option. With this thermal condition, you will need to set the **Heat Transfer Coefficient**, **Free Stream Temperature**, **External Emissivity**, and **External Radiation Temperature**.

7.3.13.3.6. Thin-Wall Thermal Resistance Parameters

By default, a wall will have a thickness of zero. You can, however, in conjunction with any of the thermal conditions, model a thin layer of material on the wall. For example, you can model the effect of a piece of sheet metal between two fluid zones, a coating on a solid zone, or contact resistance between two solid regions. ANSYS FLUENT will solve a 1D steady heat conduction equation to compute the thermal resistance offered by the wall and the heat generation in the wall.

To include these effects in the heat transfer calculation you will need to specify the type of material, the thickness of the wall, and the heat generation rate in the wall. Select the material type in the **Material Name** drop-down list, and specify the thickness in the **Wall Thickness** field. If you want to check or modify the properties of the selected material, you can click **Edit...** to open the **Edit Material** dialog box; this dialog box contains just the properties of the selected material, not the full contents of the standard **Create/Edit Materials** dialog box.

When you specify a thickness, the original wall is then treated as a coupled wall, where the surface that is adjacent to the fluid/solid cells is referred to as the “outer” surface, and the surface that is away from the adjacent fluid/solid cells is referred to as the “inner” surface. See [Figure 7.35 \(p. 325\)](#). Note that the definition for the inner surface of a thin wall differs from the definition used for thin walls with shell conduction (compare [Figure 7.35 \(p. 325\)](#) with [Figure 14.4 \(p. 749\)](#)).

Figure 7.35 Surfaces of a Thin Wall Without Shell Conduction

The thermal resistance of the wall is $\Delta x/k$, where k is the conductivity of the wall material and Δx is the wall thickness. If shell conduction is not applied on the wall, the thermal wall boundary condition you set will be specified on the inner surface of the thin wall; otherwise, it will be specified on the external surface, as defined in [Figure 14.4 \(p. 749\)](#). The temperature specified at this side of the wall is T_b . Whether or not shell conduction is applied to the thin wall, the outer surface stores the face temperature of the wall.

Important

Note that for thin walls, you can only specify a constant thermal conductivity. If you want to use a non-constant thermal conductivity for a wall with non-zero thickness, you should use the shell conduction model (see below for details).

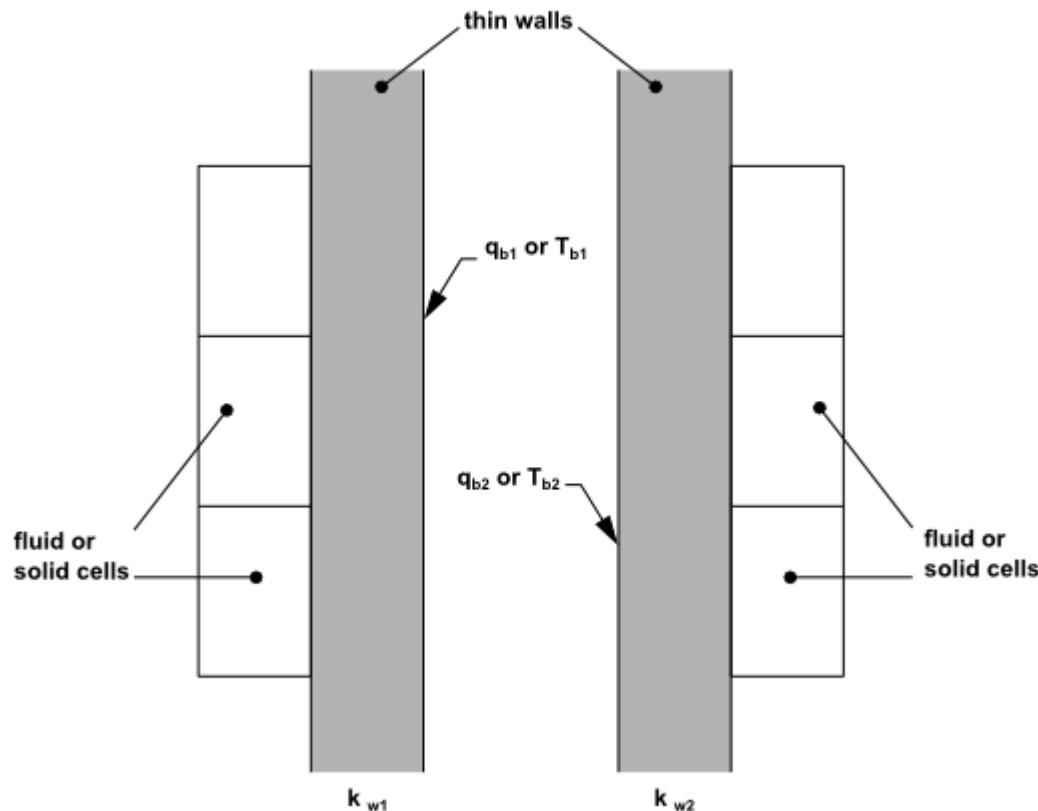

Specify the heat generation rate inside the wall in the **Heat Generation Rate** field. This option is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits.

7.3.13.3.7. Thermal Conditions for Two-Sided Walls

If the wall zone has a fluid or solid region on each side, it is called a “two-sided wall.” When you read a mesh with this type of wall zone into ANSYS FLUENT, a “shadow” zone will automatically be created so that each side of the wall is a distinct wall zone. Note that this shadow zone will not be relevant if you then go on to apply shell conduction to the thin wall. In the **Wall** dialog box, the shadow zone’s name will be shown in the **Shadow Face Zone** field. You can choose to specify different thermal conditions on each zone, or to couple the two zones:

- To couple the two sides of the wall, select the **Coupled** option under **Thermal Conditions**. (This option will appear in the **Wall** dialog box only when the wall is a two-sided wall.) No additional thermal boundary conditions are required, because the solver will calculate heat transfer directly from the solution in the adjacent cells. You can, however, specify the material type, wall thickness, and heat generation rate for thin-wall thermal resistance calculations, as described above. Note that the resistance parameters you set for one side of the wall will automatically be assigned to its shadow wall zone. Specifying the heat generation rate inside the wall is useful if, for example, you are modeling printed circuit boards where you know the electrical power dissipated in the circuits but not the heat flux or wall temperature.
- To uncouple the two sides of the wall and specify different thermal conditions on each one, choose **Temperature** or **Heat Flux** as the thermal condition type. (**Convection** and **Radiation** are not applicable for two-sided walls.) The relationship between the wall and its shadow will be retained, so that you can couple them again at a later time, if desired. You will need to set the relevant parameters for the selected thermal condition, as described above. The two uncoupled walls can have different thicknesses, and are effectively insulated from one another. If you specify a non-zero wall thickness for the uncoupled walls, the thermal boundary conditions you set will be specified on the inner surfaces of the two thin walls, as shown in *Figure 7.36 (p. 327)*, where T_{b1} is the **Temperature** (or q_{b1} is the **Heat Flux**) specified on one wall and T_{b2} is the **Temperature** (or q_{b2} is the **Heat Flux**) specified on the other wall. k_{w1} and k_{w2} are the thermal conductivities of the uncoupled thin walls. Note that the gap between the walls in *Figure 7.36 (p. 327)* is not part of the model; it is included in the figure only to show where the thermal boundary condition for each uncoupled wall is applied.

Figure 7.36 Thermal Conditions are Specified on the Inner Surfaces of the Uncoupled Thin Walls

7.3.13.3.8. Shell Conduction in Thin-Walls

To enable shell conduction for a wall, turn on the **Shell Conduction** option in the **Wall** boundary condition dialog box. When this option is enabled, ANSYS FLUENT will compute heat conduction within the wall, in addition to conduction across the wall (which is always computed when the energy equation is solved). The **Shell Conduction** option will appear in the **Wall** dialog box for all walls when solution of the energy equation is active. For information about how the thermal conditions are applied on a wall with shell conduction enabled, an alternate method of enabling the shell conduction model, and postprocessing shell conduction walls, see *Shell Conduction Considerations* (p. 748).

ANSYS FLUENT cases with shell conduction can be read in serial or parallel. Either a partitioned or an unpartitioned case file can be read in parallel (see *Mesh Partitioning and Load Balancing* (p. 1733) for more information on partitioning). After reading a case file in parallel, shell zones can be created on any wall with a positive thickness.

To delete existing shell conduction zones all at once, the TUI command `define/boundary-conditions/modify-zones/delete-all-shells` is used. This capability is available in both serial and parallel mode.

Important

You must specify a non-zero **Wall Thickness** in the **Wall** dialog box, because the shell conduction model is relevant only for walls with non-zero thickness.

Important

Note that the shell conduction model has several limitations:

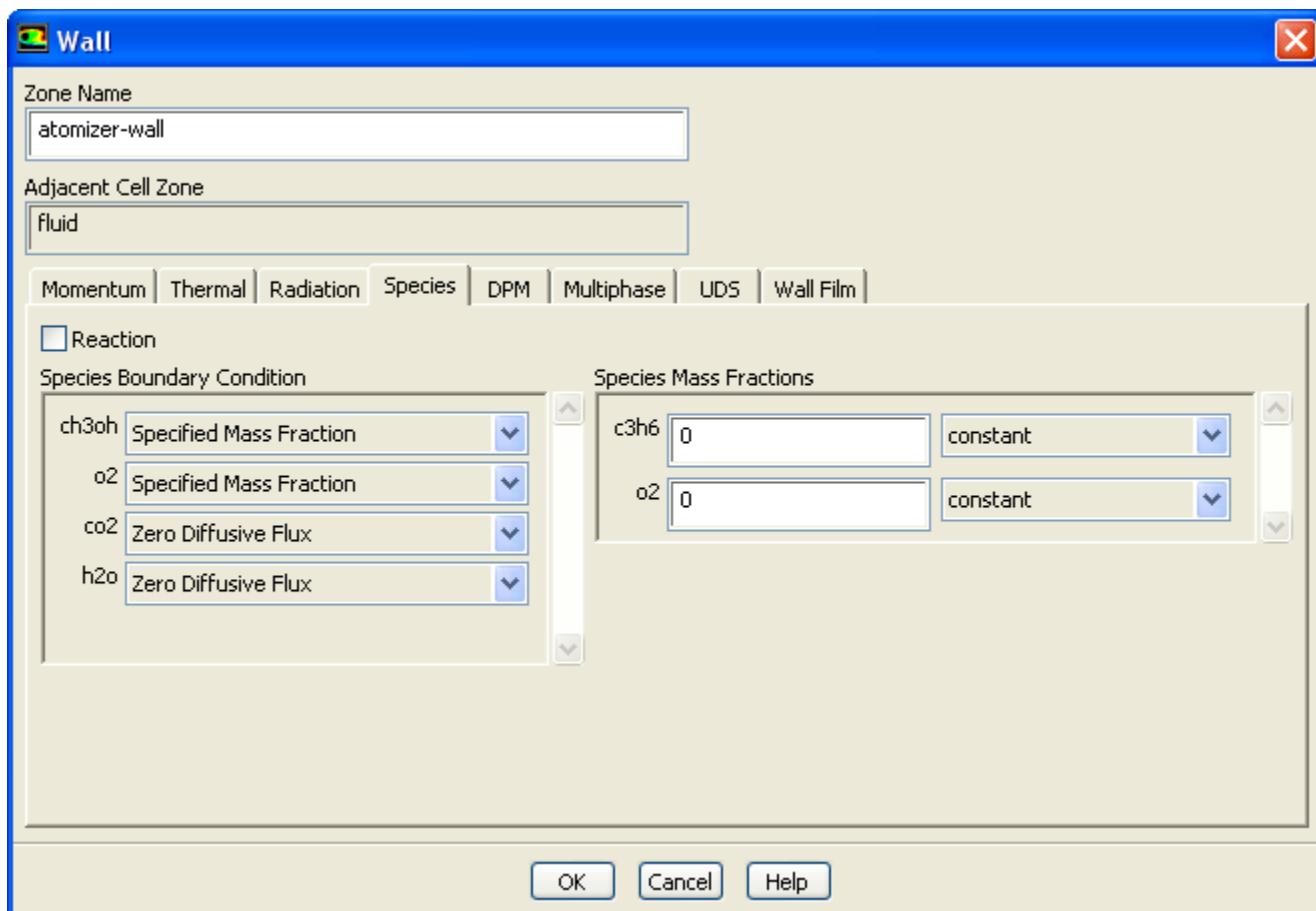

- It cannot be applied on non-conformal interfaces.
- It cannot be applied on moving wall zones.
- It cannot be used with FMG initialization.
- It is available only in 3D.
- It is available only when the pressure-based solver is used.
- Shell conducting walls cannot be split or merged. If you need to split or merge a shell conducting wall, disable the **Shell Conduction** option for the wall, perform the split or merge operation, and then enable **Shell Conduction** for the new wall zones.
- The shell conduction model cannot be used on a wall zone that has been adapted. If you want to perform adaption elsewhere in the computational domain, be sure to use the mask register described in *Manipulating Adaption Registers* (p. 1459)
- Fluxes at the ends of a shell conducting wall are not included in the heat balance reports. These fluxes are accounted for correctly in the ANSYS FLUENT solution, but not in the flux report itself.

7.3.13.4. Species Boundary Conditions for Walls

By default, a zero-gradient condition for all species is assumed at walls (except for species that participate in surface reactions), but it is also possible to specify species mass fractions at walls. That is, Dirichlet boundary conditions such as those that are specified at inlets can be used at walls as well.

If you wish to retain the default zero-gradient condition for a species, no inputs are required. If you want to specify the mass fraction for a species at the wall, the steps are as follows:

1. Click the **Species** tab in the *Wall Dialog Box* (p. 2011) to view the species boundary conditions for the wall (see *Figure 7.37* (p. 329)).
2. Under **Species Boundary Condition**, select **Specified Mass Fraction** (rather than **Zero Diffusive Flux**) in the drop-down list to the right of the species name. The dialog box will expand to include a field for **Species Mass Fractions**.

Figure 7.37 The Wall Dialog Box for Species Boundary Condition Input

3. Under **Species Mass Fractions**, specify the mass fraction for the species.

The boundary condition type for each species is specified separately, so you can choose to use different methods for different species.

If you are modeling species transport with reactions, you can, alternatively, enable a reaction mechanism at a wall by turning on the **Reaction** option and selecting an available mechanism from the **Reaction Mechanisms** drop-down list. See *Defining Zone-Based Reaction Mechanisms* (p. 872) for more information about defining reaction mechanisms.

You can also model unresolved surface washcoats, which greatly increase the catalytic surface area, by specifying the **Surface Area Washcoat Factor**. The surface washcoat increases the area available for surface reaction.

7.3.13.4.1. Reaction Boundary Conditions for Walls

If you have enabled the modeling of wall surface reactions in the *Species Model Dialog Box* (p. 1814), you can indicate whether or not surface reactions should be activated for the wall. In the **Species** tab of the **Wall** dialog box (*Figure 7.37* (p. 329)), turn the **Surface Reactions** option on or off.

Note that a zero-gradient condition is assumed at the wall for species that do not participate in any surface reactions.

7.3.13.5. Radiation Boundary Conditions for Walls

If you are using the gray P-1 radiation model, the DTRM, the gray DO model, or the surface-to-surface model, you will need to set the emissivity of the wall (**Internal Emissivity**) in the **Thermal** tab of the **Wall** dialog box. If you are using the Rosseland model you do not need to set the emissivity, because ANSYS FLUENT assumes the emissivity is 1.

For the non-gray P-1 and the non-gray DO model, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see *Creating a New Parameter* (p. 218)). If you are using the non-gray DO model, you will also need to define the wall as opaque or semi-transparent in the **Radiation** tab. See *Defining Boundary Conditions for Radiation* (p. 772) for details.

7.3.13.6. Discrete Phase Model (DPM) Boundary Conditions for Walls

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the wall in the **DPM** section of the **Wall** dialog box. See *Setting Boundary Conditions for the Discrete Phase* (p. 1124) for details.

7.3.13.6.1. Wall Adhesion Contact Angle for VOF Model

If you are using the VOF model and you are modeling wall adhesion, you can specify the contact angle for each pair of phases at the wall in the **Momentum** tab of the **Wall** dialog box. See *Steps for Setting Boundary Conditions* (p. 1198) for details.

7.3.13.7. User-Defined Scalar (UDS) Boundary Conditions for Walls

If you have defined UDS transport equations in your model, you can specify boundary conditions for each equation in the **UDS** section of the **Wall** dialog box. See *Setting Up UDS Equations in ANSYS FLUENT* (p. 508) for details.

7.3.13.8. Wall Film Boundary Conditions for Walls

If you are using the Eulerian Wall Film model (see *Modeling Eulerian Wall Films* (p. 1305) for details), you can set boundary conditions for liquid films at the wall in the **Wall Film** tab of the **Wall** dialog box. This tab is available only if you have enabled the Eulerian Wall Film model in the *Models Task Page* (p. 1771).

To define a film wall condition for any wall, select the **Eulerian Film Wall** option. Then, you can enter film boundary condition values for the **Film Mass Flux**, and **X-Momentum Flux**, **Y-Momentum Flux**, and **Z-Momentum Flux**. Alternatively, you can set initial film conditions for the **Film Height** and the **X-Velocity**, **Y-Velocity**, and **Z-Velocity** components. You can also select the **Flow Momentum Coupling** option, that allows the liquid film and the gas flow to share the same velocity at the interface of the liquid-gas interface using a two-way coupling. When this option is not selected, the coupling between the liquid film and the gas flow is only one-way, namely, while the gas flow impacts the film flow, the film flow does not impact the bulk of the gas flow.

7.3.13.9. Default Settings at Wall Boundaries

The default thermal boundary condition is a fixed heat flux of zero. Walls are, by default, not moving.

7.3.13.10. Shear-Stress Calculation Procedure at Wall Boundaries

For no-slip wall conditions, ANSYS FLUENT uses the properties of the flow adjacent to the wall/fluid boundary to predict the shear stress on the fluid at the wall. In laminar flows this calculation simply depends on the velocity gradient at the wall, while in turbulent flows one of the approaches described in [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#) is used.

For specified-shear walls, ANSYS FLUENT will compute the tangential velocity at the boundary.

If you are modeling inviscid flow with ANSYS FLUENT, all walls use a slip condition, so they are frictionless and exert no shear stress on the adjacent fluid.

7.3.13.10.1. Shear-Stress Calculation in Laminar Flow

In a laminar flow, the wall shear stress is defined by the normal velocity gradient at the wall as

$$\tau_w = \mu \frac{\partial v}{\partial n} \quad (7-91)$$

When there is a steep velocity gradient at the wall, you must be sure that the mesh is sufficiently fine to accurately resolve the boundary layer. Guidelines for the appropriate placement of the near-wall node in laminar flows are provided in [Mesh Element Distribution](#) (p. 147).

7.3.13.10.2. Shear-Stress Calculation in Turbulent Flows

Wall treatments for turbulent flows are described in [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#).

7.3.13.11. Heat Transfer Calculations at Wall Boundaries

7.3.13.11.1. Temperature Boundary Conditions

When a fixed temperature condition is applied at the wall, the heat flux to the wall from a fluid cell is computed as

$$q = h_f (T_w - T_f) + q_{rad} \quad (7-92)$$

where

h_f = fluid-side local heat transfer coefficient

T_w = wall surface temperature

T_f = local fluid temperature

q_{rad} = radiative heat flux

Note that the fluid-side heat transfer coefficient is computed based on the local flow-field conditions (e.g., turbulence level, temperature, and velocity profiles), as described by [Equation 7-99](#) (p. 333).

Heat transfer to the wall boundary from a solid cell is computed as

$$q = \frac{k_s}{\Delta n} (T_w - T_s) + q_{rad} \quad (7-93)$$

where

k_s = thermal conductivity of the solid

T_s = local solid temperature

Δn = distance between wall surface and the solid cell center

7.3.13.11.2. Heat Flux Boundary Conditions

When you define a heat flux boundary condition at a wall, you specify the heat flux at the wall surface. ANSYS FLUENT uses [Equation 7-92 \(p. 331\)](#) and your input of heat flux to determine the wall surface temperature adjacent to a fluid cell as

$$T_w = \frac{q - q_{rad}}{h_f} + T_f \quad (7-94)$$

where, as noted above, the fluid-side heat transfer coefficient is computed based on the local flow-field conditions. When the wall borders a solid region, the wall surface temperature is computed as

$$T_w = \frac{(q - q_{rad}) \Delta n}{k_s} + T_s \quad (7-95)$$

7.3.13.11.3. Convective Heat Transfer Boundary Conditions

When you specify a convective heat transfer coefficient boundary condition at a wall, ANSYS FLUENT uses your inputs of the external heat transfer coefficient and external heat sink temperature to compute the heat flux to the wall as

$$\begin{aligned} q &= h_f (T_w - T_f) + q_{rad} \\ &= h_{ext} (T_{ext} - T_w) \end{aligned} \quad (7-96)$$

where

h_{ext} = external heat transfer coefficient defined by you

T_{ext} = external heat-sink temperature defined by you

q_{rad} = radiative heat flux

[Equation 7-96 \(p. 332\)](#) assumes a wall of zero thickness.

7.3.13.11.4. External Radiation Boundary Conditions

When the external radiation boundary condition is used in ANSYS FLUENT, the heat flux to the wall is computed as

$$\begin{aligned} q &= h_f(T_w - T_f) + q_{rad} \\ &= \varepsilon_{ext}\sigma(T_\infty^4 - T_w^4) \end{aligned} \quad (7-97)$$

where

ε_{ext} = emissivity of the external wall surface defined by you

σ = Stefan-Boltzmann constant

T_w = surface temperature of the wall

T_∞ = temperature of the radiation source or sink on the exterior of the domain, defined by you

q_{rad} = radiative heat flux to the wall from within the domain

Equation 7-97 (p. 333) assumes a wall of zero thickness.

7.3.13.11.5. Combined External Convection and Radiation Boundary Conditions

When you choose the combined external heat transfer condition, the heat flux to the wall is computed as

$$\begin{aligned} q &= h_f(T_w - T_f) + q_{rad} \\ &= h_{ext}(T_{ext} - T_w) + \varepsilon_{ext}\sigma(T_\infty^4 - T_w^4) \end{aligned} \quad (7-98)$$

where the variables are as defined above. *Equation 7-98 (p. 333)* assumes a wall of zero thickness.

7.3.13.11.6. Calculation of the Fluid-Side Heat Transfer Coefficient

In laminar flows, the fluid side heat transfer at walls is computed using Fourier's law applied at the walls. ANSYS FLUENT uses its discrete form:

$$q = k_f \left(\frac{\partial T}{\partial n} \right)_{wall} \quad (7-99)$$

where n is the local coordinate normal to the wall.

For turbulent flows, ANSYS FLUENT uses the law-of-the-wall for temperature derived using the analogy between heat and momentum transfer [43] (p. 2369). See **Standard Wall Functions** in the separate **Theory Guide** for details.

7.3.14. Symmetry Boundary Conditions

Symmetry boundary conditions are used when the physical geometry of interest, and the expected pattern of the flow/thermal solution, have mirror symmetry. They can also be used to model zero-shear slip walls in viscous flows. This section describes the treatment of the flow at symmetry planes and provides examples of the use of symmetry. You do not define any boundary conditions at symmetry boundaries, but you must take care to correctly define your symmetry boundary locations.

Important

At the centerline of an axisymmetric geometry, you should use the axis boundary type rather than the symmetry boundary type, as illustrated in [Figure 7.45 \(p. 339\)](#). See [Axis Boundary Conditions \(p. 338\)](#) for details.

7.3.14.1. Examples of Symmetry Boundaries

Symmetry boundaries are used to reduce the extent of your computational model to a symmetric subsection of the overall physical system. [Figure 7.38 \(p. 334\)](#) and [Figure 7.39 \(p. 335\)](#) illustrate two examples of symmetry boundary conditions used in this way.

Figure 7.38 Use of Symmetry to Model One Quarter of a 3D Duct

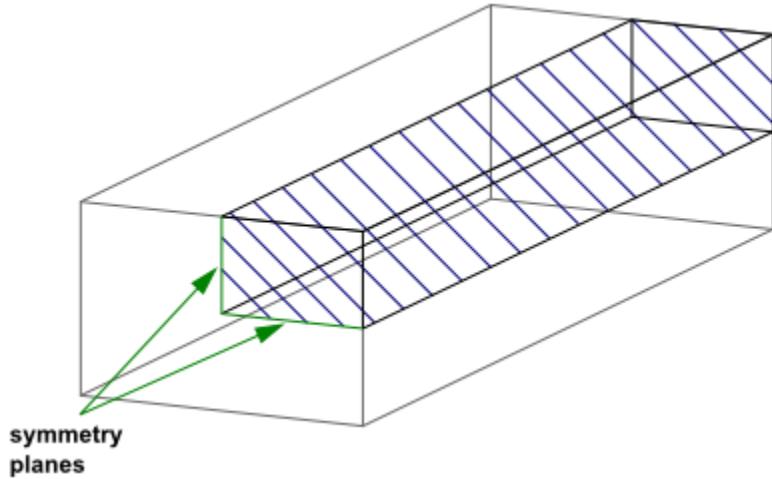

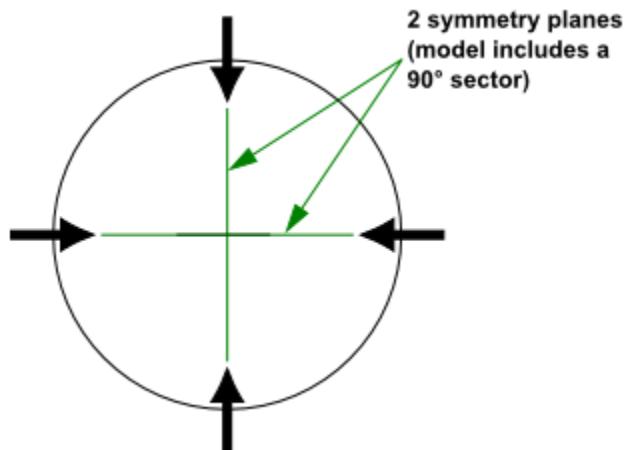

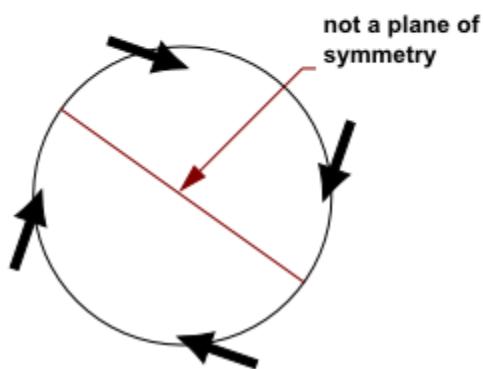

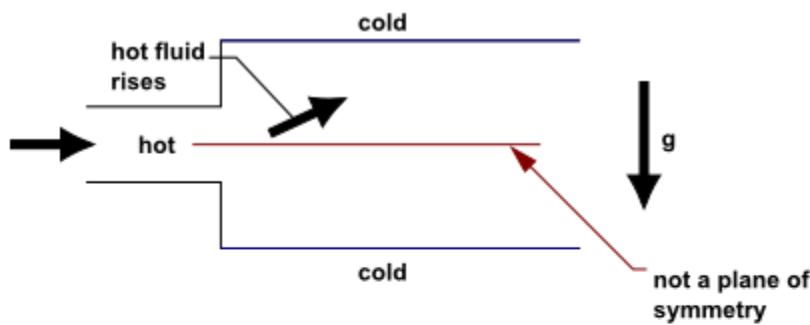

Figure 7.39 Use of Symmetry to Model One Quarter of a Circular Cross-Section

Figure 7.40 (p. 335) illustrates two problems in which a symmetry plane would be *inappropriate*. In both examples, the problem geometry is symmetric but the flow itself does not obey the symmetry boundary conditions. In the first example, buoyancy creates an asymmetric flow. In the second, swirl in the flow creates a flow normal to the would-be symmetry plane. Note that this second example should be handled using rotationally periodic boundaries (as illustrated in *Figure 7.41 (p. 336)*).

Figure 7.40 Inappropriate Use of Symmetry

7.3.14.2. Calculation Procedure at Symmetry Boundaries

ANSYS FLUENT assumes a zero flux of all quantities across a symmetry boundary. There is no convective flux across a symmetry plane: the normal velocity component at the symmetry plane is thus zero. There

is no diffusion flux across a symmetry plane: the normal gradients of all flow variables are thus zero at the symmetry plane. The symmetry boundary condition can therefore be summarized as follows:

- zero normal velocity at a symmetry plane
- zero normal gradients of all variables at a symmetry plane

As stated above, these conditions determine a zero flux across the symmetry plane, which is required by the definition of symmetry. Since the shear stress is zero at a symmetry boundary, it can also be interpreted as a "slip" wall when used in viscous flow calculations.

7.3.15. Periodic Boundary Conditions

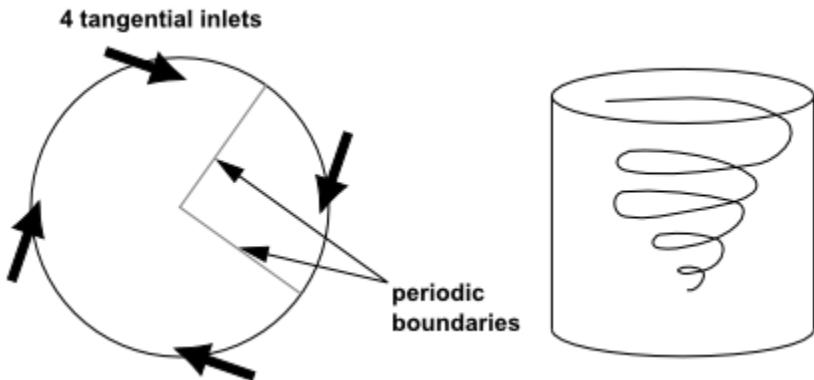

Periodic boundary conditions are used when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic conditions are available in ANSYS FLUENT. The first type does not allow a pressure drop across the periodic planes. (Note to FLUENT 4 users: This type of periodic boundary is referred to as a "cyclic" boundary in FLUENT 4.) The second type allows a pressure drop to occur across translationally periodic boundaries, enabling you to model "fully-developed" periodic flow. (In FLUENT 4 this is a "periodic" boundary.)

This section discusses the no-pressure-drop periodic boundary condition. A complete description of the fully-developed periodic flow modeling capability is provided in [Periodic Flows \(p. 514\)](#).

7.3.15.1. Examples of Periodic Boundaries

Periodic boundary conditions are used when the flows across two opposite planes in your computational model are identical. [Figure 7.41 \(p. 336\)](#) illustrates a typical application of periodic boundary conditions. In this example the flow entering the computational model through one periodic plane is identical to the flow exiting the domain through the opposite periodic plane. Periodic planes are always used in pairs as illustrated in this example.

Figure 7.41 Use of Periodic Boundaries to Define Swirling Flow in a Cylindrical Vessel

7.3.15.2. Inputs for Periodic Boundaries

For a periodic boundary without any pressure drop, there is only one input you need to consider: whether the geometry is rotationally or translationally periodic. (Additional inputs are required for a periodic flow with a periodic pressure drop. See [Periodic Flows \(p. 514\)](#).)

Rotationally periodic boundaries are boundaries that form an included angle about the centerline of a rotationally symmetric geometry. [Figure 7.41 \(p. 336\)](#) illustrates rotational periodicity. Translationally

periodic boundaries are boundaries that form periodic planes in a rectilinear geometry. [Figure 7.42 \(p. 337\)](#) illustrates translationally periodic boundaries.

Figure 7.42 Example of Translational Periodicity - Physical Domain

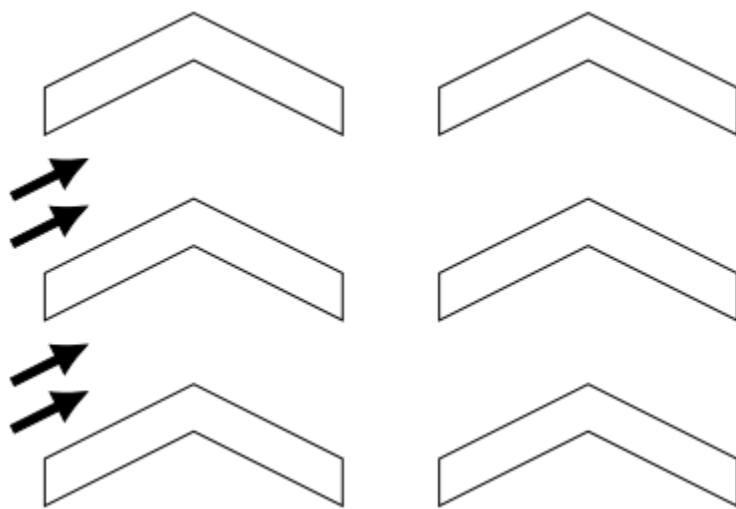

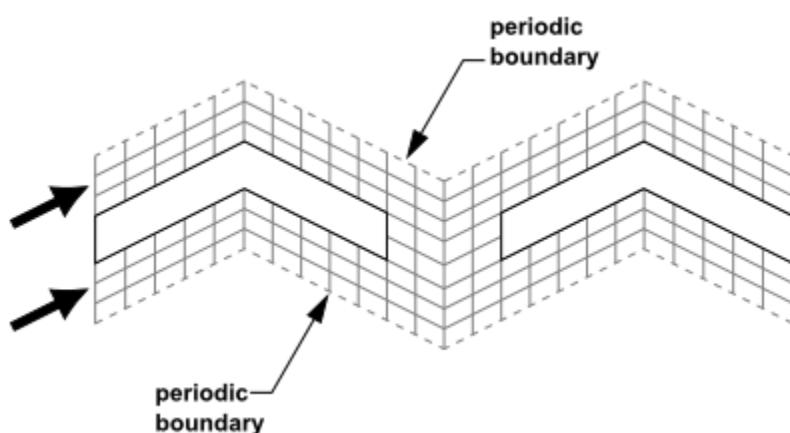

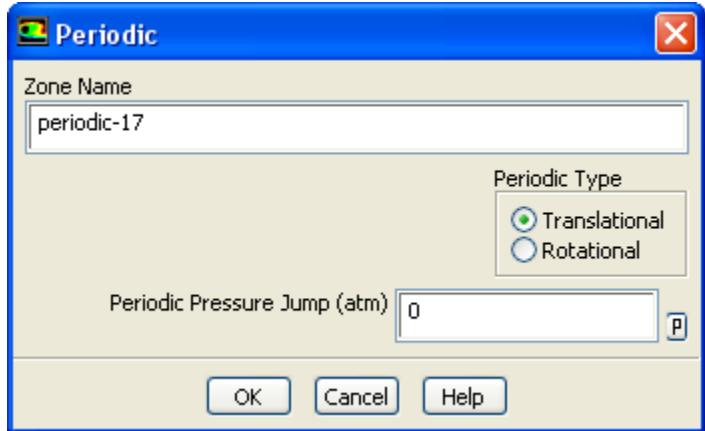

Figure 7.43 Example of Translational Periodicity - Modeled Domain

You will specify translational or rotational periodicity for a periodic boundary in the [Periodic Dialog Box](#) (p. 1988) ([Figure 7.44 \(p. 338\)](#)), which is opened from the **Boundary Conditions** task page (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.44 The Periodic Dialog Box

Note that there will be an additional item in the **Periodic** dialog box for the density-based solver, which allows you to specify the periodic pressure jump. See [Periodic Flows \(p. 514\)](#) for details.

If the domain is rotationally periodic, select **Rotational** as the **Periodic Type**; if it is translationally periodic, select **Translational**. For rotationally periodic domains, the solver will automatically compute the angle through which the periodic zone is rotated. The axis used for this rotation is the axis of rotation specified for the adjacent cell zone.

Note that there is no need for the adjacent cell zone to be moving for you to use a rotationally periodic boundary. You could, for example, model pipe flow in 3D using a stationary reference frame with a pie-slice of the pipe; the sides of the slice would require rotational periodicity.

You can use the **Mesh/Check** menu item (see [Checking the Mesh \(p. 173\)](#)) to compute and display the minimum, maximum, and average rotational angles of all faces on periodic boundaries. If the difference between the minimum, maximum, and average values is not negligible, then there is a problem with the mesh: the mesh geometry is not periodic about the specified axis.

7.3.15.3. Default Settings at Periodic Boundaries

By default, all periodic boundaries are translational.

7.3.15.4. Calculation Procedure at Periodic Boundaries

ANSYS FLUENT treats the flow at a periodic boundary as though the opposing periodic plane is a direct neighbor to the cells adjacent to the first periodic boundary. Thus, when calculating the flow through the periodic boundary adjacent to a fluid cell, the flow conditions at the fluid cell adjacent to the opposite periodic plane are used.

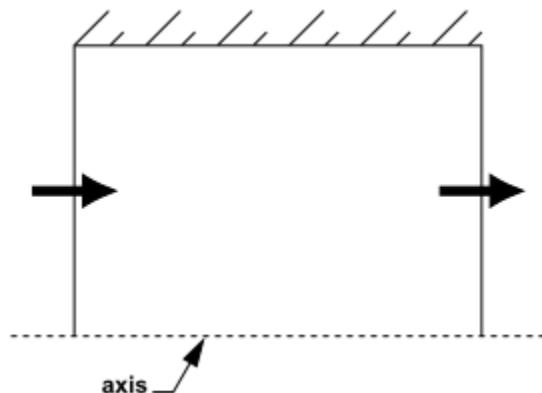

7.3.16. Axis Boundary Conditions

The axis boundary type must be used as the centerline of an axisymmetric geometry (see [Figure 7.45 \(p. 339\)](#)). It can also be used for the centerline of a cylindrical-polar quadrilateral or hexahedral mesh (e.g., a mesh created for a structured-mesh code such as FLUENT 4). You do not need to define any boundary conditions at axis boundaries.

Important

When creating 2D axisymmetric geometry, the axis boundary must lie on the $y=0$ line.

Figure 7.45 Use of an Axis Boundary as the Centerline in an Axisymmetric Geometry

7.3.16.1. Calculation Procedure at Axis Boundaries

To determine the appropriate physical value for a particular variable at a point on the axis, ANSYS FLUENT uses the cell value in the adjacent cell.

7.3.17. Fan Boundary Conditions

The fan model is a lumped parameter model that can be used to determine the impact of a fan with known characteristics upon some larger flow field. The fan boundary type allows you to input an empirical fan curve which governs the relationship between head (pressure rise) and flow rate (velocity) across a fan element. You can also specify radial and tangential components of the fan swirl velocity. The fan model does not provide an accurate description of the detailed flow through the fan blades. Instead, it predicts the amount of flow through the fan. Fans may be used in conjunction with other flow sources, or as the sole source of flow in a simulation. In the latter case, the system flow rate is determined by the balance between losses in the system and the fan curve.

ANSYS FLUENT also provides a connection for a special user-defined fan model that updates the pressure jump function during the calculation. This feature is described in [User-Defined Fan Model \(p. 375\)](#).

7.3.17.1. Fan Equations

7.3.17.1.1. Modeling the Pressure Rise Across the Fan

A fan is considered to be infinitely thin, and the discontinuous pressure rise across it is specified as a function of the velocity through the fan. The relationship may be a constant, a polynomial, piecewise-linear, or piecewise-polynomial function, or a user-defined function.

In the case of a polynomial, the relationship is of the form

$$\Delta p = \sum_{n=1}^N f_n v^n - 1 \quad (7-100)$$

where Δp is the pressure jump, f_n are the pressure-jump polynomial coefficients, and v is the magnitude of the local fluid velocity normal to the fan.

Important

The velocity v can be either positive or negative. You must be careful to model the fan so that a pressure rise occurs for forward flow through the fan.

You can, optionally, use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone.

7.3.17.1.2. Modeling the Fan Swirl Velocity

For three-dimensional problems, the values of the convected tangential and radial velocity fields can be imposed on the fan surface to generate swirl. These velocities can be specified as functions of the radial distance from the fan center. The relationships may be constant or polynomial functions, or user-defined functions.

Important

You must use SI units for all fan swirl velocity inputs.

For the case of polynomial functions, the tangential and radial velocity components can be specified by the following equations:

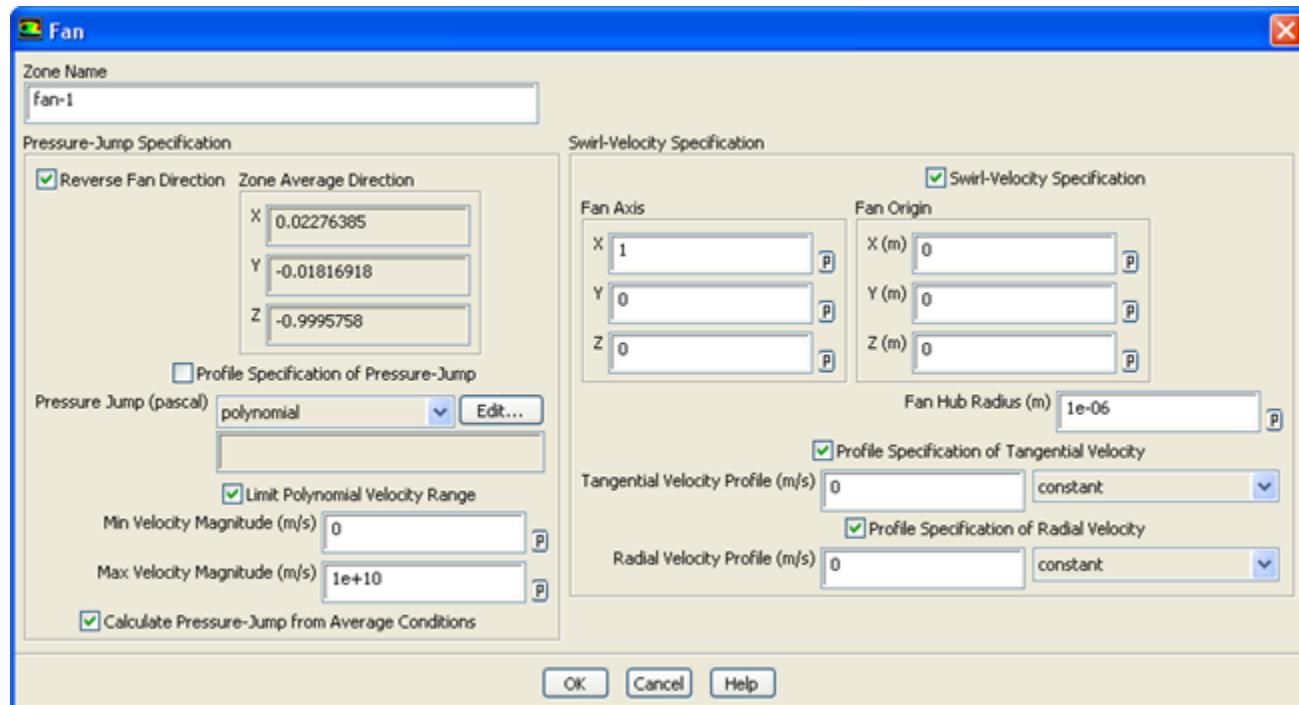

$$U_\theta = \sum_{n=-1}^N f_n r^n; \quad -1 \leq N \leq 6 \quad (7-101)$$

$$U_r = \sum_{n=-1}^N g_n r^n; \quad -1 \leq N \leq 6 \quad (7-102)$$

where U_θ and U_r are, respectively, the tangential and radial velocities on the fan surface in m/s, f_n and g_n are the tangential and radial velocity polynomial coefficients, and r is the distance to the fan center.

7.3.17.2. User Inputs for Fans

Once the fan zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the fan in the *Fan Dialog Box* (p. 1965) (*Figure 7.46* (p. 341)), which is opened from the *Boundary Conditions Task Page* (p. 1958) (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

Figure 7.46 The Fan Dialog Box

Inputs for a fan are as follows:

1. Identify the fan zone.
2. Define the pressure jump across the fan.
3. Define the discrete phase boundary condition for the fan (for discrete phase calculations).
4. Define the swirl velocity, if desired (3D only).

7.3.17.2.1. Identifying the Fan Zone

Since the fan is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Thus the fan zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into ANSYS FLUENT, the fan zone is identified as an **interior** zone, use the **Boundary Conditions** task page (see *Boundary Conditions Task Page (p. 1958)*) (as described in *Changing Cell and Boundary Zone Types (p. 213)*) to change the appropriate **interior** zone to a **fan** zone.

Boundary Conditions

Once the interior zone has been changed to a fan zone, you can open the **Fan** dialog box and specify the pressure jump and, optionally, the swirl velocity.

7.3.17.2.2. Defining the Pressure Jump

To define the pressure jump, you will specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, a user-defined function, or a constant value. You should also check the **Zone Average Direction** vector to be sure that a pressure rise occurs for forward flow through the fan. The **Zone Average Direction**, calculated by the solver, is the face-averaged direction vector for the fan zone. If this

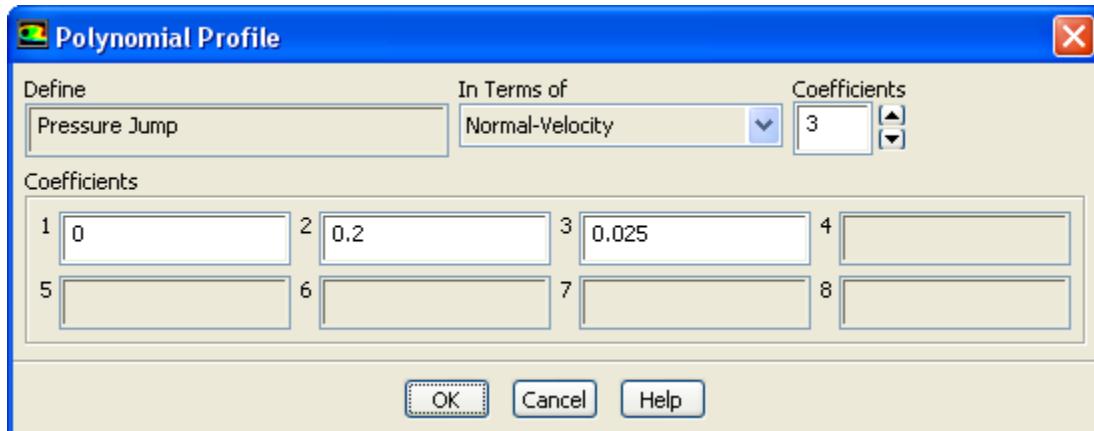

vector is pointing in the direction you want the fan to blow, do not select **Reverse Fan Direction**; if it is pointing in the opposite direction, select **Reverse Fan Direction**.

7.3.17.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure jump:

1. Check that the **Profile Specification of Pressure-Jump** option is off in the *Fan Dialog Box* (p. 1965).
2. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Pressure-Jump**. (If the function type you want is already selected, you can click the **Edit...** button to open the dialog box where you will define the function.)
3. In the dialog box that appears for the definition of the **Pressure Jump** function (e.g., *Figure 7.47* (p. 342)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See *Defining Properties Using Temperature-Dependent Functions* (p. 417) to find out how to use them.

Figure 7.47 Polynomial Profile Dialog Box for Pressure Jump Definition

4. Set any of the optional parameters described below. (optional)

When you define the pressure jump using any of these types of functions, you can choose to limit the minimum and maximum velocity magnitudes used to calculate the pressure jump. Enabling the **Limit Polynomial Velocity Range** option limits the pressure jump when a **Min Velocity Magnitude** and a **Max Velocity Magnitude** are specified.

Important

The values corresponding to the **Min Velocity Magnitude** and the **Max Velocity Magnitude** do not limit the flow field velocity to this range. However, this range does limit the value of the pressure jump, which is a polynomial and a function of velocity, as seen in *Equation 7-100* (p. 340). If the calculated normal velocity magnitude exceeds the **Max Velocity Magnitude** that has been specified, then the pressure jump at the **Max Velocity Magnitude** value will be used. Similarly, if the calculated velocity is less than the specified **Min Velocity Magnitude**, the pressure jump at the **Min Velocity Magnitude** will be substituted for the pressure jump corresponding to the calculated velocity.

You also have the option to use the mass-averaged velocity normal to the fan to determine a single pressure-jump value for all faces in the fan zone. Turning on **Calculate Pressure-Jump from Average Conditions** enables this option.

7.3.17.2.2.2. Constant Value

To define a constant pressure jump, follow these steps:

1. Turn off the **Profile Specification of Pressure-Jump** option in the *Fan Dialog Box* (p. 1965).
2. Choose **constant** in the drop-down list to the right of **Pressure-Jump**.
3. Enter the value for Δp in the **Pressure-Jump** field.

You can follow the procedure below, if it is more convenient:

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Select **constant** in the drop-down list below **Pressure Jump Profile**, and enter the value for Δp in the **Pressure Jump Profile** field.

7.3.17.2.2.3. User-Defined Function or Profile

For a user-defined pressure-jump function or a function defined in a boundary profile file, you will follow these steps:

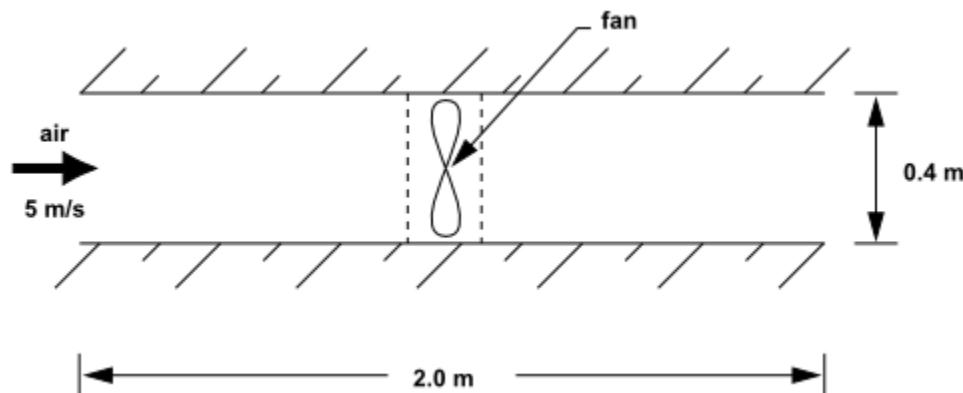

1. Turn on the **Profile Specification of Pressure-Jump** option.
2. Choose the appropriate function in the drop-down list below **Pressure Jump Profile**.

See the [UDF Manual](#) for information about user-defined functions, and [Profiles](#) (p. 382) for details about profile files.

7.3.17.2.2.4. Example: Determining the Pressure Jump Function

This example shows you how to determine the function for the pressure jump. Consider the simple two-dimensional duct flow illustrated in [Figure 7.48](#) (p. 343). Air at constant density enters the 2.0 m \times 0.4 m duct with a velocity of 15 m/s. Centered in the duct is a fan.

Figure 7.48 A Fan Located In a 2D Duct

Assume that the fan characteristics are as follows when the fan is operating at 2000 rpm:

Q (m^3/s)	Δp (Pa)
25	0.0
20	175
15	350
10	525
5	700
0	875

where Q is the flow through the fan and Δp is the pressure rise across the fan. The fan characteristics in this example follow a simple linear relationship between pressure rise and flow rate. To convert this into a relationship between pressure rise and velocity, the cross-sectional area of the fan must be known.

In this example, assuming that the duct is 1.0 m deep, this area is 0.4 m^2 , so that the corresponding velocity values are as follows:

v (m/s)	Δp (Pa)
62.5	0.0
50.0	175
37.5	350
25.0	525
12.5	700
0	875

The polynomial form of this relationship is the following equation for a line:

$$\Delta p = 875 - 14v \quad (7-103)$$

7.3.17.2.3. Defining Discrete Phase Boundary Conditions for the Fan

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the fan. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.17.2.4. Defining the Fan Swirl Velocity

If you want to set tangential and radial velocity fields on the fan surface to generate swirl in a 3D problem, follow these steps:

1. Turn on the **Swirl-Velocity Specification** option in the [Fan Dialog Box \(p. 1965\)](#).
2. Specify the fan's axis of rotation by defining the axis origin (**Fan Origin**) and direction vector (**Fan Axis**).
3. Set the value for the radius of the fan's hub (**Fan Hub Radius**). The default is 1×10^{-6} to avoid division by zero in the polynomial.
4. Set the tangential and radial velocity functions as polynomial functions of radial distance, constant values, or user-defined functions.

Important

You must use SI units for all fan swirl velocity inputs.

7.3.17.2.4.1. Polynomial Function

To define a polynomial function for tangential or radial velocity, follow the steps below:

1. Check that the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option is off in the *Fan Dialog Box* (p. 1965).
2. Enter the coefficients f_n in *Equation 7–101* (p. 340) or g_n in *Equation 7–102* (p. 340) in the **Tangential- or Radial-Velocity Polynomial Coefficients** field. Enter f_{-1} first, then f_0 , etc. Separate each coefficient by a blank space. Remember that the first coefficient is for $\frac{1}{r}$.

7.3.17.2.4.2. Constant Value

To define a constant tangential or radial velocity, the steps are as follows:

1. Turn on the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the *Fan Dialog Box* (p. 1965).
2. Select **constant** in the drop-down list under **Tangential or Radial Velocity Profile**.
3. Enter the value for U_θ or U_r in the **Tangential or Radial Velocity Profile** field.

You can follow the procedure below, if it is more convenient:

1. Turn off the **Profile Specification of Tangential Velocity** or **Profile Specification of Radial Velocity** option in the *Fan Dialog Box* (p. 1965).
2. Enter the value for U_θ or U_r in the **Tangential- or Radial-Velocity Polynomial Coefficients** field.

7.3.17.2.4.3. User-Defined Function or Profile

For a user-defined tangential or radial velocity function or a function contained in a profile file, follow the procedure below:

1. Turn on the **Profile Specification of Tangential or Radial Velocity** option.
2. Choose the appropriate function from the drop-down list under **Tangential or Radial Velocity Profile**.

See the *UDF Manual* for information about user-defined functions, and *Profiles* (p. 382) for details about profile files.

7.3.17.3. Postprocessing for Fans

7.3.17.3.1. Reporting the Pressure Rise Through the Fan

You can use the *Surface Integrals Dialog Box* (p. 2188) to report the pressure rise through the fan, as described in *Surface Integration* (p. 1644). There are two steps to this procedure:

1. Create a surface on each side of the fan zone. Use the *Transform Surface Dialog Box* (p. 2297) (as described in *Transforming Surfaces* (p. 1493)) to translate the fan zone slightly upstream and slightly downstream to create two new surfaces.

2. In the **Surface Integrals** dialog box, report the average **Static Pressure** just upstream and just downstream of the fan. You can then calculate the pressure rise through the fan.

7.3.17.3.2. Graphical Plots

Graphical reports of interest with fans are as follows:

- Contours or profiles of **Static Pressure** and **Static Temperature**.
- XY plots of **Static Pressure** and **Static Temperature** vs position.

Displaying Graphics (p. 1499) explains how to generate graphical displays of data.

Important

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the fan. (If you display node values, the cell values on either side of the fan will be averaged to obtain a node value, and you will not see, for example, the pressure jump across the fan.)

7.3.18. Radiator Boundary Conditions

A lumped-parameter model for a heat exchange element (for example, a radiator or condenser), is available in ANSYS FLUENT. The radiator boundary type allows you to specify both the pressure drop and heat transfer coefficient as functions of the velocity normal to the radiator.

A more detailed heat exchanger model is also available in ANSYS FLUENT. See *Modeling Heat Exchangers* (p. 819) for details.

7.3.18.1. Radiator Equations

7.3.18.1.1. Modeling the Pressure Loss Through a Radiator

A radiator is considered to be infinitely thin, and the pressure drop through the radiator is assumed to be proportional to the dynamic head of the fluid, with an empirically determined loss coefficient which you supply. That is, the pressure drop, Δp , varies with the normal component of velocity through the radiator, v , as follows:

$$\Delta p = k_L \frac{1}{2} \rho v^2 \quad (7-104)$$

where ρ is the fluid density, and k_L is the non-dimensional loss coefficient, which can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

In the case of a polynomial, the relationship is of the form

$$k_L = \sum_{n=1}^N r_n v^n - 1 \quad (7-105)$$

where r_n are polynomial coefficients and v is the magnitude of the local fluid velocity normal to the radiator.

7.3.18.1.2. Modeling the Heat Transfer Through a Radiator

The heat flux from the radiator to the surrounding fluid is given as

$$q = h (T_{air,d} - T_{ext}) \quad (7-106)$$

where q is the heat flux, $T_{air,d}$ is the temperature downstream of the heat exchanger (radiator), and T_{ext} is the reference temperature for the liquid. The convective heat transfer coefficient, h , can be specified as a constant or as a polynomial, piecewise-linear, or piecewise-polynomial function.

For a polynomial, the relationship is of the form

$$h = \sum_{n=0}^N h_n v^n; \quad 0 \leq N \leq 7 \quad (7-107)$$

where h_n are polynomial coefficients and v is the magnitude of the local fluid velocity normal to the radiator in m/s.

Either the actual heat flux (q) or the heat transfer coefficient and radiator temperature (h, T_{ext}) may be specified. q (either the entered value or the value calculated using [Equation 7-106 \(p. 347\)](#)) is integrated over the radiator surface area.

7.3.18.1.2.1. Calculating the Heat Transfer Coefficient

To model the thermal behavior of the radiator, you must supply an expression for the heat transfer coefficient, h , as a function of the fluid velocity through the radiator, v . To obtain this expression, consider the heat balance equation:

$$q = \frac{\dot{m}c_p \Delta T}{A} = h (T_{air,d} - T_{ext}) \quad (7-108)$$

where

q = heat flux (W/m^2)

\dot{m} = fluid mass flow rate (kg/s)

c_p = specific heat capacity of fluid ($\text{J}/\text{kg}\cdot\text{K}$)

h = empirical heat transfer coefficient ($\text{W}/\text{m}^2\cdot\text{K}$)

T_{ext} = external temperature (reference temperature for the liquid) (K)

$T_{air,d}$ = temperature downstream from the heat exchanger (K)

A = heat exchanger frontal area (m^2)

Equation 7-108 (p. 347) can be rewritten as

$$q = \frac{\dot{m}c_p(T_{air,u} - T_{air,d})}{A} = h(T_{air,d} - T_{ext}) \quad (7-109)$$

where $T_{air,u}$ is the upstream air temperature. The heat transfer coefficient, h , can therefore be computed as

$$h = \frac{\dot{m}c_p(T_{air,u} - T_{air,d})}{A(T_{air,d} - T_{ext})} \quad (7-110)$$

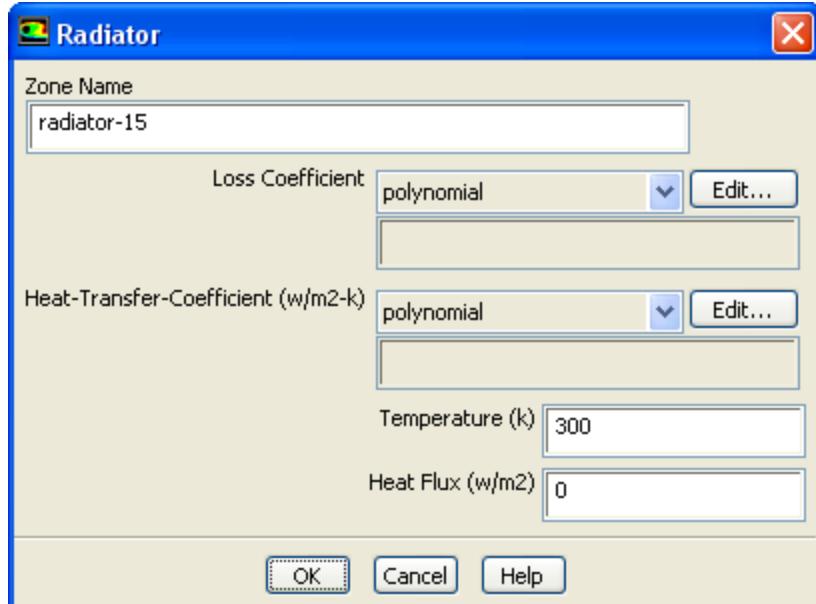

or, in terms of the fluid velocity,

$$h = \frac{\rho v c_p(T_{air,u} - T_{air,d})}{T_{air,d} - T_{ext}} \quad (7-111)$$

7.3.18.2. User Inputs for Radiators

Once the radiator zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the radiator in the *Radiator Dialog Box* (p. 2003) (Figure 7.49 (p. 348)), which is opened from the *Boundary Conditions Task Page* (p. 1958) (as described in *Setting Cell Zone and Boundary Conditions* (p. 214)).

Figure 7.49 The Radiator Dialog Box

The inputs for a radiator are as follows:

1. Identify the radiator zone.
2. Define the pressure loss coefficient.
3. Define either the heat flux or the heat transfer coefficient and radiator temperature.
4. Define the discrete phase boundary condition for the radiator (for discrete phase calculations).

7.3.18.2.1. Identifying the Radiator Zone

Since the radiator is considered to be infinitely thin, it must be modeled as the interface between cells, rather than a cell zone. Thus the radiator zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If, when you read your mesh into ANSYS FLUENT, the radiator zone is identified as an **interior** zone, use the [Boundary Conditions Task Page](#) (p. 1958) (as described in [Changing Cell and Boundary Zone Types](#) (p. 213)) to change the appropriate **interior** zone to a **radiator** zone.

Boundary Conditions

Once the interior zone has been changed to a radiator zone, you can open the **Radiator** dialog box and specify the loss coefficient and heat flux information.

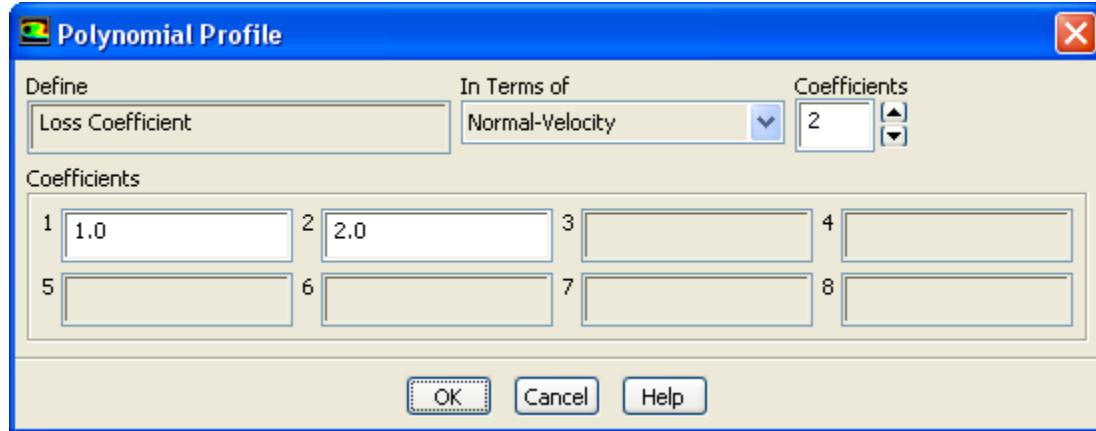

7.3.18.2.2. Defining the Pressure Loss Coefficient Function

To define the pressure loss coefficient k_L you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

7.3.18.2.2.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the pressure loss coefficient:

1. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Loss Coefficient**. (If the function type you want is already selected, you can click the **Edit...** button to open the dialog box where you will define the function.)
2. In the dialog box that appears for the definition of the **Loss Coefficient** function (e.g., [Figure 7.50](#) (p. 350)), enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) to find out how to use them.

Figure 7.50 Polynomial Profile Dialog Box for Loss Coefficient Definition

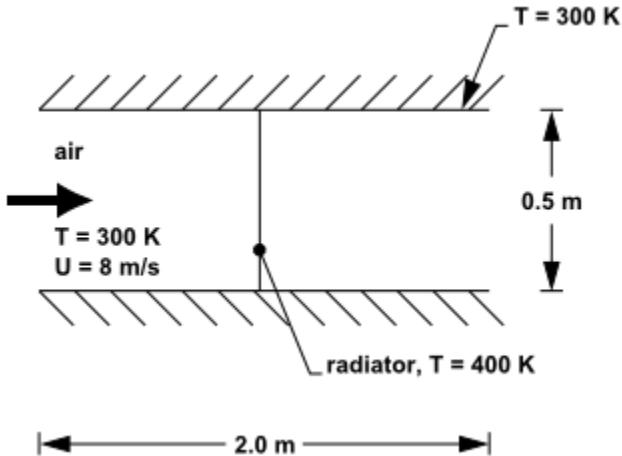

7.3.18.2.2.2. Constant Value

To define a constant loss coefficient, follow these steps:

1. Choose **constant** in the **Loss Coefficient** drop-down list.
2. Enter the value for k_L in the **Loss Coefficient** field.

7.3.18.2.2.3. Example: Calculating the Loss Coefficient

This example shows you how to determine the loss coefficient function. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in *Figure 7.51* (p. 350).

Figure 7.51 A Simple Duct with a Radiator

The radiator characteristics must be known empirically. For this case, assume that the radiator to be modeled yields the test data shown in *Table 7.2: Airside Radiator Data* (p. 351), which was taken with a waterside flow rate of 7 kg/min and an inlet water temperature of 400.0 K. To compute the loss coefficient, it is helpful to construct a table with values of the dynamic head, $\frac{1}{2}\rho V^2$, as a function of pressure

drop, Δp , and the ratio of these two values, k_L (from [Equation 7-104](#) (p. 346)). (The air density, defined in [Figure 7.51](#) (p. 350), is 1.0 kg/m^3 .) The reduced data are shown in [Table 7.3: Reduced Radiator Data](#) (p. 351).

Table 7.2 Airside Radiator Data

Velocity (m/s)	Upstream Temp (K)	Downstream Temp (K)	Pressure Drop
5.0	300.0	330.0	75.0
10.0	300.0	322.5	250.0
15.0	300.0	320.0	450.0

Table 7.3 Reduced Radiator Data

v (m/s)	$\frac{1}{2}\rho v^2$ (Pa)	Δp (Pa)	k_L
5.0	12.5	75.0	6.0
10.0	50.0	250.0	5.0
15.0	112.5	450.0	4.0

The loss coefficient is a linear function of the velocity, decreasing as the velocity increases. The form of this relationship is

$$k_L = 7.0 - 0.2v \quad (7-112)$$

where v is now the absolute value of the velocity through the radiator.

7.3.18.2.3. Defining the Heat Flux Parameters

As mentioned in [Radiator Equations](#) (p. 346), you can either define the actual heat flux (q) in the **Heat Flux** field, or set the heat transfer coefficient and radiator temperature (h, T_{ext}). All inputs are in the [Radiator Dialog Box](#) (p. 2003).

To define the actual heat flux, specify a **Temperature** of 0, and set the constant **Heat Flux** value.

To define the radiator temperature, enter the value for T_{ext} in the **Temperature** field. To define the heat transfer coefficient, you can specify a polynomial, piecewise-linear, or piecewise-polynomial function of velocity, or a constant value.

7.3.18.2.3.1. Polynomial, Piecewise-Linear, or Piecewise-Polynomial Function

Follow these steps to set a polynomial, piecewise-linear, or piecewise-polynomial function for the heat transfer coefficient:

1. Choose **polynomial**, **piecewise-linear**, or **piecewise-polynomial** in the drop-down list to the right of **Heat-Transfer-Coefficient**. (If the function type you want is already selected, you can click on the **Edit...** button to open the dialog box where you will define the function.)
2. In the dialog box that appears for the definition of the **Heat-Transfer-Coefficient** function, enter the appropriate values. These profile input dialog boxes are used the same way as the profile input dialog boxes for temperature-dependent properties. See [Defining Properties Using Temperature-Dependent Functions](#) (p. 417) to find out how to use them.

7.3.18.2.3.2. Constant Value

To define a constant heat transfer coefficient, follow these steps:

1. Choose **constant** in the **Heat-Transfer-Coefficient** drop-down list.
2. Enter the value for h in the **Heat-Transfer-Coefficient** field.

7.3.18.2.3.3. Example: Determining the Heat Transfer Coefficient Function

This example shows you how to determine the function for the heat transfer coefficient. Consider the simple two-dimensional duct flow of air through a water-cooled radiator, shown in [Figure 7.51 \(p. 350\)](#).

The data supplied in [Table 7.2: Airside Radiator Data \(p. 351\)](#) along with values for the air density (1.0 kg/m^3) and specific heat (1000 J/kg-K) can be used to obtain the following values for the heat transfer coefficient h :

Velocity (m/s)	$h (\text{W/m}^2\text{-K})$
5.0	2142.9
10.0	2903.2
15.0	3750.0

The heat transfer coefficient obeys a second-order polynomial relationship (fit to the points in the table above) with the velocity, which is of the form

$$h = 1469.1 + 126.11v + 1.73v^2 \quad (7-113)$$

Note that the velocity v is assumed to be the absolute value of the velocity passing through the radiator.

7.3.18.2.4. Defining Discrete Phase Boundary Conditions for the Radiator

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the radiator. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.18.3. Postprocessing for Radiators

7.3.18.3.1. Reporting the Radiator Pressure Drop

You can use the [Surface Integrals Dialog Box \(p. 2188\)](#) to report the pressure drop across the radiator, as described in [Surface Integration \(p. 1644\)](#). There are two steps to this procedure:

1. Create a surface on each side of the radiator zone. Use the [Transform Surface Dialog Box \(p. 2297\)](#) (as described in [Transforming Surfaces \(p. 1493\)](#)) to translate the radiator zone slightly upstream and slightly downstream to create two new surfaces.
2. In the **Surface Integrals** dialog box, report the average **Static Pressure** just upstream and just downstream of the radiator. You can then calculate the pressure drop across the radiator.

To check this value against the expected value based on [Equation 7-104 \(p. 346\)](#), you can use the **Surface Integrals** dialog box to report the average normal velocity through the radiator. (If the radiator is not aligned with the x , y , or z axis, you will need to use the [Custom Field Function Calculator Dialog Box \(p. 2264\)](#) to generate a function for the velocity normal to the radiator.) Once you have the average normal velocity,

you can use [Equation 7–105 \(p. 347\)](#) to determine the loss coefficient and then [Equation 7–104 \(p. 346\)](#) to calculate the expected pressure loss.

7.3.18.3.2. Reporting Heat Transfer in the Radiator

To determine the temperature rise across the radiator, follow the procedure outlined above for the pressure drop to generate surfaces upstream and downstream of the radiator. Then use the [Surface Integrals Dialog Box \(p. 2188\)](#) (as for the pressure drop report) to report the average **Static Temperature** on each surface. You can then calculate the temperature rise across the radiator.

7.3.18.3.3. Graphical Plots

Graphical reports of interest with radiators are as follows:

- Contours or profiles of **Static Pressure** and **Static Temperature**.
- XY plots of **Static Pressure** and **Static Temperature** vs position.

[Displaying Graphics \(p. 1499\)](#) explains how to generate graphical displays of data.

Important

When generating these plots, be sure to turn off the display of node values so that you can see the different values on each side of the radiator. (If you display node values, the cell values on either side of the radiator will be averaged to obtain a node value, and you will not see, for example, the pressure loss across the radiator.)

7.3.19. Porous Jump Boundary Conditions

Porous jump conditions are used to model a thin “membrane” that has known velocity (pressure-drop) characteristics. It is essentially a 1D simplification of the porous media model available for cell zones. Examples of uses for the porous jump condition include modeling pressure drops through screens and filters, and modeling radiators when you are not concerned with heat transfer. This simpler model should be used whenever possible (instead of the full porous media model) because it is more robust and yields better convergence.

The thin porous medium has a finite thickness over which the pressure change is defined as a combination of Darcy’s Law and an additional inertial loss term:

$$\Delta p = - \left(\frac{\mu}{\alpha} v + C_2 \frac{1}{2} \rho v^2 \right) \Delta m \quad (7-114)$$

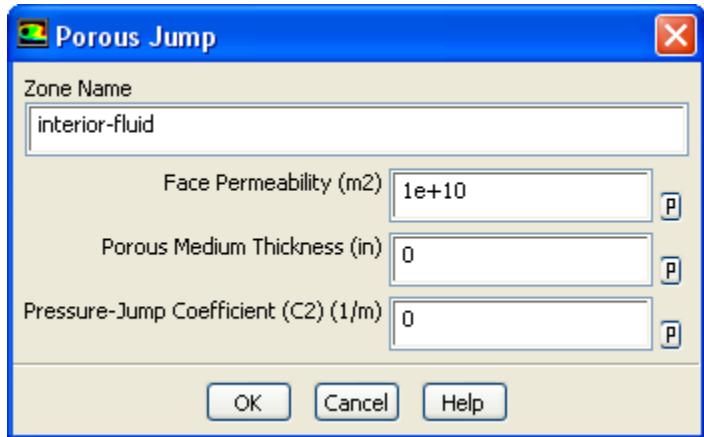

where μ is the laminar fluid viscosity, α is the permeability of the medium, C_2 is the pressure-jump coefficient, v is the velocity normal to the porous face, and Δm is the thickness of the medium. Appropriate values for α and C_2 can be calculated using the techniques described in [User Inputs for Porous Media \(p. 235\)](#).

7.3.19.1. User Inputs for the Porous Jump Model

Once the porous jump zone has been identified (in the **Boundary Conditions** task page), you will set all modeling inputs for the porous jump in the [Porous Jump Dialog Box \(p. 1988\)](#) ([Figure 7.52 \(p. 354\)](#)),

which is opened from the [Boundary Conditions Task Page \(p. 1958\)](#) (as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)).

Figure 7.52 The Porous Jump Dialog Box

The inputs required for the porous jump model are as follows:

1. Identify the porous-jump zone.
2. Set the **Face Permeability** of the medium (α in [Equation 7–114 \(p. 353\)](#)).
3. Set the **Porous Medium Thickness** (Δm).
4. Set the **Pressure-Jump Coefficient** (C_2).

Note

The unit for the pressure-jump coefficient (C_2) is the inverse of length. Should you want to define different units, you can do so by opening the **Units** dialog box and selecting **length-inverse** from the **Quantities** list.

5. Define the discrete phase boundary condition for the porous jump (for discrete phase calculations).
6. If you have enabled the solar load model, define the **Solar Boundary Conditions** for the porous jump. These settings allow you to define the boundary such that it acts as a semi-transparent surface (with respect to the solar radiation calculation only), and thus allows a portion of the solar radiation to pass through it. See [Solar Ray Tracing \(p. 803\)](#) for details.

7.3.19.1.1. Identifying the Porous Jump Zone

Since the porous jump model is a 1D simplification of the porous media model, the porous-jump zone must be modeled as the interface between cells, rather than a cell zone. Thus the porous-jump zone is a type of internal face zone (where the faces are line segments in 2D or triangles/quadrilaterals in 3D). If the porous-jump zone is not identified as such by default when you read in the mesh (i.e., if it is identified as another type of internal face zone), you can use the [Boundary Conditions Task Page \(p. 1958\)](#) to change the appropriate face zone to a **porous-jump** zone.

Define → Boundary Conditions...

The procedure for changing a zone's type is described in [Changing Cell and Boundary Zone Types \(p. 213\)](#). Once the zone has been changed to a porous jump, you can open the [Porous Jump Dialog Box \(p. 1988\)](#).

(as described in [Setting Cell Zone and Boundary Conditions \(p. 214\)](#)) and specify the porous jump parameters listed above.

7.3.19.1.2. Defining Discrete Phase Boundary Conditions for the Porous Jump

If you are modeling a discrete phase of particles, you can set the fate of particle trajectories at the porous jump. See [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#) for details.

7.3.19.2. Postprocessing for the Porous Jump

Postprocessing suggestions for a problem that includes a porous jump are the same as for porous media problems. See [Postprocessing for Porous Media \(p. 253\)](#).

7.4. Non-Reflecting Boundary Conditions

The standard pressure boundary condition, imposed on the boundaries of artificially truncated domain, results in the reflection of the outgoing waves. As a consequence, the interior domain will contain spurious wave reflections. Many applications require precise control of the wave reflections from the domain boundaries to obtain accurate flow solutions. Non-reflecting boundary conditions provide a special treatment to the domain boundaries to control these spurious wave reflections.

In ANSYS FLUENT, two types of non-reflecting boundary conditions (NRBC) are available:

- turbo-specific NRBC
- general NRBC

Turbo-specific NRBC, can be used in both steady and unsteady calculations, and have no geometric restrictions. Both methods are available in the density-based solver and when the compressible ideal-gas law is used.

Important

NRBCs are not available in the pressure-based solver.

Information about non-reflecting boundary conditions (NRBCs) is provided in the following sections.

- [7.4.1.Turbo-Specific Non-Reflecting Boundary Conditions](#)
- [7.4.2.General Non-Reflecting Boundary Conditions](#)

7.4.1. Turbo-Specific Non-Reflecting Boundary Conditions

Information about turbo-specific NRBCs is provided in the following sections.

- [7.4.1.1.Overview](#)
- [7.4.1.2.Limitations](#)
- [7.4.1.3.Theory](#)
- [7.4.1.4.Using Turbo-Specific Non-Reflecting Boundary Conditions](#)

7.4.1.1. Overview

The standard pressure boundary conditions for compressible flow fix specific flow variables at the boundary (e.g., static pressure at an outlet boundary). As a result, pressure waves incident on the boundary will reflect in an unphysical manner, leading to local errors. The effects are more pronounced

for internal flow problems where boundaries are usually close to geometry inside the domain, such as compressor or turbine blade rows.

The turbo-specific non-reflecting boundary conditions permit waves to “pass” through the boundaries without spurious reflections. The method used in ANSYS FLUENT is based on the Fourier transformation of solution variables at the non-reflecting boundary [27] (p. 2368). Similar implementations have been investigated by other authors [56] (p. 2370) [72] (p. 2371). The solution is rearranged as a sum of terms corresponding to different frequencies, and their contributions are calculated independently. While the method was originally designed for axial turbomachinery, it has been extended for use with radial turbomachinery.

7.4.1.2. Limitations

Note the following limitations of turbo-specific NRBCs:

- They are available only with the density-based solver (explicit or implicit).
 - The current implementation applies to steady compressible flows, with the density calculated using the ideal gas law.
 - Inlet and outlet boundary conditions must be pressure inlets and outlets only.
-

Important

Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

- Quad-mapped (structured) surface meshes must be used for inflow and outflow boundaries in a 3D geometry (i.e., triangular or quad-paved surface meshes are not allowed). See *Figure 7.53* (p. 357) and *Figure 7.54* (p. 357) for examples.
-

Important

Note that you may use unstructured meshes in 2D geometries (*Figure 7.55* (p. 358)), and an unstructured mesh may be used away from the inlet and outlet boundaries in 3D geometries.

- The turbo-specific NRBC [27] (p. 2368) has been extended for use on 3D geometries [72] (p. 2371) by decoupling the tangential flow variations from the radial variations. This approximation works best for geometries with a blade pitch that is small compared to the radius of the geometry.
- Reverse flow on the inflow and outflow boundaries are not allowed. If strong reverse flow is present, then you should consider using the General NRBCs instead.
- NRBCs are not compatible with species transport models. They are mainly used to solve ideal-gas single-species flow.

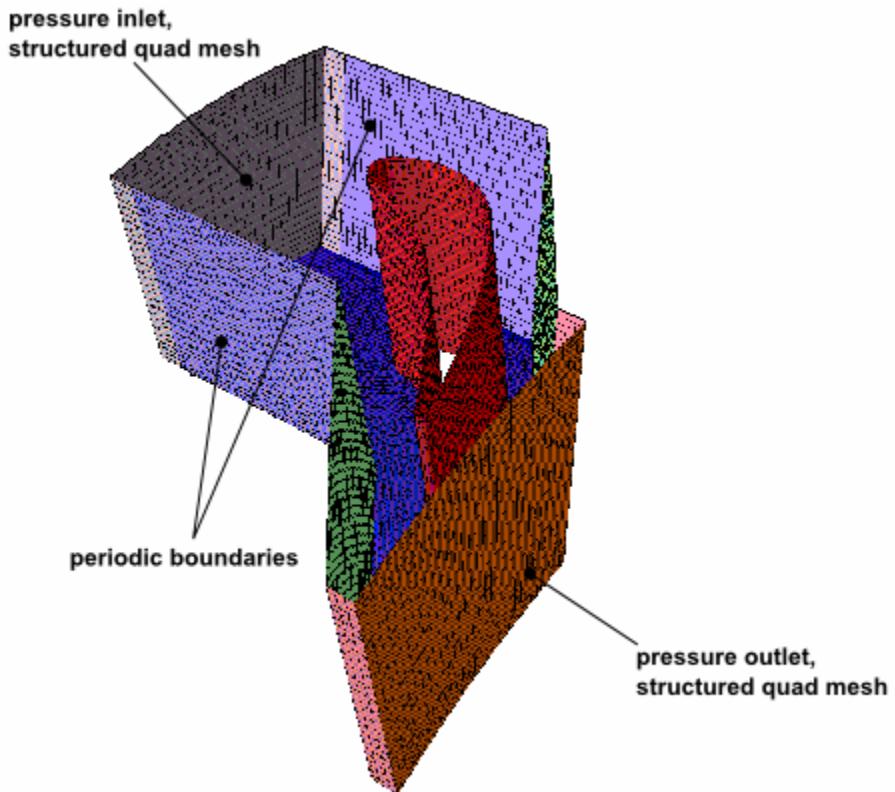

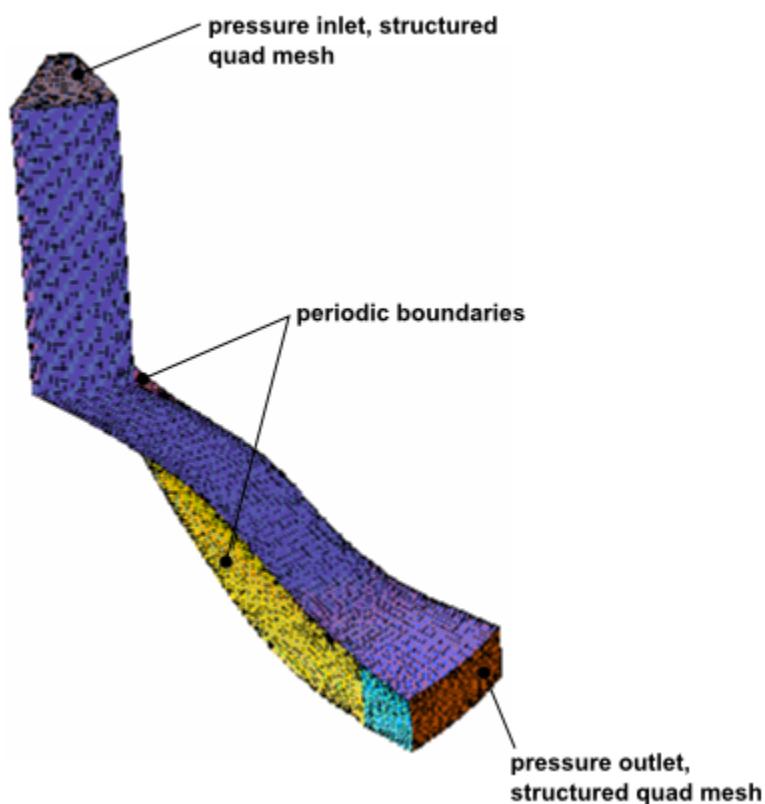

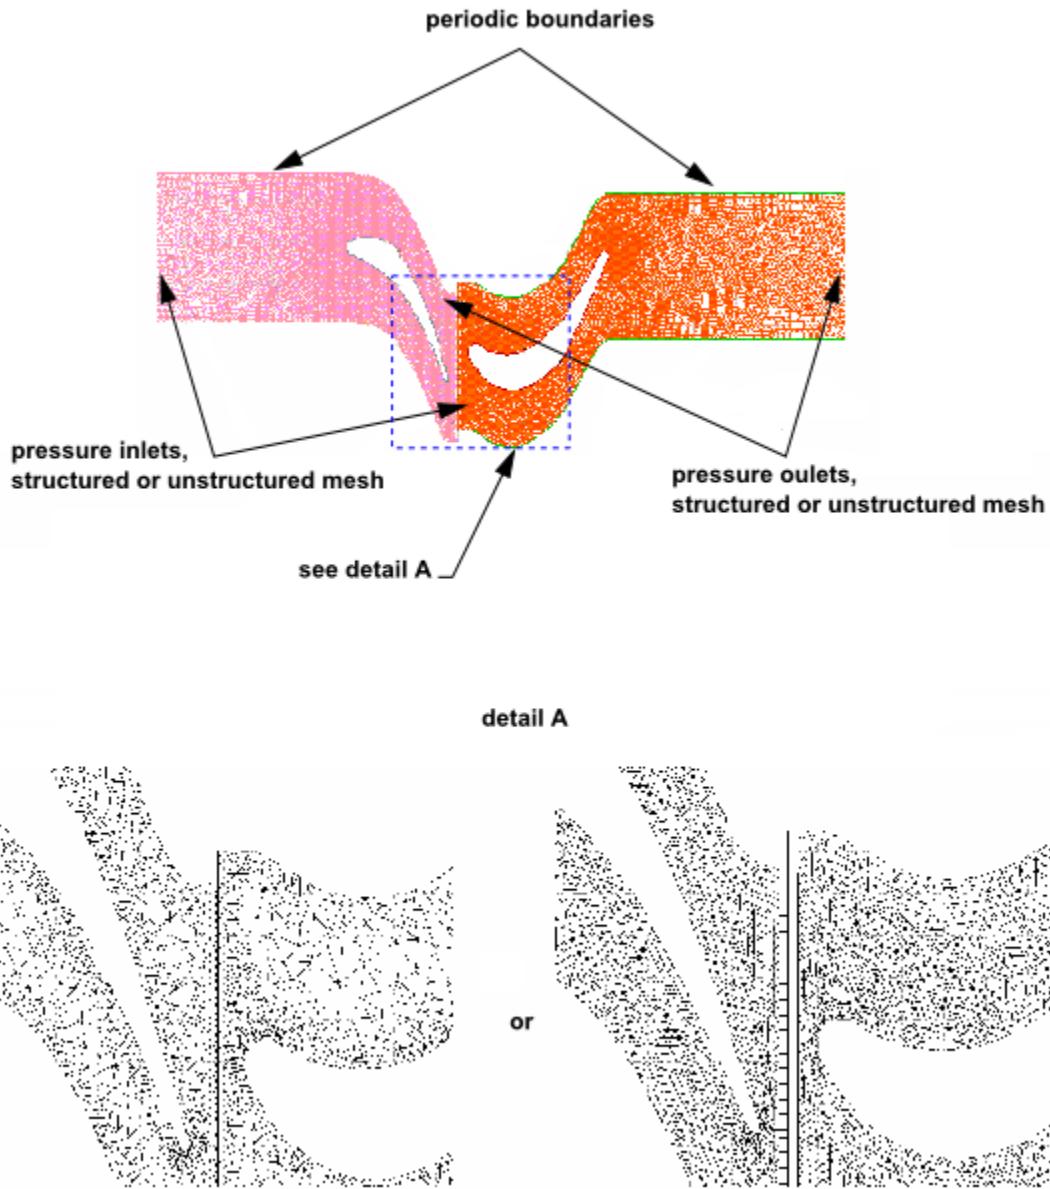

Figure 7.53 Mesh and Prescribed Boundary Conditions in a 3D Axial Flow Problem**Figure 7.54 Mesh and Prescribed Boundary Conditions in a 3D Radial Flow Problem**

Figure 7.55 Mesh and Prescribed Boundary Conditions in a 2D Case

7.4.1.3. Theory

Turbo-specific NRBCs are based on Fourier decomposition of solutions to the linearized Euler equations. The solution at the inlet and outlet boundaries is circumferentially decomposed into Fourier modes, with the 0th mode representing the average boundary value (which is to be imposed as a user input), and higher harmonics that are modified to eliminate reflections [72] (p. 2371).

7.4.1.3.1. Equations in Characteristic Variable Form

In order to treat individual waves, the linearized Euler equations are transformed to characteristic variable (C_i) form. If we first consider the 1D form of the linearized Euler equations, it can be shown that the characteristic variables C_i are related to the solution variables as follows:

$$\tilde{Q} = T^{-1} C \quad (7-115)$$

where

$$\tilde{Q} = \begin{Bmatrix} \tilde{\rho} \\ \tilde{u}_a \\ \tilde{u}_t \\ \tilde{u}_r \\ \tilde{p} \end{Bmatrix}, T^{-1} = \begin{bmatrix} -\frac{1}{\bar{a}^2} & 0 & 0 & \frac{1}{2\bar{a}^2} & \frac{1}{2\bar{a}^2} \\ 0 & 0 & 0 & \frac{1}{2\bar{p}\bar{a}} & \frac{1}{2\bar{p}\bar{a}} \\ 0 & \frac{1}{\bar{p}\bar{a}} & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{\bar{p}\bar{a}} & 0 & 0 \\ 0 & 0 & 0 & \frac{1}{2} & \frac{1}{2} \end{bmatrix}, C = \begin{Bmatrix} C_1 \\ C_2 \\ C_3 \\ C_4 \\ C_5 \end{Bmatrix} \quad (7-116)$$

where \bar{a} is the average acoustic speed along a boundary zone, $\tilde{\rho}$, \tilde{u}_a , \tilde{u}_t , \tilde{u}_r , and \tilde{p} represent perturbations from a uniform condition (e.g., $\tilde{\rho} = \rho - \bar{\rho}$, $\tilde{p} = p - \bar{p}$, etc.).

Note that the analysis is performed using the cylindrical coordinate system. All overlined (averaged) flow field variables (e.g., $\bar{\rho}$, \bar{a}) are intended to be averaged along the pitchwise direction.

In quasi-3D approaches [27] (p. 2368) [56] (p. 2370) [72] (p. 2371), a procedure is developed to determine the changes in the characteristic variables, denoted by δC_i , at the boundaries such that waves will not reflect. These changes in characteristic variables are determined as follows:

$$\delta C = T \delta Q \quad (7-117)$$

where

$$\delta C = \begin{Bmatrix} \delta C_1 \\ \delta C_2 \\ \delta C_3 \\ \delta C_4 \\ \delta C_5 \end{Bmatrix}, T = \begin{bmatrix} -\bar{a}^2 & 0 & 0 & 0 & 1 \\ 0 & 0 & \bar{p}\bar{a} & 0 & 0 \\ 0 & 0 & 0 & \bar{p}\bar{a} & 0 \\ 0 & \bar{p}\bar{a} & 0 & 0 & 1 \\ 0 & -\bar{p}\bar{a} & 0 & 0 & 1 \end{bmatrix}, \delta Q = \begin{Bmatrix} \delta \rho \\ \delta u_a \\ \delta u_t \\ \delta u_r \\ \delta p \end{Bmatrix} \quad (7-118)$$

The changes to the outgoing characteristics — one characteristic for subsonic inflow (δC_5), and four characteristics for subsonic outflow ($\delta C_1, \delta C_2, \delta C_3, \delta C_4$) — are determined from extrapolation of the flow field variables using [Equation 7-117](#) (p. 359).

The changes in the incoming characteristics — four characteristics for subsonic inflow ($\delta C_1, \delta C_2, \delta C_3, \delta C_4$), and one characteristic for subsonic outflow (δC_5) — are split into two components: average change

along the boundary ($\delta\bar{C}_i$), and local changes in the characteristic variable due to harmonic variation along the boundary (δC_{iL}). The incoming characteristics are therefore given by

$$\delta C_{i,j} = \delta C_{iold,j} + \sigma \left(\delta C_{inew,j} - \delta C_{iold,j} \right) \quad (7-119)$$

$$\delta C_{inew,j} = \left(\delta\bar{C}_i + \delta C_{iL,j} \right) \quad (7-120)$$

where $i = 1, 2, 3, 4$ on the inlet boundary or $i = 5$ on the outlet boundary, and $j = 1, \dots, N$ is the grid index in the pitchwise direction including the periodic point once. The under-relaxation factor σ has a default value of 0.75. Note that this method assumes a periodic solution in the pitchwise direction.

The flow is decomposed into mean and circumferential components using Fourier decomposition. The 0th Fourier mode corresponds to the average circumferential solution, and is treated according to the standard 1D characteristic theory. The remaining parts of the solution are described by a sum of harmonics, and treated as 2D non-reflecting boundary conditions [27] (p. 2368).

7.4.1.3.2. Inlet Boundary

For subsonic inflow, there is one outgoing characteristic (δC_5) determined from [Equation 7-117 \(p. 359\)](#), and four incoming characteristics ($\delta C_1, \delta C_2, \delta C_3, \delta C_4$) calculated using [Equation 7-119 \(p. 360\)](#). The average changes in the incoming characteristics are computed from the requirement that the entropy (s), radial and tangential flow angles (α_r and α_t), and stagnation enthalpy (h_0) are specified. Note that in ANSYS FLUENT you can specify p_0 and T_0 at the inlet, from which s_{in} and $h_{0,in}$ are easily obtained. This is equivalent to forcing the following four residuals to be zero:

$$R_1 = \bar{\rho} (\bar{s} - s_{in}) \quad (7-121)$$

$$R_2 = \bar{\rho} \bar{a} (\bar{u}_t - \bar{u}_a \tan \alpha_t) \quad (7-122)$$

$$R_3 = \bar{\rho} \bar{a} (\bar{u}_r - \bar{u}_a \tan \alpha_r) \quad (7-123)$$

$$R_4 = \bar{\rho} \left(\bar{h}_0 - h_{0,in} \right) \quad (7-124)$$

where

$$s_{in} = \gamma \ln \left(T_{0_{in}} \right) - (\gamma - 1) \ln \left(p_{0_{in}} \right) \quad (7-125)$$

$$h_{0_{in}} = c_p T_{0_{in}} \quad (7-126)$$

The average characteristic is then obtained from residual linearization as follows (see also *Figure 7.56 (p. 362)*)

$$\begin{Bmatrix} \delta \bar{C}_1 \\ \delta \bar{C}_2 \\ \delta \bar{C}_3 \\ \delta \bar{C}_4 \end{Bmatrix} = \begin{bmatrix} -1 & 0 & 0 & 0 \\ \frac{\tan \alpha_t}{(1-\gamma) M} & \frac{M_t}{M} & \frac{-M_t}{M} \tan \alpha_t & \frac{\tan \alpha_t}{M} \\ \frac{\tan \alpha_r}{(\gamma-1) M} & \frac{M_t}{M} \tan \alpha_t & \frac{M_2}{M} & \frac{-\tan \alpha_r}{M} \\ \frac{2}{(\gamma-1) M} & 2 \frac{M_t}{M} & 2 \frac{M_r}{M} & \frac{-2}{M} \end{bmatrix} \begin{Bmatrix} R_1 \\ R_2 \\ R_3 \\ R_4 \end{Bmatrix} \quad (7-127)$$

where

$$M_a = \frac{\bar{u}_a}{\bar{a}} \quad (7-128)$$

$$M_t = \frac{\bar{u}_t}{\bar{a}} \quad (7-129)$$

$$M_r = \frac{\bar{u}_r}{\bar{a}} \quad (7-130)$$

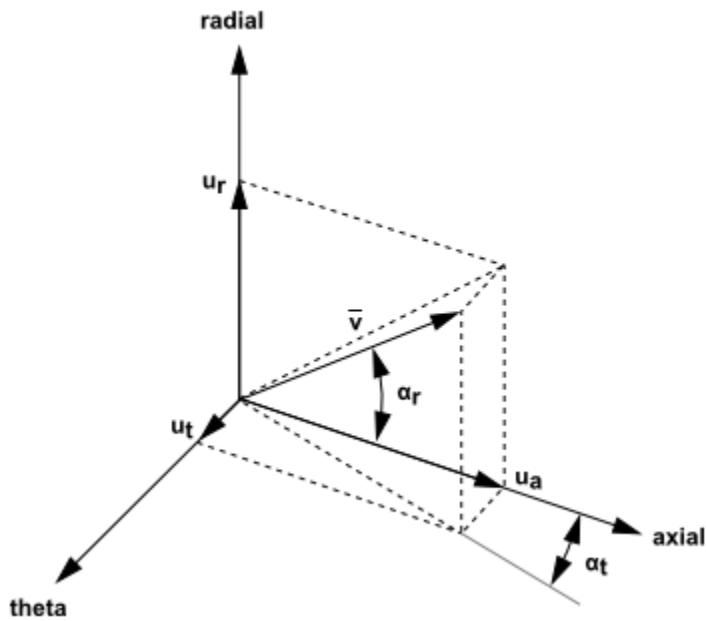

and

$$M = 1 + M_a - M_t \tan \alpha_t + M_r \tan \alpha_r \quad (7-131)$$

$$M_t = -1 - M_a - M_r \tan \alpha_r \quad (7-132)$$

$$M_2 = -1 - M_a - M_t \tan \alpha_t \quad (7-133)$$

Figure 7.56 Prescribed Inlet Angles

where

$$|v| = \sqrt{u_t^2 + u_r^2 + u_a^2} \quad (7-134)$$

$$e_t = \frac{u_t}{|v|} \quad (7-135)$$

$$e_r = \frac{u_r}{|v|} \quad (7-136)$$

$$e_a = \frac{u_a}{|v|} \quad (7-137)$$

$$\tan \alpha_t = \frac{e_t}{e_a} \quad (7-138)$$

$$\tan \alpha_r = \frac{e_r}{e_a} \quad (7-139)$$

To address the local characteristic changes at each j grid point along the inflow boundary, the following relations are developed [27] (p. 2368) [72] (p. 2371):

$$\begin{aligned} \delta C_{1L_j} &= \bar{p} (s_j - \bar{s}) \\ \delta C_{2L_j} &= C'_{2j} - \bar{\rho} \bar{a} (u_{tj} - \bar{u}_t) \\ \delta C_{3L_j} &= -\bar{\rho} \bar{a} (u_{rj} - \bar{u}_r) \\ \delta C_{4L_j} &= \frac{-2}{(1 + M_{aj})} \left(\frac{1}{\gamma - 1} \delta C_{1L_j} + M_{tj} \delta C_{2L_j} + M_{rj} \delta C_{3L_j} + \bar{p} (h_{0j} - \bar{h}_0) \right) \end{aligned} \quad (7-140)$$

Note that the relation for the first and fourth local characteristics force the local entropy and stagnation enthalpy to match their average steady-state values.

The characteristic variable C'_{2j} is computed from the inverse discrete Fourier transform of the second characteristic. The discrete Fourier transform of the second characteristic in turn is related to the discrete Fourier transform of the fifth characteristic. Hence, the characteristic variable C'_{2j} is computed along the pitch as follows:

$$C'_{2_j} = 2\Re \left(\sum_{n=1}^{\frac{N}{2}-1} \hat{C}_{2_n} \exp \left(i2\pi n \frac{\theta_j - \theta_l}{\theta_N - \theta_l} \right) \right) \quad (7-141)$$

The Fourier coefficients C'_{2_n} are related to a set of equidistant distributed characteristic variables C_5^* by the following [56] (p. 2370):

$$\hat{C}_{2_n} = \begin{cases} -\frac{\bar{u}_t + B}{N(\bar{a} + \bar{u}_a)} \sum_{j=1}^N C_5^*_j \exp \left(-i2\pi \frac{jn}{N} \right) & \beta > 0 \\ -\frac{\bar{u}_t + B}{\bar{a} + \bar{u}_a} C_5_j & \beta < 0 \end{cases} \quad (7-142)$$

where

$$B = \begin{cases} i\sqrt{\beta} & \beta > 0 \\ -\text{sign}(\bar{u}_t) \sqrt{|\beta|} & \beta < 0 \end{cases} \quad (7-143)$$

and

$$\beta = \bar{a}^2 - \bar{u}_a^2 - \bar{u}_t^2 \quad (7-144)$$

The set of equidistributed characteristic variables C_5^* is computed from arbitrary distributed C_5_j by using a cubic spline for interpolation, where

$$C_5_j = -\bar{p} \bar{a} (u_{a_j} - \bar{u}_a) + (p_j - \bar{p}) \quad (7-145)$$

For supersonic inflow the user-prescribed static pressure ($p_{s_{in}}$) along with total pressure ($p_{0_{in}}$) and total temperature ($T_{0_{in}}$) are sufficient for determining the flow condition at the inlet.

7.4.1.3.3. Outlet Boundary

For subsonic outflow, there are four outgoing characteristics ($\delta C_1, \delta C_2, \delta C_3$, and δC_4) calculated using [Equation 7-117 \(p. 359\)](#), and one incoming characteristic (δC_5) determined from [Equation 7-119 \(p. 360\)](#). The average change in the incoming fifth characteristic is given by

$$\delta \bar{C}_5 = -2 (\bar{p} - p_{out}) \quad (7-146)$$

where \bar{p} is the current averaged pressure at the exit plane and p_{out} is the desirable average exit pressure (this value is specified by you for single-blade calculations or obtained from the assigned profile for mixing-plane calculations). The local changes (δC_{5L_j}) are given by

$$\delta C_{5L_j} = C'_{5j} + \bar{p} \bar{a} (u_{aj} - \bar{u}_a) - (p_j - \bar{p}) \quad (7-147)$$

The characteristic variable C'_{5j} is computed along the pitch as follows:

$$C'_{5j} = 2\Re \left(\sum_{n=1}^{\frac{N}{2}-1} \hat{C}_{5n} \exp \left(i2\pi n \frac{\theta_j - \theta_l}{\theta_N - \theta_l} \right) \right) \quad (7-148)$$

The Fourier coefficients \hat{C}_{5n} are related to two sets of equidistantly distributed characteristic variables (C_{2j}^* and C_{4j}^* respectively) and given by the following [56] (p. 2370):

$$\hat{C}_{5n} = \begin{cases} \frac{A_2}{N} \sum_{j=1}^N C_{2j}^* \exp \left(i2\pi \frac{jn}{N} \right) - \frac{A_4}{N} \sum_{j=1}^N C_{4j}^* \exp \left(i2\pi \frac{jn}{N} \right) & \beta > 0 \\ A_2 C_{2j} - A_4 C_{4j} & \beta < 0 \end{cases} \quad (7-149)$$

where

$$A_2 = \frac{2\bar{u}_a}{B - \bar{u}_t} \quad (7-150)$$

$$A_4 = \frac{B + \bar{u}_t}{B - \bar{u}_t} \quad (7-151)$$

The two sets of equidistributed characteristic variables (C_{2j}^* and C_{4j}^*) are computed from arbitrarily distributed C_{2j} and C_{4j} characteristics by using a cubic spline for interpolation, where

$$C_{2j} = \bar{\rho} \bar{a} (u_{tj} - \bar{u}_t) \quad (7-152)$$

$$C_{4j} = \bar{\rho} \bar{a} (u_{aj} - \bar{u}_a) + (p_j - \bar{p}) \quad (7-153)$$

For supersonic outflow all flow field variables are extrapolated from the interior.

7.4.1.3.4. Updated Flow Variables

Once the changes in the characteristics are determined on the inflow or outflow boundaries, the changes in the flow variables δQ can be obtained from [Equation 7-117 \(p. 359\)](#). Therefore, the values of the flow variables at the boundary faces are as follows:

$$p_f = p_j + \delta p \quad (7-154)$$

$$u_{af} = u_{aj} + \delta u_a \quad (7-155)$$

$$u_{tf} = u_{tj} + \delta u_t \quad (7-156)$$

$$u_{rf} = u_{rj} + \delta u_r \quad (7-157)$$

$$T_f = T_j + \delta T \quad (7-158)$$

7.4.1.4. Using Turbo-Specific Non-Reflecting Boundary Conditions

Important

If you intend to use turbo-specific NRBCs in conjunction with the density-based implicit solver, it is recommended that you first converge the solution before turning on turbo-specific NRBCs, then converge it again with turbo-specific NRBCs turned on. If the solution is diverging, then you should lower the CFL number. These steps are necessary because only approximate flux Jacobians are used for the pressure-inlet and pressure-outlet boundaries when turbo-specific NRBCs are activated with the density-based implicit solver.

The procedure for using the turbo-specific NRBCs is as follows:

1. Turn on the turbo-specific NRBCs using the `non-reflecting-bc` text command:

```
define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc
→ enable?
```

- If you are not sure whether or not NRBCs are turned on, use the `show-status` text command.
2. Perform NRBC initialization using the `initialize` text command:

```
define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc
→ initialize
```

If the initialization is successful, a summary printout of the domain extent will be displayed. If the initialization is not successful, an error message will be displayed indicating the source of the problem. The initialization will set up the pressure-inlet and pressure-outlet boundaries for use with turbo-specific NRBCs.

Important

Note that the pressure inlet boundaries must be set to the cylindrical coordinate flow specification method when turbo-specific NRBCs are used.

3. If necessary, modify the parameters in the `set` / `submenu`:

```
define → boundary-conditions → non-reflecting-bc → turbo-specific-nrbc
→ set
```

under-relaxation

allows you to set the value of the under-relaxation factor σ in [Equation 7-119 \(p. 360\)](#). The default value is 0.75.

discretization

allows you to set the discretization scheme. The default is to use higher-order reconstruction if available.

verbosity

allows you to control the amount of information printed to the console during an NRBC calculation.

- 0 : silent
- 1 : basic information (default)
- 2: detailed information (for debugging purposes only)

7.4.1.4.1. Using the NRBCs with the Mixing-Plane Model

If you want to use the NRBCs with the mixing-plane model you must define the mixing plane interfaces as pressure-outlet and pressure-inlet zone type pairs.

Important

Turbo-specific NRBCs should not be used with the mixing-plane model if reverse flow is present across the mixing-plane.

7.4.1.4.2. Using the NRBCs in Parallel ANSYS FLUENT

When the turbo-specific NRBCs are used in conjunction with the parallel solver, all cells in each boundary zone, where NRBCs will be applied, must be located or contained within a single partition. You can ensure this by manually partitioning the mesh (see [Partitioning the Mesh Manually and Balancing the Load \(p. 1736\)](#) for more information).

7.4.2. General Non-Reflecting Boundary Conditions

Information about general NRBCs is provided in the following sections.

7.4.2.1. Overview

7.4.2.2. Restrictions and Limitations

7.4.2.3. Theory

7.4.2.4. Using General Non-Reflecting Boundary Conditions

7.4.2.1. Overview

The general non-reflecting boundary conditions in ANSYS FLUENT are based on characteristic wave relations derived from the Euler equations, and applied only on pressure-outlet boundary conditions. To obtain the primitive flow quantities (P, u, v, w, T) on the pressure-outlet, reformulated Euler equations are solved on the boundary of the domain in an algorithm similar to the flow equations applied to the interior of the domain.

Unlike the turbo-specific NRBC method is not restricted by geometric constraints or mesh type. However, good cell skewness near the boundaries where the NRBCs can be applied to steady or transient flows as long as the compressible ideal-gas law is used.

7.4.2.2. Restrictions and Limitations

Note the following restrictions and limitations on the general NRBCs:

- The general NRBC is available only with the density-based solver.
- The general NRBC is available only with compressible flow while using the ideal-gas law.

Important

The general NRBC should not be used with the wet steam or real gas models.

- The general NRBC is not available if the target mass flow rate is activated in the pressure-outlet dialog box.
- The general NRBC is activated.

Important

If you switch from Turbo-specific NRBC or vice versa, then make sure you switch off one NRBC models at the same time.

- NRBCs are not compatible with species transport models. They are mainly used to solve ideal-gas single-species flow.

7.4.2.3. Theory

General NRBCs are derived by first recasting the Euler equations in an orthogonal coordinate system (x_1, x_2, x_3) such that one of the coordinates, x_l , is normal to the boundary [Figure 7.57 \(p. 370\)](#). The characteristic analysis [96] (p. 2372) [97] (p. 2372) is then used to modify terms corresponding to waves propagating in the x_l normal direction. When doing so, a system of equations can be written to describe the wave propagation as follows:

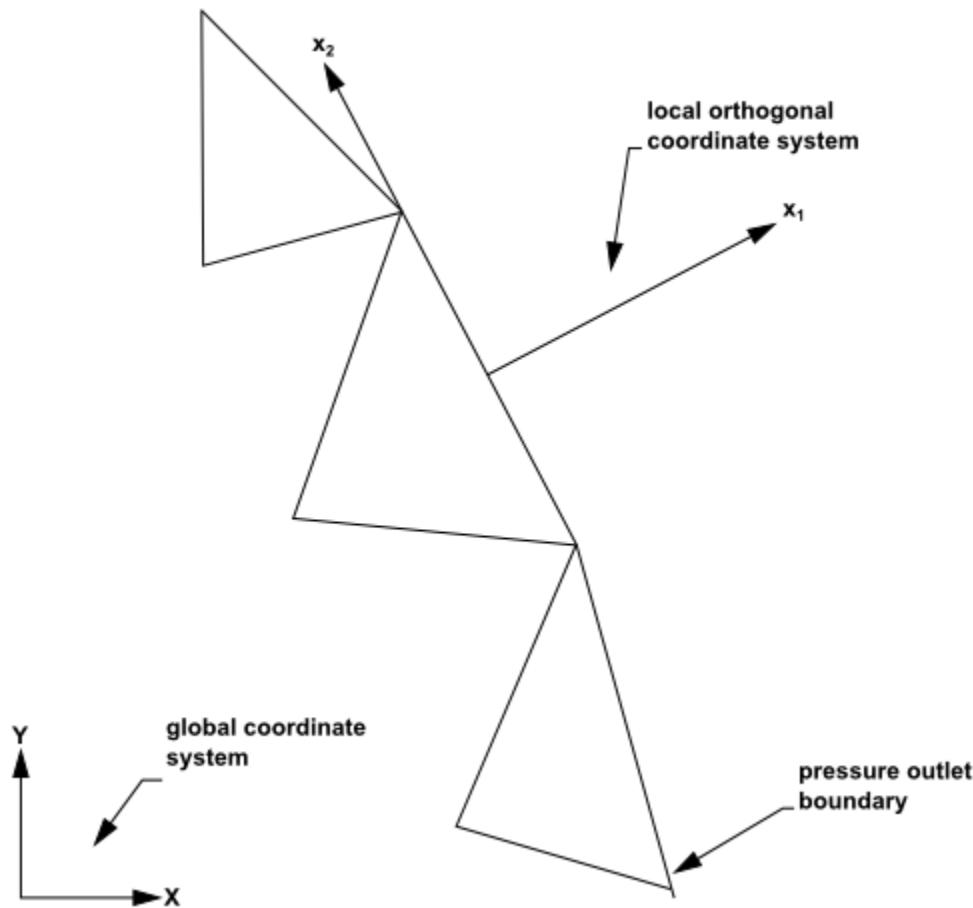

$$\begin{aligned}
 \frac{\partial \rho}{\partial t} + d_l + \frac{\partial m_2}{\partial x_2} + \frac{\partial m_3}{\partial x_3} &= 0 \\
 \frac{\partial m_l}{\partial t} + U_l d_l + \rho d_3 + \frac{\partial (m_l U_2)}{\partial x_2} + \frac{\partial (m_l U_3)}{\partial x_3} &= 0 \\
 \frac{\partial m_2}{\partial t} + U_2 d_l + \rho d_4 + \frac{\partial (m_2 U_2)}{\partial x_2} + \frac{\partial (m_2 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_2} &= 0 \\
 \frac{\partial m_3}{\partial t} + U_3 d_l + \rho d_5 + \frac{\partial (m_3 U_2)}{\partial x_2} + \frac{\partial (m_3 U_3)}{\partial x_3} + \frac{\partial P}{\partial x_3} &= 0 \\
 \frac{\partial \rho E}{\partial t} + \frac{1}{2} |V|^2 d_l + \frac{d_2}{(\gamma - 1)} + m_l d_3 + m_2 d_4 + m_3 d_5 + \frac{\partial [(\rho E + P) U_2]}{\partial x_2} + \frac{\partial [(\rho E + P) U_3]}{\partial x_3} &= 0
 \end{aligned} \tag{7-159}$$

Where $m_l = \rho U_l$, $m_2 = \rho U_2$ and $m_3 = \rho U_3$ and U_l, U_2 and U_3 are the velocity components in the coordinate system (x_l, x_2, x_3) . The equations above are solved on pressure-outlet boundaries, along with the interior governing flow equations, using similar time stepping algorithms to obtain the values of the primitive flow variables (P, u, v, w, T) .

Important

Note that a transformation between the local orthogonal coordinate system (x_l, x_2, x_3) and the global Cartesian system (X, Y, Z) must be defined on each face on the boundary to obtain the velocity components (u, v, w) in a global Cartesian system.

Figure 7.57 The Local Orthogonal Coordinate System onto which Euler Equations are Recasted for the General NRBC Method

The d_i terms in the transformed Euler equations contain the outgoing and incoming characteristic wave amplitudes, L_i , and are defined as follows:

$$\begin{aligned}
 d_1 &= \frac{1}{c^2} \left[L_2 + \frac{1}{2} (L_5 + L_1) \right] \\
 d_2 &= \frac{1}{2} (L_5 + L_1) \\
 d_3 &= \frac{1}{2\rho c} (L_5 - L_1) \\
 d_4 &= L_3 \\
 d_5 &= L_4
 \end{aligned} \tag{7-160}$$

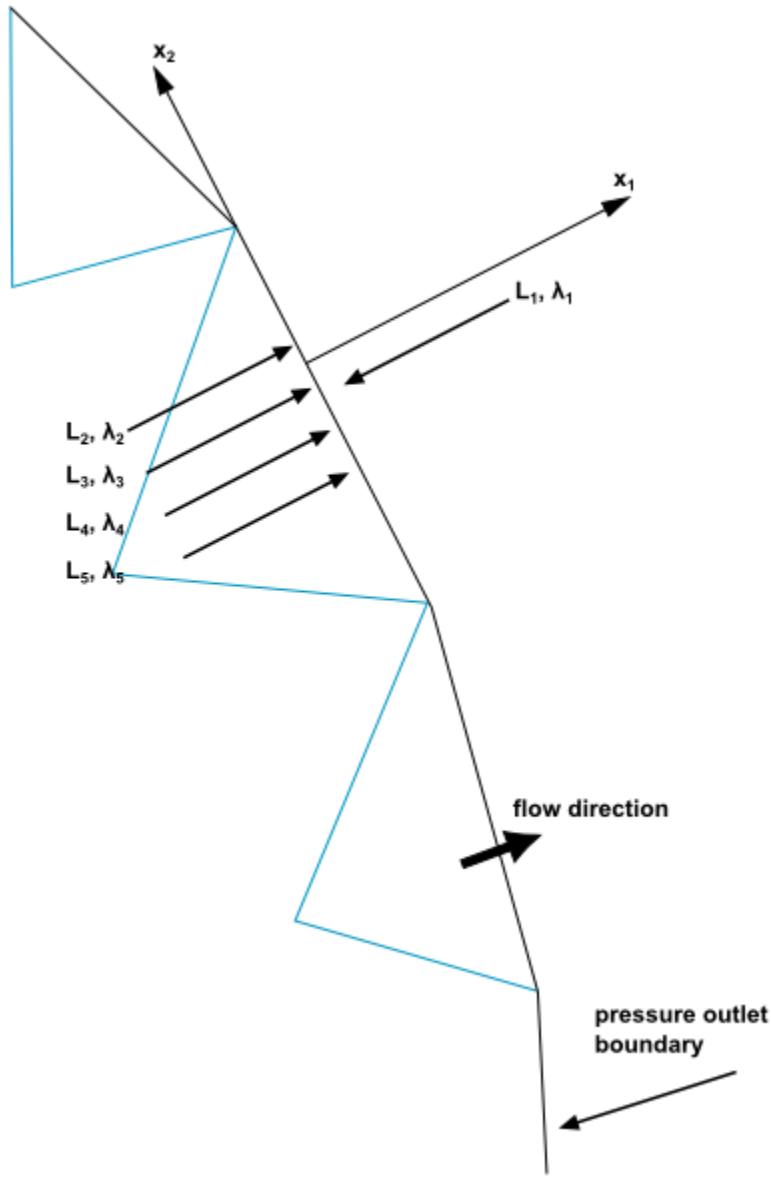

From characteristic analyses, the wave amplitudes, L_i , are given by:

$$\begin{aligned}
 L_1 &= \lambda_1 \left(\frac{\partial P}{\partial x_l} - \rho c \frac{\partial U_l}{\partial x_l} \right) \\
 L_2 &= \lambda_2 \left(c^2 \frac{\partial P}{\partial x_l} - \frac{\partial P}{\partial x_l} \right) \\
 L_3 &= \lambda_3 \frac{\partial U_2}{\partial x_l} \\
 L_4 &= \lambda_4 \frac{\partial U_3}{\partial x_l} \\
 L_5 &= \lambda_5 \left(\frac{\partial P}{\partial x_l} + \rho c \frac{\partial U_l}{\partial x_l} \right)
 \end{aligned} \tag{7-161}$$

The outgoing and incoming characteristic waves are associated with the characteristic velocities of the system (i.e eigenvalues), λ_i , as seen in *Figure 7.58* (p. 372). These eigenvalues are given by:

$$\begin{aligned}\lambda_1 &= U_l - c \\ \lambda_2 = \lambda_3 = \lambda_4 &= U_l \\ \lambda_5 &= U_l + c\end{aligned}\tag{7-162}$$

Figure 7.58 Waves Leaving and Entering a Boundary Face on a Pressure-Outlet Boundary. The Wave Amplitudes are Shown with the Associated Eigenvalues for a Subsonic Flow Condition

For subsonic flow leaving a pressure-outlet boundary, four waves leave the domain (associated with positive eigenvalues $\lambda_2, \lambda_3, \lambda_4$, and λ_5) and one enters the domain (associated with negative eigenvalue λ_1).

To solve [Equation 7–159](#) (p. 369) on a pressure-outlet boundary, the values of L_2, L_3, L_4 and L_5 must be first determined from [Equation 7–161](#) (p. 371) by using extrapolated values of $\frac{\partial P}{\partial x_l}, \frac{\partial U_1}{\partial x_l}, \frac{\partial U_2}{\partial x_l}$, and $\frac{\partial U_3}{\partial x_l}$ from inside the domain. Then, for the lone incoming wave, the Linear Relaxation Method (LRM) of Poinsot [65] (p. 2370) [66] (p. 2370) is used to determine the value of the L_l wave amplitude. The LRM method sets the value of the incoming wave amplitude to be proportional to the differences between the local pressure on a boundary face and the imposed exit pressure. Therefore, L_l is given by

$$L_l = K (P - P_{exit}) \quad (7-163)$$

where P_{exit} is the imposed pressure at the exit boundary, K is the relaxation factor, and P is the local pressure value at the boundary.

In general, the desirable average pressure on a non-reflecting boundary can be either relaxed toward a pressure value at infinity or enforced to be equivalent to some desired pressure at the exit of the boundary.

If you want the average pressure at the boundary to relax toward P at infinity (i.e. $P_{exit} = P_\infty$), the suggested K factor is given by:

$$K = \sigma_l (1 - M_{max}^2) \frac{c}{h} \quad (7-164)$$

where c is the acoustic speed, h is the domain size, M_{max} is the maximum Mach number in the domain, and σ_l is the under-relaxation factor (default value is 0.15). On the other hand, if the desired average pressure at the boundary is to approach a specific imposed value at the boundary, then the K factor is given by:

$$K = \sigma_2 c \quad (7-165)$$

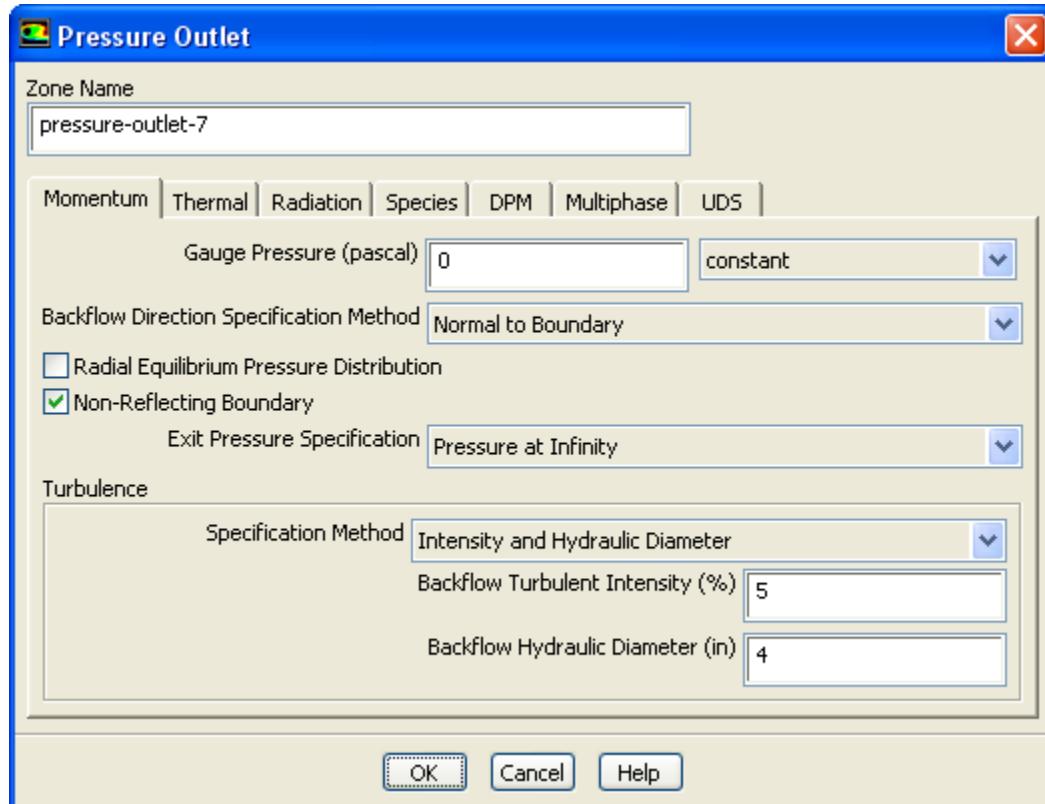

where the default value for σ_2 is 5.0

7.4.2.4. Using General Non-Reflecting Boundary Conditions

The general NRBC is available for use in the **Pressure Outlet** dialog box when either the density-based explicit or the density-based implicit solvers are activated to solve for compressible flows using the ideal-gas law.

To activate the general NRBC

1. Select **pressure-outlet** from the **Boundary Conditions** task page and click the **Edit...** button.
2. In the **Pressure Outlet** dialog box, enable the **Non-Reflecting Boundary** option.
3. Select one of the two **Exit Pressure Specification** options: **Pressure at Infinity** or **Average Boundary Pressure**.

Figure 7.59 The Pressure Outlet Dialog Box With the Non-Reflecting Boundary Enabled

- a. The **Pressure at Infinity** boundary is typically used in unsteady calculations or when the exit pressure value is imposed at infinity. The boundary is designed so that the pressure at the boundary relaxes toward the imposed pressure at infinity. The speed at which this relaxation takes place is controlled by the parameter, *sigma*, which can be adjusted in the TUI:

```
define → boundary-conditions → non-reflecting-bc → general-nrbc → set
```

In the *set* / submenu, you can set the *sigma* value. The default value for *sigma* is 0.15.

- b. The **Average Boundary Pressure** specification is usually used in steady-state calculations when you want to force the average pressure on the boundary to approach the exit pressure value. The matching of average exit pressure to the imposed average pressure is controlled by the parameter *sigma2* which can be adjusted in the TUI:

```
define → boundary-conditions → non-reflecting-bc → general-nrbc → set
```

In the *set* / submenu, you can set the *sigma2* value. The default value for *sigma2* is 5.0.

Important

There is no guarantee that the *sigma2* value of 5.0 will force the average boundary pressure to match the specified exit pressure in all flow situations. In the case where the desired average boundary pressure has not been achieved, the user can intervene to adjust the *sigma2* value so that the desired average pressure on the boundary is approached.

Usually, the solver can operate at higher CFL values without the NRBCs being turned on. Therefore, for steady-state solutions the best practice is to first achieve a good stable solution (not necessarily converged) before activating the non-reflecting boundary condition. In many flow situations, the CFL value must be reduced from the normal operation to keep the solution stable. This is particularly true with the density-based implicit solver since the boundary update is done in an explicit manner. A typical CFL value in the density-based implicit solver, with the NRBC activated, is 2.0.

7.5. User-Defined Fan Model

The user-defined fan model in ANSYS FLUENT allows you to periodically regenerate a profile file that can be used to specify the characteristics of a fan, including pressure jump across the fan, and radial and swirling components of velocity generated by the fan.

For example, consider the calculation of the pressure jump across the fan. You can, through the standard interface, input a constant for the pressure jump, specify a polynomial that describes the pressure jump as a function of axial velocity through the fan, or use a profile file that describes the pressure jump as a function of the axial velocity or location at the fan face. If you use a profile file, the same profile will be used consistently throughout the course of the solution. Suppose, however, that you want to change the profile as the flow field develops. This would require a periodic update to the profile file itself, based upon some instructions that you supply. The user-defined fan model is designed to help you do this.

To use this model, you need to generate an executable that reads a fan profile file that is written by ANSYS FLUENT, and writes out a modified one, which ANSYS FLUENT will then read. The source code for this executable can be written in any programming language (Fortran or C, for example). Your program will be called and executed automatically, according to inputs that you supply through the standard interface.

Information about the user-defined fan model is provided in the following sections.

- [7.5.1. Steps for Using the User-Defined Fan Model](#)
- [7.5.2. Example of a User-Defined Fan](#)

7.5.1. Steps for Using the User-Defined Fan Model

To make use of the user-defined fan model, follow the steps below.

1. In your model, identify one or more interior faces to represent one or more fan zones.

Boundary Conditions

2. Input the name of your executable and the instructions for reading and writing profile files in the [User-Defined Fan Model Dialog Box \(p. 2273\)](#).

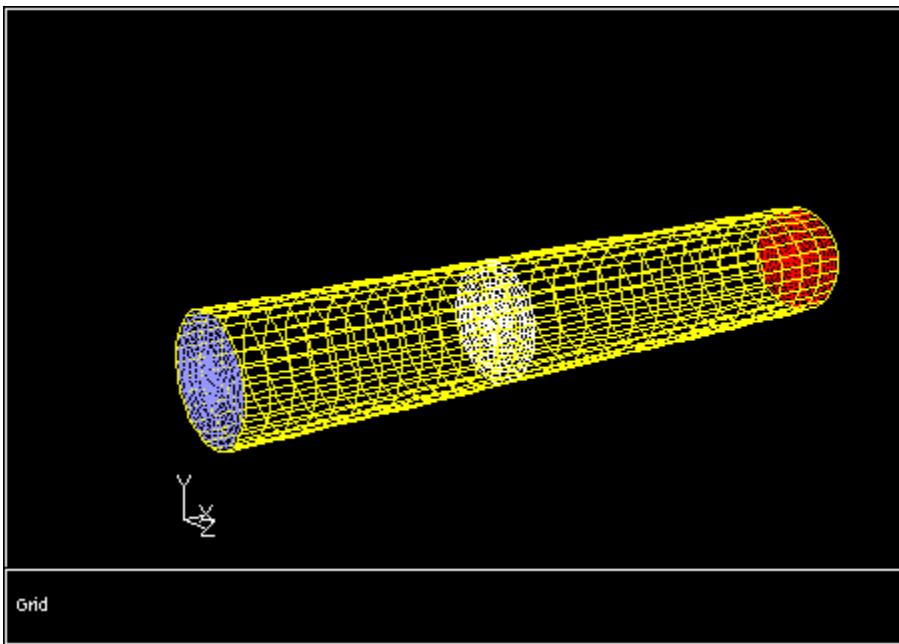

Define → User-Defined → Fan Model...

3. Initialize the flow field and the profile files.
4. Enter the fan parameters using the standard [Fan Dialog Box \(p. 1965\)](#) (opened from the [Boundary Conditions Task Page \(p. 1958\)](#)).
5. Perform the calculation.

7.5.2. Example of a User-Defined Fan

Usage of the user-defined fan model is best demonstrated by an example. With this in mind, consider the domain shown in [Figure 7.60 \(p. 376\)](#). An inlet supplies air at 10 m/s to a cylindrical region, 1.25 m long and 0.2 m in diameter, surrounded by a symmetry boundary. At the center of the flow domain is a circular fan. A pressure outlet boundary is at the downstream end.

Figure 7.60 The Inlet, Fan, and Pressure Outlet Zones for a Circular Fan Operating in a Cylindrical Domain

Solving this problem with the user-defined fan model will cause ANSYS FLUENT to periodically write out a radial profile file with the current solution variables at the fan face. These variables (static pressure, pressure jump, axial, radial, and swirling (tangential) velocity components) will represent averaged quantities over annular sections of the fan. The sizes of the annular regions are determined by the size of the fan and the number of radial points to be used in the profiles.

Once the profile file is written, ANSYS FLUENT will invoke an executable, which will perform the following tasks:

1. Read the profile file containing the current flow conditions at the fan.
2. Perform a calculation to compute new values for the pressure jump, radial velocity, and swirl velocity for the fan.
3. Write a new profile file that contains the results of these calculations.

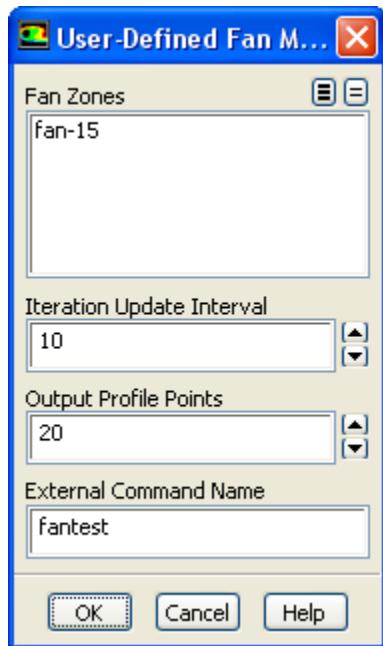

ANSYS FLUENT will then read the new profile file and continue with the calculation.

7.5.2.1. Setting the User-Defined Fan Parameters

Specification of the parameters for the user-defined fan begins in the [User-Defined Fan Model Dialog Box \(p. 2273\)](#) ([Figure 7.61 \(p. 377\)](#)).

Define → User-Defined → Fan Model...

Figure 7.61 The User-Defined Fan Model Dialog Box

In this dialog box, you can select the fan zone(s) on which your executable will operate under **Fan Zones**. In this example, there is only one fan, **fan-8**. If you have multiple fan zones in a simulation, for which you have different profile specifications, you can select them all at this point. Your executable will be able to differentiate between the fan zones because the zone ID for each fan is included in the solution profile file. The executable will be invoked once for each zone, and separate profile files will be written for each.

The executable file will be called on to update the profile file periodically, based on the input for the **Iteration Update Interval**. An input of 10, as shown in the dialog box, means that the fan executable in this example will act every 10 iterations to modify the profile file.

The number of points in the profile file to be written by ANSYS FLUENT is entered under **Output Profile Points**. This profile file can have the same or a different number of points as the one that is written by the external executable.

Finally, the name of the executable should be entered under **External Command Name**. In the current example, the name of the executable is **fantest**.

Important

If the executable is not located in your working directory, then you must type the complete path to the executable.

7.5.2.2. Sample User-Defined Fan Program

The executable file will be built from the Fortran program, **fantest.f**, which is shown below. You can obtain a copy of this subroutine and the two that it calls (to read and write profile files) by contacting your ANSYS FLUENT technical support engineer.

```
c
c  This program is invoked at intervals by ANSYS FLUENT to
c  read a profile-format file that contains radially
```

```

c averaged data at a fan face, compute new pressure-jump
c and swirl-velocity components, and write a new profile
c file that will subsequently be read by ANSYS FLUENT to
c update the fan conditions.
c
c Usage: fatest input_profile output_profile
c

integer npmax
parameter (npmax = 900)
integer inp          ! input: number of profile points
integer iptype       ! input: profile type (0=radial, 1=point)
real ir(npmax)      ! input: radial positions
real ip(npmax)      ! input: pressure
real idp(npmax)     ! input: pressure-jump
real iva(npmax)     ! input: axial velocity
real ivr(npmax)     ! input: radial velocity
real ivt(npmax)     ! input: tangential velocity
character*80 zoneid
integer rfanprof    ! function to read a profile file
integer status

c
status = rfanprof(npmax,zoneid,iptype,
$   inp,ir,ip,idp,iva,ivr,ivt)
if (status.ne.0) then
  write(*,*) 'error reading input profile file'
else
  do 10 i = 1, inp
    idp(i) = 200.0 - 10.0*iva(i)
    ivt(i) = 20.0*ir(i)
    ivr(i) = 0.0
10 continue
call wfanprof(6,zoneid,iptype,inp,ir,idp,ivr,ivt)
endif
stop
end

```

After the variable declarations, which have comments on the right, the subroutine `rfanprof` is called to read the profile file, and pass the current values of the relevant variables (as defined in the declaration list) to `fatest`. A loop is done on the number of points in the profile to compute new values for:

- The pressure jump across the fan, `idp`, which in this example is a function of the axial velocity, `iva`.
- The swirling or tangential velocity, `ivt`, which in this example is proportional to the radial position, `ir`.
- The radial velocity, `ivr`, which in this example is set to zero.

After the loop, a new profile is written by the subroutine `wfanprof`, shown below. (For more information on profile file formats, see [Profile File Format \(p. 383\)](#).)

```

subroutine wfanprof(unit,zoneid,ptype,n,r,dp,vr,vt)
c
c writes an ANSYS FLUENT profile file for input by the
c user fan model
c
integer unit        ! output unit number
character*80 zoneid
integer ptype       ! profile type (0=radial, 1=point)
integer n           ! number of points
real r(n)          ! radial position
real dp(n)         ! pressure jump
real vr(n)         ! radial velocity
real vt(n)         ! tangential velocity
character*6 typenam
if (ptype.eq.0) then
  typenam = 'radial'
else
  typenam = 'point'
endif

```

```

write(unit,*) '(', zoneid(1:index(zoneid,'\'0')-1), ' ',
$ typenam, n, ')'

write(unit,*) '(r'
write(unit,100) r
write(unit,*) ')'

write(unit,*) '(pressure-jump'
write(unit,100) dp
write(unit,*) ')'

write(unit,*) '(radial-velocity'
write(unit,100) vr
write(unit,*) ')'

write(unit,*) '(tangential-velocity'
write(unit,100) vt
write(unit,*) ')'

100 format(5(e15.8,1x))
return
end

```

This subroutine will write a profile file in either radial or point format, based on your input for the integer `ptype`. (See [Profiles \(p. 382\)](#) for more details on the types of profile files that are available.) The names that you use for the various profiles are arbitrary. Once you have initialized the profile files, the names you use in `wfanprof` will appear as profile names in the [Fan Dialog Box \(p. 1965\)](#).

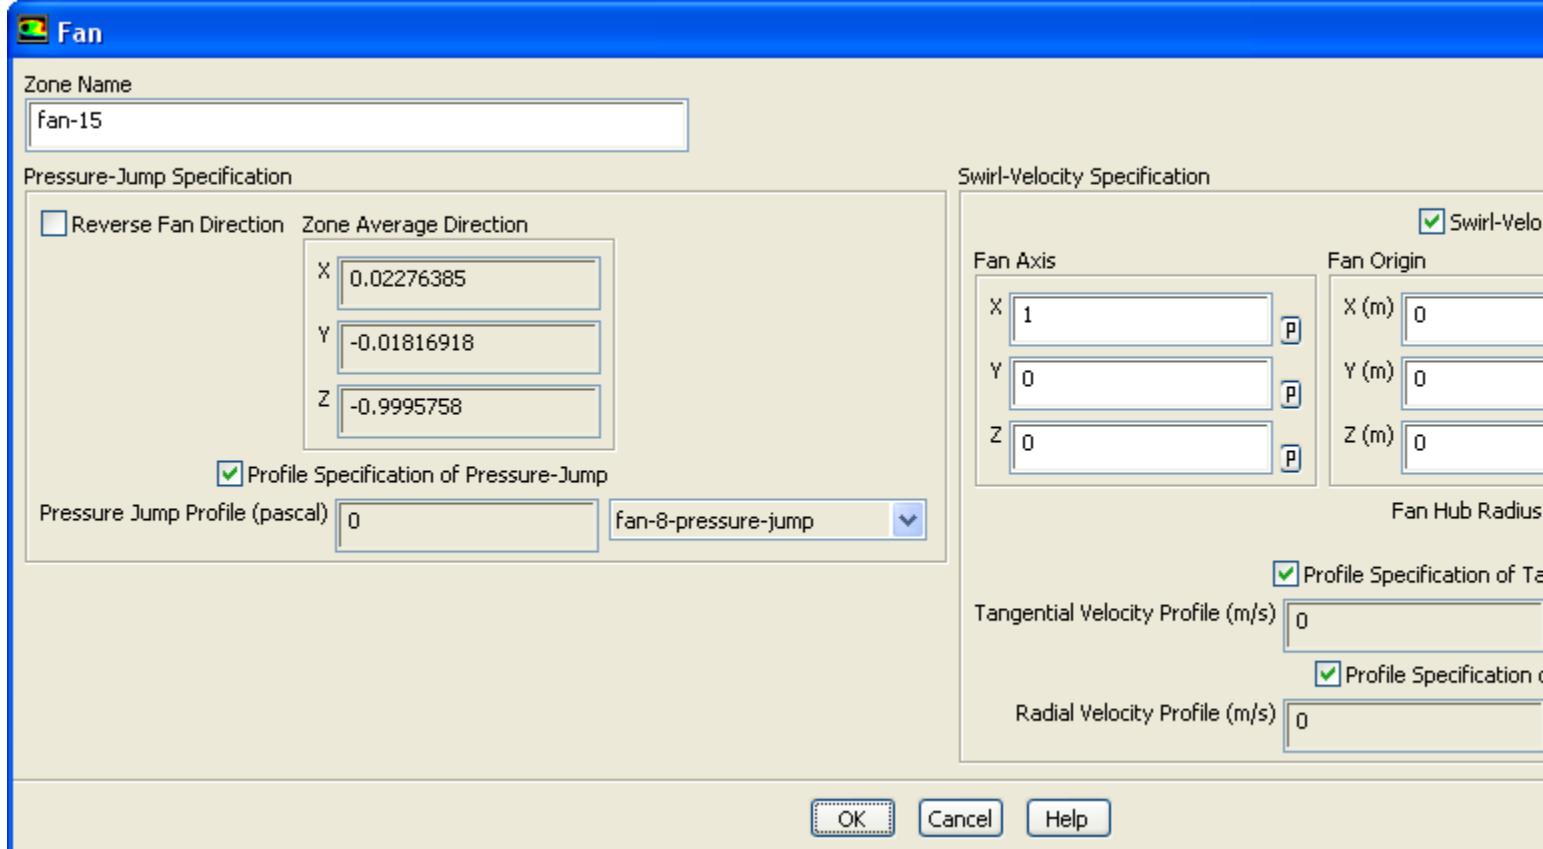

7.5.2.3. Initializing the Flow Field and Profile Files

The next step in the setup of the user-defined fan is to initialize (create) the profile files that will be used. To do this, first initialize the flow field with the [Solution Initialization Task Page \(p. 2088\)](#) (using the velocity inlet conditions, for example), and then type the command (`update-user-fans`) in the console window. (The parentheses are part of the command, and must be typed in.)

This will create the profile names that are given in the subroutine `wfanprof`.

7.5.2.4. Selecting the Profiles

Once the profile names have been established, you will need to visit the [Fan Dialog Box \(p. 1965\)](#) ([Figure 7.62 \(p. 380\)](#)) to complete the problem setup. (See [Fan Boundary Conditions \(p. 339\)](#) for general information on using the **Fan** dialog box.)

Figure 7.62 The Fan Dialog Box

At this time, the **Fan Axis**, **Fan Origin**, and **Fan Hub Radius** can be entered, along with the choice of profiles for the calculation of pressure jump, tangential velocity, and radial velocity. With the profile options enabled, you can select the names of the profiles from the drop-down lists. In the dialog box above, the selected profiles are named **fan-8 pressure-jump**, **fan-8 tangential-velocity**, and **fan-8 radial-velocity**, corresponding to the names that were used in the subroutine wfanprof.

7.5.2.5. Performing the Calculation

The solution is now ready to run. As it begins to converge, the report in the console window shows that the profile files are being written and read every 10 iterations:

```

iter continuity x-velocity y-velocity z-velocity k
!    1 residual normalization factors changed (continuity)
    1 1.0000e+00 1.0000e+00 1.0000e+00 1.0000e+00 1.0000e+00
!    2 residual normalization factors changed (continuity)
    2 1.0000e+00 1.0000e+00 1.0000e+00 1.0000e+00 9.4933e-01
    3 6.8870e-01 7.2663e-01 7.3802e-01 7.5822e-01 6.1033e-01
    .
    .
    .

Writing "fan-8-out.prof"...
Done.
Reading "fan-8-in.prof"...

Reading profile file...
10 "fan-8" radial-profile points, r, pressure-jump,
radial-velocity, tangential-velocity.

Done.
10 1.7612e-01 7.4618e-02 2.5194e-01 2.4538e-01 2.4569e-01

```

```

11    1.6895e-01    8.3699e-02    2.0316e-01    2.0280e-01    2.1169e-01
.
.
.
.
```

The file `fan-8-out.prof` is written out by ANSYS FLUENT and read by the executable `fantest`. It contains values for pressure, pressure jump, axial velocity, radial velocity, and tangential velocity at 20 radial locations at the site of the fan. The file `fan-8-in.prof` is generated by `fantest` and contains updated values for pressure jump and radial and tangential velocity only. It is therefore a smaller file than `fan-8-out.prof`. The prefix for these files takes its name from the fan zone with which the profiles are associated. An example of the profile file `fan-8-in.prof` is shown below. This represents the last profile file to be written by `fantest` during the convergence history.

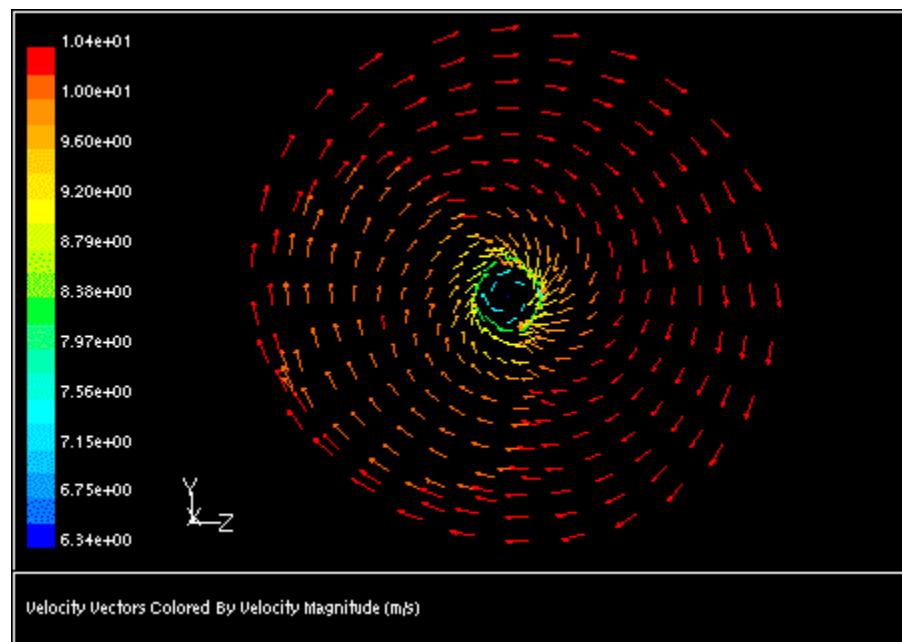

```

((fan-8 radial 10)

)
```

7.5.2.6. Results

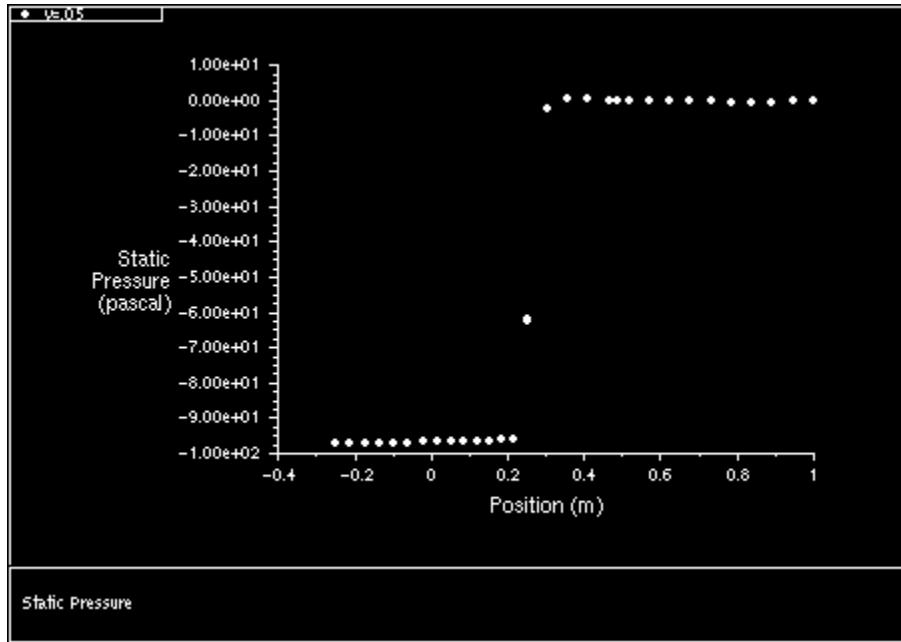

A plot of the transverse velocity components at the site of the fan is shown in [Figure 7.63 \(p. 381\)](#). As expected, there is no radial component, and the tangential (swirling) component increases with radius.

Figure 7.63 Transverse Velocities at the Site of the Fan

As a final check on the result, an XY plot of the static pressure as a function of x position is shown ([Figure 7.64 \(p. 382\)](#)). This XY plot is made on a line at $y=0.05$ m, or at about half the radius of the duct. According to the input file shown above, the pressure jump at the site of the fan should be approximately 97.8 Pa/m. Examination of the figure supports this finding.

Figure 7.64 Static Pressure Jump Across the Fan

7.6. Profiles

Profiles can be boundary conditions, cell zone conditions, and initial conditions for discrete phases. ANSYS FLUENT provides a very flexible profile definition mechanism. This feature allows you to use experimental data, data calculated by an external program, or data written from a previous solution using the [Write Profile Dialog Box \(p. 1957\)](#) (as described in [Reading and Writing Profile Files \(p. 72\)](#)) as the boundary condition for a variable.

Information about profiles is presented in the following subsections:

- 7.6.1. Profile Specification Types
- 7.6.2. Profile File Format
- 7.6.3. Using Profiles
- 7.6.4. Reorienting Profiles
- 7.6.5. Defining Transient Cell Zone and Boundary Conditions

7.6.1. Profile Specification Types

The following is a list of the six types of profiles that can be read into ANSYS FLUENT, as well as information about the interpolation method employed by ANSYS FLUENT for each type.

- Point profiles are specified by an unordered set of n points: (x_i, y_i, v_i) for 2D problems or (x_i, y_i, z_i, v_i) for 3D problems, where $1 \leq i \leq n$. Profiles written using the **Write Profile** dialog box and profiles of experimental data in random order are examples of point profiles.

ANSYS FLUENT will interpolate the point cloud to obtain values at the boundary faces. The default interpolation method for the unstructured point data is zeroth order. In other words, for each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, to get an accurate specification of an inlet profile using the default interpolation method, your profile file should contain a sufficiently high point density. For information about other available interpolation methods for point profiles, see [Using Profiles \(p. 385\)](#).

- Line profiles are specified for 2D problems by an ordered set of n points: (x_i, y_i, v_i) , where $1 \leq i \leq n$. Zeroth-order interpolation is performed between the points. An example of a line profile is a profile of data obtained from an external program that calculates a boundary-layer profile.
- Mesh profiles are specified for 3D problems by an m by n mesh of points: $(x_{ij}, y_{ij}, z_{ij}, v_{ij})$, where $1 \leq i \leq m$ and $1 \leq j \leq n$. Zeroth-order interpolation is performed between the points. Examples of mesh profiles are profiles of data from a structured mesh solution and experimental data in a regular array.
- Radial profiles are specified for 2D and 3D problems by an ordered set of n points: (r_i, v_i) , where $1 \leq i \leq n$. The data in a radial profile are a function of radius only. Linear interpolation is performed between the points, which must be sorted in ascending order of the r field. The axis for the cylindrical coordinate system is determined as follows:
 - For 2D problems, it is the z -direction vector through (0,0).
 - For 2D axisymmetric problems, it is the x -direction vector through (0,0).
 - For 3D problems involving a swirling fan, it is the fan axis defined in the [Fan Dialog Box \(p. 1965\)](#) (unless you are using local cylindrical coordinates at the boundary, as described below).
 - For 3D problems without a swirling fan, it is the rotation axis of the adjacent fluid zone, as defined in the [Fluid Dialog Box \(p. 1942\)](#) (unless you are using local cylindrical coordinates at the boundary, as described below).
 - For 3D problems in which you are using local cylindrical coordinates to specify conditions at the boundary, it is the axis of the specified local coordinate system.
- Axial profiles are specified for 3D problems by an ordered set of n points: (z_i, v_i) , where $1 \leq i \leq n$. The data in an axial profile are a function of the axial direction. Linear interpolation is performed between the points, which must be sorted in ascending order of the z field.
- Transient profiles are specified for 2D and 3D profiles by an ordered set of n points: $(t_i, v_{0,i}, v_{1,i}, v_{2,i}, \dots)$. Linear interpolations is done between the points which must be sorted in ascending order of the t (time or crank angle) field. Examples of transient profiles are transient cell zone and boundary conditions (see [Defining Transient Cell Zone and Boundary Conditions \(p. 393\)](#)) and point properties for particle injections (see [Point Properties for Transient Injections \(p. 1123\)](#)).

7.6.2. Profile File Format

The format of the profile files is fairly simple. The file can contain an arbitrary number of profiles. Each profile consists of a header that specifies the profile name, profile type (point, line, mesh, radial, or axial), and number of defining points, and is followed by an arbitrary number of named "fields". Some of these fields contain the coordinate points and the rest contain boundary data.

Important

All quantities, including coordinate values, must be specified in SI units because ANSYS FLUENT does not perform unit conversion when reading profile files.

Parentheses are used to delimit profiles and the fields within the profiles. Any combination of tabs, spaces, and newlines can be used to separate elements.

Important

In the general format description below, “ | ” indicates that you should input only one of the items separated by |’s and “ . . . ” indicates a continuation of the list.

```
((profile1-name point|line|radial n)
 (field1-name a1 a2 ... an)
 (field2-name b1 b2 ... bn)
 .
 .
 .
 (fieldf-name f1 f2 ... fn))

((profile2-name mesh m n)
 (field1-name   a11 a12 ... a1n
              a21 a22 ... a2n
              .
              .
              .
              am1 am2 ... amn)
 .

.
.

(fieldf-name   f11  f12 ... f1n
      f21  f22 ... f2n
      .
      .
      .
      fm1 fm2 ... fmn))
```

Profile names must have all lowercase letters (e.g., name). Uppercase letters in profile names are not acceptable. Each profile of type point, line, and mesh must contain fields with names x, y, and, for 3D, z. Each profile of type radial must contain a field with name r. Each profile of type axial must contain a field with name z. The rest of the names are arbitrary, but must be valid Scheme symbols. For compatibility with old-style profile files, if the profile type is missing, point is assumed.

7.6.2.1. Example

A typical usage of a profile file is to specify the profile of the boundary layer at an inlet. For a compressible flow calculation, this will be done using profiles of total pressure, k, and ε. For an incompressible flow, it might be preferable to specify the inlet value of streamwise velocity, together with k and ε.

Below is an example of a profile file that does this:

```
((turb-prof point 8)
 (x
  4.00000E+00  4.00000E+00  4.00000E+00  4.00000E+00
  4.00000E+00  4.00000E+00  4.00000E+00  4.00000E+00 )
 (y
  1.06443E-03  3.19485E-03  5.33020E-03  7.47418E-03
  2.90494E-01  3.31222E-01  3.84519E-01  4.57471E-01 )
 (u
  5.47866E+00  6.59870E+00  7.05731E+00  7.40079E+00
```

```

```

7.6.3. Using Profiles

The procedure for using a profile to define a particular cell zone or boundary condition is outlined below.

1. Create a file that contains the desired profile, following the format described in [Profile File Format \(p. 383\)](#).
2. Read the profile using the **Read...** button in the [Profiles Dialog Box \(p. 1954\)](#) ([Figure 7.65 \(p. 386\)](#)) or the **File/Read/Profile...** menu item.

 **Cell Zone Conditions → Profiles...**

 **Boundary Conditions → Profiles...**

File → Read → Profile...

Note that if you use the **Profiles** dialog box to read a file, and a profile in the file has the same name as an existing profile, the old profile will be overwritten.

3. If it is a point profile, you can choose the method of interpolation using the **Profiles** dialog box ([Figure 7.65 \(p. 386\)](#)):

 **Cell Zone Conditions → Profiles...**

 **Boundary Conditions → Profiles...**

Select the point profile in the **Profile** selection list. Then select one of the three choices in the **Interpolation Method** list and click the **Apply** button. The three choices include:

- **Constant**

This method is zeroth-order interpolation. For each cell face at the boundary, the solver uses the value from the profile file located closest to the cell. Therefore, the accuracy of the interpolated profile will be affected by the density of the data points in your profile file. This is the default interpolation method for point profiles.

- **Inverse Distance**

This method assigns a value to each cell face at the boundary based on weighted contributions from the values in the profile file. The weighting factor is inversely proportional to the distance between the profile point and the cell face center.

- **Least Squares**

This method assigns values to the cell faces at the boundary through a first-order interpolation method that tries to minimizes the sum of the squares of the offsets (residuals) between the profile data points and the cell face centers. The least squares solution is found using Singular Value Decomposition (SVD).

For information about the interpolation methods employed for other profile types (i.e., line, mesh, radial, or axial profiles), see [Profile Specification Types \(p. 382\)](#).

4. In the boundary conditions dialog boxes (e.g., the **Velocity Inlet** and **Pressure Inlet** dialog boxes), the fields defined in the profile file (and those defined in any other profile file that you have read in) will appear in the drop-down list to the right of or below each parameter for which profile specification is allowed. To use a particular profile, select it in the appropriate list.
5. Initialize the solution to interpolate the profile.

Important

Profiles *cannot* be used to define volumetric source terms. If you want to define a non-constant source term, you will need to use a user-defined function.

For more information on UDFs, refer to the [UDF Manual](#).

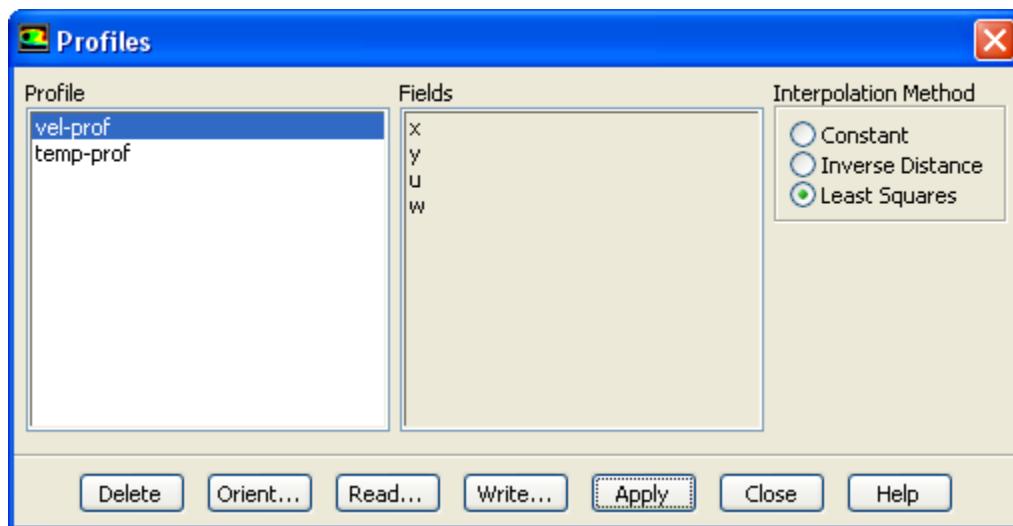

7.6.3.1. Checking and Deleting Profiles

Each profile file contains one or more profiles, and each profile has one or more fields defined in it. Once you have read in a profile file, you can check which fields are defined in each profile, and you can also delete a particular profile. These tasks are accomplished in the [Profiles Dialog Box \(p. 1954\)](#) (*Figure 7.65 (p. 386)*).

↳ **Cell Zone Conditions** → **Profiles...**

↳ **Boundary Conditions** → **Profiles...**

Figure 7.65 The Profiles Dialog Box

To check which fields are defined in a particular profile, select the profile name in the **Profile** list. The available fields in that file will be displayed in the **Fields** list. In *Figure 7.65 (p. 386)*, the profile fields from the profile file of *Example* (p. 384) are shown.

To delete a profile, select it in the **Profile** list and click the **Delete** button. When a profile is deleted, all fields defined in it will be removed from the **Fields** list.

7.6.3.2. Viewing Profile Data

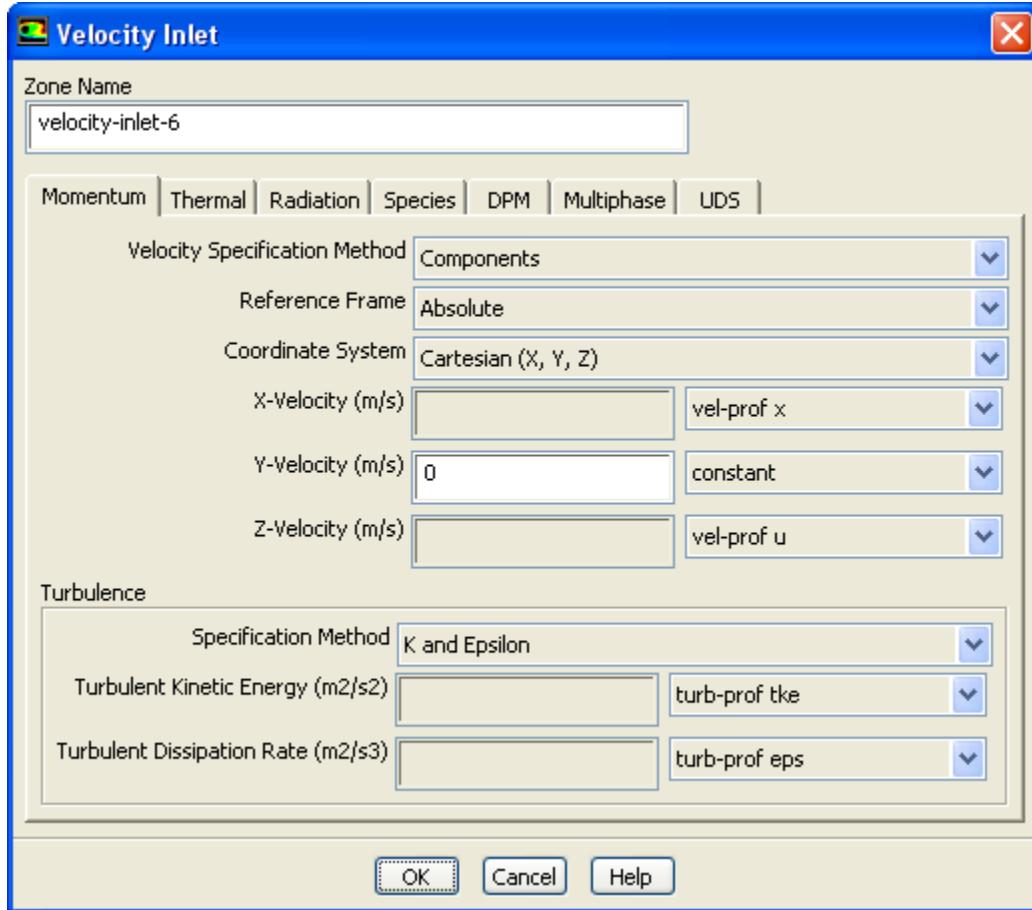

The **Plots** task page options allow you to generate XY plots of data related to profiles. You can plot the original data points from the profile file you have read into ANSYS FLUENT, or you can plot the values assigned to the cell faces on the boundary after the profile file has been interpolated. See [XY Plots of Profiles \(p. 1595\)](#) for the steps to generate these plots.

You have the additional option of viewing the parameters) using the **Plot** or the **Contours** options. Note that these display options do not allow you to plot the actual values of the cell faces (as is done with the **Interpolated Data** option), because they interpolate the values stored in the adjacent cells. To view the boundary condition parameters you must first read in the profile, save a boundary condition with a profile field selected as a parameter, and initialize the flow solution. Then you can view the surface data as follows:

- For 2D calculations, open the **Solution XY Plot** dialog box. Select the appropriate boundary zone in the **Surfaces** list, the variable of interest in the **Y Axis Function** drop-down list, and the desired **Plot Direction**. Ensure that the **Node Values** check button is turned on, and then click **Plot**. You should then see the profile plotted. If the data plotted does not agree with your specified profile, this means that there is an error in the profile file.
- For 3D calculations, use the **Contours** dialog box to display contours on the appropriate boundary zone surface. The **Node Values** check button must be turned on in order for you to view the profile data. If the data shown in the contour plot does not agree with your specified profile, this means that there is an error in the profile file.

7.6.3.3. Example

For the example given in [Example \(p. 384\)](#), the profiles are used for inlet values of x velocity, turbulent kinetic energy, and turbulent kinetic energy dissipation rate, as illustrated in [Figure 7.66 \(p. 388\)](#). (The y velocity is set to a constant value of zero, since it is assumed negligible. However, a profile of y velocity could also be used.)

Figure 7.66 Example of Using Profiles as Boundary Conditions

7.6.4. Reorienting Profiles

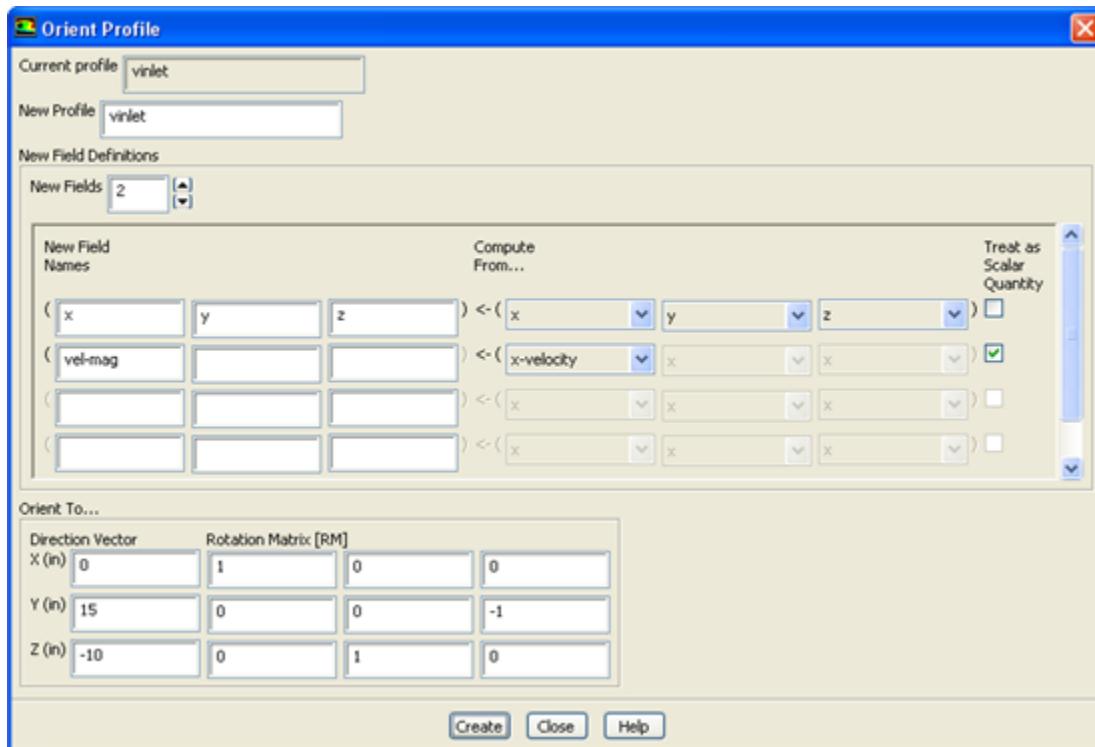

For 3D cases only, ANSYS FLUENT allows you to change the orientation of an existing profile so that it can be used at a boundary positioned arbitrarily in space. This allows you, for example, to take experimental data for an inlet with one orientation and apply it to an inlet in your model that has a different spatial orientation. Note that ANSYS FLUENT assumes that the profile and the boundary are planar.

7.6.4.1. Steps for Changing the Profile Orientation

The procedure for orienting the profile data in the principal directions of a boundary is outlined below:

1. Define and read the profile as described in [Using Profiles \(p. 385\)](#).
2. In the [Profiles Dialog Box \(p. 1954\)](#), select the profile in the **Profile** list, and then click the **Orient...** button. This will open the [Orient Profile Dialog Box \(p. 1956\)](#) ([Figure 7.67 \(p. 389\)](#)).

Figure 7.67 The Orient Profile Dialog Box

3. In the **Orient Profile** dialog box, enter the name of the new profile you want to create in the **New Profile** box.
4. Specify the number of fields you want to create using the up/down arrows next to the **New Fields** box. The number of new fields is equal to the number of vectors and scalars to be defined plus 1 (for the coordinates).
5. Define the coordinate field.
 - a. Enter the names of the three coordinates (x, y, z) in the first row under **New Field Names**.

Important

Ensure that the coordinates are named x, y , and z only. Do not use any other names or upper case letters in this field.

- b. Select the appropriate local coordinate fields for x, y , and z from the drop-down lists under **Compute From....** (A selection of **0** indicates that the coordinate does not exist in the original profile; i.e., the original profile was defined in 2D.)
6. Define the vector fields in the new profile.
 - a. Enter the names of the 3 components in the directions of the coordinate axes of the boundary under **New Field Names**.

Important

Do not use upper case letters in these fields.

- b. Select the names of the 3 components of the vector in the local x , y , and z directions of the profile from the drop-down lists under **Compute From....**
7. Define the scalar fields in the new profile.
- a. Enter the name of the scalar in the first column under **New Field Names**.

Important

Do not use upper case letters in these fields.

- b. Click the button under **Treat as Scalar Quantity** in the same row.
- c. Select the name of the scalar in the corresponding drop-down list under **Compute From....**
8. Under **Orient To...**, specify the rotational matrix RM under the **Rotation Matrix [RM]**. The rotational matrix used here is based on Euler angles (γ , β , and α) that define an orthogonal system $x'y'z'$ as the result of the three successive rotations from the original system xyz . In other words,

$$\begin{bmatrix} x' \\ y' \\ z' \end{bmatrix} = [RM] \begin{bmatrix} x \\ y \\ z \end{bmatrix} \quad (7-166)$$

$$RM = [C] [B] [A] \quad (7-167)$$

where C, B, and A are the successive rotations around the z , y , and x axes, respectively.

Rotation around the z axis:

$$C = \begin{bmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (7-168)$$

Rotation around the y axis:

$$B = \begin{bmatrix} \cos\beta & 0 & \sin\beta \\ 0 & 1 & 0 \\ -\sin\beta & 0 & \cos\beta \end{bmatrix} \quad (7-169)$$

Rotation around the x axis:

$$A = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha \\ 0 & \sin \alpha & \cos \alpha \end{bmatrix} \quad (7-170)$$

9. Under **Orient To...**, specify the **Direction Vector**. The **Direction Vector** is the vector that translates a profile to the new position, and is defined between the centers of the profile fields.

Important

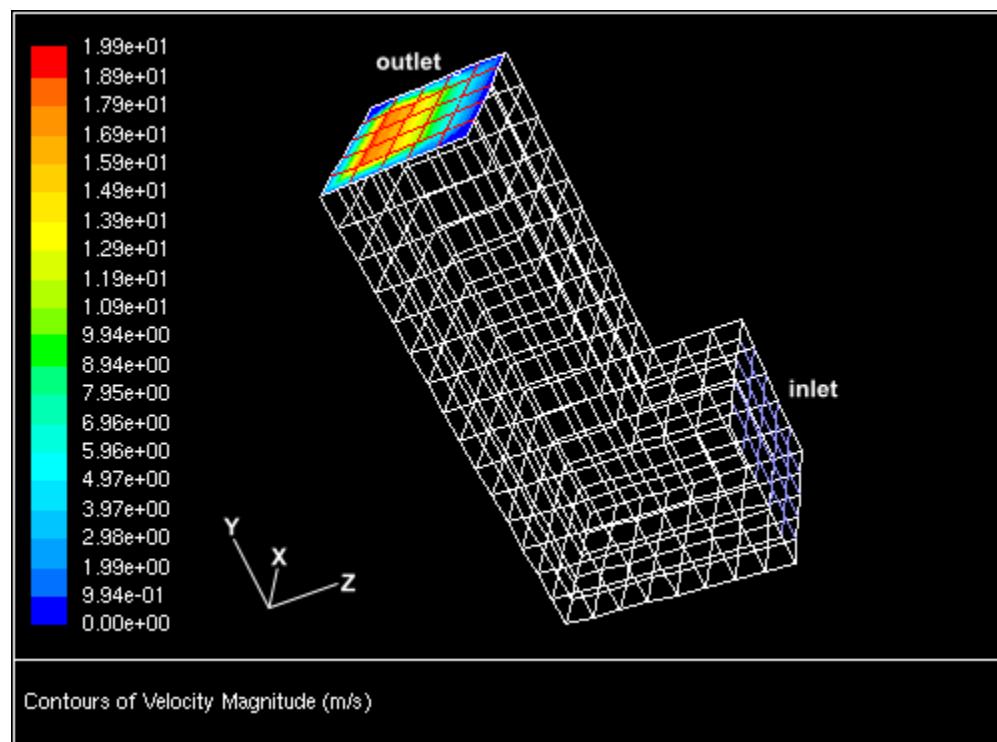

Note that depending on your case, it may be necessary to perform only a rotation, only a translation, or a combination of a translation and a rotation.

10. Click the **Create** button in the **Orient Profile** dialog box, and your new profile will be created. Its name, which you entered in the **New Profile** box, will now appear in the **Profiles** dialog box and will be available for use at the desired boundary.

7.6.4.2. Profile Orienting Example

Consider the domain with a square inlet and outlet, shown in *Figure 7.68* (p. 391). A scalar profile at the outlet is written out to a profile file. The purpose of this example is to impose this outlet profile on the inlet boundary via a 90° rotation about the x axis. However, the rotation will locate the profile away from the inlet boundary. To align the profile to the inlet boundary, a translation via a directional vector needs to be performed.

Figure 7.68 Scalar Profile at the Outlet

The problem is shown schematically in [Figure 7.69](#) (p. 393). Φ_{out} is the scalar profile of the outlet. Φ'_{out} is the image of the Φ_{out} rotated 90° around the x axis. In this example, since $\gamma = \beta = 0$, then $C = B = I$, where I is the identity matrix, and the rotation matrix is

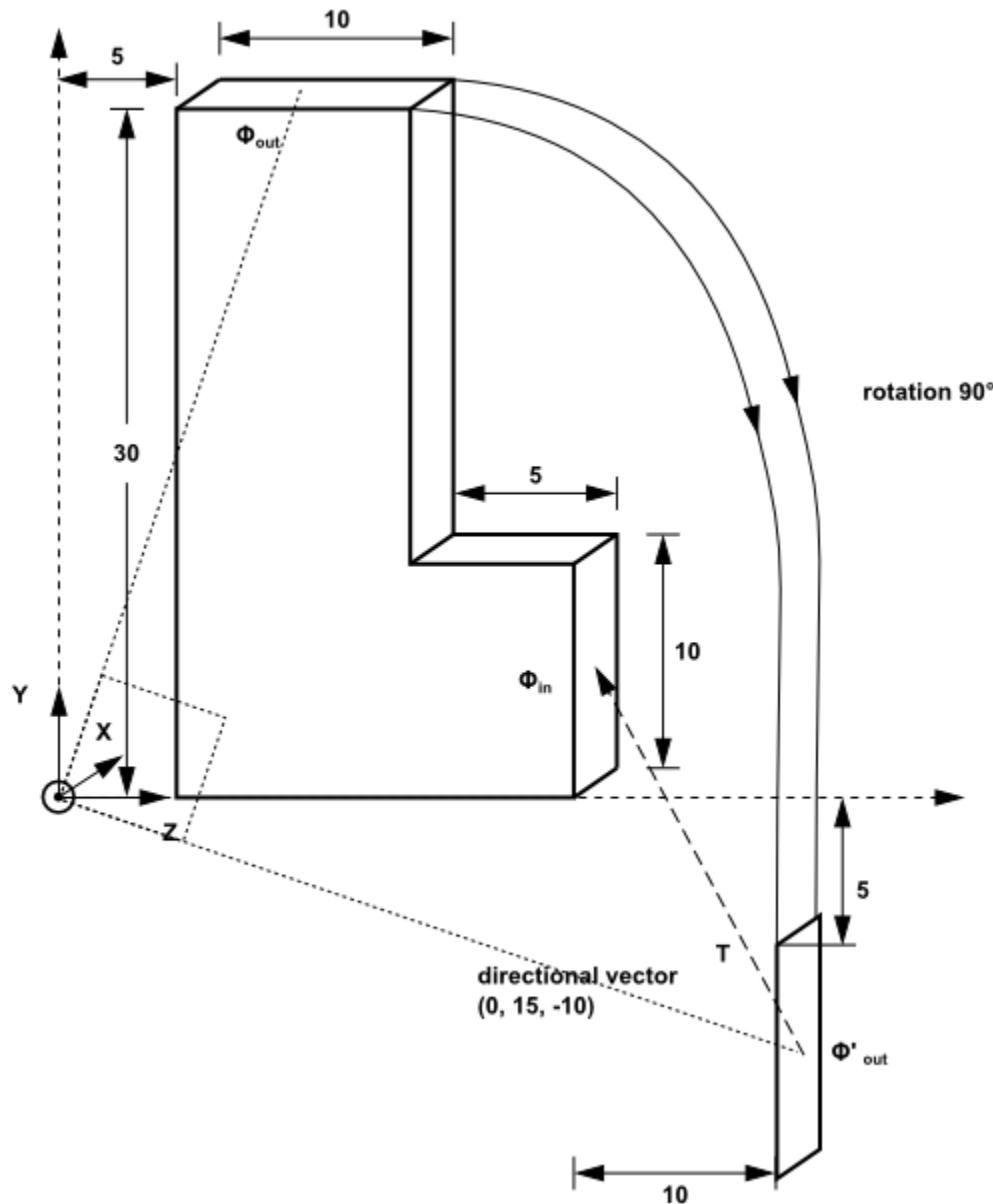

$$RM = [C] [B] [A] = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos 90^\circ & -\sin 90^\circ \\ 0 & \sin 90^\circ & \cos 90^\circ \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \quad (7-171)$$

To overlay the outlet profile on the inlet boundary, a translation will be performed.

To overlay the outlet profile on the inlet boundary, a translation will be performed. The directional vector is the vector that translates Φ'_{out} to Φ_{in} . In this example, the directional vector is $(0, 15, -10)^T$. The appropriate inputs for the **Orient Profile** dialog box are shown in [Figure 7.67](#) (p. 389).

Note that if the profile being imposed on the inlet boundary was due to a rotation of -90° about the x axis, then the rotational matrix RM must be found for $\gamma = \beta = 0$ and $\alpha = -90^\circ$, and a new directional vector must be found to align the profile to the boundary.

Figure 7.69 Problem Specification

7.6.5. Defining Transient Cell Zone and Boundary Conditions

There are two ways you can specify transient cell zone and boundary conditions:

- transient profile with a format similar to the standard profiles described in [Profiles](#) (p. 382)
 - transient profile in a tabular format

Important

For both methods, the cell zone or boundary condition will vary only in time; it must be spatially uniform. However, if the in-cylinder model is activated ([In-Cylinder Settings \(p. 618\)](#)), then you have the option to use the crank angle instead of time. Crank angles can be included in transient tables as well as transient profiles, in a similar fashion to time. Examples of transient profiles and transient tables in crank angle can be found in the sections that follow.

For information about boundary profiles, please refer to [Reading and Writing Profile Files \(p. 72\)](#).

7.6.5.1. Standard Transient Profiles

The format of the standard transient profile file (based on the profiles described in [Profiles \(p. 382\)](#)) is

```
((profile-name transient n periodic?)  
(field_name-1 a1 a2 a3 .... an)  
(field_name-2 b1 b2 b3 .... bn)  
. . .  
(field_name-r r1 r2 r3 .... rn))
```

The profile name as well as the field names have to be shorter than 64 characters. One of the field_name s should be used for the time field, and the time field section *must* be in ascending order. n is the number of entries per field. The periodic? entry indicates whether or not the profile is time-periodic. Set it to 1 for a time-periodic profile, or 0 if the profile is not time-periodic.

An example is shown below:

```
((sampleprofile transient 3 0)  
(time  
1  
2  
3  
)  
(u  
10  
20  
30  
)  
)
```

This example demonstrates the use of crank angle in a transient profile

```
((example transient 3 1)  
(angle  
0.000000e+00 1.800000e+02 3.600000e+02)  
(temperature  
3.000000e+02 5.000000e+02 3.000000e+02)  
)
```

Important

All quantities, including coordinate values, must be specified in SI units because ANSYS FLUENT does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (e.g., name). Uppercase letters in profile names are not acceptable.

You can read this file into ANSYS FLUENT using the [Profiles Dialog Box \(p. 1954\)](#) or the **File/Read/Profile...** menu item.

Cell Zone Conditions → Profiles...

Boundary Conditions → Profiles...

File → Read → Profile...

See [Using Profiles \(p. 385\)](#) for details.

7.6.5.2. Tabular Transient Profiles

The format of the tabular transient profile file is

```
profile-name n_field n_data periodic?
field-name-1 field-name-2 field-name-3 .... field-name-n_field
v-1-1 v-2-1... ... ... v-n_field-1
v-1-2 v-2-2... ... ... v-n_field-2
.
.
.
.
v-1-n_data v-2-n_data ... ... ... v-n_field-n_data
```

The first field name (e.g. `field-name-1`) should be used for the `time` field, and the `time` field section, which represents the flow time, *must* be in ascending order. The `periodic?` entry indicates whether or not the profile is time-periodic. Set it to 1 for a time-periodic profile, or 0 if the profile is not time-periodic.

An example is shown below:

```
samplatabprofile 2 3 0
time u
1 10
2 20
3 30
```

This file defines the same transient profile as the standard profile example above.

If the periodicity is set to 1, then `n_data` must be the number that closes one period.

An example is shown below:

```
periodtabprofile 2 4 1
time u
0 10
1 20
2 30
3 10
```

The following example uses crank angle instead of time:

```
example 2 3 1
angle temperature
0 300
180 500
360 300
```

Important

All quantities, including coordinate values, must be specified in SI units because ANSYS FLUENT does not perform unit conversion when reading profile files. Also, profile names must have all lowercase letters (e.g., `name`). Uppercase letters in profile names are not acceptable. When choosing the field names, spaces or parentheses should not be included.

You can read this file into ANSYS FLUENT using the `read-transient-table` text command.

`file → read-transient-table`

After reading the table into ANSYS FLUENT, the profile will be listed in the *Profiles Dialog Box* (p. 1954) and can be used in the same way as a boundary profile. See *Using Profiles* (p. 385) for details.

7.7. Coupling Boundary Conditions with GT-Power

GT-Power users can define time-dependent boundary conditions in ANSYS FLUENT based on information from GT-Power. During the ANSYS FLUENT simulation, ANSYS FLUENT and GT-Power are coupled together and information about the boundary conditions at each time step is transferred between them.

7.7.1. Requirements and Restrictions

7.7.2. User Inputs

7.7.1. Requirements and Restrictions

Note the following requirements and restrictions for the GT-Power coupling:

- The flow must be unsteady.
- The compressible ideal gas law must be used for density.
- Each boundary zone for which you plan to define conditions using GT-Power must be a flow boundary of one of the following types:
 - velocity inlet
 - mass flow inlet
 - pressure inlet
 - pressure outlet

Also, a maximum of 20 boundary zones can be coupled to GT-Power.

- If a mass flow inlet or pressure inlet is coupled to GT-Power, you must select **Normal to Boundary** as the **Direction Specification Method** in the **Mass-Flow Inlet** or **Pressure Inlet** dialog box. For a velocity inlet, you must select **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in the **Velocity Inlet** dialog box.
- The mass flow specification method in the **Mass-Flow Inlet** boundary has to always be **Mass Flux** and not **Mass Flow Rate** when coupling with GTPower.
- Boundary conditions for the following variables can be obtained from GT-Power:
 - velocity
 - temperature
 - pressure
 - density
 - species mass fractions
 - k and ε (Note that it is recommended that you define these conditions in ANSYS FLUENT yourself, rather than using the data provided by GT-Power, since the GT-Power values are based on a 1D model.)
- Make sure that the material properties you set in ANSYS FLUENT are the same as those used in GT-Power, so that the boundary conditions will be valid for your coupled simulation.
- If your model includes species, make sure that the name of each species in GT-Power corresponds to the **Chemical Formula** for that species material in the **Materials** dialog box. Also, recall that ANSYS FLUENT can handle a maximum of 50 species.

- You can install the GT-Power libraries in a directory other than the default location. If the GT-Power libraries are loaded into a non-default location, you need to set the following environment variables:
 - FLUENT_GTIHOME - the GTI installation directory where GT-Power is installed
 - FLUENT_GTIVERSION - the current version of the GTI installation

Important

GTI is not backwards compatible.

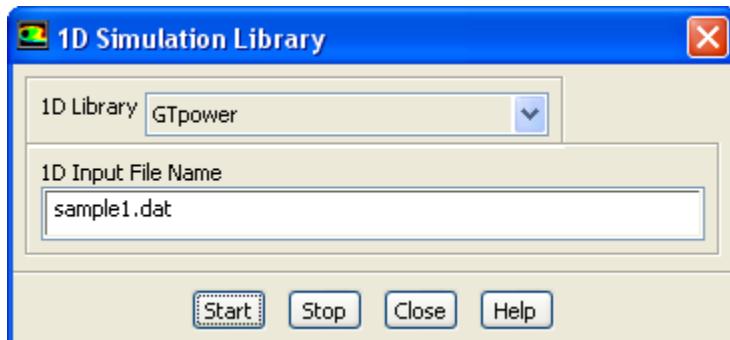

7.7.2. User Inputs

The procedure for setting up the GT-Power coupling in ANSYS FLUENT is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types (but *not* the actual boundary conditions), noting the requirements and restrictions listed in *Requirements and Restrictions* (p. 396).
2. Specify the location of the GT-Power data and have ANSYS FLUENT use them to generate user-defined functions for the relevant boundary conditions (using the *1D Simulation Library Dialog Box* (p. 2274), shown in *Figure 7.70* (p. 397)).

Define → User-Defined → 1D Coupling...

Figure 7.70 The 1D Simulation Library Dialog Box

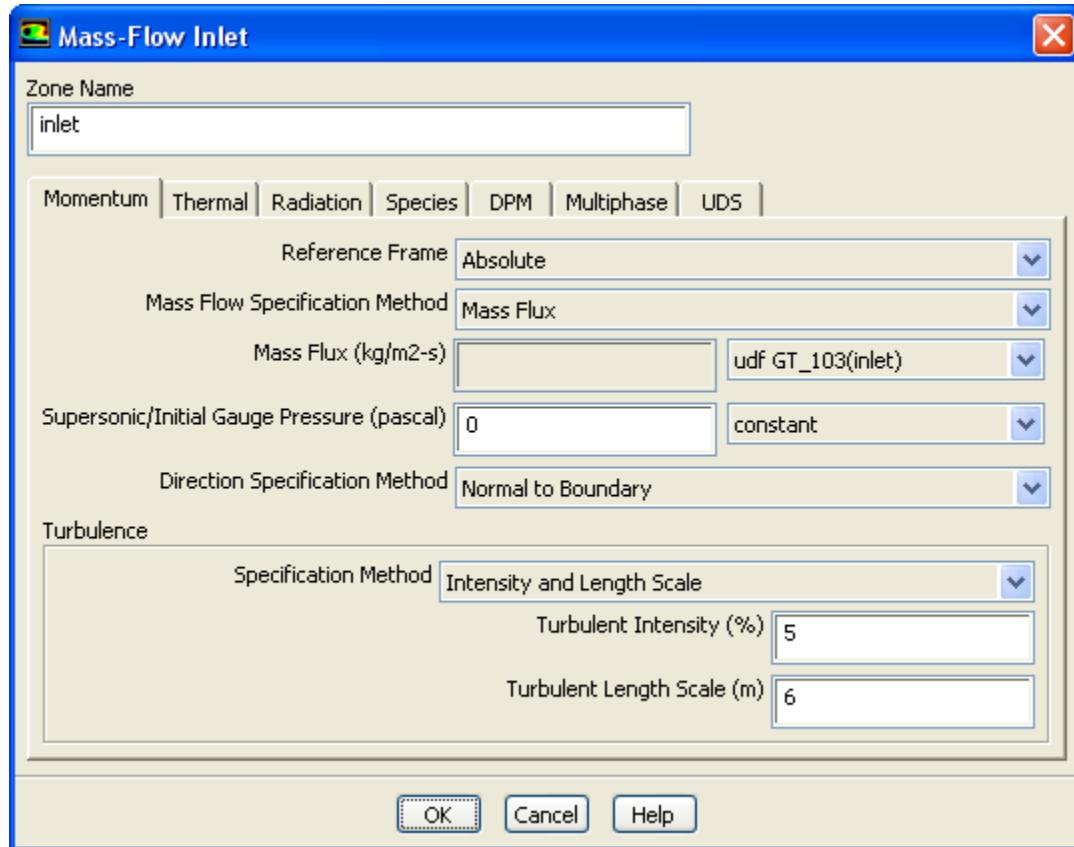

- a. Select **GTpower** in the **1D Library** drop-down list.
- b. Specify the name of the GT-Power input file in the **1D Input File Name** field.
- c. Click the **Start** button.

When you click **Start**, GT-Power will start up and ANSYS FLUENT user-defined functions for each boundary in the input file will be generated.

3. Set boundary conditions for all zones. For flow boundaries for which you are using GT-Power data, select the appropriate UDFs as the conditions.

Important

Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in *Figure 7.71* (p. 398)); this UDF contains all of the conditions at that boundary.

Figure 7.71 Using GT-Power Data for Boundary Conditions

4. If you plan to continue the simulation at a later time, starting from the final data file of the current simulation, specify how often you want to have the case and data files saved automatically.

◆ Calculation Activities (Autosave Case/Data) → Edit...

To use a GT-Power restart file to restart an ANSYS FLUENT calculation, you must edit the GT-Power input data file. See the GT-Power User's Guide for instructions.

5. Continue the problem setup and calculate a solution in the usual manner.

7.8. Coupling Boundary Conditions with WAVE

WAVE users can define time-dependent boundary conditions in ANSYS FLUENT based on information from WAVE. During the ANSYS FLUENT simulation, ANSYS FLUENT and WAVE are coupled together and information about the boundary conditions at each time step is transferred between them.

7.8.1. Requirements and Restrictions

7.8.2. User Inputs

7.8.1. Requirements and Restrictions

Note the following requirements and restrictions for the WAVE coupling:

- WAVE needs to be installed and licensed.
- There are always five species that must be modeled in ANSYS FLUENT just as they are defined in WAVE (F1, F2, F3, F4, and F5). It is recommended that realistic material properties be assigned to each of the five species.

- The flow must be unsteady.
- The compressible ideal gas law must be used for density.
- Each boundary zone for which you plan to define conditions using WAVE must be a flow boundary of one of the following types:
 - velocity inlet
 - mass flow inlet
 - pressure inlet
 - pressure outlet

Also, a maximum of 20 boundary zones can be coupled to WAVE.

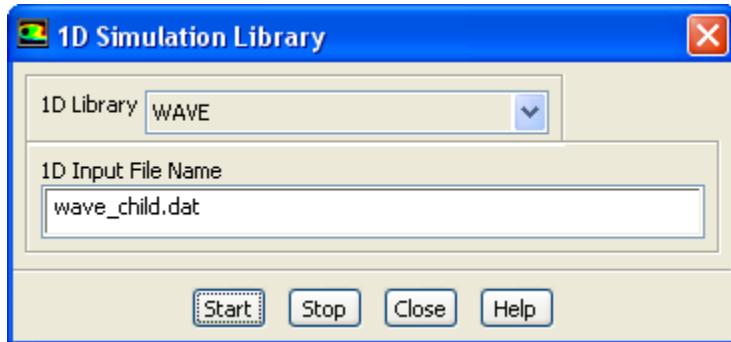

- If a mass flow inlet or pressure inlet is coupled to WAVE, you must select **Normal to Boundary** as the **Direction Specification Method** in the **Mass-Flow Inlet** or **Pressure Inlet** Dialog Box. For a velocity inlet, you must select **Magnitude, Normal to Boundary** as the **Velocity Specification Method** in the **Velocity Inlet** Dialog Box.
- Boundary conditions for the following variables can be obtained from WAVE:
 - velocity
 - temperature
 - pressure
 - density
 - species mass fractions
 - k and ϵ (Note that you are required to define these conditions in ANSYS FLUENT yourself, since WAVE does not calculate them.)
- Make sure that the material properties you set in ANSYS FLUENT are the same as those used in WAVE, so that the boundary conditions will be valid for your coupled simulation.
- If your model includes species, make sure that the name of each species in WAVE corresponds to the **Chemical Formula** for that species material in the **Create/Edit Materials** dialog Box. Also, recall that ANSYS FLUENT can handle a maximum of 50 species.

7.8.2. User Inputs

The procedure for setting up the WAVE coupling in ANSYS FLUENT is presented below.

1. Read in the mesh file and define the models, materials, and boundary zone types.
2. Specify the location of the WAVE data and have ANSYS FLUENT use them to generate user-defined functions for the relevant boundary conditions (using the *1D Simulation Library Dialog Box* (p. 2274), shown in *Figure 7.72* (p. 400)).

Define → User-Defined → 1D Coupling...

Figure 7.72 The 1D Simulation Library Dialog Box with WAVE Selected

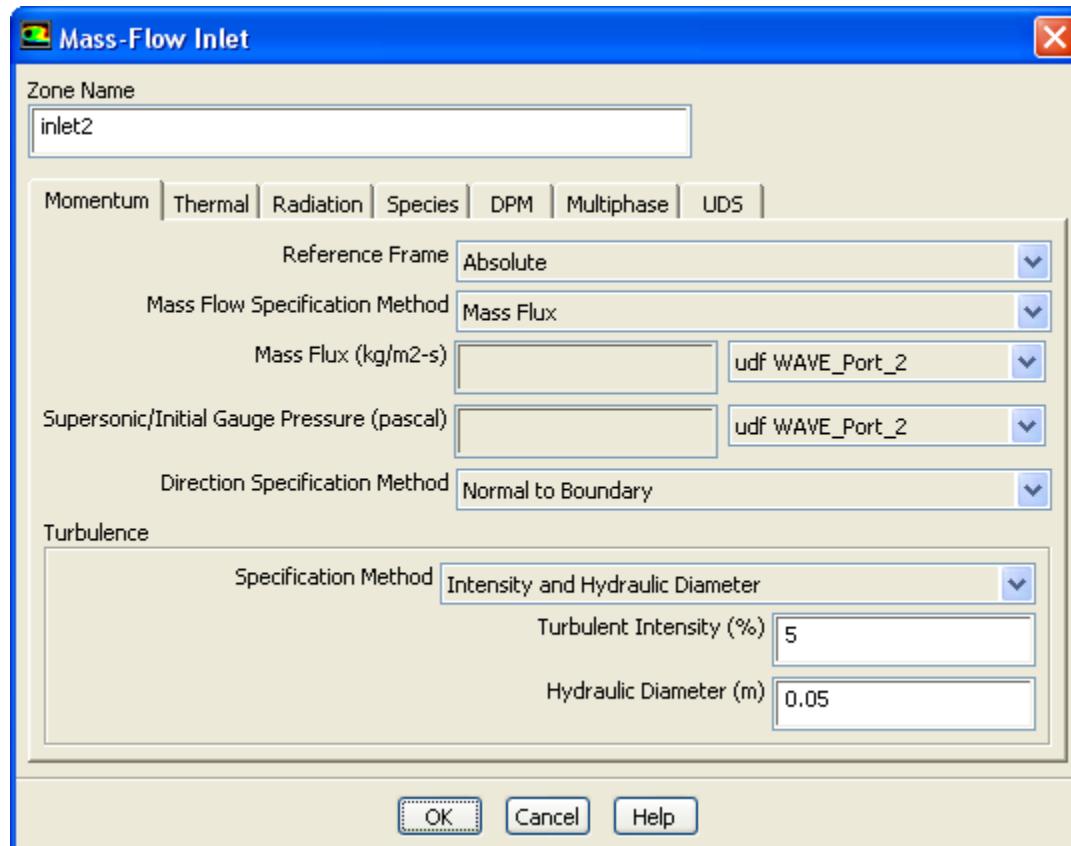

- a. Select **WAVE** in the **1D Library** drop-down list.
- b. Specify the name of the WAVE input file in the **1D Input File Name** field.
- c. Click the **Start** button.

When you click **Start**, WAVE will start up and ANSYS FLUENT user-defined functions for each boundary in the input file will be generated.

3. Set boundary conditions for all zones. For flow boundaries for which you are using WAVE data, select the appropriate UDFs as the conditions.

Important

Note that you must select the same UDF for all conditions at a particular boundary zone (as shown, for example, in *Figure 7.73 (p. 401)*); this UDF contains all of the conditions at that boundary.

Figure 7.73 Using WAVE Data for Boundary Conditions

4. If you plan to continue the simulation at a later time, restarting from the final data file of the current simulation, you need to instruct both ANSYS FLUENT and WAVE how often that you want to automatically save your data. You should instruct ANSYS FLUENT to automatically save case and data files at specified intervals using the autosave feature.

Calculation Activities (Autosave Case/Data) → Edit...

In addition, you should instruct WAVE as to how often it should generate its own restart files. See the WAVE User's Guide for instructions on this feature.

Important

To use the restart feature, the time interval for writing data files must be set to the same value in both ANSYS FLUENT and WAVE. For example, if ANSYS FLUENT has set the autosave feature to 100, then WAVE must also set the restart file write frequency to 100 as well.

5. Continue the problem setup and calculate a solution in the usual manner.

Chapter 8: Physical Properties

This chapter describes how to define materials, the physical equations used to compute material properties, and the methods you can use for each property input. Each property is described in detail in the following sections. If you are using one of the general multiphase models (VOF, mixture, or Eulerian), see [Defining the Phases \(p. 1180\)](#) for information about how to define the individual phases and their material properties.

- 8.1. Defining Materials
- 8.2. Defining Properties Using Temperature-Dependent Functions
- 8.3. Density
- 8.4. Viscosity
- 8.5. Thermal Conductivity
- 8.6. User-Defined Scalar (UDS) Diffusivity
- 8.7. Specific Heat Capacity
- 8.8. Radiation Properties
- 8.9. Mass Diffusion Coefficients
- 8.10. Standard State Enthalpies
- 8.11. Standard State Entropies
- 8.12. Molecular Heat Transfer Coefficient
- 8.13. Kinetic Theory Parameters
- 8.14. Operating Pressure
- 8.15. Reference Pressure Location
- 8.16. Real Gas Models

8.1. Defining Materials

An important step in the setup of the model is to define the materials and their physical properties. Material properties are defined in the [Materials Task Page \(p. 1880\)](#), where you can enter values for the properties that are relevant to the problem scope you have defined in the [Models Task Page \(p. 1771\)](#). These properties may include the following:

- density and/or molecular weights
- viscosity
- heat capacity
- thermal conductivity
- UDS diffusion coefficients
- mass diffusion coefficients
- standard state enthalpies
- kinetic theory parameters

Properties may be temperature-dependent and/or composition-dependent, with temperature dependence based on a polynomial, piecewise-linear, or piecewise-polynomial function and individual component properties either defined by you or computed via kinetic theory.

The [Materials Task Page](#) (p. 1880) will show the properties that need to be defined for the active physical models. If any property you define requires the energy equation to be solved (e.g., ideal gas law for density, temperature-dependent profile for viscosity), ANSYS FLUENT will automatically activate the energy equation. Then you have to define the thermal boundary conditions and other parameters yourself.

For additional information, please see the following sections:

- [8.1.1. Physical Properties for Solid Materials](#)
- [8.1.2. Material Types and Databases](#)
- [8.1.3. Using the Materials Task Page](#)
- [8.1.4. Using a User-Defined Materials Database](#)

8.1.1. Physical Properties for Solid Materials

For solid materials, only density, thermal conductivity, and heat capacity are defined. If you are modeling semi-transparent media, case radiation properties are also defined. You can specify a constant value, a temperature-dependent function, or a user-defined function for thermal conductivity; a constant value or temperature-dependent function for heat capacity; and a constant value for density.

If you are using the pressure-based solver, density and heat capacity for a solid material are not required unless you are modeling transient flow or moving solid zones. Heat capacity will appear in the list of solid properties for steady flows as well. The value will be used just for postprocessing enthalpy; not in the calculation.

8.1.2. Material Types and Databases

In ANSYS FLUENT, you can define six types of materials: fluids, solids, mixtures, combusting-particles, droplet-particles, and inert-particles. Physical properties of fluids and solids are associated with named materials and are then assigned as boundary conditions for zones.

When you model species transport, define a mixture material, consisting of the various species involved in the problem. Properties will be defined for the mixture, as well as for the constituent species, which are fluid materials. The mixture material concept is discussed in detail in [Mixture Materials](#) (p. 856). Combusting-particles, droplet-particles, and inert-particles are available for the discrete-phase model, as described in [The Concept of Discrete-Phase Materials](#) (p. 1131).

ANSYS FLUENT provides a built-in global database of approximately 675 predefined materials from this global (site-wide) database and use the default properties or define new materials database is located in the following file:

`path /Fluent.Inc/fluent14.0/cortex/lib/propdb.scm`

where `path` is the directory in which you have installed ANSYS FLUENT.

In addition to using the ANSYS FLUENT materials, and use it to define the materials in your problem setup. See [Using a User-Defined Materials Database](#) (p. 409) for information about creating and using user-defined custom material databases.

Important

All the materials list will be saved in the case file (when you write one). The materials specified by you will be available to you if you read this case file into a new solver session.

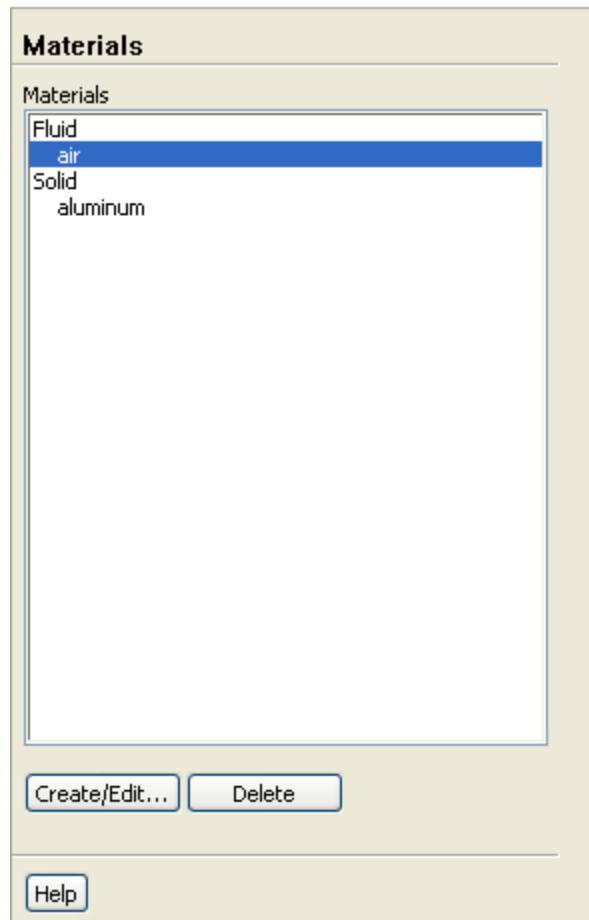

8.1.3. Using the Materials Task Page

The *Materials Task Page* (p. 1880) (*Figure 8.1* (p. 405)) allows you to define the materials and their properties in your problem setup using either the **FLUENT Database** or a **User-Defined Database**. It allows you to copy materials, and modify material properties.

These generic functions are described in this section. The inputs for temperature-dependent properties are explained in *Defining Properties Using Temperature-Dependent Functions* (p. 417). The specific inputs for each material property are discussed in the remaining sections of this chapter.

Materials

Figure 8.1 The Materials Task Page

By default, your local materials list will include a single fluid material (air) and a single solid material (aluminum). If the fluid involved in your problem is air, you can use the default properties for air or modify the properties. If the fluid in your problem is water, you can either copy water from the ANSYS FLUENT database or create a new "water" material from scratch. If you copy water from the database, you can still make modifications to the properties of your local copy of water. The editing or creating of material properties is done in the *Create/Edit Materials Dialog Box* (p. 1882). To display the *Create/Edit Materials Dialog Box* (p. 1882), select the **Create/Edit...** button in the *Materials Task Page* (p. 1880). See the following sections for detailed information on how to change material properties.

Mixture materials will not exist in your local list unless you have enabled species transport (see *Modeling Species Transport and Finite-Rate Chemistry* (p. 855)). Similarly, inert, droplet, and combusting particle

materials will not be available unless you have created a discrete phase injection of these particle types (see [Modeling Discrete Phase \(p. 1075\)](#)). When a mixture material is copied from the database, all of its constituent fluid materials (species) will automatically be copied over as well.

8.1.3.1. Modifying Properties of an Existing Material

Probably, the most common operation you will perform in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) is the modification of properties for an existing material. The steps for this procedure are as follows:

1. Select the material you want to modify and the **Create/Edit...** button in the [Materials Task Page \(p. 1880\)](#).
2. In the [Create/Edit Materials Dialog Box \(p. 1882\)](#) select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.
3. Choose the material for which you want to modify properties, in the **FLUENT Fluid Materials** drop-down list, **FLUENT Solid Materials** list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.
4. Make the required changes to the properties listed in the **Properties** section of the dialog box. You can use the scroll bar to the right of the **Properties** section to scroll through the listed items.
5. Click the **Change/Create** button to change the properties of the selected material to your new property settings.

To change the properties of an additional material, repeat the process described above. Click the **Change/Create** button after making changes to the properties for each material.

8.1.3.2. Renaming an Existing Material

Each material is identified by a name and a chemical formula (if one exists). You can change the name of a material, but not its chemical formula (unless you are creating a new material). The procedure for renaming a material is as follows:

1. Select the material you want to rename and the **Create/Edit...** button in the [Materials Task Page \(p. 1880\)](#).
2. In the [Create/Edit Materials Dialog Box \(p. 1882\)](#), choose the material for which you want to modify properties, in the **FLUENT Fluid Materials** list, **FLUENT Solid Materials** list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step.
3. Enter the new name in the **Name** field at the top of the [Create/Edit Materials Dialog Box \(p. 1882\)](#).

Important

The maximum character length you can enter in the **Name** field is 29. If you enter a material name that is more than 29 characters long, ANSYS FLUENT will print an error message in the console window.

4. Click the **Change/Create** button.

A [Question Dialog Box \(p. 33\)](#) will appear, asking you if the original material should be overwritten.

If you are renaming the original material, click **Yes** to overwrite it. If you were creating a new material, click **No** to retain the original material.

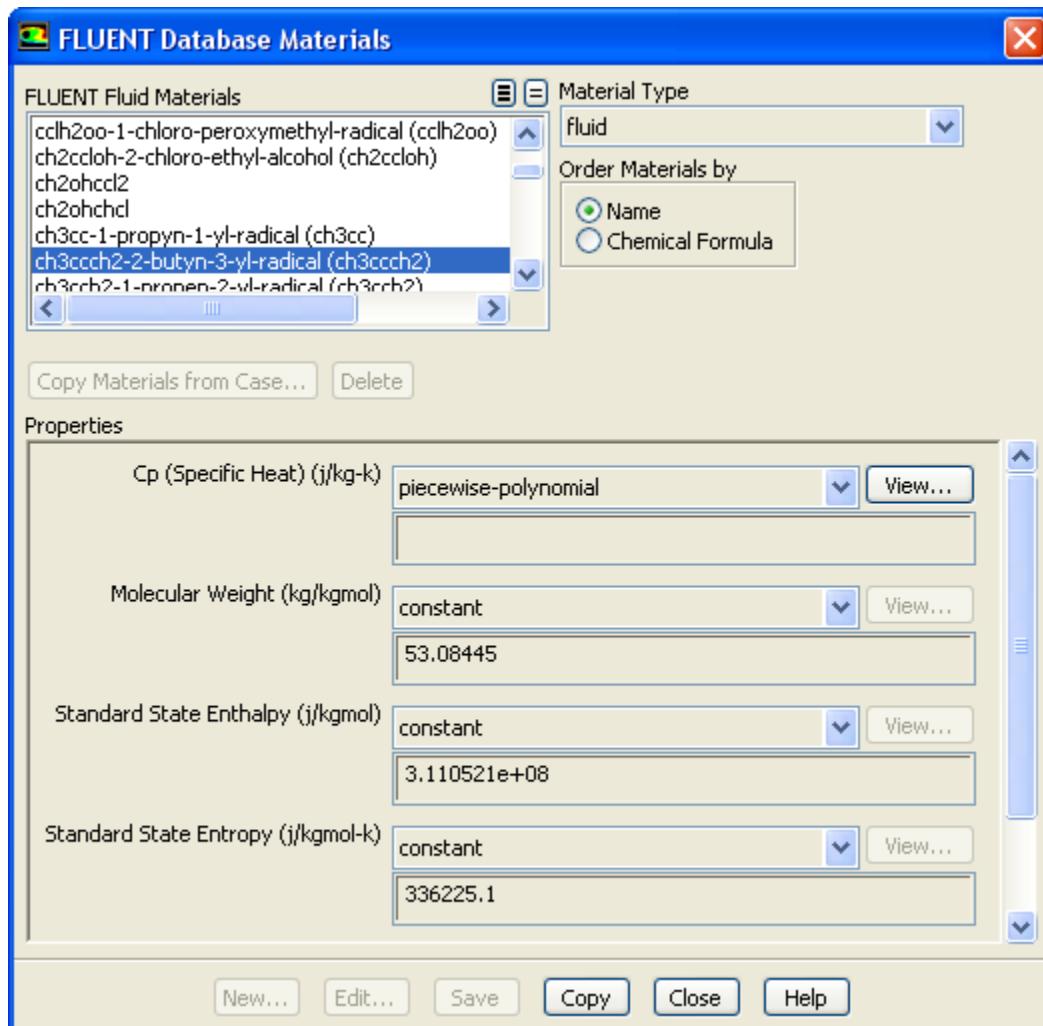

To rename another material, repeat the process described above. Click the **Change/Create** button after renaming each material.

8.1.3.3. Copying Materials from the ANSYS FLUENT Database

The global (site-wide) materials database contains many commonly used fluid, solid, and mixture materials, with property data from several different sources [51] (p. 2369), [71] (p. 2370), [101] (p. 2372), [35] (p. 2368). To use one of these materials in your problem, copy it from the ANSYS FLUENT database to your local materials list. The procedure for copying a material is as follows:

1. Click the **FLUENT Database...** button in the *Create/Edit Materials Dialog Box* (p. 1882) to open the *FLUENT Database Materials Dialog Box* (p. 1890) (*Figure 8.2* (p. 407)).

Figure 8.2 FLUENT Database Materials Dialog Box

2. Select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.
3. In the **FLUENT Fluid Materials** list, **FLUENT Solid Materials** list, or other similarly named list, choose the materials you wish to copy by clicking on them. The properties of the selected material will be displayed in the **Properties** area.
4. To check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items. For some properties, temperature-dependent functions are available in addition to the constant values. Select one of the function types in the drop-down list to the right of the property and the relevant parameters will be displayed. You cannot edit these values, but the dialog boxes in which they are displayed function in the same way as those used for setting temperature-dependent property functions (*Defining Properties Using Temperature-Dependent Functions* (p. 417)).

The inactive buttons in the [FLUENT Database Materials Dialog Box \(p. 1890\)](#) are operations that are applicable only for a user-defined database. These operations will be available when you click the **User-Defined Database...** button in the [Create/Edit Materials Dialog Box \(p. 1882\)](#).

5. Click **Copy**. The materials and their properties will be downloaded from the database into your local list, and your copy of properties will now be displayed in the [Materials Task Page \(p. 1880\)](#).
6. Close the [FLUENT Database Materials Dialog Box \(p. 1890\)](#).

After copying a material from the database, you can modify its properties or change its name, as described earlier in this section. The original material in the database will not be affected by any changes made to your local copy of the material.

8.1.3.4. Creating a New Material

If the material you want to use is not available in the database, you can easily create a new material for the local list. This material will be available for use only for the current problem and will not be saved in the ANSYS FLUENT database. The procedure for creating a new material is as follows:

1. Select the **Create/Edit...** button in the [Materials Task Page \(p. 1880\)](#).
2. Select the new material type (**fluid**, **solid**, etc.) in the **Material Type** drop-down list. It does not matter which material is selected in the **FLUENT Fluid Materials**, **FLUENT Solid Materials**, or other similarly named list.
3. Enter the new material name in the **Name** field.

Important

The maximum character length you can enter in the **Name** field is 29. If you enter a material name that is more than 29 characters long, ANSYS FLUENT will print an error message in the console window.

4. Set the material's properties in the **Properties** area. If there are many properties listed, you may use the scroll bar to the right of the **Properties** area to scroll through the listed items.
5. Click the **Change/Create** button. A [Question Dialog Box \(p. 33\)](#) will appear, asking you if the original material should be overwritten.
 - a. Click **No** to retain the original material and *add* your new material to the list. A dialog box will appear asking you to enter the chemical formula of your new material.
 - b. Click **OK**, enter the formula if it is known. Else, leave the formula blank and click **OK**. Select the **Change/Create** button and answer the [Question](#).

The [Materials Task Page \(p. 1880\)](#) will be updated to show the new material name and chemical formula in the **FLUENT Fluid Materials** list (or **FLUENT Solid Materials** or other similarly named list).

8.1.3.5. Saving Materials and Properties

All the materials and properties in your local list are saved in the case file when it is written. If you read this case file into a new solver session, all of your materials and properties will be available for use in the new session.

8.1.3.6. Deleting a Material

If there are materials list that you no longer need, you can delete them:

1. Choose the material to be deleted in the *Materials Task Page* (p. 1880).
2. Click the **Delete** button at the bottom of the *Materials Task Page* (p. 1880).

You can also delete materials in the *Create/Edit Materials Dialog Box* (p. 1882).

1. Select the material to be deleted and click the **Create/Edit...** button in the *Materials Task Page* (p. 1880).
2. In the *Create/Edit Materials Dialog Box* (p. 1882), select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.
3. Choose the material to be deleted in the **FLUENT Fluid Materials** drop-down list, **FLUENT Solid Materials** list, or other similarly named list. The list's name will be the same as the material type you selected in the previous step.
4. Click the **Delete** button at the bottom of the *Materials Task Page* (p. 1880).

Deleting materials from your local list will have no effect on the materials contained in the global database.

8.1.3.7. Changing the Order of the Materials List

By default, the materials in your local list and those in the database are listed alphabetically by name (e.g., **air**, **atomic-oxygen (o)**, **carbon-dioxide (co2)**). If you prefer to list them alphabetically by chemical formula, select the **Chemical Formula** option under **Order Materials By**. The example materials listed, will now be in the order of: **air**, **co2 (carbon-dioxide)**, **o (atomic-oxygen)**. To change back to the alphabetical listing by name, choose the **Name** option under **Order Materials By**.

You may specify the ordering method separately for the *Create/Edit Materials Dialog Box* (p. 1882) and *FLUENT Database Materials Dialog Box* (p. 1890). For example, you can order the database materials list by name. Each dialog box has its own **Order Materials By** options.

8.1.4. Using a User-Defined Materials Database

In addition to the *FLUENT Database Materials Dialog Box* (p. 1890), you can also use or create a user-defined materials database using the *User-Defined Database Materials Dialog Box* (p. 1892). You can browse and do the following:

- select from existing user-defined databases
- copy materials from a user-defined database
- create a new database, create new materials
- add them to the user-defined database
- delete materials from the database
- copy materials from a case to a user-defined database
- view the database

The following sections will address each of these functionalities in detail.

8.1.4.1. Opening a User-Defined Database

If you have a database of custom materials as .scm files with data saved in the specified format you can open these databases in ANSYS FLUENT and use them to define the materials in your problem setup.

Examples:

The prescribed format for saving material properties information is shown here for air and aluminum. These files can be created in a text editor and saved with a .scm extension.

```
((air
fluid
(chemical-formula . #f)
(density (constant . 1.225)
(premixed-combustion 1.225 300))
(specific-heat (constant . 1006.43))
(thermal-conductivity (constant . 0.0242))
(viscosity (constant . 1.7894e-05)
(sutherland 1.7894e-05 273.11 110.56)
(power-law 1.7894e-05 273.11 0.666))
(molecular-weight (constant . 28.966))
)
(aluminum
solid
(chemical-formula . al)
(density (constant . 2719))
(specific-heat (constant . 871))
(thermal-conductivity (constant . 202.4))
(formation-entropy (constant . 164448.08))
))
```

To select a user-defined database, click the **User-Defined Database...** button in the *Create/Edit Materials Dialog Box* (p. 1882). This will open the *Open Database Dialog Box* (p. 1892).

Figure 8.3 Open Database Dialog Box

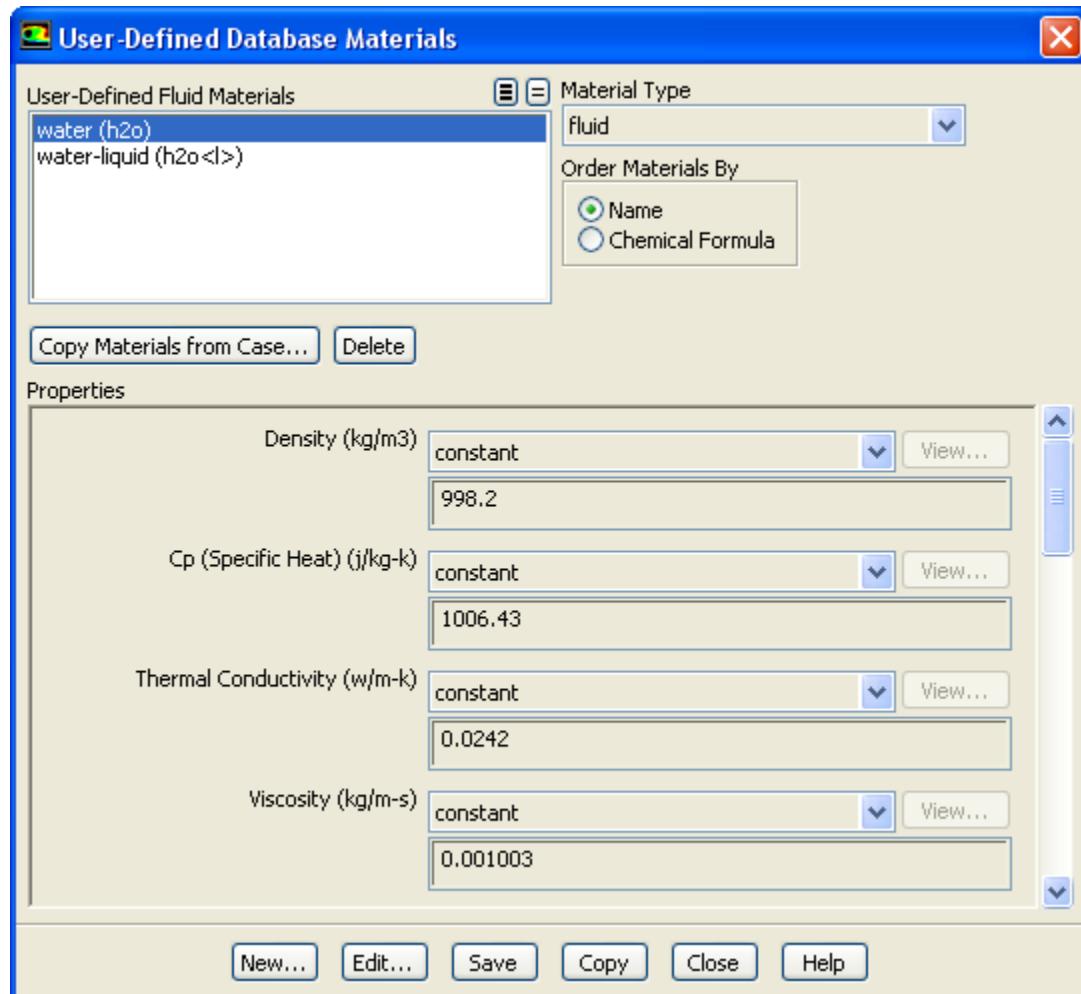

Click the **Browse...** button, select the database in *The Select File Dialog Box* (p. 33) that opens and click **OK**. Click **OK** in the *Open Database Dialog Box* (p. 1892) to open the *User-Defined Database Materials Dialog Box* (p. 1892).

8.1.4.2. Viewing Materials in a User-Defined Database

When an existing user-defined database is opened, the materials present in the database are listed in the *User-Defined Database Materials Dialog Box* (p. 1892). You can select the material type in the **Material Type** drop-down list and the corresponding materials will appear in the **User-Defined Fluid Materials**, **User-Defined Solid Materials** or other similarly named list. The name of the list will be the same as the material type you selected.

Figure 8.4 User-Defined Database Materials Dialog Box

The properties of the selected material will appear in the **Properties** section of the dialog box. This dialog box is similar to the *FLUENT Database Materials Dialog Box* (p. 1890) in function and operation.

8.1.4.3. Copying Materials from a User-Defined Database

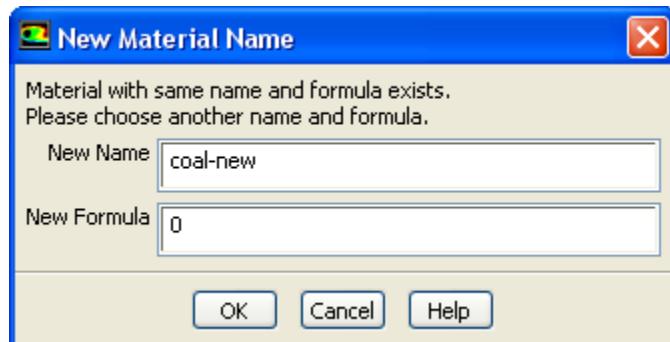

The procedure for copying a material from a custom database is as follows:

1. In the *Create/Edit Materials Dialog Box* (p. 1882), click the **User-Defined Database...** button and open the database from which you want to copy the material.
2. In the *User-Defined Database Materials Dialog Box* (p. 1892) of the selected database, select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.
3. In the **User-Defined Fluid Materials** list, **User-Defined Solid Materials** list, or other similarly named list (the list's name will be the same as the material type you selected in the previous step), choose the materials you wish to copy by clicking on them. The properties are displayed in the **Properties** area.
4. If you want to check the material properties, use the scroll bar to the right of the **Properties** area to scroll through the listed items.
5. Click the **Copy** button. The selected materials and their properties will be copied from the database into your local list, and your copy of the properties will now be displayed in the *Materials Task Page* (p. 1880).

To copy all the materials from the database in one step, click the shaded icon to the right of the **User-Defined Materials** title and click **Copy**.

If a material with the same name is already defined in the case, ANSYS FLUENT will prompt you to enter a new name and formula in the [New Material Name Dialog Box \(p. 1896\)](#). Enter a new name and formula in the respective fields and click **OK** to make a local copy of the material.

Figure 8.5 New Material Name Dialog Box

6. Close the [User-Defined Database Materials Dialog Box \(p. 1892\)](#).

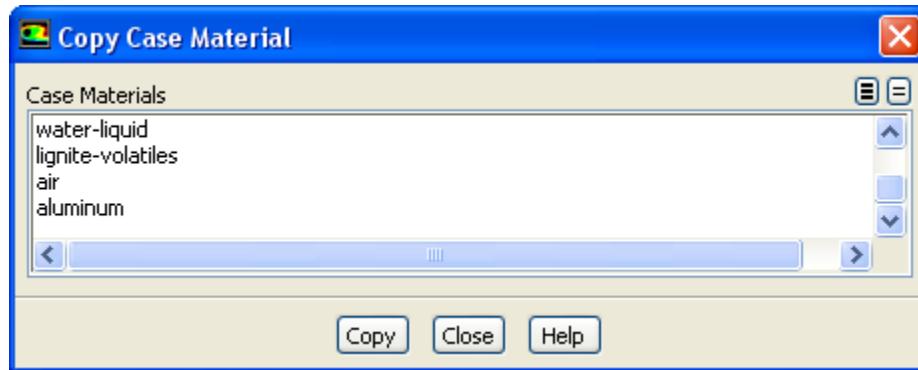

After copying a material from the database, you may modify its properties or change its name, as described earlier in [Using the Materials Task Page \(p. 405\)](#). The material in the database will not be affected by any changes you make to your local copy of the material.

8.1.4.4. Copying Materials from the Case to a User-Defined Database

You can copy materials from the case file to a database as follows:

1. In the [Create/Edit Materials Dialog Box \(p. 1882\)](#), click **User-Defined Database....**
2. In the [Open Database Dialog Box \(p. 1892\)](#), select the database to which you want to copy the material. If you want to create a new database, enter the name of the new database in the **Database Name** field and click **OK**. A [Question Dialog Box \(p. 33\)](#) will ask you to confirm if you want to create a new file. Click **Yes** to confirm.
3. In the [User-Defined Database Materials Dialog Box \(p. 1892\)](#), click **Copy Materials From Case....**. This will open the [Copy Case Material Dialog Box \(p. 1894\)](#).

Figure 8.6 Copy Case Material Dialog Box

- a. In the [Copy Case Material Dialog Box \(p. 1894\)](#), select the materials that you want to copy.

To select all the materials, click the shaded icon to the right of the **Case Materials** title. Clicking on the unshaded icon will deselect the selections in the list.

- b. Click **Copy** and close the dialog box.

Note

Do not copy materials one by one. This will result in previously copied materials getting overwritten by the new ones. Instead, select all the materials to be copied and click **Copy**.

8.1.4.5. Modifying Properties of an Existing Material

You can modify the properties of an existing material and use the modified material in the problem setup and save the modified material to the materials database.

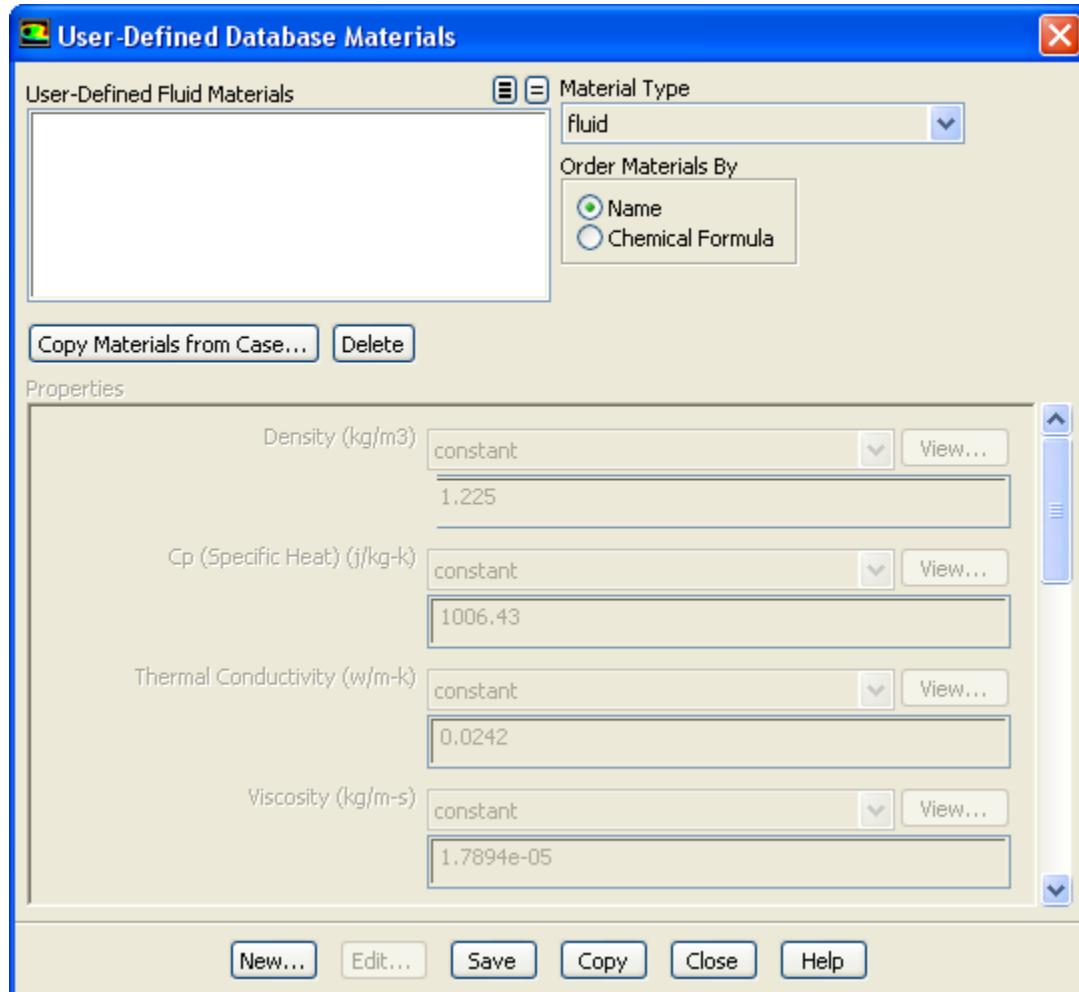

1. In the *Materials Task Page* (p. 1880), click the **User-Defined Database...** button and open the database that you want to use.
 - a. In the *User-Defined Database Materials Dialog Box* (p. 1892) of the selected database, select the type of material (**fluid**, **solid**, etc.) in the **Material Type** drop-down list.
 - b. In the **User-Defined Fluid Materials** list, **User-Defined Solid Materials** list, or other similarly named list. The name of the list will be the same as the material type you selected in the previous step. Select the material to be modified.
 - c. Click **Edit...** to open the *Material Properties Dialog Box* (p. 1894).
 - i. In the **Materials Properties** list, select the property to be modified and click **Edit...** to open the *Edit Property Methods Dialog Box* (p. 1895).
 - ii. Select the method to be modified in the **Material Properties** list of the *Edit Property Methods Dialog Box* (p. 1895) and click **Edit...** under **Edit Properties**, in order to modify the properties.
 - iii. Make the changes in the corresponding method dialog box and click **OK**.
 - iv. Click **Apply** in the *Material Properties Dialog Box* (p. 1894).
 - d. To use the modified material in the problem setup, click **Copy** in the *User-Defined Database Materials Dialog Box* (p. 1892) and close the dialog box.
 - e. To save the modified material to the database, click **Save**.

8.1.4.6. Creating a New Materials Database and Materials

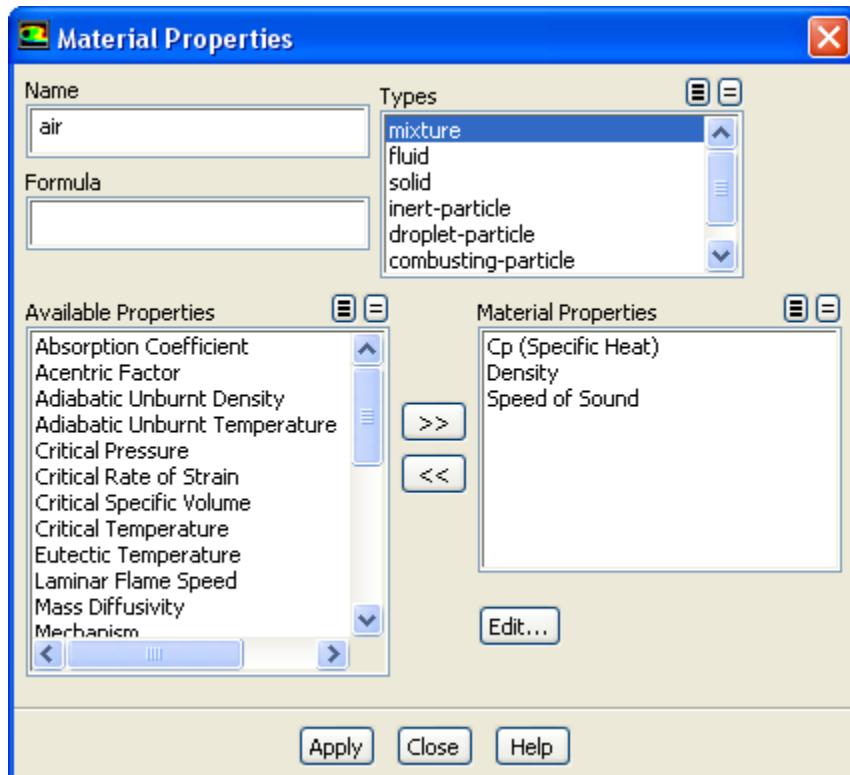

Using the *User-Defined Database Materials Dialog Box* (p. 1892), you can create a new materials to this database, and also create new materials to the database is as follows:

1. In the *Materials Task Page* (p. 1880), click **User-Defined Database....**
2. In the *Open Database Dialog Box* (p. 1892), enter the name of the database that you are creating and click **OK**.
3. A dialog box will appear asking you confirm the creation of a new file. Click **Yes** to confirm.

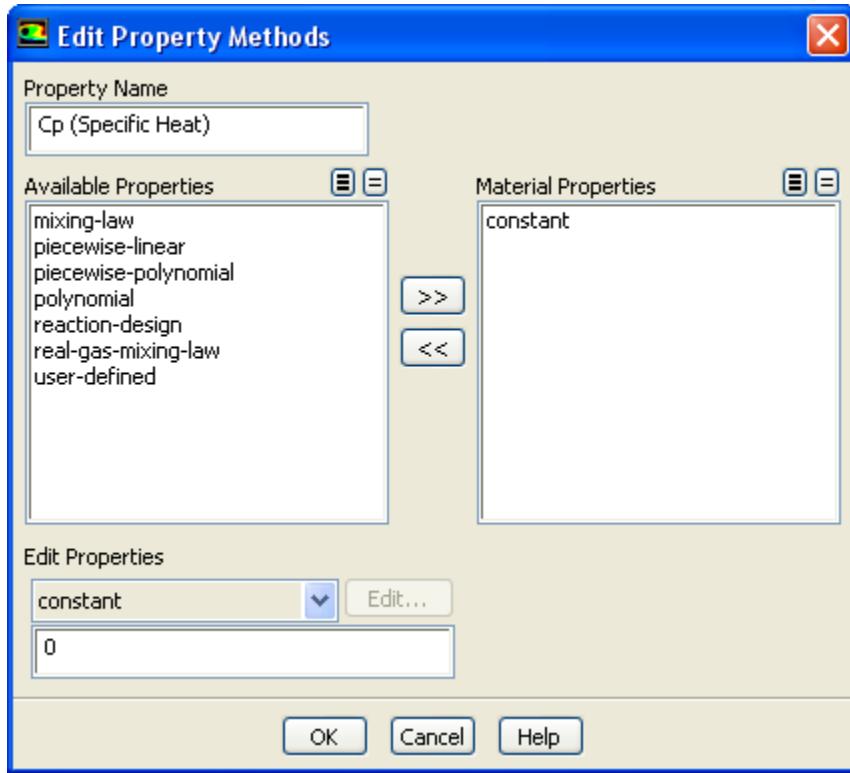

This will open a blank *User-Defined Database Materials Dialog Box* (p. 1892) (Figure 8.7 (p. 414)).

Figure 8.7 User-Defined Database Materials Dialog Box: Blank

4. Click **New...** in the *User-Defined Database Materials Dialog Box* (p. 1892). This will open a blank **Material Properties** dialog box.

Figure 8.8 Material Properties Dialog Box: Blank

- a. In the *Material Properties Dialog Box* (p. 1894), under **Types**, select the material type. You can select from **fluid**, **solid**, **inert-particle**, **droplet-particle**, **combusting-particle**, and **mixture** materials.
 - b. Enter the name and formula (if required) of the material that you are creating in the **Name** and **Formula** fields.
 - c. Depending on the type of material selected in the **Types** list, properties applicable to that material type will appear in the **Available Properties** list. Select the properties that are applicable for the material that you are defining by clicking on them.
 - d. Click the **>>** button to move these properties to the **Material Properties** list on the right and click **Apply**. You can use the **<<** button to move the property from the **Material Properties** list to the **Available Properties** list.
5. To edit the parameters that define a property, select the property in the **Material Properties** list and click **Edit...**. This opens the *Edit Property Methods Dialog Box* (p. 1895).

Figure 8.9 Edit Property Methods Dialog Box

- a. The methods that can be used to define the selected property are listed in the **Available Properties** list. You can select one or more methods and specify them for the material that you are defining, by selecting and moving them to the **Material Properties** list.
 - b. To modify each of these methods, you can select the method in the **Edit Properties** drop-down list and click **Edit...**. This will open the corresponding property dialog box, where you can modify the parameters used by the property method. Refer to *Defining Properties Using Temperature-Dependent Functions* (p. 417) to *Real Gas Models* (p. 471) for details of these properties, methods used to define the properties and the parameters for each method.
 - c. Click **OK** in the *Edit Property Methods Dialog Box* (p. 1895).
6. Click **Apply** in the *Material Properties Dialog Box* (p. 1894).
7. Click **Save** in the *User-Defined Database Materials Dialog Box* (p. 1892) to save the changes to the new materials database.

Similarly, you can also append new materials and click save to append these materials to the existing database.

8.1.4.7. Deleting Materials from a Database

To delete a material from a database, click the **User-Defined Database** button in the *Open Database Dialog Box* (p. 1892). Select the database and click **OK** in the *Open Database Dialog Box* (p. 1892). Select the **Material Type** and the materials that you want to delete in the **User-Defined Materials** list and click **Delete**. Click **Save** to save the database.

8.2. Defining Properties Using Temperature-Dependent Functions

Material properties can be defined as functions of temperature. For most properties, you can define a polynomial, piecewise-linear, or piecewise-polynomial function of temperature.

- polynomial:

$$\phi(T) = A_1 + A_2T + A_3T^2 + \dots \quad (8-1)$$

- piecewise-linear:

$$\phi(T) = \phi_n + \frac{\phi_{n+1} - \phi_n}{T_{n+1} - T_n}(T - T_n) \quad (8-2)$$

where $1 \leq n \leq N$ and N is the number of segments

- piecewise-polynomial:

$$\begin{aligned} \text{for } T_{min,1} \leq T < T_{max,1}: \phi(T) &= A_1 + A_2T + A_3T^2 + \dots \\ \text{for } T_{min,2} \leq T < T_{max,2}: \phi(T) &= B_1 + B_2T + B_3T^2 + \dots \end{aligned} \quad (8-3)$$

In the equations above, ϕ is the property.

Important

If you define a polynomial or piecewise-polynomial function of temperature, the temperature in the function is always in units of Kelvin or Rankine. If you use Celsius or Kelvin as the temperature unit, then polynomial coefficient values must be entered in terms of Kelvin. If you use Fahrenheit or Rankine as the temperature unit, enter the values in terms of Rankine.

Some properties have additional functions available and for some only a subset of these three functions can be used. See the section on the property in question to determine which temperature-dependent functions you can use.

For additional information, please see the following sections:

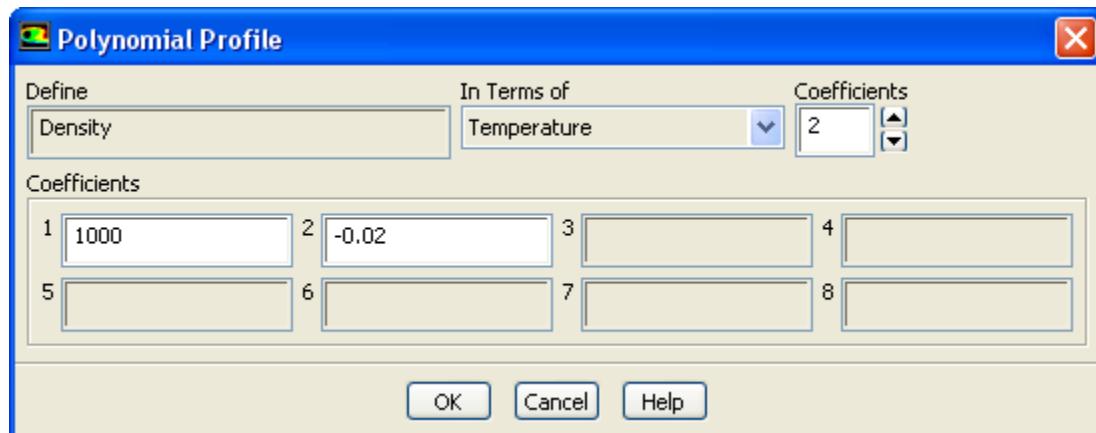

- [8.2.1. Inputs for Polynomial Functions](#)
- [8.2.2. Inputs for Piecewise-Linear Functions](#)
- [8.2.3. Inputs for Piecewise-Polynomial Functions](#)
- [8.2.4. Checking and Modifying Existing Profiles](#)

8.2.1. Inputs for Polynomial Functions

To define a polynomial function of temperature for a material property, do the following:

- In the *Create/Edit Materials Dialog Box* (p. 1882), choose **polynomial** in the drop-down list to the right of the property name (e.g., **Viscosity**). The *Polynomial Profile Dialog Box* (p. 1897) (*Figure 8.10* (p. 418)) will open automatically.

Figure 8.10 The Polynomial Profile Dialog Box

Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

- Specify the number of **Coefficients** up to 8 coefficients are available. The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 0. The property will be constant and equal to the single coefficient A_1 . An input of 2 defines a polynomial of order 1 and the property will vary linearly with temperature and so on.
- Define the coefficients. Coefficients **1, 2, 3...** correspond to A_1, A_2, A_3, \dots in *Equation 8–1* (p. 417). The dialog box in *Figure 8.10* (p. 418) shows the inputs for the following function:

$$\rho(T) = 1000 - 0.02T \quad (8-4)$$

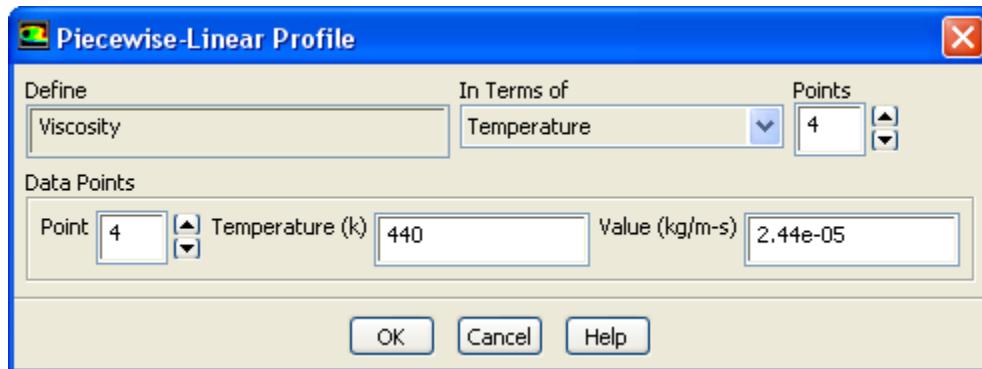

Important

Note the restriction on the units for temperature, as described in the previous section.

8.2.2. Inputs for Piecewise-Linear Functions

To define a piecewise-linear function of temperature for a material property, do the following:

- In the *Create/Edit Materials Dialog Box* (p. 1882), choose **piecewise-linear** in the drop-down list to the right of the property name (e.g., **Viscosity**). The *Piecewise-Linear Profile Dialog Box* (p. 1897) (*Figure 8.11* (p. 419)) will open automatically.

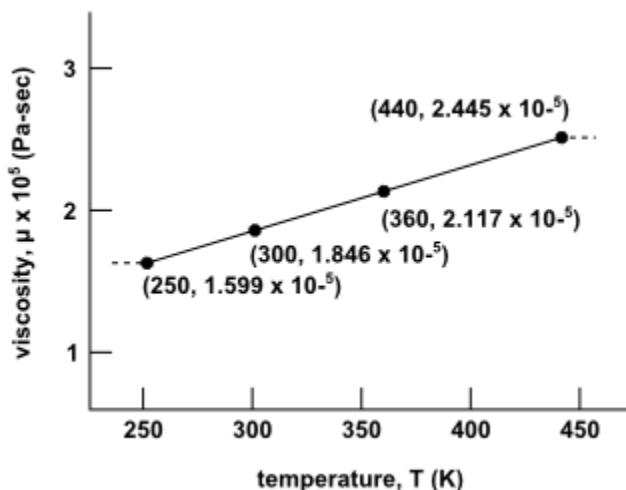

Figure 8.11 The Piecewise-Linear Profile Dialog Box

Since this is a modal dialog box, the solver will not allow you to do anything else until you perform the following steps.

- Set the number of **Points** defining the piecewise distribution.
- Under **Data Points**, enter the data pairs for each point. First enter the independent and dependent variable values for **Point 1**, then increase the **Point** number and enter the appropriate values for each additional pair of variables. The pairs of points must be supplied in the order of increasing value of temperature. The solver will not sort them for you. A maximum of 30 piecewise points can be defined for each property. The dialog box in *Figure 8.11* (p. 419) shows the final inputs for the profile depicted in *Figure 8.12* (p. 419).

Important

If the temperature exceeds the maximum **Temperature** (T_{max}) you have specified for the profile, ANSYS FLUENT will use the **Value** corresponding to T_{max} . If the temperature falls below the minimum **Temperature** (T_{min}) specified for your profile, ANSYS FLUENT will use the **Value** corresponding to T_{min} .

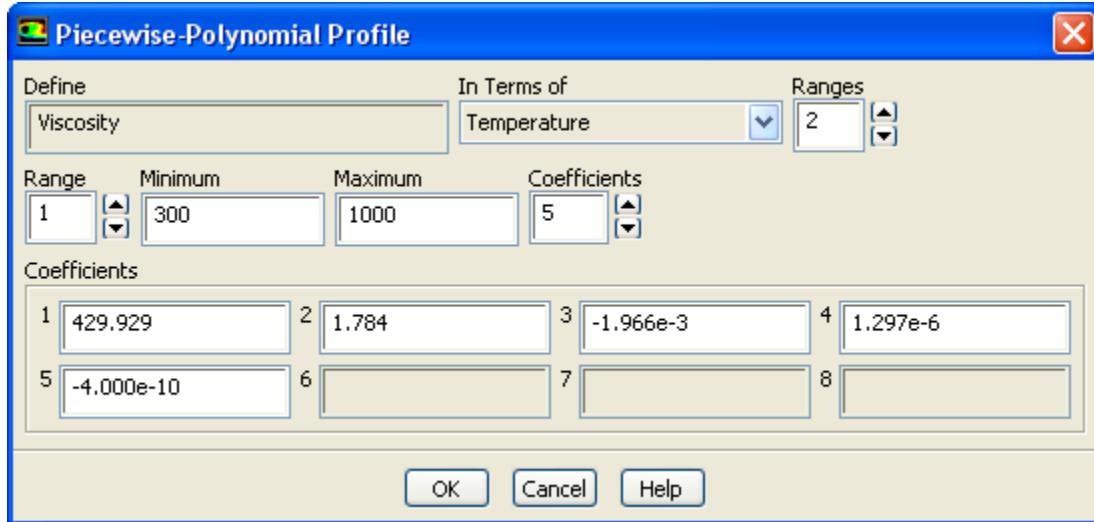

Figure 8.12 Piecewise-Linear Definition of Viscosity as a Function of Temperature

8.2.3. Inputs for Piecewise-Polynomial Functions

To define a piecewise-polynomial function of temperature for a material property, follow these steps:

1. In the *Create/Edit Materials Dialog Box* (p. 1882), choose **piecewise-polynomial** in the drop-down list to the right of the property name (e.g., **Cp**). The *Piecewise-Polynomial Profile Dialog Box* (p. 1898) (*Figure 8.13* (p. 420)) will open automatically. Since this is a modal dialog box, first perform the following steps.

Figure 8.13 The Piecewise-Polynomial Profile Dialog Box

2. Specify the number of **Ranges**. For the example of *Equation 8-5* (p. 420), two ranges of temperatures are defined:

$$c_p(T) = \begin{cases} 429.929 + 1.784T - 1.966 \times 10^{-3}T^2 \\ + 1.297 \times 10^{-6}T^3 - 4.000 \times 10^{-10}T^4 & \text{for } 300 \leq T < 1000 \\ 841.377 + 0.593T - 2.415 \times 10^{-4}T^2 \\ + 4.523 \times 10^{-8}T^3 - 3.153 \times 10^{-12}T^4 & \text{for } 1000 \leq T < 5000 \end{cases} \quad (8-5)$$

You may define up to three ranges. The ranges must be supplied in the order of increasing value of temperature. The solver will *not* sort them for you.

3. For the first range (**Range** = 1), specify the **Minimum** and **Maximum** temperatures, and the number of **Coefficients**. (Up to eight coefficients are available.) The number of coefficients defines the order of the polynomial. The default of 1 defines a polynomial of order 0. The property will be constant and equal to the single coefficient A_1 . An input of 2 defines a polynomial of order 1. The property will vary linearly with temperature and so on.
4. Define the coefficients. Coefficients **1, 2, 3,...** correspond to $A_1, A_2, A_3,...$ in *Equation 8-3* (p. 417). The dialog box in *Figure 8.13* (p. 420) shows the inputs for the first range of *Equation 8-5* (p. 420).
5. Increase the value of **Range** and enter the **Minimum** and **Maximum** temperatures, number of **Coefficients**, and the **Coefficients** ($B_1, B_2, B_3,...$) for the next range. Repeat if there is a third range.

8.2.4. Checking and Modifying Existing Profiles

If you want to check or change the coefficients, data pairs, or ranges for a previously-defined profile, click the **Edit...** button to the right of the property name. The appropriate dialog box will open, and you can check or modify the inputs as desired.

Important

In the *FLUENT Database Materials Dialog Box* (p. 1890), you cannot edit the profiles, but you can examine them by clicking on the **View...** button (instead of the **Edit...** button.)

8.3. Density

ANSYS FLUENT provides several options for definition of the fluid density:

- constant density
- temperature and/or composition-dependent density

Each of these input options and the governing physical models are explained in the following sections. In all cases, you will define the **Density** in the *Create/Edit Materials Dialog Box* (p. 1882).

Materials

For additional information, please see the following sections:

- 8.3.1. Defining Density for Various Flow Regimes
- 8.3.2. Input of Constant Density
- 8.3.3. Inputs for the Boussinesq Approximation
- 8.3.4. Density as a Profile Function of Temperature
- 8.3.5. Incompressible Ideal Gas Law
- 8.3.6. Ideal Gas Law for Compressible Flows
- 8.3.7. Composition-Dependent Density for Multicomponent Mixtures

8.3.1. Defining Density for Various Flow Regimes

The selection of density in ANSYS FLUENT is very important. Set the density relationship based on your flow regime.

- For compressible flows, the ideal gas law is the appropriate density relationship.
- For incompressible flows, you may choose one of the following methods:
 - Constant density, if you do not want density to be a function of temperature.
 - The incompressible ideal gas law, when pressure variations are small enough that the flow is fully incompressible but you wish to use the ideal gas law to express the relationship between density and temperature (e.g., for a natural convection problem).
 - Density as a polynomial, piecewise-linear, or piecewise-polynomial function of temperature, when the density is a function of temperature only, as in a natural convection problem.
 - The Boussinesq model, for natural convection problems involving small changes in temperature.

8.3.1.1. Mixing Density Relationships in Multiple-Zone Models

If your model has multiple fluid zones that use different materials, you should be aware of the following:

- For calculations with the pressure-based solver that do not use one of the general multiphase models, the compressible ideal gas law cannot be mixed with any other density methods. This means that if the compressible ideal gas law is used for one material, it must be used for all materials.
This restriction does not apply to the density-based solvers.
- There is only one specified operating pressure and one specified operating temperature. This means that if you are using the ideal gas law for more than one material, they will share the same operating pressure. If you are using the Boussinesq model for more than one material, they will share the same operating temperature.

8.3.2. Input of Constant Density

If you want to define the density of the fluid as a constant, select **constant** in the **Density** drop-down list under **Properties** in the *Create/Edit Materials Dialog Box* (p. 1882). Enter the value of density for the material.

For the default fluid (air), the density is 1.225 kg/m³.

8.3.3. Inputs for the Boussinesq Approximation

To enable the Boussinesq approximation for density, choose **boussinesq** from the **Density** drop-down list in the *Create/Edit Materials Dialog Box* (p. 1882) and specify a constant value for **Density**. You will also need to set the **Thermal Expansion Coefficient**, as well as relevant operating conditions, as described in *The Boussinesq Model* (p. 744).

8.3.4. Density as a Profile Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the density as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$\rho(T) = \rho_n + \frac{\rho_{n+1} - \rho_n}{T_{n+1} - T_n} (T - T_n) \quad (8-6)$$

- piecewise-polynomial:

$$\begin{aligned} \text{for } T_{min,1} \leq T < T_{max,1}: \rho(T) &= A_1 + A_2 T + A_3 T^2 + \dots \\ \text{for } T_{min,2} \leq T < T_{max,2}: \rho(T) &= B_1 + B_2 T + B_3 T^2 + \dots \end{aligned} \quad (8-7)$$

- polynomial:

$$\rho(T) = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-8)$$

For one of the these methods, select **piecewise-linear**, **piecewise-polynomial**, or **polynomial** in the **Density** drop-down list. You can enter the data pairs (T_n, ρ_n) , ranges and coefficients, or coefficients that describe these functions using the *Create/Edit Materials Dialog Box* (p. 1882), as described in *Defining Properties Using Temperature-Dependent Functions* (p. 417).

8.3.5. Incompressible Ideal Gas Law

In ANSYS FLUENT, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

$$\rho = \frac{p_{op}}{\frac{R}{M_w} T} \quad (8-9)$$

where,

R = the universal gas constant

M_w = the molecular weight of the gas

p_{op} = the operating pressure

In this form, the density depends only on the operating pressure and not on the local relative pressure field.

8.3.5.1. Density Inputs for the Incompressible Ideal Gas Law

The inputs for the incompressible ideal gas law are as follows:

1. Enable the ideal gas law for an incompressible fluid by choosing **incompressible-ideal-gas** from the drop-down list to the right of **Density** in the *Create/Edit Materials Dialog Box* (p. 1882).

Specify the incompressible ideal gas law individually for each material that you want to use it for. See *Composition-Dependent Density for Multicomponent Mixtures* (p. 425) for information on specifying the incompressible ideal gas law for mixtures.

2. Set the operating pressure by defining the **Operating Pressure** in the *Operating Conditions Dialog Box* (p. 1952).

 **Cell Zone Conditions** → **Operating Conditions...**

Important

By default, operating pressure is set to 101325 Pa. The input of the operating pressure is of great importance when you are computing density with the ideal gas law. See *Operating Pressure* (p. 468) for recommendations on setting appropriate values for the operating pressure.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the **Molecular Weight** in the *Create/Edit Materials Dialog Box* (p. 1882).

8.3.6. Ideal Gas Law for Compressible Flows

For compressible flows, the gas law is as following:

$$\rho = \frac{p_{op} + p}{\frac{R}{M_w} T} \quad (8-10)$$

where,

p = the local relative (or gauge) pressure predicted by ANSYS FLUENT

p_{op} = the operating pressure

8.3.6.1. Density Inputs for the Ideal Gas Law for Compressible Flows

The inputs for the ideal gas law are as follows:

1. Enable the ideal gas law for a compressible fluid by choosing **ideal-gas** from the drop-down list to the right of **Density** in the *Create/Edit Materials Dialog Box* (p. 1882).

Specify the ideal gas law individually for each material that you want to use it for. See *Composition-Dependent Density for Multicomponent Mixtures* (p. 425) for information on specifying the ideal gas law for mixtures.

2. Set the operating pressure by defining the **Operating Pressure** in the *Operating Conditions Dialog Box* (p. 1952).

 **Cell Zone Conditions** → **Operating Conditions...**

Important

The input of the operating pressure is of great importance when you are computing density with the ideal gas law. *Equation 8-10* (p. 424) notes that the operating pressure is added to the relative pressure field computed by the solver, yielding the absolute static pressure. See *Operating Pressure* (p. 468) for recommendations on setting appropriate values for the operating pressure. By default, operating pressure is set to 101325 Pa.

3. Set the molecular weight of the homogeneous or single-component fluid (if no chemical species transport equations are to be solved), or the molecular weights of each fluid material (species) in a multicomponent mixture. For each fluid material, enter the value of the **Molecular Weight** in the *Create/Edit Materials Dialog Box* (p. 1882).

8.3.7. Composition-Dependent Density for Multicomponent Mixtures

If you are solving species transport equations, set properties for the mixture material and for the constituent fluids (species), as described in detail in *Defining Properties for the Mixture and Its Constituent Species* (p. 861). To define a composition-dependent density for a mixture, do the following:

1. Select the density method:
 - For non-ideal-gas mixtures, select the **volume-weighted-mixing-law** method for the mixture material in the drop-down list to the right of **Density** in the *Create/Edit Materials Dialog Box* (p. 1882).
 - If you are modeling compressible flow, select **ideal-gas** for the mixture material in the drop-down list to the right of **Density** in the *Create/Edit Materials Dialog Box* (p. 1882).
 - If you are modeling incompressible flow using the ideal gas law, select **incompressible-ideal-gas** for the mixture material in the **Density** drop-down list in the *Create/Edit Materials Dialog Box* (p. 1882).
 - If you have a user-defined function that you want to use to model the density, you can choose either the **user-defined** method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.

The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

2. Click **Change/Create**.
3. If you have selected **volume-weighted-mixing-law**, define the density for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent densities for the individual species.
4. If you selected **user-defined-mixing-law**, define the density for each of the fluid materials that comprise the mixture. You may define constant, or (if applicable) temperature-dependent densities, or user-defined densities for the individual species. More information on defining properties with user-defined functions can be found in the [UDF Manual](#).

If you are modeling a non-ideal-gas mixture, ANSYS FLUENT will compute the mixture density as

$$\rho = \frac{1}{\sum_i \frac{Y_i}{\rho_i}} \quad (8-11)$$

where Y_i is the mass fraction and ρ_i is the density of species i .

For compressible flows, the gas law has the following form:

$$\rho = \frac{p_{op} + p}{RT \sum_i \frac{Y_i}{M_{w,i}}} \quad (8-12)$$

where,

p = the local relative (or gauge) pressure predicted by ANSYS FLUENT

R = the universal gas constant

Y_i = the mass fraction of species i

$M_{w,i}$ = the molecular weight of species i

p_{op} = the operating pressure

In ANSYS FLUENT, if you choose to define the density using the ideal gas law for an incompressible flow, the solver will compute the density as

$$\rho = \frac{p_{op}}{RT \sum_i Y_i M_{w,i}} \quad (8-13)$$

where,

R = the universal gas constant

Y_i = the mass fraction of species i

$M_{w,i}$ = the molecular weight of species i

p_{op} = the operating pressure

8.4. Viscosity

ANSYS FLUENT provides several options for definition of the fluid viscosity:

- constant viscosity
- temperature dependent and/or composition-dependent viscosity
- kinetic theory
- non-Newtonian viscosity
- user-defined function

Each of these input options and the governing physical models are detailed in this section. (User-defined functions are described in the [UDF Manual](#)). In all cases, define the **Viscosity** in the [Create/Edit Materials Dialog Box](#) (p. 1882).

Materials

Viscosities are input as dynamic viscosity (μ) in units of kg/m-s in SI units or lb_m/ft-s in British units. ANSYS FLUENT does not ask for input of the kinematic viscosity (ν).

For additional information, please see the following sections:

[8.4.1. Input of Constant Viscosity](#)

[8.4.2. Viscosity as a Function of Temperature](#)

[8.4.3. Defining the Viscosity Using Kinetic Theory](#)

[8.4.4. Composition-Dependent Viscosity for Multicomponent Mixtures](#)

[8.4.5. Viscosity for Non-Newtonian Fluids](#)

8.4.1. Input of Constant Viscosity

If you want to define the viscosity of your fluid as a constant, select **constant** in the **Viscosity** drop-down list in the [Create/Edit Materials Dialog Box](#) (p. 1882), and enter the value of viscosity for the fluid.

For the default fluid (air), the viscosity is 1.7894×10^{-5} kg/m-s.

8.4.2. Viscosity as a Function of Temperature

If you are modeling a problem that involves heat transfer, you can define the viscosity as a function of temperature. Five types of functions are available.

- piecewise-linear:

$$\mu(T) = \mu_n + \frac{\mu_{n+1} - \mu_n}{T_{n+1} - T_n} (T - T_n) \quad (8-14)$$

- piecewise-polynomial:

$$\begin{aligned} \text{for } T_{min,1} \leq T < T_{max,1}: \mu(T) &= A_1 + A_2 T + A_3 T^2 + \dots \\ \text{for } T_{min,2} \leq T < T_{max,2}: \mu(T) &= B_1 + B_2 T + B_3 T^2 + \dots \end{aligned} \quad (8-15)$$

- polynomial:

$$\mu(T) = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-16)$$

- Sutherland's law
- power law

Important

The power law described here is different from the non-Newtonian power law described in [Viscosity for Non-Newtonian Fluids](#) (p. 431).

For one of the first three, select **piecewise-linear**, **piecewise-polynomial**, **polynomial** in the **Viscosity** drop-down list and then enter the data pairs (T_n, μ_n) , ranges and coefficients, or coefficients that describe these functions [Defining Properties Using Temperature-Dependent Functions](#) (p. 417). For Sutherland's law or the power law, choose **sutherland** or **power-law** respectively in the drop-down list and enter the parameters.

8.4.2.1. Sutherland Viscosity Law

Sutherland's viscosity law resulted from a kinetic theory by Sutherland (1893) using an idealized inter-molecular-force potential. The formula is specified using two or three coefficients.

Sutherland's law with two coefficients has the form

$$\mu = \frac{C_1 T^{3/2}}{T + C_2} \quad (8-17)$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

C_1 and C_2 = the coefficients

Y_i = the mass fraction of species i

$M_{w,i}$ = the molecular weight of species i

p_{op} = the operating pressure

For air at moderate temperatures and pressures, $C_1 = 1.458 \times 10^{-6}$ kg/m-s-K^{1/2}, and $C_2 = 110.4$ K.

Sutherland's law with three coefficients has the form

$$\mu = \mu_0 \left(\frac{T}{T_0} \right)^{3/2} \frac{T_0 + S}{T + S} \quad (8-18)$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

μ_0 = reference value in kg/m-s

T_0 = reference temperature in K

S = an effective temperature in K (Sutherland constant)

For air at moderate temperatures and pressures, $\mu_0 = 1.716 \times 10^{-5}$ kg/m-s, $T_0 = 273.11$ K, and $S = 110.56$ K.

8.4.2.1.1. Inputs for Sutherland's Law

To use Sutherland's law, choose **sutherland** in the drop-down list to the right of **Viscosity**. The *Sutherland Law Dialog Box* (p. 1900) will open, and you can enter the coefficients as follows:

1. Select the **Two Coefficient Method** or the **Three Coefficient Method**.

Important

Use SI units if you choose the two-coefficient method.

2. For the **Two Coefficient Method**, set **C1** and **C2**. For the **Three Coefficient Method**, set the **Reference Viscosity** μ_0 , the **Reference Temperature** T_0 , and the **Effective Temperature** S .

8.4.2.2. Power-Law Viscosity Law

Another common approximation for the viscosity of dilute gases is the power-law form. For dilute gases at moderate temperatures, this form is considered to be slightly less accurate than Sutherland's law.

A power-law viscosity law with two coefficients has the form

$$\mu = BT^n \quad (8-19)$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

B = a dimensional coefficient

For air at moderate temperatures and pressures, $B = 4.093 \times 10^{-7}$, and $n = 2/3$.

A power-law viscosity law with three coefficients has the form

$$\mu = \mu_0 \left(\frac{T}{T_0} \right)^n \quad (8-20)$$

where,

μ = the viscosity in kg/m-s

T = the static temperature in K

T_0 = a reference value in K

μ_0 = a reference value in kg/m-s

For air at moderate temperatures and pressures, $\mu_0 = 1.716 \times 10^{-5}$ kg/m-s, $T_0 = 273$ K, and $n = 2/3$.

Important

The non-Newtonian power law for viscosity is described in [Viscosity for Non-Newtonian Fluids](#) (p. 431).

8.4.2.2.1. Inputs for the Power Law

To use the power law, choose **power-law** in the drop-down list to the right of **Viscosity**. The *Power Law Dialog Box* (p. 1901) will open, and you can enter the coefficients as follows:

1. Select the **Two Coefficient Method** or the **Three Coefficient Method**.

Important

Note that you must use SI units if you choose the two-coefficient method.

2. For the **Two Coefficient Method**, set **B** and the **Temperature Exponent n**. For the **Three Coefficient Method**, set the **Reference Viscosity μ_0** , the **Reference Temperature T_0** , and the **Temperature Exponent n**.

8.4.3. Defining the Viscosity Using Kinetic Theory

If you are using the gas law (as described in *Density* (p. 421)), you have the option to define the fluid viscosity using kinetic theory as

$$\mu = 2.67 \times 10^{-6} \frac{\sqrt{M_w T}}{\sigma^2 Q_\mu} \quad (8-21)$$

where μ is in units of kg/m-s, T is in units of Kelvin, σ is in units of Angstroms, and $Q_\mu = Q_\mu(T^*)$ where

$$T^* = \frac{T}{(\varepsilon/k_B)} \quad (8-22)$$

The Lennard-Jones parameters, σ and ε/k_B , are inputs to the kinetic theory calculation that you supply by selecting **kinetic-theory** from the drop-down list to the right of **Viscosity** in the *Create/Edit Materials Dialog Box* (p. 1882). The solver will use these kinetic theory inputs in *Equation 8-21* (p. 430) to compute the fluid viscosity. See *Kinetic Theory Parameters* (p. 467) for details about these inputs.

8.4.4. Composition-Dependent Viscosity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent viscosity. (Note that you can also define the viscosity of the mixture as a constant value or a function of temperature.)

To define a composition-dependent viscosity for a mixture, follow these steps:

1. For the mixture material, choose **mass-weighted-mixing-law** or, if you are using the ideal gas law for density, **ideal-gas-mixing-law** in the drop-down list to the right of **Viscosity**. If you have a user-defined function that you want to use to model the viscosity, you can choose either the **user-defined** method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.
2. Click **Change/Create**.

3. Define the viscosity for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent viscosities for the individual species. You may also use kinetic theory for the individual viscosities, or specify a non-Newtonian viscosity, if applicable.
4. If you selected **user-defined-mixing-law**, define the viscosity for each of the fluid materials that comprise the mixture. You may define constant, or (if applicable) temperature-dependent viscosities, or user-defined viscosities for the individual species. More information on defining properties with user-defined functions can be found in the [UDF Manual](#).

The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. (Note that only the constant, the polynomial methods and the user-defined methods are available.)

If you are using the ideal gas law, the solver will compute the mixture viscosity based on kinetic theory as

$$\mu = \sum_i \frac{X_i \mu_i}{\sum_j X_j \phi_{ij}} \quad (8-23)$$

where

$$\phi_{ij} = \frac{\left[1 + \left(\frac{\mu_i}{\mu_j} \right)^{1/2} \left(\frac{M_{w,j}}{M_{w,i}} \right)^{1/4} \right]^2}{\left[8 \left(1 + \frac{M_{w,i}}{M_{w,j}} \right) \right]^{1/2}} \quad (8-24)$$

and X_i is the mole fraction of species i .

For non-ideal gas mixtures, the mixture viscosity is computed based on a simple mass fraction average of the pure species viscosities:

$$\mu = \sum_i Y_i \mu_i \quad (8-25)$$

8.4.5. Viscosity for Non-Newtonian Fluids

For incompressible Newtonian fluids, the shear stress is proportional to the rate-of-deformation tensor \overline{D} :

$$\overline{\tau} = \mu \overline{D} \quad (8-26)$$

where \overline{D} is defined by

$$\overline{D} = \left(\frac{\partial u_j}{\partial x_i} + \frac{\partial u_i}{\partial x_j} \right) \quad (8-27)$$

and μ is the viscosity, which is independent of \overline{D} .

For some non-Newtonian fluids, the shear stress can similarly be written in terms of a non-Newtonian viscosity η :

$$\overline{\tau} = \eta (\overline{D}) \overline{D} \quad (8-28)$$

In general, η is a function of all three invariants of the rate-of-deformation tensor \overline{D} . However, in the non-Newtonian models available in ANSYS FLUENT, η is considered to be a function of the shear rate $\dot{\gamma}$ only. $\dot{\gamma}$ is related to the second invariant of \overline{D} and is defined as

$$\dot{\gamma} = \sqrt{\frac{1}{2} \overline{D} : \overline{D}} \quad (8-29)$$

8.4.5.1. Temperature Dependent Viscosity

If the flow is non-isothermal, then the temperature dependence on the viscosity can be included along with the shear rate dependence. In this case, the total viscosity consists of two parts and is calculated as

$$\mu = \eta (\dot{\gamma}) H (T) \quad (8-30)$$

where $H(T)$ is the temperature dependence, known as the Arrhenius law.

$$H (T) = \exp \left[\alpha \left(\frac{1}{T - T_0} - \frac{1}{T_\alpha - T_0} \right) \right] \quad (8-31)$$

where α is the ratio of the activation energy to the thermodynamic constant and T_α is a reference temperature for which $H(T) = 1$. T_0 , which is the temperature shift, is set to 0 by default, and corresponds to the lowest temperature that is thermodynamically acceptable. Therefore T_α and T_0 are absolute temperatures. Temperature dependence is only included when the energy equation is enabled. Set the parameter α to 0 when you want temperature dependence to be ignored, even when the energy equation is solved.

ANSYS FLUENT provides four options for modeling non-Newtonian flows:

- power law
- Carreau model for pseudo-plastics
- Cross model
- Herschel-Bulkley model for Bingham plastics

Important

- Note that the models listed above are not available when modeling turbulent flow.
- Note that the non-Newtonian power law described below is different from the power law described in [Power-Law Viscosity Law \(p. 429\)](#).
- Non-Newtonian model for single phase is available for the mixture model and it is recommended that this should be attached to the primary phase.

Appropriate values for the input parameters for these models can be found in the literature (e.g., [\[92\] \(p. 2372\)](#)).

8.4.5.2. Power Law for Non-Newtonian Viscosity

If you choose **non-newtonian-power-law** in the drop-down list to the right of **Viscosity**, non-Newtonian flow will be modeled according to the following power law for the non-Newtonian viscosity:

$$\eta = k \dot{\gamma}^{n-1} H(T) \quad (8-32)$$

where k and n are input parameters. k is a measure of the average viscosity of the fluid (the consistency index); n is a measure of the deviation of the fluid from Newtonian (the power-law index). The value of n determines the class of the fluid:

$n = 1 \rightarrow$ Newtonian fluid

$n > 1 \rightarrow$ shear-thickening (dilatant fluids)

$n < 1 \rightarrow$ shear-thinning (pseudo-plastics)

8.4.5.2.1. Inputs for the Non-Newtonian Power Law

To use the non-Newtonian power law, choose **non-newtonian-power-law** in the drop-down list to the right of **Viscosity**. The [Non-Newtonian Power Law Dialog Box \(p. 1901\)](#) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Consistency Index k , Power-Law Index n , Minimum and Maximum Viscosity Limit, Reference Temperature T_{alpha} , and Activation Energy/R**, which is the ratio of the activation energy to the thermodynamic constant α .

8.4.5.3. The Carreau Model for Pseudo-Plastics

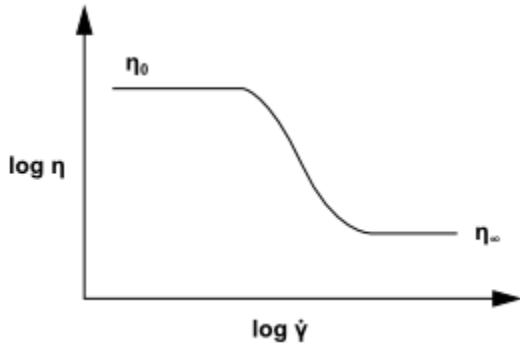

The power law model described in [Equation 8-32 \(p. 433\)](#) results in a fluid viscosity that varies with shear rate. For $\dot{\gamma} \rightarrow 0$, $\eta \rightarrow \eta_0$, and for $\dot{\gamma} \rightarrow \infty$, $\eta \rightarrow \eta_\infty$, where η_0 and η_∞ are, respectively, the upper and lower limiting values of the fluid viscosity.

The Carreau model attempts to describe a wide range of fluids by the establishment of a curve-fit to piece together functions for both Newtonian and shear-thinning ($n < 1$) non-Newtonian laws. In the Carreau model, the viscosity is

$$\eta = H(T) \left(\eta_\infty + (\eta_0 - \eta_\infty) [1 + \gamma^2 \lambda^2]^{(n-1)/2} \right) \quad (8-33)$$

and the parameters n , λ , T_α , η_0 , and η_∞ are dependent upon the fluid. λ is the time constant, n is the power-law index (as described above for the non-Newtonian power law), η_0 and η_∞ are, respectively, the zero- and infinite-shear viscosities, T_α is the reference temperature, and α is the ratio of the activation energy to thermodynamic constant. [Figure 8.14 \(p. 434\)](#) shows how viscosity is limited by η_0 and η_∞ at low and high shear rates.

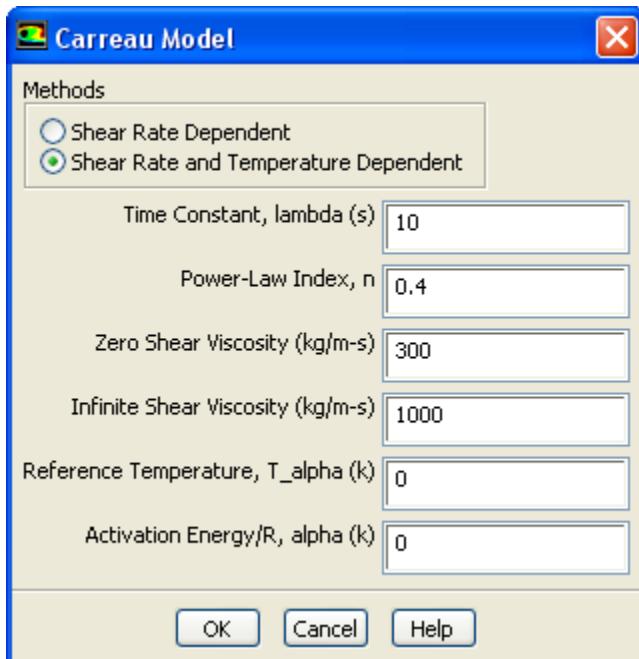

Figure 8.14 Variation of Viscosity with Shear Rate According to the Carreau Model

8.4.5.3.1. Inputs for the Carreau Model

To use the Carreau model, choose **carreau** in the drop-down list to the right of **Viscosity**. The [Carreau Model Dialog Box \(p. 1902\)](#) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Time Constant λ** , **Power-Law Index n** , **Reference Temperature T_α** , **Zero Shear Viscosity η_0** , **Infinite Shear Viscosity η_∞** , and **Activation Energy/R α** .

Figure 8.15 The Carreau Model Dialog Box

8.4.5.4. Cross Model

The Cross model for viscosity is:

$$\eta = H(T) \frac{\eta_0}{1 + (\lambda \dot{\gamma})^{1-n}} \quad (8-34)$$

where,

η_0 = zero-shear-rate viscosity

λ = natural time (i.e., inverse of the shear rate at which the fluid changes from Newtonian to power-law behavior)

n = power-law index

The Cross model is commonly used to describe the low-shear-rate behavior of the viscosity.

8.4.5.4.1. Inputs for the Cross Model

To use the Cross model, choose **cross** in the drop-down list to the right of **Viscosity**. The *Cross Model Dialog Box* (p. 1903) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Zero Shear Viscosity** η_0 , **Time Constant** λ , **Power-Law Index** n , **Reference Temperature** T_α , and **Activation Energy/R**, which is the ratio of the activation energy to the thermodynamic constant α .

8.4.5.5. Herschel-Bulkley Model for Bingham Plastics

The power law model described above is valid for fluids for which the shear stress is zero when the strain rate is zero. Bingham plastics are characterized by a non-zero shear stress when the strain rate is zero.

$$\bar{\tau} = \bar{\tau}_0 + \eta \bar{D} \quad (8-35)$$

where τ_0 is the yield stress:

- For $\tau < \tau_0$, the material remains rigid.
- For $\tau > \tau_0$, the material flows as a power-law fluid.

The Herschel-Bulkley model combines the effects of Bingham and power-law behavior in a fluid. For low strain rates ($\dot{\gamma} < \dot{\gamma}_c/\mu_0$), the “rigid” material acts like a very viscous fluid with viscosity μ_0 . As the strain rate increases and the yield stress threshold, τ_0 , is passed, the fluid behavior is described by a power law.

For $\dot{\gamma} > \dot{\gamma}_c$

$$\eta = \frac{\tau_0}{\dot{\gamma}} + k \left(\frac{\dot{\gamma}}{\dot{\gamma}_c} \right)^{n-1} \quad (8-36)$$

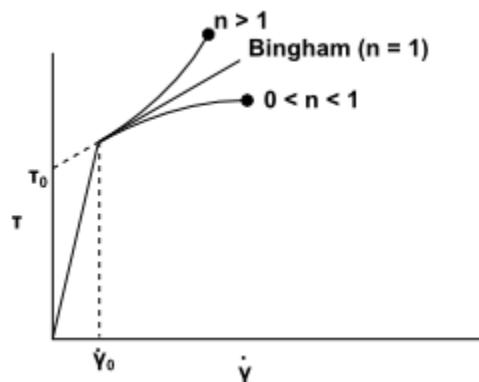

For $\dot{\gamma} < \dot{\gamma}_c$

$$\eta = \tau_0 \frac{\left(2 - \dot{\gamma}/\dot{\gamma}_c \right)}{\dot{\gamma}_c} + k \left[(2-n) + (n-1) \frac{\dot{\gamma}}{\dot{\gamma}_c} \right] \quad (8-37)$$

where k is the consistency factor, and n is the power-law index.

Figure 8.16 (p. 437) shows how shear stress (τ) varies with shear rate ($\dot{\gamma}$) for the Herschel-Bulkley model.

Figure 8.16 Variation of Shear Stress with Shear Rate According to the Herschel-Bulkley Model

If you choose the Herschel-Bulkley model for Bingham plastics, [Equation 8–36 \(p. 436\)](#) will be used to determine the fluid viscosity.

The Herschel-Bulkley model is commonly used to describe materials such as concrete, mud, dough, and toothpaste, for which a constant viscosity after a critical shear stress is a reasonable assumption. In addition to the transition behavior between a flow and no-flow regime, the Herschel-Bulkley model can also exhibit a shear-thinning or shear-thickening behavior depending on the value of n .

8.4.5.5.1. Inputs for the Herschel-Bulkley Model

To use the Herschel-Bulkley model, choose **herschel-bulkley** in the drop-down list to the right of **Viscosity**. The [Herschel-Bulkley Dialog Box \(p. 1904\)](#) will open, and you can choose between **Shear Rate Dependent** and **Shear Rate and Temperature Dependent**. Enter the **Consistency Index k** , **Power-Law Index n** , **Yield Stress Threshold τ_0** , **Critical Shear Rate $\dot{\gamma}_c$** , **Reference Temperature T_α** , and the ratio of the activation energy to thermodynamic constant α , **Activation Energy/R**.

8.5. Thermal Conductivity

The thermal conductivity must be defined when heat transfer is active. You will need to define thermal conductivity when you are modeling energy and viscous flow.

ANSYS FLUENT provides several options for definition of the thermal conductivity:

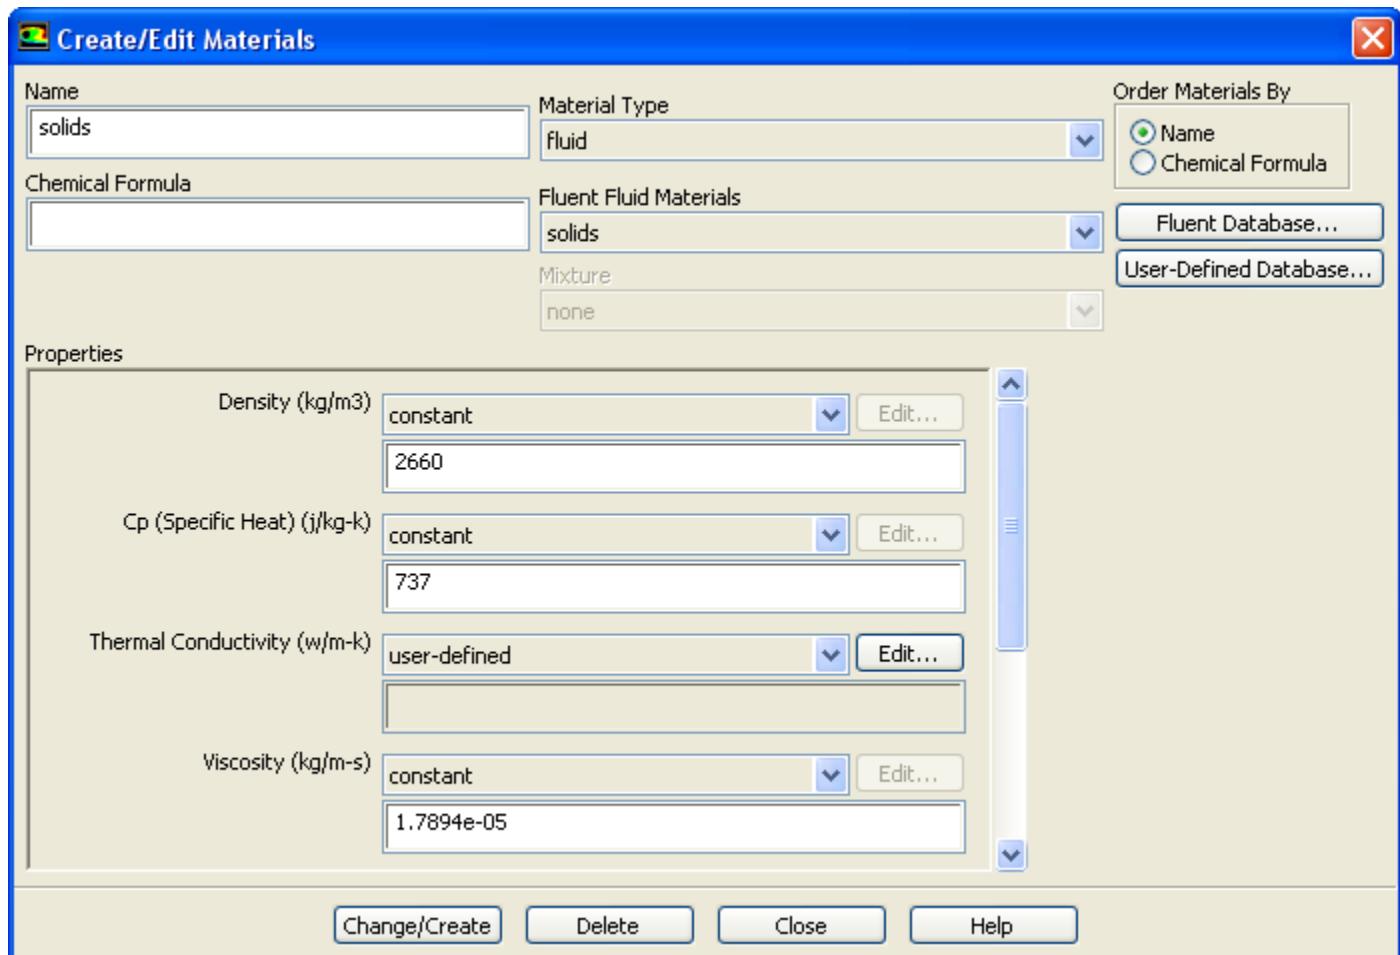

- constant thermal conductivity
- temperature- and/or composition-dependent thermal conductivity
- kinetic theory
- anisotropic (anisotropic, biaxial, orthotropic, cylindrical orthotropic) (for solid materials only)
- user-defined

Each of these input options and the governing physical models are detailed in this section. User-defined functions (UDFs) are described in the [UDF Manual](#).

In all cases, you will define the **Thermal Conductivity** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) ([Figure 8.17 \(p. 438\)](#)).

Materials → Create/Edit...

Figure 8.17 The Create/Edit Materials Dialog Box

Thermal conductivity is defined in units of W/m-K in SI units or BTU/hr-ft-°R in British units.

For additional information, please see the following sections:

- [8.5.1. Constant Thermal Conductivity](#)
- [8.5.2. Thermal Conductivity as a Function of Temperature](#)
- [8.5.3. Thermal Conductivity Using Kinetic Theory](#)
- [8.5.4. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures](#)
- [8.5.5. Anisotropic Thermal Conductivity for Solids](#)

8.5.1. Constant Thermal Conductivity

If you want to define the thermal conductivity as a constant, check that **constant** is selected in the drop-down list to the right of **Thermal Conductivity** in the *Create/Edit Materials Dialog Box* (p. 1882) (*Figure 8.17* (p. 438)), and enter the value of thermal conductivity for the material.

For the default fluid (air), the thermal conductivity is 0.0242 W/m-K.

8.5.2. Thermal Conductivity as a Function of Temperature

You can also choose to define the thermal conductivity as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$k(T) = k_n + \frac{k_{n+1} - k_n}{T_{n+1} - T_n} (T - T_n) \quad (8-38)$$

- piecewise-polynomial:

$$\begin{aligned} \text{for } T_{min,1} \leq T < T_{max,1}: k(T) &= A_1 + A_2 T + A_3 T^2 + \dots \\ \text{for } T_{min,2} \leq T < T_{max,2}: k(T) &= B_1 + B_2 T + B_3 T^2 + \dots \end{aligned} \quad (8-39)$$

- polynomial:

$$k(T) = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-40)$$

You can input the data pairs (T_n, k_n) , ranges and coefficients A_i and B_i , or coefficients A_i that describe these functions using the [Create/Edit Materials Dialog Box \(p. 1882\)](#), as described in [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#).

8.5.3. Thermal Conductivity Using Kinetic Theory

If you are using the gas law (as described in [Density \(p. 421\)](#)), you have the option to define the thermal conductivity using kinetic theory as

$$k = \frac{15}{4} \frac{R}{M_w} \mu \left[\frac{4}{15} \frac{c_p M_w}{R} + \frac{1}{3} \right] \quad (8-41)$$

where R is the universal gas constant, M_w is the molecular weight, μ is the material's specified or computed viscosity, and c_p is the material's specified or computed specific heat capacity.

To enable the use of this equation for calculating thermal conductivity, select **kinetic-theory** from the drop-down list to the right of **Thermal Conductivity** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#). The solver will use [Equation 8-41 \(p. 439\)](#) to compute the thermal conductivity.

8.5.4. Composition-Dependent Thermal Conductivity for Multicomponent Mixtures

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent thermal conductivity. (Note that you can also define

the thermal conductivity of the mixture as a constant value or a function of temperature, or using kinetic theory.)

To define a composition-dependent thermal conductivity for a mixture, follow these steps:

1. For the mixture material, choose **mass-weighted-mixing-law** or, if you are using the ideal gas law, **ideal-gas-mixing-law** in the drop-down list to the right of **Thermal Conductivity**. If you have a user-defined function that you want to use to model the thermal conductivity, you can choose either the **user-defined** method or the **user-defined-mixing-law** method for the mixture material in the drop-down list.

The only difference between the **user-defined-mixing-law** and the **user-defined** option for specifying density, viscosity and thermal conductivity of mixture materials, is that with the **user-defined-mixing-law** option, the individual properties of the species materials can also be specified. Note that only the constant, the polynomial methods and the user-defined methods are available.

Important

If you use **ideal-gas-mixing-law** for the thermal conductivity of a mixture, you must use **ideal-gas-mixing-law** or **mass-weighted-mixing-law** for viscosity, because these two viscosity specification methods are the only ones that allow specification of the component viscosities, which are used in the ideal gas law for thermal conductivity ([Equation 8–42 \(p. 440\)](#)).

2. Click **Change/Create**.
3. Define the thermal conductivity for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent thermal conductivities for the individual species. You may also use kinetic theory for the individual thermal conductivities, if applicable.
4. If you selected **user-defined-mixing-law**, define the thermal conductivity for each of the fluid materials that comprise the mixture. You may define constant, or (if applicable) temperature-dependent thermal conductivities, or user-defined thermal conductivities for the individual species. More information about defining properties with user-defined functions can be found in the [UDF Manual](#).

If you are using the ideal gas law, the solver will compute the mixture thermal conductivity based on kinetic theory as

$$k = \sum_i \frac{X_i k_i}{\sum_j X_j \phi_{ij}} \quad (8-42)$$

where

$$\phi_{ij} = \frac{\left[1 + \left(\frac{\mu_i}{\mu_j} \right)^{1/2} \left(\frac{M_{w,j}}{M_{w,i}} \right)^{1/4} \right]^2}{\left[8 \left(1 + \frac{M_{w,i}}{M_{w,j}} \right) \right]^{1/2}} \quad (8-43)$$

and X_i is the mole fraction of species i .

For non-ideal gases, the mixture thermal conductivity is computed based on a simple mass fraction average of the pure species conductivities:

$$k = \sum_i Y_i k_i \quad (8-44)$$

8.5.5. Anisotropic Thermal Conductivity for Solids

The anisotropic conductivity option in ANSYS FLUENT solves the conduction equation in solids with the thermal conductivity specified as a matrix. The heat flux vector is written as

$$q_i = -k_{ij} \frac{\partial T}{\partial x_j} \quad (8-45)$$

The following options are available for defining anisotropic thermal conductivity in ANSYS FLUENT. These are discussed below.

- anisotropic
- biaxial
- orthotropic
- cylindrical orthotropic

Important

Note that the anisotropic conductivity options are available only with the pressure-based solver; you cannot use them with the density-based solvers.

8.5.5.1. Anisotropic Thermal Conductivity

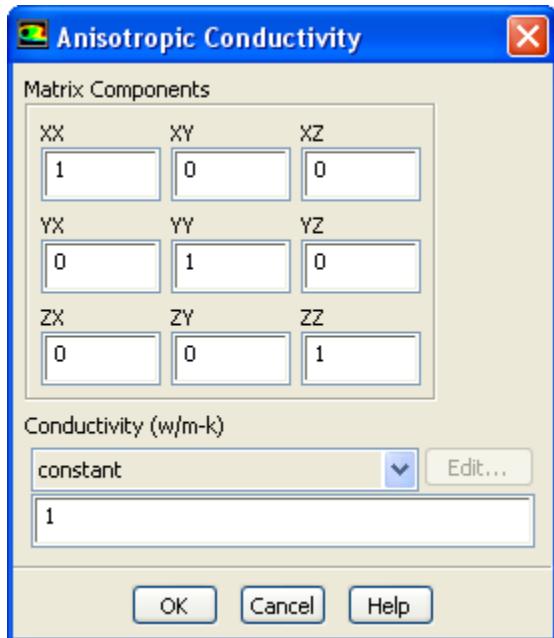

For anisotropic diffusion, the thermal conductivity matrix ([Equation 8-45 \(p. 441\)](#)) is specified as

$$k_{ij} = k \hat{e}_{ij} \quad (8-46)$$

where k is the conductivity and \hat{e}_{ij} is a matrix (2 × 2 for two dimensions and 3 × 3 for three-dimensional problems). Note that \hat{e}_{ij} can be a non-symmetric matrix.

To define anisotropic thermal conductivity for a solid material, select **anisotropic** for **Thermal Conductivity** in the *Create/Edit Materials Dialog Box* (p. 1882) (*Figure 8.17* (p. 438)). This will open the *Anisotropic Conductivity Dialog Box* (p. 1908) (*Figure 8.18* (p. 442)).

Figure 8.18 The Anisotropic Conductivity Dialog Box

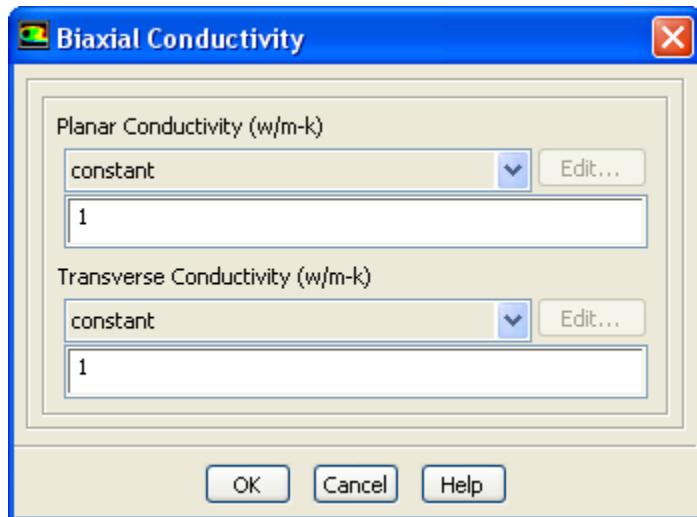

In the *Anisotropic Conductivity Dialog Box* (p. 1908), enter the **Matrix Components** of matrix \hat{e}_{ij} and then select the **Conductivity** (k in *Equation 8–46* (p. 441)) to be a **constant**, polynomial function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined** function. See *Constant Thermal Conductivity* (p. 438) and *Thermal Conductivity as a Function of Temperature* (p. 439) for details on constants and thermal polynomial functions.

When you select the **user-defined** option, the *User-Defined Functions Dialog Box* (p. 1899) will open allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. Details about user-defined functions can be found in the *UDF Manual*.

8.5.5.2. Biaxial Thermal Conductivity

Biaxial thermal conductivity is applicable to solid materials used for the wall shell conduction model. To define a biaxial thermal conductivity, select **biaxial** in the drop-down list for **Thermal Conductivity** in the *Create/Edit Materials Dialog Box* (p. 1882). This opens the *Biaxial Conductivity Dialog Box* (p. 1905) (*Figure 8.19* (p. 443)).

Figure 8.19 The Biaxial Conductivity Dialog Box

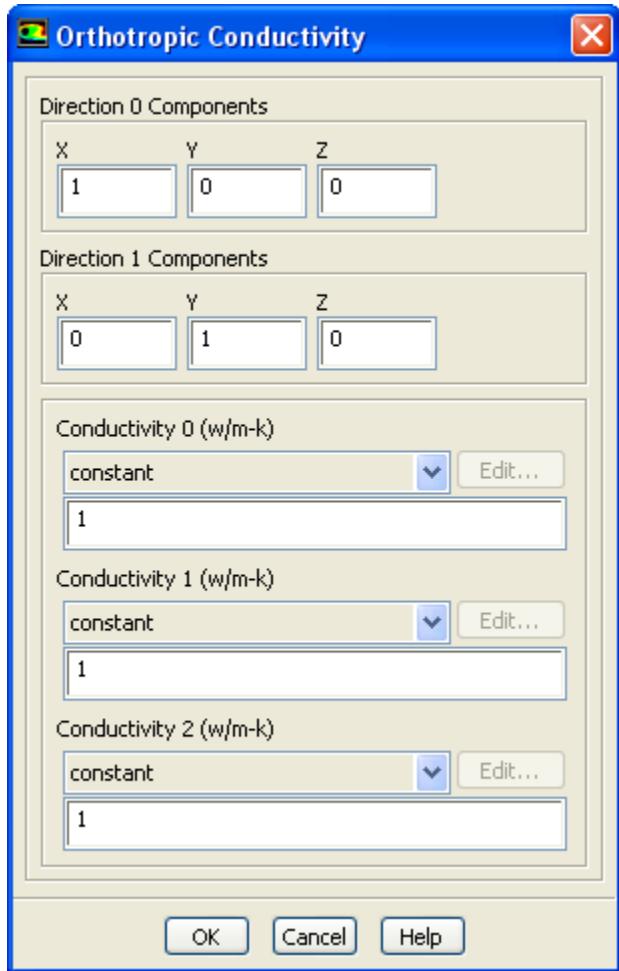

In the *Biaxial Conductivity Dialog Box* (p. 1905), both the conductivity normal to the surface of the solid region (**Transverse Conductivity**) and the conductivity within the shell or solid region (**Planar Conductivity**) can be defined as **constant**, **polynomial**, **piecewise-linear**, or **piecewise-polynomial**. See *Constant Thermal Conductivity* (p. 438) and *Thermal Conductivity as a Function of Temperature* (p. 439) for details on these parameters. Within the shell, however, the conductivity is isotropic. See *Figure 14.5* (p. 750)

8.5.5.3. Orthotropic Thermal Conductivity

When the orthotropic thermal conductivity is used, the thermal conductivities (k_ξ, k_η, k_ζ) in the principal directions $(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta)$ are specified. The conductivity matrix is then computed as

$$k_{ij} = k_\xi e_{\xi i} e_{\xi j} + k_\eta e_{\eta i} e_{\eta j} + k_\zeta e_{\zeta i} e_{\zeta j} \quad (8-47)$$

To define an orthotropic thermal conductivity in solids, select **orthotropic** in the drop-down list for **Thermal Conductivity** in the *Create/Edit Materials Dialog Box* (p. 1882). This opens the *Orthotropic Conductivity Dialog Box* (p. 1907) (Figure 8.20 (p. 444)).

Figure 8.20 The Orthotropic Conductivity Dialog Box

Since the directions $(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta)$ are mutually orthogonal, only the first two need to be specified for three-dimensional problems. \hat{e}_ξ is defined using **X, Y, Z** under **Direction 0 Components**, and \hat{e}_η is defined using **X, Y, Z** under **Direction 1 Components**. You can define **Conductivity 0** (k_ξ), **Conductivity 1** (k_η), and **Conductivity 2** (k_ζ) as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial** functions of temperature, or **user-defined**. See *Constant Thermal Conductivity* (p. 438) and *Thermal Conductivity as a Function of Temperature* (p. 439) for details on constant and temperature profile functions.

When you select the **user-defined** option, the *User-Defined Functions Dialog Box* (p. 1899) will open allowing you to hook a `DEFINE_PROPERTY` UDF only if you have previously loaded a compiled UDF library or interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the *UDF Manual*.

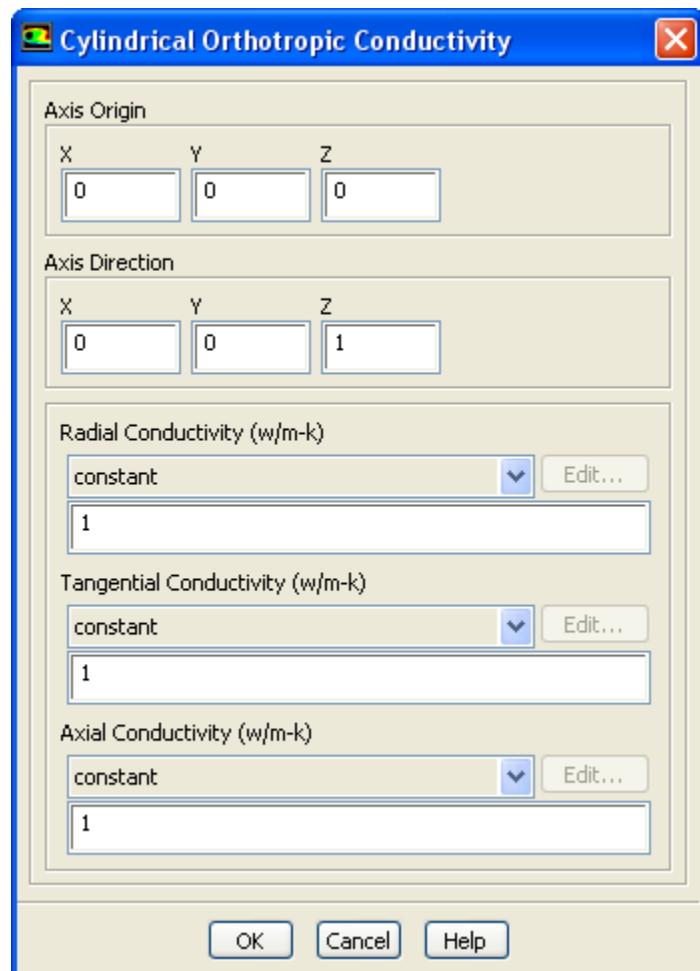

Important

For two-dimensional problems, only the functions (k_ξ, k_η) and the unit vector (\hat{e}_ξ) need to be specified.

8.5.5.4. Cylindrical Orthotropic Thermal Conductivity

The orthotropic conductivity of solids can be specified in cylindrical coordinates. To define the orthotropic thermal conductivity in cylindrical coordinates, select **cyl-orthotropic** in the drop-down list for **Thermal Conductivity** in the *Create/Edit Materials Dialog Box* (p. 1882). This opens the *Cylindrical Orthotropic Conductivity Dialog Box* (p. 1906) (*Figure 8.21* (p. 445)).

Figure 8.21 The Cylindrical Orthotropic Conductivity Dialog Box

In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the +z axis. ANSYS FLUENT will automatically compute the anisotropic conductivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

You can define the **Radial Conductivity**, **Tangential Conductivity**, and **Axial Conductivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as user-defined functions of temperature.

See *Constant Thermal Conductivity* (p. 438) and *Thermal Conductivity as a Function of Temperature* (p. 439) for details on constant and thermal profile functions.

When you select the **user-defined** option, the *User-Defined Functions Dialog Box* (p. 1899) will open allowing you to hook a `DEFINE_PROPERTY` UDF *only* if you have previously loaded a compiled UDF library or

interpreted the UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

Important

For conductivity calculations near the wall, the cell next to the wall is chosen for computing the conductivity matrix instead of the wall itself.

8.6. User-Defined Scalar (UDS) Diffusivity

There are two types of UDS diffusivity that you can specify in ANSYS FLUENT: isotropic and anisotropic. Diffusion is isotropic when it is the same in all directions. Isotropic diffusion coefficients can be specified in two ways: either as a single **user-defined** that applies to all UDS transport equations defined for your model; or on a per-scalar basis as **constants**, **polynomial** functions of temperature, or **user-defined** functions.

Diffusion is anisotropic when the diffusion coefficients are different in different directions. Anisotropic diffusion can be specified by a tensor diffusion coefficient matrix Γ ([Equation 8–48 \(p. 446\)](#)) for each UDS (in both fluid and solid zones) in four different ways: general **anisotropic**, **orthotropic**, **cyl-orthotropic**, and **user-defined-anisotropic**. All UDS diffusivity parameters are set from the [Create/Edit Materials Dialog Box \(p. 1882\)](#) and are discussed below. Note that details about how to define and use UDFs in UDS transport equations is discussed in the [UDF Manual](#).

The second-order diffusion term in the most general form is

$$\nabla \cdot (\Gamma \cdot \nabla \phi^k) \quad (8-48)$$

where Γ is a 3×3 tensor in 3D.

For additional information, please see the following sections:

- [8.6.1. Isotropic Diffusion](#)
- [8.6.2. Anisotropic Diffusion](#)
- [8.6.3. User-Defined Anisotropic Diffusivity](#)

8.6.1. Isotropic Diffusion

For isotropic diffusion, Γ in [Equation 8–48 \(p. 446\)](#) is equal to a scalar Γ times the identity matrix and the equation reduces to

$$\nabla \cdot (\Gamma \nabla \phi^k) \quad (8-49)$$

You can specify isotropic diffusivity as a single user-defined function that applies to all UDS transport equations. For this case, choose **user-defined** from the drop-down list for **UDS Diffusivity** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#).

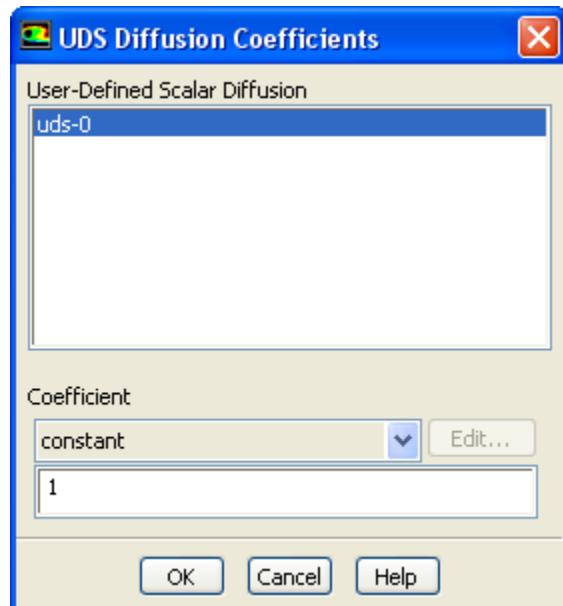

Materials

If you have previously loaded a compiled UDF library or have interpreted the UDF, then the [User-Defined Functions Dialog Box \(p. 1899\)](#) will open, allowing you to hook the `DEFINE_DIFFUSIVITY` UDF to ANSYS

FLUENT. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

Isotropic diffusion coefficients can also be defined on a per-scalar basis by selecting **defined-per-uds** from the drop-down list for **UDS Diffusivity** in the [Create/Edit Materials Dialog Box](#) (p. 1882). This will open the [UDS Diffusion Coefficients Dialog Box](#) (p. 1921) (*Figure 8.22* (p. 447)).

Figure 8.22 The UDS Diffusion Coefficients Dialog Box

In the [UDS Diffusion Coefficients Dialog Box](#) (p. 1921), select a scalar equation (e.g., **uds-0**) and then choose a **constant**, **polynomial**, or **user-defined** function from the **Coefficient** drop-down list. For the default fluid (air), the constant diffusion coefficient is 1 kg/m-s. If you choose **polynomial**, the [Polynomial Profile Dialog Box](#) (p. 1897) will open and you can specify your coefficients as a function of temperature. See [Inputs for Polynomial Functions](#) (p. 417) for details.

When you select the **user-defined** option, the [User-Defined Functions Dialog Box](#) (p. 1899) will open allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

8.6.2. Anisotropic Diffusion

You can specify anisotropic diffusion coefficients in both fluid and solid zones by defining the tensor diffusion coefficient matrix Γ ([Equation 8-48](#) (p. 446)) on a per-scalar basis. You can use anisotropic diffusivity for UDS scalar transport equations to model species transport equations in porous media and in solids where species diffusion shows anisotropic behavior.

Important

- Note that the anisotropic diffusion options discussed in the following sections are available with the pressure-based solver and the density-based solvers.
- UDS diffusion coefficients can be postprocessed only in those cells which have isotropic diffusivity. In all other cells, the diffusion coefficient will be zero.

In all cases, you enable anisotropic diffusion by selecting **defined-per-uds** under **UDS Diffusivity** in the *Create/Edit Materials Dialog Box* (p. 1882). This will open the *UDS Diffusion Coefficients Dialog Box* (p. 1921) (*Figure 8.22* (p. 447)).

Materials

In the *UDS Diffusion Coefficients Dialog Box* (p. 1921), select a scalar equation (e.g., **uds-0**) and then choose one of the following methods under **Coefficient** to specify the anisotropic diffusion coefficient. These methods are described in detail below.

- anisotropic
- orthotropic
- cylindrical orthotropic
- user-defined anisotropic

8.6.2.1. Anisotropic Diffusivity

For anisotropic diffusivity, you can specify Γ in *Equation 8-48* (p. 446) in the form $K\Gamma$ where K is a constant 3×3 matrix in 3D and Γ is a scalar multiplier.

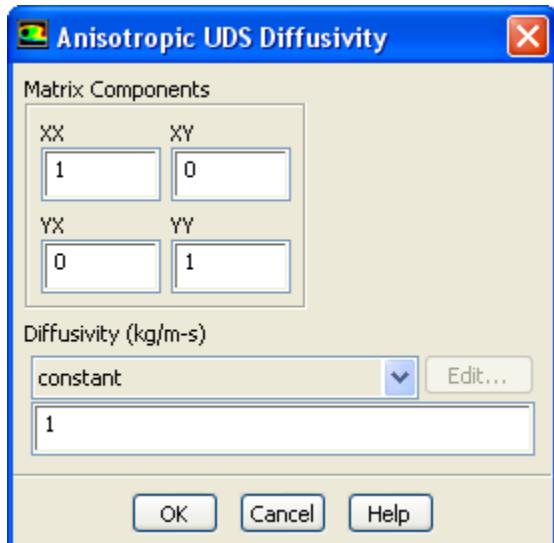

The diffusion coefficient matrix is specified as

$$k_{ij} = k \hat{e}_{ij} \quad (8-50)$$

where k is the diffusivity and \hat{e}_{ij} is a matrix (2×2 for two dimensions and 3×3 for three-dimensional problems). Note that \hat{e}_{ij} can be a non-symmetric matrix.

To specify anisotropic diffusion coefficients, first select a scalar equation (e.g., **uds-0**) from the **User-Defined Scalar Diffusion** list in the *UDS Diffusion Coefficients Dialog Box* (p. 1921) (*Figure 8.22* (p. 447)). Then choose **anisotropic** in the drop-down list under **Coefficient**. This will open the **Anisotropic UDS Diffusivity** dialog box (*Figure 8.23* (p. 448)).

Figure 8.23 The Anisotropic UDS Diffusivity Dialog Box

In the **Anisotropic UDS Diffusivity** dialog box, enter the **Matrix Components** and then select the **Diffusivity** to be a **constant**, polynomial function of temperature (**polynomial**, **piecewise-linear**, **piecewise-polynomial**), or **user-defined**. See [Inputs for Polynomial Functions \(p. 417\)](#), [Inputs for Piecewise-Linear Functions \(p. 418\)](#), and [Inputs for Piecewise-Polynomial Functions \(p. 420\)](#) for details on polynomial temperature functions.

When you select the **user-defined** option, the [User-Defined Functions Dialog Box \(p. 1899\)](#) will open allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

8.6.2.2. Orthotropic Diffusivity

For orthotropic diffusivity, you can specify Γ in [Equation 8–48 \(p. 446\)](#) through ‘principal’ direction vectors and diffusion coefficients along these directions. ANSYS FLUENT, in turn, computes Γ from parameters that you supply. The principal directions are the same everywhere, but each of the directional diffusion coefficients can be specified as a constant, polynomial function of temperature, or through user-defined functions.

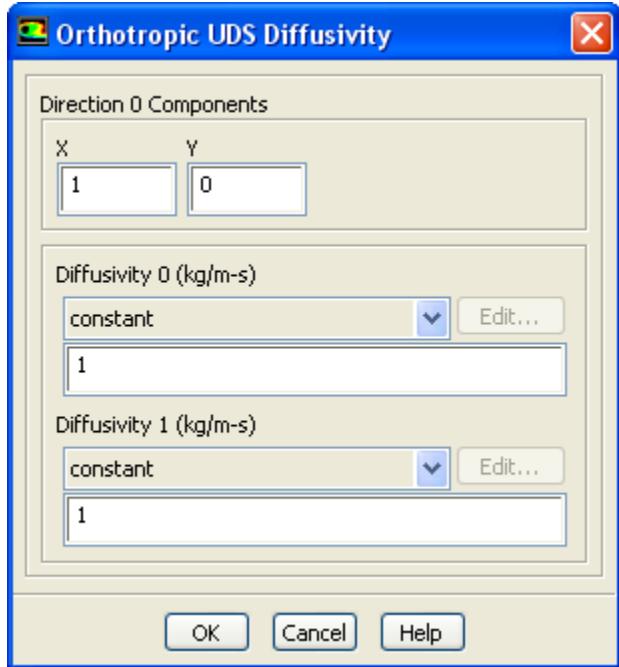

When orthotropic diffusivity is used, the diffusion coefficients (k_ξ, k_η, k_ζ) in the principal directions $(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta)$ are specified. The diffusivity matrix is then computed as

$$k_{ij} = k_\xi e_{\xi i} e_{\xi j} + k_\eta e_{\eta i} e_{\eta j} + k_\zeta e_{\zeta i} e_{\zeta j} \quad (8-51)$$

Important

For two-dimensional problems, only the functions (k_ξ, k_η) and the unit vector (\hat{e}_ξ) need to be specified.

To specify orthotropic diffusion coefficients, first select a scalar equation (e.g., **uds-0**) from the **User-Defined Scalar Diffusion** list in the [UDS Diffusion Coefficients Dialog Box \(p. 1921\)](#) ([Figure 8.22 \(p. 447\)](#)). Then choose **orthotropic** in the drop-down list under **Coefficient**. This will open the **Orthotropic UDS Diffusivity** dialog box ([Figure 8.24 \(p. 450\)](#)).

Figure 8.24 The Orthotropic UDS Diffusivity Dialog Box

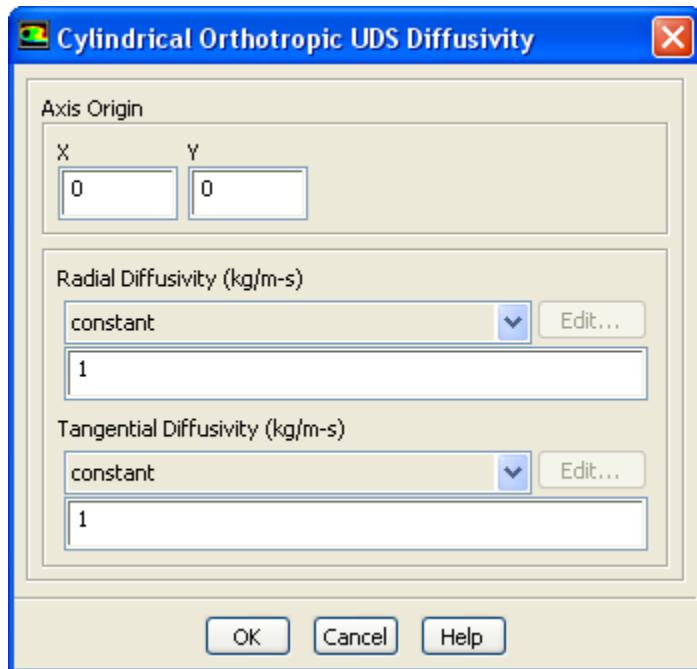

Since the directions $(\hat{e}_\xi, \hat{e}_\eta, \hat{e}_\zeta)$ are mutually orthogonal, only the first two need to be specified for three-dimensional problems. \hat{e}_ξ is defined using **X,Y,Z** under **Direction 0 Components**, and \hat{e}_η is defined using **X,Y,Z** under **Direction 1 Components**. You can define **Diffusivity 0** (k_ξ), **Diffusivity 1** (k_η), and **Diffusivity 2** (k_ζ) as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial** functions of temperature, or **user-defined**. See *Inputs for Polynomial Functions* (p. 417), *Inputs for Piecewise-Linear Functions* (p. 418), and *Inputs for Piecewise-Polynomial Functions* (p. 420) for details on polynomial temperature functions.

When you select the **user-defined** option, the *User-Defined Functions Dialog Box* (p. 1899) will open allowing you to hook a `DEFINE_DIFFUSIVITY` UDF only if you have previously loaded a compiled UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the *UDF Manual*.

8.6.2.3. Cylindrical Orthotropic Diffusivity

Orthotropic UDS diffusivity can also be specified on a per-scalar basis in cylindrical coordinates. This method is similar to orthotropic UDS diffusivity, except that the principal directions are specified as radial, tangential, and axial.

To specify cylindrical orthotropic diffusion coefficients, first select a scalar equation (e.g., **uds-0**) from the **User-Defined Scalar Diffusion** list in the *UDS Diffusion Coefficients Dialog Box* (p. 1921) (Figure 8.22 (p. 447)). Then choose **cyl-orthotropic** in the drop-down list under **Coefficient**. This will open the **Cylindrical Orthotropic UDS Diffusivity** dialog box (Figure 8.25 (p. 451)).

Figure 8.25 The Cylindrical Orthotropic UDS Diffusivity Dialog Box

In three-dimensional cases, the origin and the direction of the cylindrical coordinate system must be specified along with the radial, tangential, and axial direction conductivities. In two-dimensional cases, the origin of the cylindrical coordinate system must be specified along with the radial and tangential direction conductivities. Note that in two-dimensional cases, the direction is always along the $+z$ axis. ANSYS FLUENT will automatically compute the anisotropic diffusivity matrix at each cell from this input. The calculation is based on the location of the cell in the cylindrical coordinate system specified.

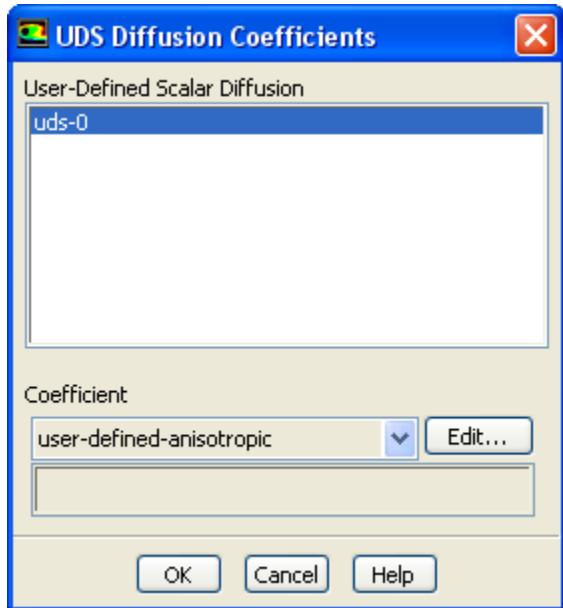

You can define the **Radial Diffusivity**, **Tangential Diffusivity**, and **Axial Diffusivity** as **constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or as **user-defined** functions of temperature, using the drop-down list below each of the diffusivities. See [Inputs for Polynomial Functions \(p. 417\)](#), [Inputs for Piecewise-Linear Functions \(p. 418\)](#), and [Inputs for Piecewise-Polynomial Functions \(p. 420\)](#) for details on polynomial temperature functions.

When you select the **user-defined** option, the [User-Defined Functions Dialog Box \(p. 1899\)](#) will open allowing you to hook a `DEFINE_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. If no functions have been loaded, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

8.6.3. User-Defined Anisotropic Diffusivity

You can specify Γ in [Equation 8-48 \(p. 446\)](#) on a per-scalar basis, directly, through user-defined functions (UDFs).

To specify a UDF for anisotropic diffusivity on a per-scalar basis, first select a scalar equation (e.g., **uds-0**) from the **User-Defined Scalar Diffusion** list in the [UDS Diffusion Coefficients Dialog Box \(p. 1921\)](#) ([Figure 8.26 \(p. 452\)](#)).

Figure 8.26 The UDS Diffusion Coefficients Dialog Box

Then choose **user-defined-anisotropic** in the drop-down list under **Coefficient**. The *User-Defined Functions Dialog Box* (p. 1899) will open allowing you to hook a `DEFINE_ANISOTROPIC_DIFFUSIVITY` UDF *only* if you have previously loaded a compiled UDF library or interpreted a UDF. Otherwise, you will get an error message. More information about user-defined functions can be found in the [UDF Manual](#).

8.7. Specific Heat Capacity

The specific heat capacity must be defined when the energy equation is active. ANSYS FLUENT provides several options for definition of the heat capacity:

- constant heat capacity
- temperature- and/or composition-dependent heat capacity
- kinetic theory

Each of these input options and the governing physical models are detailed in this section. In all cases, you will define the **Cp** in the *Create/Edit Materials Dialog Box* (p. 1882).

Materials

Specific heat capacity is input in units of J/kg-K in SI units or BTU/lbm-°R in British units.

Important

For combustion applications, a temperature-dependent specific heat is recommended.

For additional information, please see the following sections:

- [8.7.1. Input of Constant Specific Heat Capacity](#)
- [8.7.2. Specific Heat Capacity as a Function of Temperature](#)
- [8.7.3. Defining Specific Heat Capacity Using Kinetic Theory](#)

8.7.4. Specific Heat Capacity as a Function of Composition

8.7.1. Input of Constant Specific Heat Capacity

If you want to define the heat capacity as a constant, check that **constant** is selected in the drop-down list to the right of **Cp** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#), and enter the value of heat capacity.

The specific heat for the default fluid (air) is 1006.43 J/kg-K.

8.7.2. Specific Heat Capacity as a Function of Temperature

You can also choose to define the specific heat capacity as a function of temperature. Three types of functions are available:

- piecewise-linear:

$$c_p(T) = c_{p_n} + \frac{c_{p_{n+1}} - c_{p_n}}{T_{n+1} - T_n} (T - T_n) \quad (8-52)$$

- piecewise-polynomial:

$$\text{for } T_{min,1} \leq T < T_{max,1}: c_p(T) = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-53)$$

$$\text{for } T_{min,2} \leq T < T_{max,2}: c_p(T) = B_1 + B_2 T + B_3 T^2 + \dots$$

- polynomial:

$$c_p(T) = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-54)$$

You can input the data pairs (T_n, c_{p_n}) , ranges and coefficients A_i and B_i , or coefficients A_i that describe these functions using the [Create/Edit Materials Dialog Box \(p. 1882\)](#), as described in [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#).

8.7.3. Defining Specific Heat Capacity Using Kinetic Theory

If you are using the gas law (as described in [Density \(p. 421\)](#)), you have the option to define the specific heat capacity using kinetic theory as

$$c_{p,i} = \frac{1}{2} \frac{R}{M_{w,i}} (f_i + 2) \quad (8-55)$$

where f_i is the number of modes of energy storage (degrees of freedom) for the gas species i which you can input by selecting **kinetic-theory** from the drop-down list to the right of **Cp** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#). The solver will use your kinetic theory inputs in [Equation 8-55 \(p. 453\)](#) to

compute the specific heat capacity. See *Kinetic Theory Parameters* (p. 467) for details about kinetic theory inputs.

8.7.4. Specific Heat Capacity as a Function of Composition

If you are modeling a flow that includes more than one chemical species (multicomponent flow), you have the option to define a composition-dependent specific heat capacity. You can also define the heat capacity of the mixture as a constant value or a function of temperature, or using kinetic theory.

To define a composition-dependent specific heat capacity for a mixture, follow these steps:

1. For the mixture material, choose **mixing-law** in the drop-down list to the right of **Cp**.
2. Click **Change/Create**.
3. Define the specific heat capacity for each of the fluid materials that comprise the mixture. You may define constant or (if applicable) temperature-dependent heat capacities for the individual species. You may also use kinetic theory for the individual heat capacities, if applicable.

The solver will compute the mixture's specific heat capacity as a mass fraction average of the pure species heat capacities:

$$c_p = \sum_i Y_i c_{p,i} \quad (8-56)$$

8.8. Radiation Properties

When you have activated one of the radiation models (except for the surface-to-surface model, which requires no additional properties), there will be additional properties for you to set in the *Create/Edit Materials Dialog Box* (p. 1882):

- For the P-1 model, you will need to set the radiation **Absorption Coefficient** and **Scattering Coefficient** (α and σ_s in [Equation 5-18](#) in the [Theory Guide](#)).
- For the Rosseland radiation model, you will also need to set the **Absorption Coefficient** and **Scattering Coefficient** (α and σ_s in [Equation 5-19](#) in the [Theory Guide](#)).
- For the DTRM, only the **Absorption Coefficient** is required (α in [Equation 5-52](#) in the [Theory Guide](#)).
- For the DO model set both, the **Absorption Coefficient** and the **Scattering Coefficient** (α and σ_s in [Equation 5-59](#) in the [Theory Guide](#)). In addition, if you are modeling semi-transparent media, specify the **Refractive Index** (n_a or n_b in [Equation 5-78](#) in the [Theory Guide](#)). With the DO model, you can specify radiation properties for solid materials, to be used when semi-transparent media are modeled.

For additional information, please see the following sections:

- [8.8.1. Absorption Coefficient](#)
- [8.8.2. Scattering Coefficient](#)
- [8.8.3. Refractive Index](#)
- [8.8.4. Reporting the Radiation Properties](#)

8.8.1. Absorption Coefficient

To define the absorption coefficient, you can specify a constant value, a temperature-dependent function (see *Defining Properties Using Temperature-Dependent Functions* (p. 417)), a composition-dependent function, or a user-defined function. The absorbing and emitting parts of the radiative transfer equation

(RTE), [Equation 5–17](#) in the [Theory Guide](#), is a function of the absorption coefficient. The absorbing or emitting effects depend on the chosen radiation model. If there are only absorption effects, then Lambert's Law of absorption applies

$$I = I_o \exp(-ax) \quad (8-57)$$

where I is the radiation intensity, a is the absorption coefficient, and x is the distance through the material.

If you are modeling non-gray radiation with the P-1 or the DO radiation model, you also have the option to specify a constant absorption coefficient in each of the gray bands. The absorption coefficient is requested in units of 1/length. Along with the scattering coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. Absorption coefficients can be computed using tables of emissivity for CO₂ and H₂O, which are generally available in textbooks on radiation heat transfer.

8.8.1.1. Inputs for a Constant Absorption Coefficient

To define a constant absorption coefficient, simply enter the value in the field next to **Absorption Coefficient** in the [Create/Edit Materials Dialog Box](#) (p. 1882). Select **constant** in the drop-down list first if it is not already selected.

8.8.1.2. Inputs for a Composition-Dependent Absorption Coefficient

ANSYS FLUENT also allows you to input a composition-dependent absorption coefficient, where the local value of a is a function of the local mass fractions of water vapor and carbon dioxide. This modeling option can be useful for the simulation of radiation in combustion applications. The variable-absorption-coefficient model used by ANSYS FLUENT is the weighted-sum-of-gray-gases model (WSGGM) described in [Radiation in Combusting Flows](#) in the [Theory Guide](#). To activate it, first enable the species calculation and make sure that CO₂ and H₂O are present in the mixture. Next, select **wsggm-domain-based**, **wsggm-user-specified** or **user-defined-wsggm** in the drop-down list to the right of **Absorption Coefficient** in the [Create/Edit Materials](#) dialog box. If you select **user-defined-wsggm**, the **User-Defined Functions** dialog box will open, allowing you to select a previously loaded compiled UDF library or a previously interpreted UDF (see [Hooking DEFINE_WSGGM_ABS_COEFF UDFs](#) in the [UDF Manual](#)). The WSGGM options differ in the method used to compute the path length, as described in the section that follows.

8.8.1.2.1. Path Length Inputs

When the WSGGM is used to compute the absorption coefficient, you will have a choice of methods used to calculate the path length s in [Equation 5–101](#) in the [Theory Guide](#). See [Radiation in Combusting Flows](#) in the [Theory Guide](#) to determine which method is appropriate for your case.

You will select the path length method when you choose the property input method for **Absorption Coefficient** as described previously.

- If you choose **wsggm-domain-based**, the mean-beam-length approach will be used for the calculation of a and ANSYS FLUENT will compute the mean beam length based on an average dimension of the domain; no further inputs are required.
- If you choose **wsggm-user-specified**, the mean-beam-length approach will be used, but you will set the mean beam length yourself in the **Path Length** field in the [Create/Edit Materials Dialog Box](#) (p. 1882).

This dialog box will open when you choose **wsggm-user-specified**, and since it is a modal dialog box, you must tend to it immediately.

- If you choose **user-defined-wsggm**, ANSYS FLUENT will initially compute the absorption coefficient in the same manner as described for the **wsggm-domain-based** option; however, you have the option of writing a user-defined function that customizes this calculated value. If the soot model is enabled, you can also use the UDF to customize the soot absorption coefficient computed by ANSYS FLUENT. See [DEFINE_WSGGM_ABS_COEFF](#) in the [UDF Manual](#) for further details.

8.8.1.2.1.1. Inputs for a Non-Gray Radiation Absorption Coefficient

If you are using the non-gray DO model (see [The DO Model Equations](#) of the [Theory Guide](#) and [Defining Non-Gray Radiation for the DO Model](#) (p. 769)) or the non-gray P-1 model (see [The P-1 Model Equations](#) of the [Theory Guide](#) and [Setting Up the P-1 Model with Non-Gray Radiation](#) (p. 753)), you can specify a different constant absorption coefficient for each of the bands used by the gray-band model. Select **gray-band** from the **Absorption Coefficient** drop-down list in the **Create/Edit Materials** dialog box and then define the absorption coefficient for each band in the [Gray-Band Absorption Coefficient Dialog Box](#) (p. 1922). (Note that because this is a modal dialog box, you must tend to it immediately.)

8.8.1.2.1.2. Effect of Particles and Soot on the Absorption Coefficient

ANSYS FLUENT will include the effect of particles on the absorption coefficient if you have turned on the **Particle Radiation Interaction** option in the [Discrete Phase Model Dialog Box](#) (p. 1859) (only for the P-1 and DO radiation models).

If you are modeling soot formation and you want to include the effect of soot formation on the absorption coefficient, turn on the **Soot-Radiation Interaction** in the [Soot Model Dialog Box](#) (p. 1850). The soot effects can be included for any of the radiation models, as long as you are using the WSGGM to compute a composition-dependent absorption coefficient. Note that you can use the **user-defined-wsggm** option to customize the soot absorption coefficient calculated by ANSYS FLUENT, as described previously.

8.8.2. Scattering Coefficient

The scattering coefficient is, by default, set to zero, and it is assumed to be isotropic. You can specify a constant value, a temperature-dependent function (see [Defining Properties Using Temperature-Dependent Functions](#) (p. 417)), or a user-defined function. You can also specify a non-isotropic phase function.

The scattering coefficient is requested in units of 1/length. Along with the absorption coefficient, it describes the change in radiation intensity per unit length along the path through the fluid medium. You may wish to increase the scattering coefficient in combustion systems, where particulates may be present.

8.8.2.1. Inputs for a Constant Scattering Coefficient

To define a constant scattering coefficient, simply enter the value in the field next to **Scattering Coefficient** in the [Create/Edit Materials Dialog Box](#) (p. 1882). (Select **constant** in the drop-down list first if it is not already selected.)

8.8.2.2. Inputs for the Scattering Phase Function

Scattering is assumed to be isotropic, by default, but you can also specify a linear-anisotropic scattering function. If you are using the DO model, Delta-Eddington and user-defined scattering functions are also available.

8.8.2.2.1. Isotropic Phase Function

To model isotropic scattering, select **isotropic** in the **Scattering Phase Function** drop-down list. No further inputs are necessary. This is the default setting in ANSYS FLUENT.

8.8.2.2.2. Linear-Anisotropic Phase Function

To model anisotropic scattering, select **linear-anisotropic** in the **Scattering Phase Function** drop-down list and set the value of the phase function coefficient (C in [Equation 5–19](#) in the [Theory Guide](#)).

8.8.2.2.3. Delta-Eddington Phase Function

To use a Delta-Eddington phase function, select **delta-eddington** in the **Scattering Phase Function** drop-down list. This will open the [Delta-Eddington Scattering Function Dialog Box \(p. 1923\)](#), in which you can specify the **Forward Scattering Factor** and **Asymmetry Factor** (f and C in [Equation 5–68](#) in the [Theory Guide](#)). Since this is a modal dialog box, you must tend to it immediately.

8.8.2.2.4. User-Defined Phase Function

To use a user-defined phase function, select **user-defined** in the **Scattering Phase Function** drop-down list. The user-defined function will contain specifications for Φ^* and f in [Equation 5–69](#) in the [Theory Guide](#). More information about user-defined functions can be found in the [UDF Manual](#).

8.8.3. Refractive Index

The refractive index is the ratio of speed of light in the medium to the speed of light in vacuum. It is by default set to 1. You can specify a constant value in the field next to **Refractive Index**.

If you are using the non-gray DO model (see [The DO Model Equations](#) of the [Theory Guide](#) and [Defining Non-Gray Radiation for the DO Model \(p. 769\)](#)) or the non-gray P-1 model (see [The P-1 Model Equations](#) of the [Theory Guide](#) and [Setting Up the P-1 Model with Non-Gray Radiation \(p. 753\)](#)), you can specify a different constant refractive index for each of the bands used by the gray-band model. Select **refractive-band** from the **Refractive Index** drop-down list in the **Create/Edit Materials** dialog box and then define the refractive index for each band in the [Gray-Band Refractive Index Dialog Box \(p. 1923\)](#). Note that because this is a modal dialog box, you must tend to it immediately.

8.8.4. Reporting the Radiation Properties

You can display the computed local values for α and σ_s using the **Absorption Coefficient** and **Scattering Coefficient** items in the **Radiation...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. You will also find the **Refractive Index** in the **Radiation...** category.

8.9. Mass Diffusion Coefficients

For species transport calculations, there are two ways to model the diffusion of chemical species. For most applications the Fick's law approximation is adequate, but for some applications (e.g., diffusion-dominated laminar flows such as chemical vapor deposition), the full multicomponent diffusion model is recommended.

Important

The full multicomponent diffusion model is enabled in the *Species Model Dialog Box* (p. 1814) and is computationally expensive.

For additional information, please see the following sections:

[8.9.1. Fickian Diffusion](#)

[8.9.2. Full Multicomponent Diffusion](#)

[8.9.3. Thermal Diffusion Coefficients](#)

[8.9.4. Mass Diffusion Coefficient Inputs](#)

[8.9.5. Mass Diffusion Coefficient Inputs for Turbulent Flow](#)

8.9.1. Fickian Diffusion

Mass diffusion coefficients are required whenever you are solving species transport equations in multi-component flows. Mass diffusion coefficients are used to compute the diffusion flux of a chemical species in a laminar flow using (by default) Fick's law:

$$J_i = -\rho D_{i,m} \nabla Y_i - D_{T,i} \frac{\nabla T}{T} \quad (8-58)$$

where $D_{i,m}$ is the mass diffusion coefficient for species i in the mixture and $D_{T,i}$ is the thermal (Soret) diffusion coefficient.

Equation 8–58 (p. 458) is strictly valid when the mixture composition is not changing, or when $D_{i,m}$ is independent of composition. This is an acceptable approximation in dilute mixtures when $Y_i \ll 1$, for all i except the carrier gas. ANSYS FLUENT can also compute the transport of non-dilute mixtures in laminar flows by treating such mixtures as multicomponent systems. Within ANSYS FLUENT, $D_{i,m}$ can be specified in a variety of ways, including by specifying \mathcal{D}_{ij} , the binary mass diffusion coefficient of component i in component j . \mathcal{D}_{ij} is not used directly, however; instead, the diffusion coefficient in the mixture, $D_{i,m}$, is computed as

$$D_{i,m} = \frac{1 - X_i}{\sum_{j,j \neq i} (X_j / \mathcal{D}_{ij})} \quad (8-59)$$

where X_i is the mole fraction of species i . You can input $D_{i,m}$ or \mathcal{D}_{ij} for each chemical species, as described in *Mass Diffusion Coefficient Inputs* (p. 461).

In turbulent flows, *Equation 8–58* (p. 458) is replaced with the following form:

$$J_i = - \left(\rho D_{i,m} + \frac{\mu_t}{Sc_t} \right) \nabla Y_i - D_{T,i} \frac{\nabla T}{T} \quad (8-60)$$

where Sc_t is the effective Schmidt number for the turbulent flow:

$$Sc_t = \frac{\mu_t}{\rho D_t} \quad (8-61)$$

and D_t is the effective mass diffusion coefficient due to turbulence.

In turbulent flows your mass diffusion coefficient inputs consist of defining the molecular contribution to diffusion $D_{i,m}$ using the same methods available for the laminar case, with the added option to alter the default settings for the turbulent Schmidt number. As seen from [Equation 8-61 \(p. 459\)](#), this parameter relates the effective mass diffusion coefficient due to turbulence with the eddy viscosity μ_t . As discussed in [Mass Diffusion Coefficient Inputs for Turbulent Flow \(p. 466\)](#), the turbulent diffusion coefficient normally overwhelms the laminar diffusion coefficient, so the default constant value for the laminar diffusion coefficient is usually acceptable.

8.9.2. Full Multicomponent Diffusion

A careful treatment of chemical species diffusion in the species transport and energy equations is important when details of the molecular transport processes are significant (e.g., in diffusion-dominated laminar flows). As one of the laminar-flow diffusion models, ANSYS FLUENT has the ability to model full multicomponent species transport.

8.9.2.1. General Theory

For multicomponent systems it is not possible, in general, to derive relations for the diffusion fluxes containing the gradient of only one component (as described in [Fickian Diffusion \(p. 458\)](#)). Here, the Maxwell-Stefan equations will be used to obtain the diffusive mass flux. This will lead to the definition of generalized Fick's law diffusion coefficients [93] (p. 2372). This method is preferred over computing the multicomponent diffusion coefficients since their evaluation requires the computation of N^2 co-factor determinants of size $(N - 1) \times (N - 1)$, and one determinant of size $N \times N$ [87] (p. 2371), where N is the number of chemical species.

8.9.2.2. Maxwell-Stefan Equations

From Merk [55] (p. 2370), the Maxwell-Stefan equations can be written as

$$\sum_{\substack{j=1 \\ j \neq i}}^N \frac{X_i X_j}{\mathcal{D}_{ij}} (\vec{V}_j - \vec{V}_i) = \vec{d}_i - \frac{\nabla T}{T} \sum_{\substack{j=1 \\ j \neq i}}^N \frac{X_i X_j}{\mathcal{D}_{ij}} \left(\frac{D_{T,j}}{\rho_j} - \frac{D_{T,i}}{\rho_i} \right) \quad (8-62)$$

where,

X = the mole fraction

\vec{V} = the diffusion velocity

\mathcal{D}_{ij} = the binary mass diffusion coefficient of specie i in specie j

D_T = the thermal diffusion coefficient.

For an ideal gas the Maxwell diffusion coefficients are equal to the binary diffusion coefficients. If the external force is assumed to be the same on all species and that pressure diffusion is negligible, then $\vec{d}_i = \nabla X_i$. Since the diffusive mass flux vector is $\vec{J}_i = \rho_i \vec{V}_i$, the above equation can be written as

$$\sum_{\substack{j=1 \\ j \neq i}}^N \frac{X_i X_j}{\mathcal{D}_{ij}} \left(\frac{\vec{J}_j}{\rho_j} - \frac{\vec{J}_i}{\rho_i} \right) = \nabla X_i - \frac{\nabla T}{T} \sum_{\substack{j=1 \\ j \neq i}}^N \frac{X_i X_j}{\mathcal{D}_{ij}} \left(\frac{D_{T,j}}{\rho_j} - \frac{D_{T,i}}{\rho_i} \right) \quad (8-63)$$

After some mathematical manipulations, the diffusive mass flux vector, \vec{J}_i , can be obtained from

$$\vec{J}_i = - \sum_{j=1}^{N-1} \rho D_{ij} \nabla Y_j - D_{T,i} \frac{\nabla T}{T} \quad (8-64)$$

where Y_j is the mass fraction of species j . Other terms are defined as follows:

$$\begin{aligned} D_{ij} &= [D] = [A]^{-1} [B] \\ M_{w,m} &= \left(\sum_{i=1}^N \frac{Y_i}{M_{w,i}} \right) \\ A_{ii} &= - \left(\frac{X_i}{\mathcal{D}_{iN}} \frac{M_{w,m}}{M_{w,N}} + \sum_{\substack{j=1 \\ j \neq i}}^N \frac{X_j}{\mathcal{D}_{ij}} \frac{M_{w,m}}{M_{w,i}} \right) \\ A_{ij} &= X_i \left(\frac{1}{\mathcal{D}_{ij}} \frac{M_{w,m}}{M_{w,j}} - \frac{1}{\mathcal{D}_{iN}} \frac{M_{w,m}}{M_{w,N}} \right) \\ B_{ii} &= - \left(X_i \frac{M_{w,m}}{M_{w,N}} + (1-X_i) \frac{M_{w,m}}{M_{w,i}} \right) \\ B_{ij} &= X_i \left(\frac{M_{w,m}}{M_{w,j}} - \frac{M_{w,m}}{M_{w,N}} \right) \end{aligned} \quad (8-65)$$

where,

$[A]$ and $[B] = (N-1) \times (N-1)$ matrices

$[D]$ = an $(N-1) \times (N-1)$ matrix of the generalized Fick's law diffusion coefficients D_{ij} [93]

M_w = the molecular weight

m = a subscript for the mixture

8.9.3. Thermal Diffusion Coefficients

The thermal diffusion coefficients can be defined as constants, polynomial functions, user-defined functions, or using the following empirically-based composition-dependent expression derived from [42] (p. 2369):

$$D_{T,i} = -2.59 \times 10^{-7} T^{0.659} \left[\frac{M_{w,i}^{0.511} X_i}{\sum_{i=1}^N M_{w,i}^{0.511} X_i} - Y_i \right] \cdot \left[\frac{\sum_{i=1}^N M_{w,i}^{0.511} X_i}{\sum_{i=1}^N M_{w,i}^{0.489} X_i} \right] \quad (8-66)$$

This form of the Soret diffusion coefficient will cause heavy molecules to diffuse less rapidly, and light molecules to diffuse more rapidly, towards heated surfaces.

8.9.4. Mass Diffusion Coefficient Inputs

By default, the solver computes the species diffusion using [Equation 8–58 \(p. 458\)](#) (for laminar flows) with your inputs for $D_{i,m}$, the diffusion coefficient for species i in the mixture. For turbulent flows, species diffusion is computed with [Equation 8–60 \(p. 458\)](#).

You can input the mass diffusion coefficients using one of the following methods:

- Constant dilute approximation (Fickian diffusion only): define one constant for all $D_{i,m}$.
- Dilute approximation (Fickian diffusion only): define each $D_{i,m}$ as a constant or as a polynomial function of temperature (if heat transfer is enabled).
- Multicomponent method: define the binary diffusion of species i in each species j , \mathcal{D}_{ij} as a constant or a polynomial function of temperature, or (for ideal gases only) using kinetic theory.
- User-defined function (UDF): define a single function that will apply to all mass diffusion coefficients. This is done using the `DEFINE_DIFFUSIVITY` macro and is explained in the [UDF Manual](#).

You should choose to input $D_{i,m}$ (using one of the first two methods) if you are modeling a dilute mixture, with chemical species present at low mass fraction in a “carrier” fluid that is present at high concentration. You may wish to define the individual binary mass diffusion coefficients, \mathcal{D}_{ij} , if you are modeling a non-dilute mixture. If you choose to define \mathcal{D}_{ij} , the solver will compute the diffusion of species i in the mixture using [Equation 8–59 \(p. 458\)](#), unless you have enabled full multicomponent diffusion.

Important

If you want to use the full multicomponent diffusion model described in [Full Multicomponent Diffusion \(p. 459\)](#), turn on the **Full Multicomponent Diffusion** option in the [Species Model Dialog Box \(p. 1814\)](#), and then select the multicomponent diffusion model.

You will define $D_{i,m}$ or \mathcal{D}_{ij} for each chemical species using the [Create/Edit Materials Dialog Box \(p. 1882\)](#).

Materials

The diffusion coefficients have units of m^2/s in SI units or ft^2/s in British units.

8.9.4.1. Constant Dilute Approximation Inputs

To use the constant dilute approximation method, follow these steps:

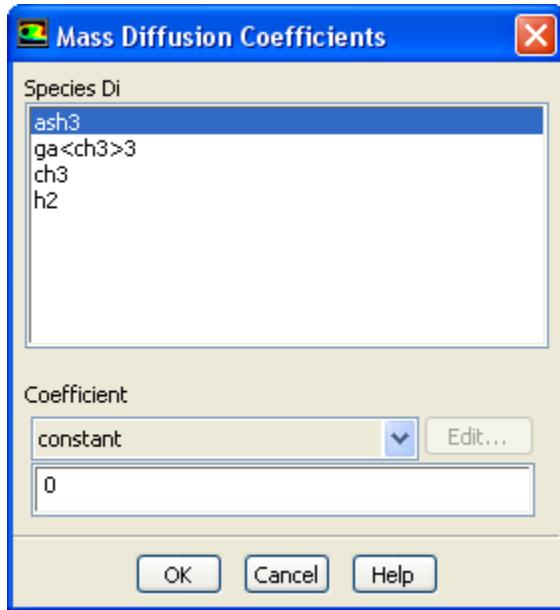

1. Select **constant-dilute-appx** in the drop-down list to the right of **Mass Diffusivity**.
2. Enter a single value of $D_{i,m}$. The same value will be used for the diffusion coefficient of each species in the mixture.

8.9.4.2. Dilute Approximation Inputs

To use the dilute approximation method, follow the steps below:

1. Select **dilute-approx** in the drop-down list to the right of **Mass Diffusivity**.
2. In the resulting *Mass Diffusion Coefficients Dialog Box* (p. 1919) (*Figure 8.27* (p. 462)), select the species in the **Species Di** list for which you are going to define the mass diffusion coefficient.

Figure 8.27 The Mass Diffusion Coefficients Dialog Box for Dilute Approximation

3. You can define $D_{i,m}$ for the selected species either as a constant value or (if heat transfer is active) as a polynomial function of temperature:
 - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
 - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in *Inputs for Polynomial Functions* (p. 417).

$$D_{i,m} = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-67)$$

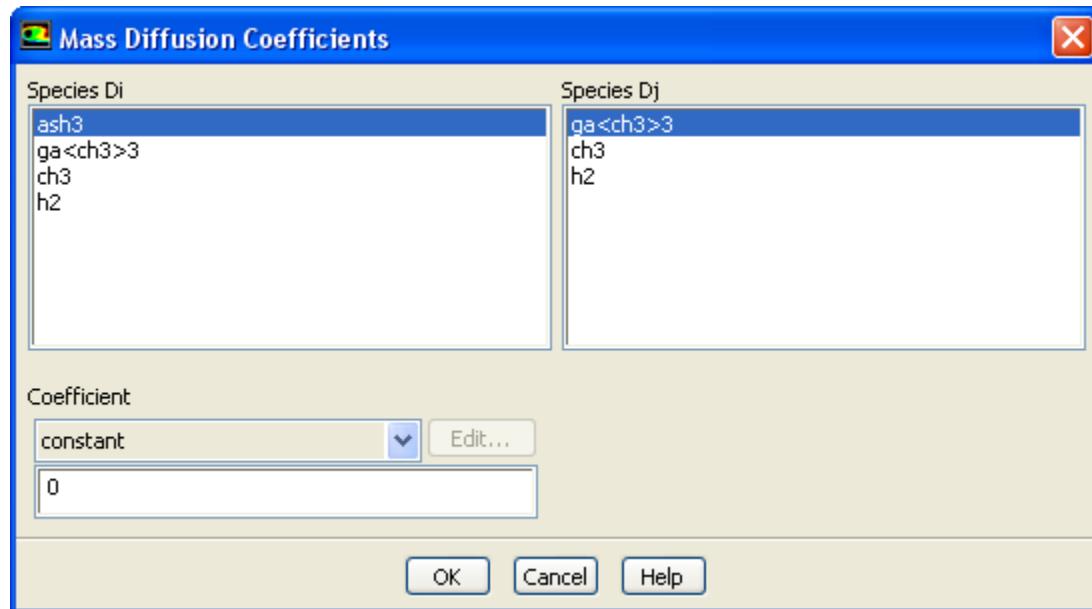

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all species in the **Species Di** list in the *Mass Diffusion Coefficients Dialog Box* (p. 1919).

8.9.4.3. Multicomponent Method Inputs

To use the multicomponent method, and define constant or temperature-dependent diffusion coefficients, follow the steps below:

1. Select **multicomponent** in the drop-down list to the right of **Mass Diffusivity**.
2. In the resulting *Mass Diffusion Coefficients Dialog Box* (p. 1919) (*Figure 8.28* (p. 463)), select the species in the **Species Di** list and the **Species Dj** list for which you are going to define the mass diffusion coefficient D_{ij} for species i in species j .

Figure 8.28 The Mass Diffusion Coefficients Dialog Box for the Multicomponent Method

3. You can define D_{ij} for the selected pair of species as a constant value or as a polynomial function of temperature (if heat transfer is active).
 - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
 - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in *Inputs for Polynomial Functions* (p. 417).

$$\mathcal{D}_{ij} = A_1 + A_2 T + A_3 T^2 + \dots \quad (8-68)$$

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all pairs of species in the **Species Di** and **Species Dj** lists in the *Mass Diffusion Coefficients Dialog Box* (p. 1919).

To use the multicomponent method, and define the diffusion coefficient using kinetic theory (available only when the ideal gas law is used), follow these steps:

1. Choose **kinetic-theory** in the drop-down list to the right of **Mass Diffusivity**.
2. Click **Change/Create** after completing other property definitions for the mixture material.
3. Define the Lennard-Jones parameters, σ_i and $(\varepsilon/k_B)_{ij}$, for each species (fluid material), as described in *Kinetic Theory Parameters* (p. 467).

The solver will use a modification of the Chapman-Enskog formula [52] (p. 2369) to compute the diffusion coefficient using kinetic theory:

$$\mathcal{D}_{ij} = 0.00188 \frac{\left[T^3 \left(\frac{1}{M_{w,i}} + \frac{1}{M_{w,j}} \right) \right]^{1/2}}{p_{abs} \sigma_{ij}^2 Q_D} \quad (8-69)$$

where,

p_{abs} is the absolute pressure

Q_D is the diffusion collision integral, which is a measure of the interaction of the molecules in the system

Q_D is a function of the quantity T_D^* , where

$$T_D^* = \frac{T}{(\varepsilon/k_B)_{ij}} \quad (8-70)$$

k_B is the Boltzmann constant, which is defined as the gas constant, R , divided by Avogadro's number.

$(\varepsilon/k_B)_{ij}$ for the mixture is the *geometric average*:

$$(\varepsilon/k_B)_{ij} = \sqrt{(\varepsilon/k_B)_i (\varepsilon/k_B)_j} \quad (8-71)$$

For a binary mixture, σ_{ij} is calculated as the *arithmetic average* of the individual σ s:

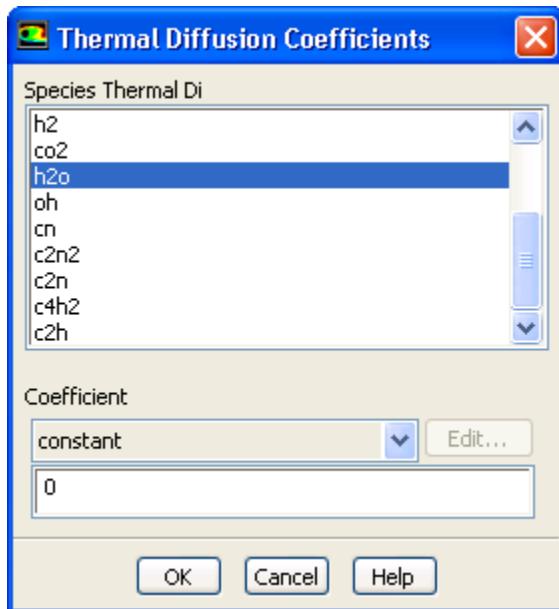

$$\sigma_{ij} = \frac{1}{2} (\sigma_i + \sigma_j) \quad (8-72)$$

8.9.4.4. Thermal Diffusion Coefficient Inputs

If you have enabled thermal diffusion (in the [Species Model Dialog Box \(p. 1814\)](#)), you can define the thermal diffusion coefficients in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) as follows:

1. Select one of the following three methods in the drop-down list to the right of **Thermal Diffusion Coefficient**:
 - Choose **kinetic-theory** to have ANSYS FLUENT compute the thermal diffusion coefficients using the empirically-based expression in [Equation 8-66 \(p. 461\)](#). No further inputs are required for this option.
 - Choose **specified** to input the coefficient for each species. The [Thermal Diffusion Coefficients Dialog Box \(p. 1920\)](#) (*Figure 8.29 (p. 465)*) will open. Further inputs are described in the step 2.
 - Choose **user-defined** to use a user-defined function. More information about user-defined functions can be found in the [UDF Manual](#).
2. If you choose **specified**, select the species in the **Species Thermal Di** list for which you are going to define the thermal diffusion coefficient.

Figure 8.29 The Thermal Diffusion Coefficients Dialog Box

3. Define $D_{T,i}$ for the selected species either as a constant value or as a polynomial function of temperature:
 - To define a constant diffusion coefficient, select **constant** (the default) in the drop-down list below **Coefficient**, and then enter the value in the field below the list.
 - To define a temperature-dependent diffusion coefficient, choose **polynomial** in the **Coefficient** drop-down list and then define the polynomial coefficients as described in [Defining Properties Using Temperature-Dependent Functions \(p. 417\)](#).

4. Repeat steps 2 and 3 until you have defined diffusion coefficients for all species in the **Species Thermal Di** list in the *Thermal Diffusion Coefficients Dialog Box* (p. 1920).

8.9.5. Mass Diffusion Coefficient Inputs for Turbulent Flow

When your flow is turbulent, you will define $D_{i,m}$ or \mathcal{D}_{ij} , as described for laminar flows in *Mass Diffusion Coefficient Inputs* (p. 461), and you will also have the option to alter the default setting for the turbulent Schmidt number, Sc_t , as defined in *Equation 8–61* (p. 459).

Usually, in a turbulent flow, the mass diffusion is dominated by the turbulent transport as determined by the turbulent Schmidt number (*Equation 8–61* (p. 459)). The turbulent Schmidt number measures the relative diffusion of momentum and mass due to turbulence and is on the order of unity in all turbulent flows. Because the turbulent Schmidt number is an empirical constant that is relatively insensitive to the molecular fluid properties, you will have little reason to alter the default value (0.7) for any species.

Should you wish to modify the Schmidt number, enter a new value for **Turb. Schmidt Number** in the *Viscous Model Dialog Box* (p. 1778).

Models → Viscous → Edit...

Important

Note that the full multicomponent diffusion model described in *Full Multicomponent Diffusion* (p. 459) is not recommended for turbulent flows.

8.10. Standard State Enthalpies

When you are solving a reacting flow using the finite-rate or eddy dissipation model, you will need to define the standard state enthalpy (also known as the formation enthalpy or heat of formation), h_j^0 for each species j . These inputs are used to define the mixture enthalpy as

$$H = \sum_j Y_j \left[M_j h_j^0 + \int_{T_{ref,j}}^T c_{p,j} dT \right] \quad (8-73)$$

where $T_{ref,j}$ is the reference temperature at which h_j^0 is defined. Standard state enthalpies are input in units of J/kg mol in SI units or in units of Btu/lb_mmol in British units.

For each species involved in the reaction (i.e., each fluid material contained in the mixture material), you can set the **Standard State Enthalpy** and **Reference Temperature** in the *Create/Edit Materials Dialog Box* (p. 1882).

8.11. Standard State Entropies

If you are using the finite-rate model with reversible reactions (see [The Laminar Finite-Rate Model](#) in the [Theory Guide](#)), you will need to define the standard state entropy, s_j^0 for each species j . These inputs are used to define the mixture entropy as

$$S = \sum_j Y_j \left[M_j s_j^0 + \int_{T_{ref,j}}^T \frac{c_{p,j}}{T} dT \right] \quad (8-74)$$

where $T_{ref,j}$ is the reference temperature at which s_j^0 is defined. Standard state entropies are input in units of J/kmol-K in SI units or in units of Btu/lb_mmol-°R in British units.

For each species involved in the reaction (i.e., each fluid material contained in the mixture material), you can set the **Standard State Entropy** and **Reference Temperature** in the [Create/Edit Materials Dialog Box](#) (p. 1882).

8.12. Molecular Heat Transfer Coefficient

If you are modeling premixed combustion (see [Modeling Premixed Combustion](#) (p. 957)), the fluid material in your domain should be assigned the properties of the unburned mixture, including the molecular heat transfer coefficient (α in [Equation 9-9](#) in the [Theory Guide](#)), which is also referred to as the thermal diffusivity. α is defined as $k/\rho c_p$, and values at standard conditions can be found in combustion handbooks (e.g., [42] (p. 2369)). To determine values at non-standard conditions, you will need to use a third-party 1D combustion program with detailed chemistry. You can set the **Molecular Heat Transfer Coefficient** in the [Create/Edit Materials Dialog Box](#) (p. 1882).

8.13. Kinetic Theory Parameters

You may choose to define the following properties using kinetic theory when the ideal gas law is enabled:

- viscosity (for fluids)
- thermal conductivity (for fluids)
- specific heat capacity (for fluids)
- mass diffusion coefficients (for multi-species mixtures)

If you are using kinetic theory for a fluid's viscosity ([Equation 8-21](#) (p. 430)), you will need to input the kinetic theory parameters σ and ε/k_B for that fluid. These parameters are referred to by ANSYS FLUENT as the "characteristic length" and the "energy parameter" respectively.

- When kinetic theory is applied to calculation of a fluid's thermal conductivity only, no inputs are required.
- To calculate specific heat of a fluid using kinetic theory ([Equation 8-55](#) (p. 453)), you need to enter the degrees of freedom for the fluid material.
- If you use kinetic theory to define a mixture material's mass diffusivity ([Equation 8-69](#) (p. 464)), you will need to input σ_i and $(\varepsilon/k_B)_i$ for each chemical species i .

For additional information, please see the following section:

[8.13.1. Inputs for Kinetic Theory](#)

8.13.1. Inputs for Kinetic Theory

The procedure for using kinetic theory is as follows:

1. Select **kinetic-theory** as the property specification method for the **Viscosity**, **Thermal Conductivity**, or heat capacity **C_p** of a fluid material, or for the **Mass Diffusivity** of a mixture material.
2. If the material for which you have selected the kinetic theory method for one or more properties is a fluid material, you must set the kinetic theory parameters for each of the constituent species (fluid materials).

The parameters to be set are as follows:

- **L-J Characteristic Length**
- **L-J Energy Parameter**
- **Degrees of Freedom** (only required if kinetic theory is used for specific heat)

See the beginning of this section to find out which parameters are required to calculate each property using kinetic theory.

Characteristic length is defined in units of Angstroms. The energy parameter is defined in units of absolute temperature. Degrees of freedom is a dimensionless input. All kinetic theory materials can be found in the literature (e.g., [34] (p. 2368)).

8.14. Operating Pressure

Specification of the operating pressure affects your calculation in different ways for different flow regimes. This section presents information about the operating pressure, its relevance for different cases, and how to set it correctly.

For additional information, please see the following sections:

- [8.14.1.The Effect of Numerical Roundoff on Pressure Calculation in Low-Mach-Number Flow](#)
- [8.14.2.Operating Pressure, Gauge Pressure, and Absolute Pressure](#)
- [8.14.3.Setting the Operating Pressure](#)

8.14.1.The Effect of Numerical Roundoff on Pressure Calculation in Low-Mach-Number Flow

In low-Mach-number compressible flow, the overall pressure drop is small compared to the absolute static pressure, and can be significantly affected by numerical roundoff. To understand why this is true, consider a compressible flow with $M \ll 1$. The pressure changes, Δp , are related to the dynamic head,

$\frac{1}{2}\gamma p M^2$, where p is the static pressure and γ is the ratio of specific heats. This gives the simple relationship $\Delta p/p \sim M^2$, so that $\Delta p/p \rightarrow 0$ as $M \rightarrow 0$. Therefore, unless adequate precaution is taken, low-Mach-number flow calculations are very susceptible to roundoff error.

8.14.2. Operating Pressure, Gauge Pressure, and Absolute Pressure

ANSYS FLUENT avoids the problem of roundoff error (discussed in [The Effect of Numerical Roundoff on Pressure Calculation in Low-Mach-Number Flow \(p. 468\)](#)) by subtracting the operating pressure (generally a large pressure roughly equal to the average absolute pressure in the flow) from the absolute pressure, and using the result (termed the gauge pressure). The relationship between the operating pressure, gauge pressure, and absolute pressure is shown below. The absolute pressure is simply the sum of the operating pressure and the gauge pressure:

$$p_{abs} = p_{op} + p_{gauge} \quad (8-75)$$

All pressures that you specify and all pressures computed or reported by ANSYS FLUENT are gauge pressures.

8.14.3. Setting the Operating Pressure

8.14.3.1. The Significance of Operating Pressure

Operating pressure is significant for incompressible ideal gas flows because it directly determines the density: the incompressible ideal gas law computes density as $\rho = \frac{p_{op}}{\frac{R}{M_w}T}$. You must therefore be sure to set the operating pressure appropriately.

Operating pressure is significant for low-Mach-number compressible flows because of its role in avoiding roundoff error problems, as described in [Operating Pressure, Gauge Pressure, and Absolute Pressure \(p. 469\)](#). Ensure to set the operating pressure appropriately. For time-dependent compressible flows, you may want to specify a floating operating pressure instead of a constant operating pressure. See [Floating Operating Pressure \(p. 529\)](#) for details.

Operating pressure is less significant for higher-Mach-number compressible flows. The pressure changes in such flows are much larger than those in low-Mach-number compressible flows, so there is no real problem with roundoff error and there is therefore no real need to use gauge pressure. In fact, it is common convention to use absolute pressures in such calculations. Since ANSYS FLUENT always uses gauge pressure, you can simply set the operating pressure to zero, making gauge and absolute pressures equivalent.

If the density is assumed constant or if it is derived from a profile function of temperature, the operating pressure is not used in the density calculation.

Note that the default operating pressure is 101325 Pa.

8.14.3.2. How to Set the Operating Pressure

The criteria for choosing a suitable operating pressure are based on the Mach-number regime of the flow and the relationship that is used to determine density. For example, if you use the ideal gas law in an incompressible flow calculation (e.g., for a natural convection problem), you should use a value representative of the mean flow pressure.

To place this discussion in perspective, *Table 8.1: Recommended Settings for Operating Pressure* (p. 470) shows the recommended approach for setting operating pressures. The default operating pressure is 101325 Pa.

Table 8.1 Recommended Settings for Operating Pressure

Density Relationship	Mach Number Regime	Operating Pressure
ideal gas law	$M > 0.1$	0 or \approx mean flow pressure
ideal gas law	$M < 0.1$	\approx mean flow pressure
profile function of temperature	incompressible	not used
constant	incompressible	not used
incompressible ideal gas law	incompressible	\approx mean flow pressure

You will set the **Operating Pressure** in the *Operating Conditions Dialog Box* (p. 1952).

❖ **Cell Zone Conditions → Operating Conditions...**

8.15. Reference Pressure Location

For incompressible flows that do not involve any pressure boundaries, ANSYS FLUENT adjusts the gauge pressure field after each iteration to keep it from floating. This is done using the pressure in the cell located at (or nearest to) the reference pressure location. The pressure value in this cell is subtracted from the entire gauge pressure field; as a result, the gauge pressure at the reference pressure location is always zero. If pressure boundaries are involved, the adjustment is not needed and the reference pressure location is ignored.

The reference pressure location is, by default, the cell center at or closest to (0,0,0). There may be cases in which you might want to move the reference pressure location, perhaps locating it at a point where the absolute static pressure is known (e.g., if you are planning to compare your results with experimental data). To change the location, enter new (X,Y,Z) coordinates for **Reference Pressure Location** in the *Operating Conditions Dialog Box* (p. 1952).

❖ **Cell Zone Conditions → Operating Conditions...**

For additional information, please see the following section:

8.15.1. Actual Reference Pressure Location

For cases that do not have pressure-related boundary conditions (e.g., pressure inlet, pressure outlet, pressure far-field, etc.), you need to specify the **Reference Pressure Location** at a point in the problem domain. Internally, ANSYS FLUENT sets the location of the reference pressure at a slightly different nearby location. Thus, the actual location used as the pressure reference is different than that of your input value. To report the actual reference pressure location that ANSYS FLUENT uses, use the following text command:

define → operating-conditions → used-ref-pressure-location

Important

- This text command is available only when the case is initialized and has no pressure-related boundary zones.
- Reporting the actual reference pressure location is not available through the graphical user interface.

8.16. Real Gas Models

Some engineering problems involve fluids that do not behave as ideal gases. For example, at very high-pressure or very low-temperature conditions (e.g., the flow of a refrigerant through a compressor) the flow cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model allows you to solve accurately for the fluid flow and heat transfer problems where the working fluid behavior deviates from the ideal-gas assumption.

ANSYS FLUENT provides three real gas options for solving these types of flows:

- *Cubic Equation of State Models* (p. 474)
- *The NIST Real Gas Models* (p. 488)
- *The User-Defined Real Gas Model* (p. 493)

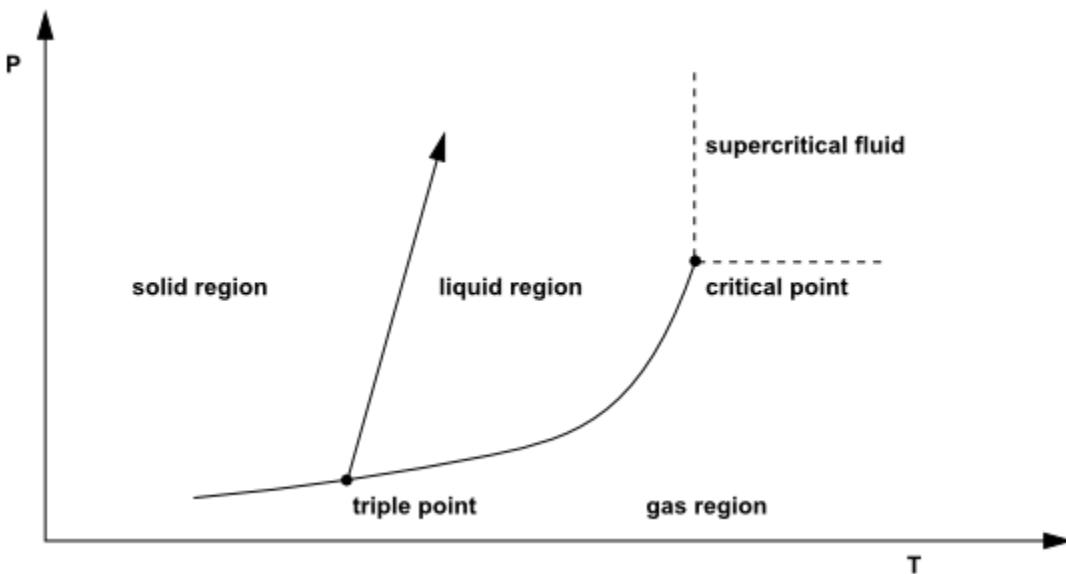

All the models allow the user to solve for either a single-species fluid flow or a multiple-species mixture fluid flow.

For additional information, please see the following sections:

- [8.16.1. Introduction](#)
- [8.16.2. Choosing a Real Gas Model](#)
- [8.16.3. Cubic Equation of State Models](#)
- [8.16.4. The NIST Real Gas Models](#)
- [8.16.5. The User-Defined Real Gas Model](#)

8.16.1. Introduction

The states at which a pure material can exist can be graphically represented in diagrams of pressure vs. temperature (PT diagrams) and pressure vs. molecular or specific volume (PV diagrams). Homogeneous fluids are normally divided into two classes, liquids and gases. However the distinction cannot always be sharply drawn, because the two phases become indistinguishable at what is called the critical point. A typical pressure-temperature (PT) diagram of a pure material is shown in [Figure 8.30](#) (p. 472).

Figure 8.30 Typical PT Diagram of a Pure Material

This figure shows the single phase regions, as well as the conditions of P and T where two phases coexist. Thus the solid and the gas region are divided by the sublimation curve, the liquid and gas regions by the vaporization curve, and the solid and liquid regions by the fusion curve. The three curves meet at the triple point, where all three phases coexist in equilibrium. Although the fusion curve continues upward indefinitely, the vaporization curve terminates at the critical point. The coordinates of this point are called the critical pressure P_c and critical temperature T_c . These represent the highest temperature and pressure at which a pure material can exist in vapor-liquid equilibrium. At temperatures and pressures above the critical point, the physical property differences that differentiate the liquid phase from the gas phase become less defined. This reflects the fact that, at extremely high temperatures and pressures, the liquid and gaseous phases become indistinguishable. This new phase, which has some properties that are similar to a liquid and some properties that are similar to a gas, is called a supercritical fluid.

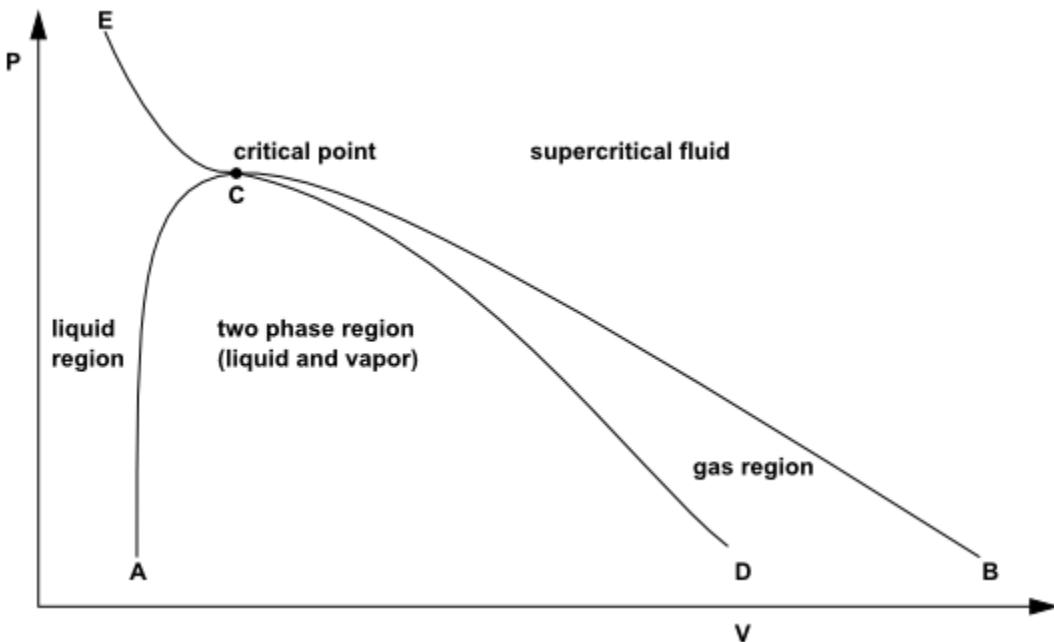

Figure 8.31 Typical PV Diagram of a Pure Material

Figure 8.31 (p. 472) presents a typical diagram of pressure versus molar or specific volume (PV diagram) of a pure material. The dome shaped curve ACD is called the saturation dome and separates the single phase regions in the diagram; curve AC represents the saturated liquid and curve CD the saturated vapor. The area under the saturation dome ACD is the two-phase region and represents all possible mixtures of vapor and liquid in equilibrium. Curve ECB is the critical isotherm and exhibits a horizontal inflection at point C at the top of the dome. This is the critical point. The specific volume corresponding to the critical point, is called the critical specific volume V_c . The conditions to the right of the critical isotherm ECB correspond to supercritical fluid.

8.16.2. Choosing a Real Gas Model

The equation of state is the mathematical expression that relates pressure, molar or specific volume, and temperature for any pure homogeneous fluid in equilibrium states.

The simplest equation of state is the ideal gas law, which is approximately valid for the low pressure gas region of the PT and PV diagrams. Ideal gas behavior can be expected when

$$P/P_c \ll 1$$

or

$$T/T_c > 2 \text{ and } P/P_c < 1$$

If your flow conditions correspond to either of those cases, you may use the ideal gas law in your simulation.

Another idealization, that of the incompressible fluid, can be employed for the low pressure region of the liquid phase. A constant density option is the appropriate selection in that case.

However, both of these approaches are not good approximations for flow conditions close to and beyond the critical point, where the fluid behavior cannot be described by the ideal gas, or the incompressible liquid assumptions. We refer to a fluid under those conditions as a real fluid, or a real gas and more complex relations are used for the determination of its physical and thermodynamic properties.

ANSYS FLUENT provides the following options for solving real fluid problems:

- The cubic equation of state models can be used to solve problems in the gas and supercritical fluid regimes. The models are not available for the two-phase region under the phase dome. For further details see *Cubic Equation of State Models (p. 474)*.
- The NIST real gas model can be used to solve problems in the liquid, or gas and supercritical fluid regimes. The model does not allow modeling of the two-phase region. For further details see *The NIST Real Gas Models (p. 488)*.
- The User-Defined real gas model allows you to solve problems in all regimes, as long as appropriate relationships are provided through the User-Defined real gas functions. For further details see *The User-Defined Real Gas Model (p. 493)*.

The concepts presented in this section for pure materials are also extended to multi-component mixtures with the introduction of appropriate composition-dependent parameters in the real gas equations of state and the material property models. All the real-gas modeling options above allow for either single-species or multi-component flow modeling. In addition, you may solve reacting flow problems with the cubic equations of state models and the User-Defined real gas functions.

8.16.3. Cubic Equation of State Models

8.16.3.1. Overview and Limitations

An equation of state is a thermodynamic equation, which provides a mathematical relationship between two or more state functions associated with the matter, such as its temperature, pressure, volume, or internal energy. One of the simplest equations of state for this purpose is the ideal gas law, which is roughly accurate for gases at low pressures and high temperatures. However, this equation becomes increasingly inaccurate at higher pressures and lower temperatures, and fails to predict condensation from a gas to a liquid.

Introduced in 1949, the Redlich-Kwong equation of state [67] (p. 2370) was a considerable improvement over other equations of that time. It is an analytic cubic equation of state and is still of interest primarily due to its relatively simple form. The original form is

$$P = \frac{RT}{V - b} - \frac{\alpha_0}{V(V + b) T_r^{0.5}} \quad (8-76)$$

where

P = absolute pressure (Pa)

R = universal gas constant

V = specific molar volume (m^3/kmol)

T = temperature (K)

T_r = reduced temperature $\frac{T}{T_c}$, where T_c is the critical temperature

α_0 and b are constants related directly to the fluid critical pressure and temperature.

Many investigators have attempted to improve the accuracy of the Redlich-Kwong equation. ANSYS FLUENT has adopted the original form of the Redlich-Kwong equation, as well as the following modified forms:

- The Soave-Redlich-Kwong [104] (p. 2372) equation is a three-parameter equation of state, which can be applied for vapor, supercritical, and liquid property predictions. It has found wide acceptance mainly in the oil and gas industry and requires knowledge of the critical temperature, critical pressure, and acentric factor. It was developed by replacing the Redlich-Kwong attractive coefficient defined as $\alpha = \alpha_0 / T_r^{0.5}$ with a two-parameter form $\alpha(T_r, \omega)$, where ω is the acentric factor.
- The Peng-Robinson equation [105] (p. 2372) is a three-parameter equation of state, also requiring the critical temperature, critical pressure and acentric factor parameters. It is thought to perform as well as the Soave-Redlich-Kwong equation, with an advantage in the prediction of the liquid densities.
- The Aungier-Redlich-Kwong [8] (p. 2367) equation provides improved predictions for vapor and supercritical fluids near the critical point, as well as for materials with a negative value of the acentric factor. The Aungier modified form is a four parameter equation and requires the critical specific volume in addition to the critical temperature, critical pressure and acentric factor.

The following limitations exist in ANSYS FLUENT for all cubic equation of state models:

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.
- Non-reflecting boundary conditions should not be used with the real gas models.
- The cubic equation of state real gas models are compatible with the Eulerian multiphase models.

Note

Please note the following restrictions:

- Only one phase can be a real gas.
- Only **constant-rate** and **user-defined Mass Transfer Mechanisms** are available.
- The cubic equation of state models are compatible with the Lagrangian Dispersed Phase Models. If you are modeling droplet or multicomponent particles, please note that the current formulation does not take into account the near-critical point phenomena, which means that accurate results can be obtained for droplet temperatures below $T_{\text{lim}} = 0.9T_c$. See [Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models \(p. 486\)](#) for more details.
- The real gas models cannot be used with the premixed, partially premixed, inert, and composition PDF transport combustion models.
- The cubic equation of state real gas models can be used with the following species models:
 - Species transport. Chemical reactions can be modeled with the finite rate and eddy dissipation models. Please note that the **Dimension Reduction** model is not available with the real gas models.
 - Non-premixed model. Please note that the **Compressibility Effects** option must be enabled in the **Species Model** dialog box in order for the real-gas models to be available. In addition the following restrictions apply when the non-premixed model is used together with a cubic equation of state real-gas model:
 - The empirical stream options cannot be used, as for the empirical species the critical properties cannot be defined.
 - Condensed species such as $\text{h}_2\text{o}\langle\text{l}\rangle$ and $\text{c}\langle\text{s}\rangle$ are not supported and should be excluded from the PDF table, so please take care to add all condensed species for your system in the excluded species list prior to the PDF table generation.

8.16.3.2. Equation of State

The general form of pressure P for the cubic equation of state models is written as [8] (p. 2367) :

$$P = \frac{RT}{V - b + c} - \frac{\alpha}{(V^2 + \delta V + \varepsilon)} \quad (8-77)$$

where

P = absolute pressure (Pa)

V = specific molar volume (m^3/kmol)

T = temperature (K)

R = universal gas constant

The coefficients α , b , c , δ , and ε are given for each equation of state as functions of the critical temperature T_c , critical pressure P_c , acentric factor ω and critical specific volume V_c . Note that the attractive coefficient α also has a temperature dependence, which varies for each equation of state model, and is commonly written as $\alpha = \alpha(T)$.

Redlich-Kwong Equation [106] (p. 2372):

$$\alpha(T) = \frac{\alpha_0}{(T/T_c)^{0.5}} \quad (8-78)$$

$$\alpha_0 = \frac{0.42747R^2 T_c^2}{P_c} \quad (8-79)$$

$$b = \frac{0.08664RT_c}{P_c} \quad (8-80)$$

The parameter δ is set equal to b , while c and ε are set to 0. The Redlich-Kwong equation is the simplest of the cubic equations of state in ANSYS FLUENT and requires two parameters only, the critical temperature T_c and the critical pressure P_c .

Soave-Redlich-Kwong Equation [104] (p. 2372):

$$\alpha(T) = \alpha_0 [1 + n (1 - (T/T_c)^{0.5})]^2 \quad (8-81)$$

$$n = 0.48 + 1.574\omega - 0.176\omega^2 \quad (8-82)$$

α_0 and b are given by [Equation 8-79](#) (p. 476) and [Equation 8-80](#) (p. 476) respectively. As in the original Redlich-Kwong equation the parameter δ is set equal to b , while c and ε are set to 0. The Soave-Redlich-Kwong requires three parameters, the critical temperature T_c , the critical pressure P_c , and the acentric factor ω .

Peng-Robinson Equation [105] (p. 2372):

$$\alpha_0 = \frac{0.457247R^2 T_c^2}{P_c} \quad (8-83)$$

$$b = \frac{0.07780RT_c}{P_c} \quad (8-84)$$

The function $\alpha(T)$ is given by [Equation 8-81](#) (p. 476), with n provided in [Equation 8-85](#) (p. 477) as follows:

$$n = 0.37464 + 1.54226\omega - 0.26992\omega^2 \quad (8-85)$$

In the Peng-Robinson equation δ is set equal to $2b$, ε is equal to $-b^2$, and c is set to 0.

Similar to the Soave-Redlich-Kwong equation, the Peng-Robinson equation is a three-parameter equation and requires the critical temperature T_c , the critical pressure P_c , and the acentric factor ω .

Aungier-Redlich-Kwong Equation [8] (p. 2367):

$$\alpha(T) = \alpha_0 \left(\frac{T}{T_c} \right)^{-n} \quad (8-86)$$

$$n = 0.4986 + 1.1735\omega + 0.4754\omega^2 \quad (8-87)$$

α_0 and b are given by [Equation 8-79 \(p. 476\)](#) and [Equation 8-80 \(p. 476\)](#), respectively. As in the original Redlich-Kwong equation, the parameter δ is set equal to b and ε is set to 0. Parameter c is given by:

$$c = \frac{RT_c}{P_c + \frac{\alpha_0}{V_c(V_c + b)}} + b - V_c \quad (8-88)$$

The Aungier-Redlich-Kwong equation requires four parameters, namely the critical temperature T_c , the critical pressure P_c , the critical specific volume V_c , and the acentric factor ω .

8.16.3.3. Enthalpy, Entropy, and Specific Heat Calculations

Enthalpy, entropy, and specific heat are computed in terms of the relevant ideal gas properties and the departure functions. The departure function F_{dep} of any conceptual property F is defined as [\[67\] \(p. 2370\)](#)

$$F_{dep} = F_{ideal}(T, P) - F(T, P) \quad (8-89)$$

where F_{ideal} is the value of the property as computed from the ideal gas relations. The departure function F_{dep} can be derived from basic thermodynamic relations and the equation of state.

Following the above definition, the enthalpy H for the equations of state models is given by the following equations [\[8\] \(p. 2367\)](#):

$$H = H_{ideal} - \frac{H_{dep}}{MW} \quad (8-90)$$

$$H_{dep} = -PV + RT - \frac{T \frac{\partial a}{\partial T} - a}{\Delta} \ln \left[\frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right] \quad (8-91)$$

$$\Delta = (\delta^2 - 4\epsilon)^{0.5} \quad (8-92)$$

where,

H_{ideal} = ideal gas enthalpy at temperature T (J/kg)

H_{dep} = departure enthalpy (J/kmol)

MW = mean molecular weight (Kg/kmol)

P = pressure (Pa)

V = specific molar volume (m^3 /kmol)

R = universal gas constant

α, δ , and ϵ are computed using [Equation 8-78 \(p. 476\)](#) – [Equation 8-88 \(p. 477\)](#) depending on the equation of state model.

Similarly, the departure internal energy U_{dep} can be shown to be

$$U_{dep} = - \frac{T \frac{\partial a}{\partial T} - a}{\Delta} \ln \left[\frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right] \quad (8-93)$$

where

U_{dep} = departure internal energy (J/kmol)

T = temperature (K)

V = specific molar volume (m^3 /kmol)

Δ is given by [Equation 8-92 \(p. 478\)](#) and α, δ , and ϵ are computed using [Equation 8-78 \(p. 476\)](#) – [Equation 8-88 \(p. 477\)](#) depending on the equation of state model.

The specific heat c_p can be computed from the ideal specific heat $c_{p,ideal}$ and the departure specific heat at constant volume $c_{v,dep}$ as follows:

$$c_p = c_{p,ideal} - \frac{c_{p,dep}}{MW} \quad (8-94)$$

$$c_{p,dep} = c_{v,dep} - R - T \frac{(\partial V / \partial T)^2}{\partial V / \partial P} \quad (8-95)$$

where

MW = mean molecular weight (kg/kmol)

P = pressure (Pa)

T = temperature (K)

V = specific molar volume (m^3 /kmol)

R = universal gas constant

In [Equation 8-95 \(p. 479\)](#) $c_{v,dep}$ is computed by differentiating the equation of departure internal energy ([Equation 8-93 \(p. 478\)](#)) with respect to T , and the partial derivatives of the specific volume are computed by differentiating [Equation 8-77 \(p. 475\)](#) appropriately.

The entropy S is computed by

$$S = S_{ideal,0} - \frac{S_{dep}}{MW} \quad (8-96)$$

$$S_{dep} = -R \ln \left(\frac{V - b + c}{V_0} \right) - \frac{da}{\Delta} \ln \left[\frac{2V + \delta + \Delta}{2V + \delta - \Delta} \right] \quad (8-97)$$

where

$S_{ideal,0}$ = ideal gas entropy at temperature T and reference pressure (J/kg/K)

V_0 = ideal gas specific molar volume at temperature T and the reference pressure (m^3 /kmol)

P = pressure (Pa)

T = temperature (K)

V = specific molar volume (m^3 /kmol)

MW = mean molecular weight (kg/kmol)

Δ is given by *Equation 8–92* (p. 478) and α , δ , and ε are computed using *Equation 8–78* (p. 476) – *Equation 8–88* (p. 477), depending on the equation of state model. Note that the pressure term in *Equation 8–96* (p. 479) cancels out as both $S_{ideal,0}$ and V_0 are evaluated at the reference pressure.

8.16.3.4. Critical Constants for Pure Components

Equations describing real-gas properties require the knowledge of the critical constants for pure components and mixtures. These comprise the critical temperature (T_c), critical pressure (P_c), critical specific volume (V_c), and the acentric factor (ω).

Several critical constants for fluid materials in the ANSYS FLUENT property database propdb.scm have been compiled from a variety of sources available in the open literature [67] (p. 2370), [59] (p. 2370), [60] (p. 2370), [81] (p. 2371), [82] (p. 2371), [85] (p. 2371), [7] (p. 2367).

For those fluid materials, for which the critical properties have not been found in the open literature, these have been estimated using the commercially available software CRANIUM by Molecular Knowledge Systems Inc. [4] (p. 2367) : <http://www.molknow.com/Cranium/cranium.htm>

Critical property values for many hydrocarbon and nitrogenous radical species have been obtained from Tang and Brezinsky [91] (p. 2372). Where the critical properties for the radicals were not available in the literature, these were estimated using a modification of the Joback method [67] (p. 2370). This assumes that the radical site constitutes a distinct group with zero group contribution and utilizes the group contribution values for stable species.

The critical properties of coal volatiles have been estimated assuming that the volatiles can be approximated by a mixture of CO, CO₂, H₂, CH₄, and C₂H₆ in such a way, that the atom composition and the net calorific value of the volatiles is similar to that of the assumed mixture. The critical properties of the lignite and biomass volatiles have been assumed equal to those of formaldehyde. The critical properties of diesel and jet-a fuels have been set equal to those of decane. The critical properties of kerosene have been set equal to those of dodecane.

8.16.3.5. Calculations for Mixtures

For the computation of properties in real-gas mixtures, ANSYS FLUENT follows the so called pseudocritical method. According to this method, the behavior and properties of a real gas mixture will be the same as that of a pure component, to which appropriate critical constants are assigned. These mixture critical constants are functions of the mixture composition and pure component critical properties, and are sometimes called pseudocritical constants, because their values are generally expected to be different from the true mixture critical constants that may be determined experimentally. However for computational purposes they are the appropriate critical constant values for the mixture. According to the pseudocritical method, ANSYS FLUENT applies *Equation 8–77* (p. 475) – *Equation 8–97* (p. 479) also for mixtures, where the critical temperature T_c , critical pressure P_c , critical specific volume V_c , and acentric factor ω , are replaced by the corresponding mixture critical constants, critical temperature T_{cm} , critical pressure P_{cm} , critical specific volume V_{cm} , and acentric factor ω_m .

The following options are available in ANSYS FLUENT for the calculation of the mixture pseudocritical constants:

- The simplest rule for computing the pseudocritical constants C_{cm} for a real gas mixture is the mole fraction average [67] (p. 2370). This method is recommended for mixtures where the pure component critical properties for all components are not very different:

$$C_{cm} = \sum_{i=1}^k x_i C_{ci} \quad (8-98)$$

where

C_{cm} = mixture pseudocritical constant (temperature, pressure, specific volume or acentric factor)

C_{ci} = critical constant of component i (temperature, pressure, specific volume or acentric factor)

x_i = mole fraction of component i

k = number of components in mixture

- An alternative approach is based on the one-fluid van der Waals mixing rules as expressed in [106] (p. 2372). According to this approach, in order to apply the equation of state models to mixtures, the coefficients a and b in [Equation 8-77](#) (p. 475) are replaced by composition-dependent expressions as follows:

$$(\alpha_m)^{0.5} = \sum_i x_i (\alpha_i)^{0.5} \quad (8-99)$$

$$b_m = \sum_i x_i b_i \quad (8-100)$$

where

x_i = mole fraction of species i

With the appropriate expressions from [Equation 8-78](#) (p. 476) – [Equation 8-88](#) (p. 477) for each equation of state, and assuming a mixture acentric factor ω_m for the evaluation of parameter n in [Equation 8-82](#) (p. 476), [Equation 8-85](#) (p. 477), and [Equation 8-87](#) (p. 477), the mixing rules [Equation 8-99](#) (p. 481) and [Equation 8-100](#) (p. 481) can be rearranged to yield direct expressions of the mixture critical properties as functions of the mole fractions and the component critical properties [8] (p. 2367).

The resulting expressions for the mixture critical specific temperature T_{cm} are as follows:

- Soave-Redlich-Kwong and Peng-Robinson models

$$T_{cm} = \frac{\left[\sum_i \left(x_i \frac{T_{ci}}{P_{ci}^{0.5}} \right) \right]^2}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}} \right)} \quad (8-101)$$

- Redlich-Kwong model and Aungier-Redlich-Kwong model:

$$T_{cm}^{1+n} = \frac{\left[\sum_i \left(x_i \sqrt{\frac{T_{ci}^{(2+n)}}{P_{ci}}} \right) \right]^2}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}} \right)} \quad (8-102)$$

where for the Aungier-Redlich-Kwong model n is obtained from [Equation 8-87](#) (p. 477) as function of the mixture acentric factor ω_m . For the Redlich-Kwong model $n = 0.5$.

The mixture critical specific pressure P_{cm} is computed as:

$$P_{cm} = \frac{T_{cm}}{\sum_i \left(\frac{x_i T_{ci}}{P_{ci}} \right)} \quad (8-103)$$

The mixture critical specific volume V_{cm} is computed as:

$$V_{cm} = \sum_I \frac{x_i P_{ci} V_{ci}}{T_{ci}} \left(\frac{T_{cm}}{P_{cm}} \right) \quad (8-104)$$

The notation for [Equation 8-101](#) (p. 481) to [Equation 8-104](#) (p. 482) is

T_{cm} = mixture pseudocritical temperature (K)

P_{cm} = mixture pseudocritical pressure (Pa)

V_{cm} = mixture pseudocritical molar volume (m^3/kmol)

T_{ci} = critical temperature for component i (K)

P_{ci} = critical pressure for component i (Pa)

V_{ci} = critical molar volume for component i (m^3/kmol)

x_i = mole fraction for component i

8.16.3.5.1. Using the Cubic Equation of State Real Gas Models

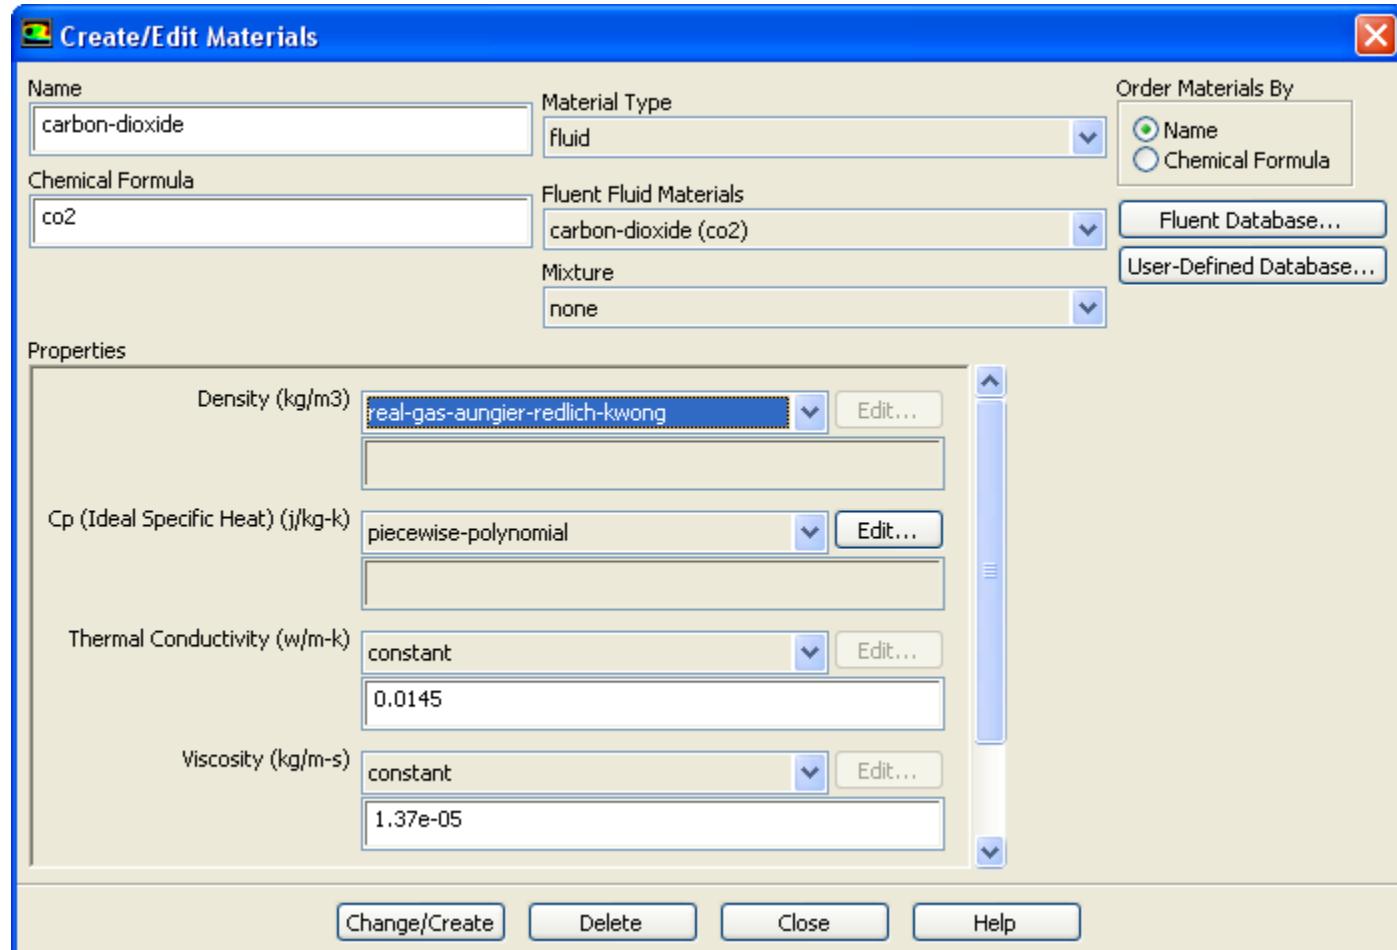

For single or multi-component flows, you will activate the cubic equation of state real gas models by selecting **real-gas-soave-redlich-kwong**, **real-gas-peng-robinson**, **real-gas-aungier-redlich-kwong**, or **real-gas-redlich-kwong** from the **Density** drop-down list in the **Create/Edit Materials** dialog box.

◀ Materials → Create/Edit...

The required inputs for the cubic equation of state real gas models for single component flow and mixtures are described below.

Single Component Flow

Figure 8.32 The Cubic Equation of State Model for a Real-Gas Fluid

When any of the cubic equation of state models is enabled, enter the following material properties in the dialog box:

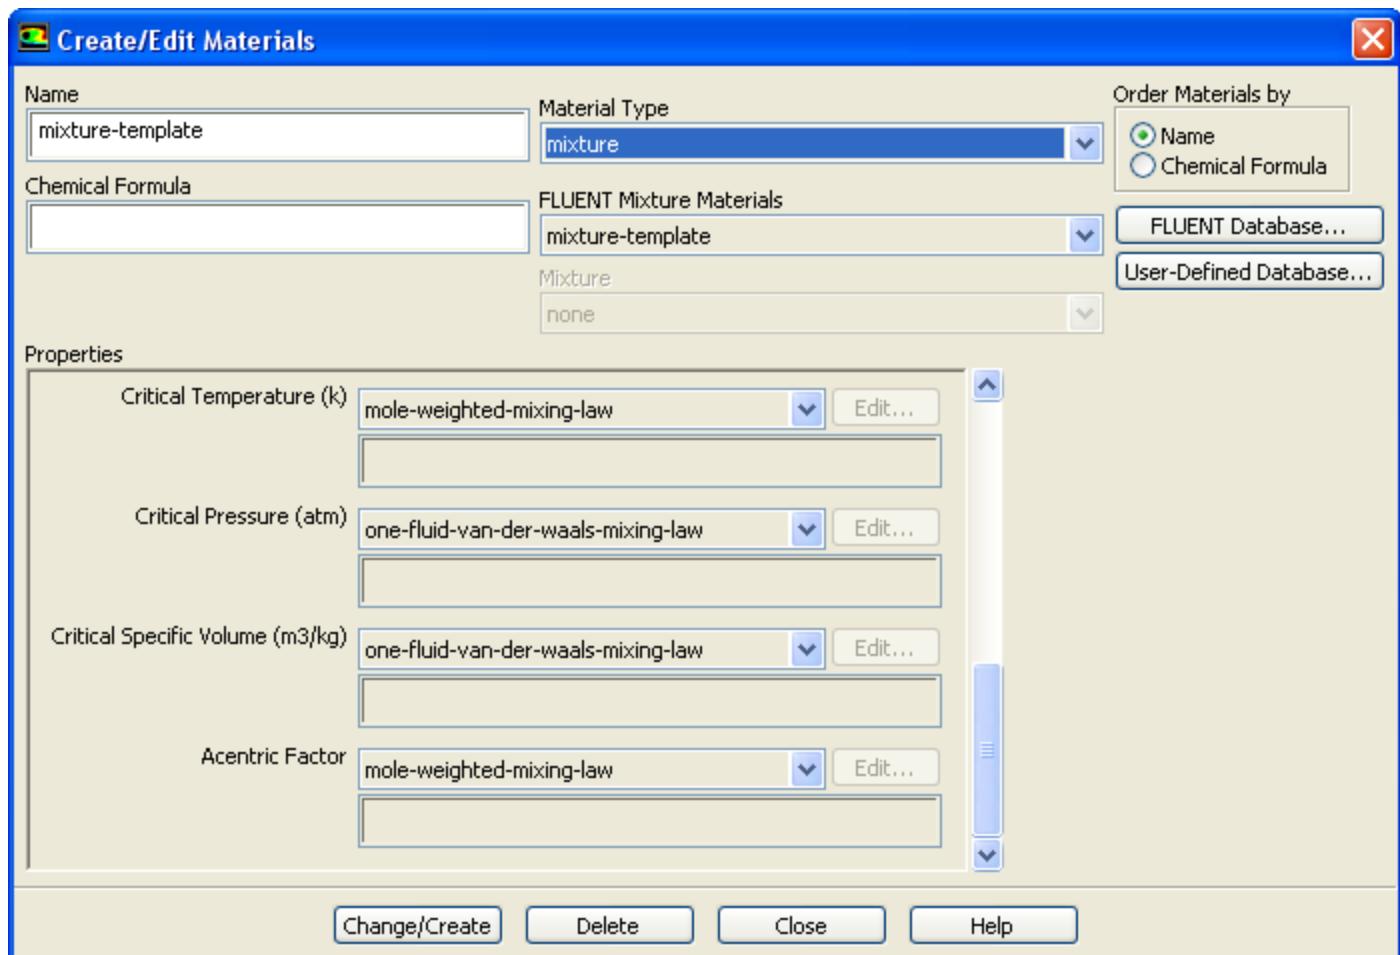

- ideal specific heat
- molecular weight
- standard state entropy
- reference temperature
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

Important

Your inputs for the specific heat in the **Materials** dialog box will now be used to compute the ideal property functions H_{ideal} , $c_{p,ideal}$, and $S_{ideal,0}$ in [Equation 8–90 \(p. 478\)](#), [Equation 8–94 \(p. 479\)](#), and [Equation 8–96 \(p. 479\)](#), respectively. In ANSYS FLUENT the departure properties will be computed and added to the ideal part, to yield the real gas specific heat, enthalpy, and entropy.

Mixtures

Figure 8.33 The Cubic Equation of State Model for a Real-Gas Mixture

When one of the cubic equation of state models is selected from the **Density** drop-down list, specify the following material properties for the mixture material in the dialog box:

- ideal specific heat
- critical temperature
- critical pressure
- critical specific volume
- acentric factor

You also need to enter the following material properties for each of the mixture components in the dialog box:

- molecular weight
- standard state entropy
- reference temperature

When you are modeling a real-gas mixture, the following methods are available for the mixture critical constants:

- **constant**: defines a constant critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.
- **mole-weighted-mixing-law**: applies [Equation 8–98 \(p. 481\)](#) for critical temperature, critical pressure, critical specific volume, or acentric factor for the mixture material.
- **one-fluid-van-der-waals-mixing-law** applies [Equation 8–101 \(p. 481\)](#) and [Equation 8–102 \(p. 482\)](#) for the mixture critical temperature (depending on the real-gas model), [Equation 8–103 \(p. 482\)](#) for the mixture critical pressure, and [Equation 8–104 \(p. 482\)](#) for the mixture critical density.

Important

- Ensure to click the **Change/Create** button so that all the above mentioned properties are uploaded and are visible in the interface.
- If you have selected **mixing-law** for the mixture ideal specific heat you will also need to enter the ideal specific heat values for the individual mixture components. If you have not selected **constant** as the option for any of the critical properties, you will need to enter the corresponding pure component critical properties for the mixture components.

8.16.3.5.2. Solution Strategies and Considerations for Cubic Equations of State Real Gas Models

The flow modeling of real-gas flow is more complex and challenging than simple ideal-gas flow. Therefore, the solution might converge at a slower rate with real-gas flow than when running ideal-gas flow. It is recommended that you first attempt to converge your solution using first-order discretization then switch to second-order discretizations and re-iterate to convergence.

It is important to realize that the cubic equations of state real gas model is not available for two-phase flows where liquid and vapor coexist. Thus the flow conditions you are prescribing must fall within the range of the model. In case the flow conditions in your case fall inside the saturation dome, the properties are computed for the vapor phase up to the vapor spinodal curve, which defines the boundary beyond which the equation of state is no longer valid, because the local derivative of pressure with respect to volume becomes positive. State points predicted inside the dome, up to the spinodal curve, are called “metastable” because normally they only temporarily exist in small local regions until phase change occurs. For cases without phase change these states can occur and continue to persist depending on the problem setup. In some instances, the actual converged state is just within the superheated vapor limits but only transitory inside the saturation dome.

While the cubic equations of state real gas models are not available for two-phase flows, they can be applied to conditions of supercritical pressure $P > P_c$ and subcritical temperature $T < T_c$, where the fluid is in the liquid state. The supercritical liquid can co-exist with gas and supercritical fluid in the same simulation. In those cases, phase change may take place, without any of the flow conditions falling

inside the saturation dome. For multicomponent simulations, when **Diffusion Energy Source** is enabled in the **Species Model** dialog box, the species energy diffusion is by default suppressed in the supercritical liquid regime and across the gas-liquid boundary. The diffusion energy source can be included in the liquid regime using the `define/models/species/liquid-energy-diffusion?` text command.

Finally, when you initialize the flow, ensure that the flow conditions fall within the vapor or supercritical flow conditions that are supported by the cubic equations of state model.

8.16.3.5.3. Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models

If your simulation contains a liquid stream, the appropriate modeling approach in the various operating condition regimes is as follows:

1. For $T > T_c$ a liquid phase does not exist.
2. In the region $P > P_c$, you should define the flow streams directly in the boundary conditions by setting the appropriate pressure and temperature and the properties will be computed directly by the cubic EOS. This is applicable for both $T < T_c$ (supercritical liquid) and $T > T_c$ (supercritical fluid) regimes.
3. For $P < P_c$ a stream can exist in liquid phase when its temperature $T < T_c$. If you would like to model phase change in this regime, the following recommendations apply:
 - The DPM droplet and multi-component models are adequate and recommended for the conditions away from the critical point. This regime can be defined as $T < 0.9 T_c$, where the liquid physical properties can be assumed independent of pressure.
 - The region $T_c > T > 0.9 T_c$ is characterized by near-critical-point phenomena, such as strong liquid density and specific heat dependence on both temperature and pressure. The DPM model can also be used in this regime, but you should be cautious, as it will not take into consideration the near-critical-point behavior. In addition, the applicability of the evaporation and boiling rate equations is questionable in this regime.

The droplet saturation vapor pressure corresponding to $T_{\text{lim}} = 0.9 T_c$ gives an indication of the maximum operating pressure for applicability of the DPM models for each droplet material. These pressure limits are listed in [Table 8.2: Pressure Limits for Droplet Materials in ANSYS FLUENT's Database prodb.scm](#) (p. 486) for many of the droplet materials in ANSYS FLUENT's `propdb.scm` materials database.

Table 8.2 Pressure Limits for Droplet Materials in ANSYS FLUENT's Database prodb.scm

Material	T _c (K)	P _c (MPa)	Normal BP (K)	T _{lim} (K)	Pressure Limit (MPa)
Argon	150.86	4.89	87.30	135.77	2.66
Benzene	562.00	4.89	353.00	505.80	2.35
Helium	5.30	0.23	4.20	4.77	0.16
Hydrogen	32.98	1.30	20.40	29.68	0.68
Methyl-alcohol	512.00	8.10	338.00	460.80	3.18
Heptanes	540.00	2.74	371.00	486.80	1.22
Hexane	507.00	3.02	342.00	456.30	1.36
Octane	569.00	2.49	399.00	512.10	1.08

Pentane	470.00	3.37	309.00	423.00	1.59
Nitrogen	126.00	3.40	77.40	113.40	1.73
Oxygen	154.00	5.04	90.20	138.60	2.62
Toluene	592.00	4.11	384.00	532.80	1.89
Water	647.00	22.00	373.00	582.30	9.71

For high pressure simulations the boiling point will be different from the normal boiling point, and for varying pressure applications the boiling point will vary with the droplet location in the domain.

When a cubic equation of state real gas model is enabled in a simulation which includes evaporating droplet particles, the boiling point is calculated from the vapor pressure data directly, as the temperature where the saturation vapor pressure equals the domain pressure. In addition, the latent heat of the evaporating or boiling droplet will vary with the droplet temperature.

The latent heat at temperature T_p is given by

$$H_{lat_T} = - \int_{T_p}^{T_{bp}} c_{p,g} dT + H_{lat} + \int_{T_p}^{T_{bp}} c_{p,p} dT \quad (8-105)$$

where T_{bp} is the normal boiling point and H_{lat} is the latent heat at the normal boiling point.

In the **Create/Edit Materials** dialog box you will need to enter the **Normal Boiling Point (NBP)** and the **Latent Heat at NBP** for the **droplet-particle Material Type**. These inputs will be used for calculating the **Latent Heat** at the reference temperature (see [Equation 16-325](#)) and the latent heat in the droplet energy balance during vaporization and boiling according to [Equation 8-105](#) (p. 487).

Important

The constant property option is disabled for the **Saturation Vapor Pressure** property when a real gas model is used in the simulation. Also, ensure to enter the appropriate droplet saturation vapor pressure data to cover the complete pressure/temperature range in your model.

Finally when a cubic equation of state real-gas model is enabled in a simulation with droplet models, the condition for switching from the vaporization to the boiling law will be

$$P_{sat} > P \quad (8-106)$$

where P_{sat} is the saturation vapor pressure and P is the domain pressure. If $P_{sat} < P$ while in the boiling law, the model will switch back to the vaporization law.

8.16.3.5.4. Postprocessing the Cubic Equations of State Real Gas Model

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the cubic equations of state real gas model include the following:

- density
- enthalpy
- entropy
- sound speed
- specific heat
- any quantities that are derived from the properties listed above (e.g., total quantities, ratio of specific heats)

In addition to the properties listed above, you can also report

- compressibility factor
- reduced temperature
- reduced pressure
- spinodal temperature

If you are modeling a real-gas mixture you can report the composition-dependent mixture critical properties

- critical temperature
- critical pressure
- critical specific volume
- acentric factor

8.16.4. The NIST Real Gas Models

The NIST real gas models use the National Institute of Standards and Technology (NIST) Thermodynamic and Transport Properties of Refrigerants and Refrigerant Mixtures Database Version 7.0 (REFPROP v7.0) to evaluate thermodynamic and transport properties of approximately 39 pure fluids or a mixture of these fluids.

The REFPROP v7.0 database is a shared library that is dynamically loaded into the solver when you activate one of the NIST real gas models in an ANSYS FLUENT session. Once the NIST real gas model is activated, control of relevant property evaluations is relinquished to the REFPROP database. All postprocessing functions will properly report and display the current thermodynamic and transport properties of the real gas.

8.16.4.1. Limitations of the NIST Real Gas Models

The following limitations exist for the NIST real gas model:

- Access to the [Create/Edit Materials Dialog Box \(p. 1882\)](#) from the navigation pane or **Define** menu is restricted. Therefore, if solid properties have to be set and modified, then it should be done in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) before activating the real gas model. Alternatively, the solid material properties can be set by editing the solid material in the [Solid Dialog Box \(p. 1949\)](#), by clicking the **Edit...** button next to the **Material Name**. In addition, if you are using the multi-species NIST real gas model, you can set the **Mass Diffusivity** property of the NIST mixture by editing the real-gas-mixture material in the [Fluid Dialog Box \(p. 1942\)](#), by clicking the **Edit...** button next to the **Material Name**. Please note that the **kinetic-theory** option is not available for the **Mass Diffusivity** property with the multi-species NIST real gas model.

- The NIST real gas model assumes that the fluid you will be using in your ANSYS FLUENT computation is superheated vapor, supercritical fluid, or liquid. Note that subcritical flow conditions, where vapor coexists with liquid in two-phase flow, are not supported. In addition, all fluid zones must contain the real gas; you cannot include a real gas and another fluid in the same problem.
- Pressure-inlet, mass flow-inlet, and pressure-outlet are the only inflow and outflow boundaries available for use with the real gas models.
- Non-reflecting boundary conditions should not be used with the real gas models.
- The mixture flow does not permit chemical reactions with the NIST real gas model.
- The real gas models cannot be used with any of the multiphase models. The model is compatible with the Lagrangian Dispersed Phase Models only for the massless and inert particle types. Please note that particle material properties have to be set in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) before activating the real gas model.
- You cannot modify material properties in the REFPROP database libraries, or add custom materials to the NIST real gas model.
- The **Diffusion Energy Source** $\nabla \cdot \left(\sum_j h_j \vec{J}_j \right)$ in the energy equation (see [The Energy Equation](#) in the [Theory Guide](#)) is not included with the nist-multiplespecies-real-gas-models and the pressure-based solver.

8.16.4.2. The REFPROP v7.0 Database

The NIST real gas model supports 83 pure fluids from the REFPROP database. These include 39 materials that were made available in the NIST web site later. The pure-fluid refrigerants and hydrocarbons that are supported by REFPROP v7.0 and used in the NIST real gas model are listed in [Table 8.3: Hydrocarbons and Refrigerants Supported by REFPROP v7.0 \(p. 489\)](#) (the corresponding property file name appears in parentheses, where it does not coincide with the fluid name).

Important

The database does not include transport property models for the following species: acetone, benzene, c4f10, c5fl2, cos, cyclohexane, cyclopropane, deuterium, fluorine, neopentane, nf3, propyne, r21, sf6, so2. As a result the NIST real gas model with those species can only be used for modeling inviscid flow.

The REFPROP v7.0 database employs accurate pure-fluid equations of state that are available from NIST. These equations are based on three models:

- modified Benedict-Webb-Rubin (MBWR) equation of state
- Helmholtz-energy equation of state
- extended corresponding states (ECS)

For a fluid that consists of a multispecies-mixture the thermodynamic properties are computed by employing mixing-rules applied to the Helmholtz energy of the mixture components.

Table 8.3 Hydrocarbons and Refrigerants Supported by REFPROP v7.0

1butene	acetone	ammonia	argon	benzene	butane
dodecane (c12.fld)	cis-butene (c2butene.fld)	c4f10	c5fl2	co	co2

cos	cyclohexane (cyclo-hex.fld)	cyclopropane (cyclopro.fld)	deuterium (d2.fld)	heavy water (d2o.fld)	decane
dimethylether (dme.fld)	ethane	ethanol	ethylene	fluorine	h2s
helium	heptane	hexane	hydrogen	ibutene	ihexane
ipentane	isobutene	krypton	methane	methanol	n2o
neon	neopentane (neopentn.fld)	nf3	nitrogen	nonane	octane
oxygen	parahydrogen (parahyd.fld)	pentane	propane	propylene (propylen.fld)	propyne
r11	r113	r114	r115	r116	r12
r123	r124	r125	r13	r134a	r14
r141b	r142b	r143a	r152a	r21	r218
r22	r227ea	r23	r236ea	r236fa	r245ca
r245fa	r32	r365mfc	r41	rc318	sf6
so2	trans-butene (t2butene.fld)	toluene	water	xenon	

8.16.4.3. Using the NIST Real Gas Models

When you enable one of the NIST real gas models (single-species fluid or multiple-species mixture) and select a valid material, ANSYS FLUENT's functionality remains the same as when you model fluid flow and heat transfer using an ideal gas, with the exception of the [Create/Edit Materials Dialog Box \(p. 1882\)](#) (see below).

8.16.4.3.1. Activating the NIST Real Gas Model

Activating one of the NIST real gas models is a two-step process. First you enable either the single-species NIST real gas model or the multi-species NIST real gas model, and then you select the fluid material from the REFPROP database.

1. Enabling the appropriate NIST real gas model:

If you are solving for a single-species flow then you should enable the single-species NIST real gas model by typing the following text command at the ANSYS FLUENT console prompt:

```
> define/user-defined/real-gas-models/nist-real-gas-model
use NIST real gas? [no] yes
```

If you are solving for multi-species mixture then you should enable the multi-species NIST real gas model by typing the following text command at the ANSYS FLUENT console prompt:

```
> define/user-defined/real-gas-models/nist-multispecies-real-gas-model
use multispecies NIST real gas? [no] yes
```

The list of available pure-fluid materials you can select from will be displayed:

1butene.fld	acetone.fld	ammonia.fld	argon.fld	benzene.fld
butene.fld	c12.fld	c2butene.fld	c4f10.fld	c5f12.fld
co.fld	co2.fld	cos.fld	cyclohex.fld	cyclopro.fld
d2.fld	d2o.fld	decane.fld	dme.fld	ethane.fld
ethanol.fld	ethylene.fld	fluorine.fld	h2s.fld	helium.fld
heptane.fld	hexane.fld	hydrogen.fld	ibutene.fld	ihexane.fld
ipentane.fld	isobutan.fld	krypton.fld	methane.fld	methanol.fld

n2o.fld	neon.fld	neopentn.fld	nf3.fld	nitrogen.fld
nonane.fld	octane.fld	oxygen.fld	parahyd.fld	pentane.fld
propane.fld	propylen.fld	propyne.fld	r11.fld	r113.fld
r114.fld	r115.fld	r116.fld	r12.fld	r123.fld
r124.fld	r125.fld	r13.fld	r134a.fld	r14.fld
r141b.fld	r142b.fld	r143a.fld	r152a.fld	r218.fld
r21.fld	r22.fld	r227ea.fld	r23.fld	r236ea.fld
r236fa.fld	r245ca.fld	r245fa.fld	r32.fld	r365mfc.fld
r41.fld	rc318.fld	sf6.fld	so2.fld	t2butene.fld
toluene.fld	water.fld	xenon.fld		

2. Select material from the REFPROP database list:

If the single-species real gas model is selected, then you need to enter the name of one fluid material when prompted:

```
select real-gas data file ["] "r125.fld"
```

Important

You *must* enter the complete name of the material (including the .fld suffix) contained within quotes (" ").

If the multiple-species real gas model is selected, then you need to enter the number of species in the mixture:

```
Number of species [] 3
```

followed by the name of each fluid selected from the list shown above:

```
select real-gas data file ["] "nitrogen.fld"
select real-gas data file ["] "co2.fld"
select real-gas data file ["] "r22.fld"
```

Upon selection of a valid material (e.g., r125.fld), ANSYS FLUENT will load data for that material from a library of pure fluids supported by the REFPROP database, and report that it is opening the shared library (librealgas.so) where the compiled REFPROP database source code is located.

```
/usr/local/Fluent.Inc/v140/fluent/fluent14.0.0/realgas/lib/r125.fld

Opening "/usr/local/Fluent.Inc/fluent14.0/realgas/
linx64/librealgas.so"...
Setting material "air" to a real-gas...

Matl name: "R125"

3. If you would like to model flow in the liquid phase, then this needs to be specified in the `set-phase` command. Note that the default phase is vapor, so if you do not go through this step, vapor is assumed. In addition, if the flow conditions do not permit liquid to exist, a vapor calculation will be performed instead.

```
> define/user-defined/real-gas-models/set-phase  
Select vapor phase (else liquid)?[yes]
```

Important

For mixture flows, not all combinations of species mixtures are allowed. This could be due to lack of data for one or more binary pairs. In such situations an error message generated by NIST will be returned and displayed on the ANSYS FLUENT console, and no real gas material is allowed to be created. In some combinations the mixing data will be estimated, a warning message will be displayed on the ANSYS FLUENT console and the mixture material allowed to be created.

8.16.4.4. Solution Strategies and Considerations for NIST Real Gas Model Simulation

The flow modeling of NIST real-gas flow is much more complex and challenging than simple ideal-gas flow. Therefore, you should expect the solution to converge at much slower rate with real-gas flow than when running ideal-gas flow. Also due to the complexity of the equations used in property evaluations, converging a solution with the real-gas model is in general done at much lower Courant values when you are using the density-based solver, or at much lower under-relaxation values if you are using the pressure-based solver. It is recommended that you first attempt to converge your solution using first-order discretization, then switch to second-order discretizations and re-iterate to convergence.

The real-gas properties in NIST are defined within a limited/bounded range. It is important that the flow conditions you are prescribing fall within the range of the database. It is possible that you specify flow at a state that is physically valid but otherwise not defined in the database. In this situation the solution will diverge or immediately generate an error message on the ANSYS FLUENT console as soon as the state crosses the limit of the database. In some instances, the actual converged state is just within the bounded defined database but only transitory outside the range. In this situation the divergence can be avoided by lowering the Courant value or under-relaxation factors so a less aggressive convergence rate is adapted.

Finally, if you attempt to initialize the flow from an inlet flow conditions and an error message is generated from one of the property routines, then this is an indicator that the flow conditions you have specified is not defined within the range of the database.

8.16.4.4.1. Writing Your Case File

When you save your completed real gas model to a case file, the linkage to the shared library containing real gas properties will be saved to the case file (along with property data for the material you selected

in the NIST real gas model). Consequently, whenever you read your case file in a later session, ANSYS FLUENT will load and report this information to the console during the read process.

8.16.4.4.2. Postprocessing

All postprocessing functions properly report and display the current thermodynamic and transport properties of the selected real gas model. The thermodynamic and transport properties controlled by the NIST real gas model include the following:

- density
- enthalpy
- entropy
- molecular weight
- molecular viscosity
- sound speed
- specific heat
- thermal conductivity In addition to the properties listed above, you can also report
- compressibility factor
- any quantities that are derived from the properties listed above (e.g., total quantities, ratio of specific heats)

8.16.5. The User-Defined Real Gas Model

The user-defined real gas model (UDRGM) has been developed to allow you to write your own custom real gas model to fit your particular modeling needs. It also allows you to simulate a single-species flow, multiple-species mixture flow, multiphase flow, or volumetric reactions.

The following limitations exist for the User-Defined real gas model:

8.16.5.1. Limitations of the User-Defined Real Gas Model

- You cannot include more than one User Defined Real Gas material (fluid or mixture) in the same problem. However, you can use other materials together with real gas in your simulation.
- When you are using the User Defined Real Gas model, the materials defined in your real gas UDF will appear in the [Create/Edit Materials Dialog Box \(p. 1882\)](#) with the name **real-gas-fluid** or **real-gas-mixture** and all physical and thermodynamic property inputs disabled. Use the [Create/Edit Materials Dialog Box \(p. 1882\)](#) to define or modify:
 - Mass diffusivity property in the real-gas-mixture material if you are modeling multi-component flow.
 - Chemical reactions in the real-gas-mixture if you are modeling reacting flow.
 - Radiation properties for the real-gas-mixture or the real-gas-fluid materials if you are modeling radiation.
 - Properties of materials other than the User Defined **real-gas-mixture** or **real-gas-fluid** materials.

Note

If you are using the User-Defined Real Gas model together with other materials from ANSYS FLUENT's property database in dispersed phase or multiphase calculations, take care to use the same reference temperature as in ANSYS FLUENT in your real-gas UDF. The reference temperature in ANSYS FLUENT is 298.15 K.

- Pressure-inlets, mass flow-inlets, and pressure-outlets are the only inflow and outflow boundaries available for use with the real gas models.
 - Non-reflecting boundary conditions should not be used with the real gas models.
 - The User Defined Real Gas model can be used with the Eulerian multiphase models.
-

Note

Note the following restrictions:

- Only one phase can be a real gas.
- Only **constant-rate** and **user-defined Mass Transfer Mechanisms** are available.

- The User Defined Real Gas model is compatible with the Lagrangian Dispersed Phase Models. Please refer to [Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models \(p. 486\)](#) for guidelines and restrictions of this approach.
- The real gas models cannot be used with the non-premixed, partially premixed, and composition PDF transport combustion models. Chemical reactions can however be modeled with the finite rate and eddy dissipation models. Please note that the **Dimension Reduction** model is not available with the real gas models.

The UDRGM requires a library of functions written in the C programming language. Moreover, there are certain coding requirements that need to be followed when writing these functions. Sample real gas function libraries are provided to assist you in writing your own UDRGM. When UDRGM functions are compiled, they will be grouped in a shared library which later will be loaded and linked with the ANSYS FLUENT executable. The procedure for using the UDRGM is defined as follows:

1. Define the real gas equation of state and all related thermodynamic and transport property equations.
2. Create a C source code file that conforms to the format defined in this section.
3. Start ANSYS FLUENT and set up your case file in the usual way.
4. Compile your UDRGM C library and build a shared library file (you can use the available compiled UDF utilities in either the graphical user interface or the text command interface).
5. Load your newly created UDRGM library via the text command menu:

If a single-species UDRGM to be used, then the text command menu is:

```
> define/user-defined/real-gas-models/user-defined-real-gas-model  
use user defined real gas? [no] yes
```

On the other hand, if you are simulating multiple-species UDRGM flow, then the text command menu to use is:

```
> define/user-defined/real-gas-models/user-defined-multispecies-real-gas-model
use user multispecies defined real gas? [no] yes
```

Upon activating the UDRGM, the function library will now supply the fluid material properties for your case.

6. You can simulate volumetric reactions with your real gas model using the [Species Model Dialog Box \(p. 1814\)](#), or the text interface (define/models/species/volumetric-reactions?).

You can access the **Species Model** by selecting **Models** from the navigation pane and double-clicking **Species** in the task page.

In the [Species Model Dialog Box \(p. 1814\)](#)

- Enable **Species Transport** under **Model**.
- Enable **Volumetric** under **Reactions**.
- Select the appropriate **Turbulence-Chemistry Interaction** option.
- Set up the reaction by clicking the **Edit...** button for the **real-gas-mixture Mixture Material**.

Important

Note that the fluid materials and their properties, appearing in the [Create/Edit Materials Dialog Box \(p. 1882\)](#), are the ones defined in your real gas UDF. You cannot modify the materials via this dialog box, however, you can set up the volumetric reaction. If you would like to modify the mixture materials and their properties, this should be done in the real gas UDF. The volumetric reactions for your real gas mixture are defined in the same way as for any ANSYS FLUENT mixture. For details, refer to [Defining Reactions \(p. 865\)](#).

Alternatively, the chemical reactions can be set up using the define/models/species and define/materials text command.

Important

Note that the chemical reactions should be activated after your real gas UDF has been built and loaded. It is also recommended to test and validate your real gas UDF, running the cold flow calculation prior to attempting to solve the reacting flow. Also, make sure that the applicability range of the real gas functions in your UDF fully covers the temperature and pressure range of the reacting flow calculation.

7. Run your calculation.

When using the UDRGM the robustness of the solver and the speed of flow convergence will largely depend on the complexity of the material properties you have defined in your UDF. It is important to understand the operational range of the property functions you are coding so you can simulate the flow within that range.

8.16.5.2. Writing the UDRGM C Function Library

Creating a UDRGM C function library is reasonably straightforward; however, your code must make use of specific function names and macros, which will be described in detail below. The basic library requirements are as follows:

- The code must contain the `udf.h` file inclusion directive at the beginning of the source code. This allows the definitions for `DEFINE` macros and other ANSYS FLUENT functions to be accessible during the compilation process.
- The code must include at least one in the UDF's `DEFINE` functions (i.e. `DEFINE_ON_DEMAND`) to be able to use the compiled UDFs utility (see the sample UDRGM codes provided below).
- Any values that are passed to the solver by the UDRGM or returned by the solver to the UDRGM are assumed to be in SI units.
- You must use the principal set of functions listed below in your UDRGM library. These functions are the mechanism by which your thermodynamic property data are transferred to the ANSYS FLUENT solver. Note that `ANYNAME` can be any string of alphanumeric characters, and allows you to provide unique names to your library functions.

Function inputs from the ANSYS FLUENT solver consist of one or more of the following variables:

T = Temperature, K

p = Pressure, Pa

ρ = Density, kg/m³

$Y_i[]$ = Species mass fraction

Important

$Y_i[]$: ANSYS FLUENT solver returns a value of 1.0 for $Y_i[]$ in single-species flows. For multiple-species flows, $Y_i[]$ is a vector array containing species mass fraction in an order defined by the user setup function.

The UDRGM function names and argument lists, followed by a short description of the function are as follows:

`void ANYNAME_error(int err, char *f, char *msg)`
prints error messages.

`void ANYNAME_Setup(Domain *domain, cxboolean vapor_phase, char *filename, int (*messagefunc)(char *format, ...), void (*errorfunc)(char *format, ...))`
performs model setup and initialization. Can be used to read data and parameters related to your UDRGM. When writing UDFs for multiple-species, use this function to specify the number of species and the name of the species as shown in the multiple-species example. The boolean variable, `vapor_phase`, passes to your UDF the setting of the text-interface command `define/user-defined/real-gas-models/set-phase`.

`double ANYNAME_density(double T, double P, double yi[])`
returns the value of density as a function of temperature, pressure and species mass-fraction if applicable. This is your equation of state.

Important

Since this function is called numerous times during each solver iteration, it is important to make this function as numerically efficient as possible.

```
double ANYNAME_specific_heat(double T, double Rho, double P, double yi[])
    returns the real gas specific heat at constant pressure as a function of temperature, density, absolute
    pressure, and species mass-fraction if applicable.
```

```
double ANYNAME_enthalpy(double T, double Rho, double P, double yi[])
    returns the enthalpy as a function of temperature, density, absolute pressure, and species mass-fraction
    if applicable.
```

```
double ANYNAME_entropy(double T, double Rho, double P, double yi[])
    returns the entropy as a function of temperature, density, absolute pressure, and species mass-fraction
    if applicable.
```

```
double ANYNAME_mw(double yi[])
    returns the fluid molecular weight.
```

```
double ANYNAME_speed_of_sound(double T, double Rho, double P, double yi[])
    returns the value of speed of sound as a function of temperature, density, absolute pressure, and species
    mass-fraction if applicable.
```

```
double ANYNAME_viscosity(double T, double Rho, double P, double yi[])
    returns the value of dynamic viscosity as a function of temperature, density, absolute pressure, and
    species mass-fraction if applicable.
```

```
double ANYNAME_thermal_conductivity(double T, double Rho, double P, double yi[])
    returns the value of thermal conductivity as a function of temperature, density, absolute pressure, and
    species mass-fraction if applicable.
```

```
double ANYNAME_rho_t(double T, double Rho, double P, double yi[])
    returns the value of  $\frac{dp}{dT}$  at constant pressure as a function of temperature, density, absolute pressure,
    and species mass-fraction if applicable.
```

```
double ANYNAME_rho_p(double T, double Rho, double P, double yi[])
    returns the value of  $\frac{dp}{dt}$  at constant temperature as a function of temperature, density, absolute pressure,
    and species mass-fraction if applicable.
```

```
double ANYNAME_enthalpy_t(double T, double Rho, double P, double yi[])
    returns the value of  $\frac{dh}{dT}$  at constant pressure as a function of temperature, density, absolute pressure,
    and species mass-fraction if applicable. Note that by definition  $dh/dt = c_p$ , so this function should
    simply return the specific heat value.
```

```
double ANYNAME_enthalpy_p(double T, double Rho, double P, double yi[])
    returns the value of  $\frac{dh}{dp}$  at constant temperature as a function of temperature, density, absolute pressure,
    and species mass-fraction if applicable.
```

```
double ANYNAME_enthalpy_prime( double T,double Rho,double P,double yi[],double hi[])
```

returns the value of the mixture enthalpy as a function of temperature, density, absolute pressure, and species mass fraction. In addition, your UDF will need to set the elements of the double array `hi[]` to the enthalpy of each species, in the same order as they are referenced in the mass fraction array `yi[]`.

Note that the enthalpy in the function `enthalpy_prime` is defined as the sum of sensible enthalpy plus species formation enthalpy, and you should make sure that its computation is consistent with the sensible enthalpy function `ANYNAME_enthalpy`. The function `ANYNAME_enthalpy_prime` is required for the calculation of the heat of reactions, if chemical reactions are being simulated. If you are not solving reacting flows, the function `ANYNAME_enthalpy_prime` can simply be omitted.

At the end of the code you must define a structure of type `RGAS_Function` whose members are pointers to the principal functions listed above. The structure is of type `RGAS_Function` and its name is `RealGasFunctionList`.

Important

It is imperative that the sequence of function pointers shown below be followed. Otherwise, your real gas model will not load properly into the ANSYS FLUENT code.

```
UDF_EXPORT RGAS_Functions RealGasFunctionList =
{
    ANYNAME_Setup,                                /* Setup initialize */
    ANYNAME_density,                               /* density */
    ANYNAME_enthalpy,                             /* sensible enthalpy */
    ANYNAME_entropy,                            /* entropy */
    ANYNAME_specific_heat,                      /* specific_heat */
    ANYNAME_mw,                                 /* molecular_weight */
    ANYNAME_speed_of_sound,                     /* speed_of_sound */
    ANYNAME_viscosity,                           /* viscosity */
    ANYNAME_thermal_conductivity,                /* thermal_conductivity */
    ANYNAME_rho_t,                                /* drho/dT |const p */
    ANYNAME_rho_p,                                /* drho/dp |const T */
    ANYNAME_enthalpy_t,                           /* dh/dT |const p */
    ANYNAME_enthalpy_p,                           /* dh/dp |const T */
    ANYNAME_enthalpy_prime                       /* enthalpy */
};
```

If volumetric reactions are not being simulated, then the function `ANYNAME_enthalpy_prime` can be removed or ignored from the `RealGasFunctionList` structure described here.

The principal set of functions described are the only functions in the UDRGM that will be interacting directly with the ANSYS FLUENT code. In many cases, your model may require further functions that will be called from the principal function set. For example, when multiple-species real gas model UDFs are written, the principal functions will return the mixture thermodynamic properties based on some specified mixing-law. Therefore, you may want to add further functions that will return the thermodynamic properties for the individual species. These auxiliary functions will be called from the principal set of functions. See [User-Defined Real Gas Models \(UDRGM\)](#) in the [UDF Manual](#) for examples that clearly illustrate this strategy.

8.16.5.3. Compiling Your UDRGM C Functions and Building a Shared Library File

This section presents the steps you will need to follow to compile your UDRGM C code and build a shared library file. This process requires the use of a C compiler. Most Linux operating systems provide a C compiler as a standard feature. If you are using a PC, you will need to ensure that a C++ compiler is installed before you can proceed (e.g., Microsoft Visual C++, v6.0 or higher). To use the UDRGM you will need to first build the UDRGM library by compiling your UDRGM C code and then load the library

into the ANSYS FLUENT code. The UDRGM shared library is built in the same way that the ANSYS FLUENT executable itself is built. Internally, a script called `Makefile` is used to invoke the system C compiler to build an object code library that contains the native machine language translation of your higher-level C source code. This shared library is then loaded into ANSYS FLUENT (either at runtime or automatically when a case file is read) by a process called *dynamic loading*. The object libraries are specific to the computer architecture being used, as well as to the particular version of the ANSYS FLUENT executable being run. The libraries must, therefore, be rebuilt any time ANSYS FLUENT is upgraded, when the computer's operating system level changes, or when the job is run on a different type of computer.

The general procedure for compiling UDRGM C code is as follows:

- Place the UDRGM C code in the folder, i.e., where your case file resides.
- Launch ANSYS FLUENT.
- Read your case file into ANSYS FLUENT.
- You can now compile your UDRGM C code and build a shared library file using either the graphical interface or the text command interface.

Important

To build UDRGM library you will use the compiled UDF utilities. However, you will not use the UDF utilities to load the library. A separate loading area for the UDRGM library will be used.

8.16.5.3.1. Compiling the UDRGM Using the Graphical Interface

If the build is successful, then the compiled library will be placed in the appropriate architecture folder (e.g., `ntx86/2d`). By default the library name is `libudf.so` (`libudf.dll` on Windows).

More information on compiled UDFs and building libraries using the ANSYS FLUENT graphical user interface can be found in the [UDF Manual](#).

8.16.5.3.2. Compiling the UDRGM Using the Text Interface

The UDRGM library can be compiled in the text command interface as follows:

- Select the menu item `define` → `user-defined` → `compiled-functions`.
- Select the `compile` option.
- Enter the compiled UDF library name.

Important

The name given here is the name of the folder where the shared library (e.g., `libudf`) will reside. For example, if you press **Enter** then a folder should exist with the name `libudf`, and this folder will contain a library file called `libudf`. If, however, you type a new library name such as `myrealgas`, then a folder called `myrealgas` will be created and it will contain the library `libudf`.

- Continue on with the procedure when prompted.
- Enter the C source file names.

Important

Ideally you should place all of your functions into a single file. However, you can split them into separate files if desired.

- Enter the header file names, if applicable. If you do not have an extra header file then hit **Enter** when prompted.

ANSYS FLUENT will then start compiling the UDRGM C code and put it in the appropriate architecture folder.

Example:

```
> define/user-defined/compiled-functions
  load OR compile ? [load] compile

Compiled UDF library name: ["libudf"] my_lib

Make sure that UDF source files are in the folder
that contains your case and data files. If you have
an existing libudf folder, please remove this
folder to ensure that latest files are used.

Continue?[yes] RETURN

Give C-Source file names:
First file name: ["] my_c_file.c RETURN

Next file name: ["] RETURN

Give header file names:
First file name: ["] my_header_file.h RETURN
```

8.16.5.3.3. Loading the UDRGM Shared Library File

Load the UDRGM library:

- Go to the following menu item in the text command interface.

```
define → user-defined → real-gas-models
```

- Select one of the following
 - user-defined-real-gas-model if you are modeling a single-species real gas fluid
 - user-defined-multispecies-real-gas-model if you are modeling a multiple-species fluid-mixture
- Turn on the real gas model.
 - For single-species:

```
use user defined real gas? [no] yes
```

- For multiple-species:

```
use multispecies user defined real gas? [no] yes
```

ANSYS FLUENT will ask for the location of the user-defined real gas library. You can enter either the name of the folder where the UDRGM shared library is called or the entire path to the UDRGM shared library.

If the loading of the UDRGM library is successful you will see a message similar to the following:

```
Opening user-defined realgas library "RealgasLibraryname"...
Library "RealgasDirName/lnamd64/2d/libudf.so" opened
Setting material "air" to a real-gas...
Loading Real-RealGasPrefexLable Library:
```

8.16.5.4. UDRGM Example: Ideal Gas Equation of State

This section describes an example of a user-defined real gas model. You can use this example as the basis for your own UDRGM code. In this simple example, the standard ideal gas equation of state is used in the UDRGM. See [User-Defined Real Gas Models \(UDRGM\)](#) in the [UDF Manual](#) for more examples of UDRGM functions, including multi-species real gas and reacting real-gas examples.

p = pressure

T = temperature

C_p = specific heat

H = enthalpy

S = entropy

ρ = density

c = speed of sound

R = universal gas constant/molecular weight

The ideal gas equation of state can be written in terms of pressure and temperature as

$$\rho = \frac{p}{RT} \quad (8-107)$$

The specific heat is defined to be constant $C_p = 1006.42$.

The enthalpy is, therefore, defined as

$$H = C_p T \quad (8-108)$$

and entropy is given by

$$S = C_p \log \left(\frac{T}{T_{ref}} \right) + R \log \left(\frac{p_{ref}}{p} \right) \quad (8-109)$$

where $T_{ref} = 288.15$ K and $p_{ref} = 101325$ Pa

The speed of sound is simply defined as

$$c = \sqrt{TC_p \frac{R}{(C_p - R)}} \quad (8-110)$$

The density derivatives are:

$$\left(\frac{d\rho}{dp}\right)_T = \frac{1}{RT} \quad (8-111)$$

$$\left(\frac{d\rho}{dT}\right)_p = -\frac{p}{RT^2} = -\frac{\rho}{T} \quad (8-112)$$

The enthalpy derivatives are:

$$\left(\frac{dH}{dT}\right)_p = C_p \quad (8-113)$$

$$\left(\frac{dH}{dp}\right)_T = \frac{C_p}{\rho R} \left[1 - \frac{p}{\rho} \frac{d\rho}{dp} \right] = 0 \quad (8-114)$$

When you activate the real gas model and load the library successfully into ANSYS FLUENT, you will be using the equation of state and other fluid properties from this library rather than the one built into the ANSYS FLUENT code.

8.16.5.4.1. Ideal Gas UDRGM Code Listing

```
/*
 * User Defined Real Gas Model :
 * For Ideal Gas Equation of State
 */

8.16.5.5. Additional UDRGM Examples

You can find the following additional UDRGM examples in the [UDF Manual](#):

- The Aungier Redlich Kwong equation of state for single component flow. See [UDRGM Example: Redlich-Kwong Equation of State](#) in the [UDF Manual](#) for details.
- A simple example of a multi-species real-gas model. See [UDRGM Example: Multiple-Species Real Gas Model](#) in the [UDF Manual](#) for details.
- A real gas model example with the Aungier Redlich Kwong equation of state, ideal gas mixing rules and volumetric reactions. See [UDRGM Example: Real Gas Model with Volumetric Reactions](#) in the [UDF Manual](#) for details.

Chapter 9: Modeling Basic Fluid Flow

This chapter describes the basic physical models that ANSYS FLUENT provides for fluid flow and the commands for defining and using them. Models for flows in moving zones (including sliding and dynamic meshes) are explained in [Modeling Flows with Moving Reference Frames \(p. 535\)](#), models for turbulence are described in [Modeling Turbulence \(p. 683\)](#), and models for heat transfer (including radiation) are presented in [Modeling Heat Transfer \(p. 737\)](#). An overview of modeling species transport and reacting flows is provided in [Modeling Species Transport and Finite-Rate Chemistry \(p. 855\)](#), details about models for species transport and reacting flows are described in [Modeling Species Transport and Finite-Rate Chemistry \(p. 855\) – Modeling a Composition PDF Transport Problem \(p. 975\)](#), and models for pollutant formation are presented in [Modeling Pollutant Formation \(p. 1009\)](#). The discrete phase model is described in [Modeling Discrete Phase \(p. 1075\)](#), general multiphase models are described in [Modeling Multiphase Flows \(p. 1173\)](#), and the melting and solidification model is described in [Modeling Solidification and Melting \(p. 1297\)](#). For information on modeling porous media, porous jumps, and lumped parameter fans and radiators, see [Cell Zone and Boundary Conditions \(p. 211\)](#).

The information in this chapter is presented in the following sections:

- 9.1. User-Defined Scalar (UDS) Transport Equations
- 9.2. Periodic Flows
- 9.3. Swirling and Rotating Flows
- 9.4. Compressible Flows
- 9.5. Inviscid Flows

9.1. User-Defined Scalar (UDS) Transport Equations

For additional information, please see the following sections:

- 9.1.1. Introduction
- 9.1.2. UDS Theory
- 9.1.3. Setting Up UDS Equations in ANSYS FLUENT

9.1.1. Introduction

ANSYS FLUENT can solve the transport equation for an arbitrary, user-defined scalar (UDS) in the same way that it solves the transport equation for a scalar such as species mass fraction. Extra scalar transport equations may be needed in certain types of combustion applications or for example in plasma-enhanced surface reaction modeling. ANSYS FLUENT allows you to define additional scalar transport equations in your model in the [User-Defined Scalars Dialog Box \(p. 2271\)](#).

9.1.2. UDS Theory

UDS theory is described in the following sections:

- 9.1.2.1. Single Phase Flow
- 9.1.2.2. Multiphase Flow

9.1.2.1. Single Phase Flow

For an arbitrary scalar ϕ_k , ANSYS FLUENT solves the equation

$$\frac{\partial \rho \phi_k}{\partial t} + \frac{\partial}{\partial x_i} \left(\rho u_i \phi_k - \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \dots, N \quad (9-1)$$

where Γ_k and S_{ϕ_k} are the diffusion coefficient and source term supplied by you for each of the N scalar equations. Note that Γ_k is defined as a tensor in the case of anisotropic diffusivity. The diffusion term is thus $\nabla \cdot (\Gamma_k \cdot \phi_k)$

For isotropic diffusivity, Γ_k could be written as $\Gamma_k I$ where I is the identity matrix.

For the steady-state case, ANSYS FLUENT will solve one of the three following equations, depending on the method used to compute the convective flux:

- If convective flux is *not* to be computed, ANSYS FLUENT will solve the equation

$$-\frac{\partial}{\partial x_i} \left(\Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi_k} \quad k = 1, \dots, N \quad (9-2)$$

where Γ_k and S_{ϕ_k} are the diffusion coefficient and source term supplied by you for each of the N scalar equations.

- If convective flux is to be computed with mass flow rate, ANSYS FLUENT will solve the equation

$$\frac{\partial}{\partial x_i} \left(\rho u_i \phi_k - \Gamma_k \frac{\partial \phi_k}{\partial x_i} \right) = S_{\phi} \quad k = 1, \dots, N \quad (9-3)$$

- It is also possible to specify a user-defined function to be used in the computation of convective flux. In this case, the user-defined mass flux is assumed to be of the form

$$F = \int_S \rho \vec{u} \cdot d\vec{S} \quad (9-4)$$

where $d\vec{S}$ is the face vector area.

Important

User-defined scalars in solid zones do not take into account the convective term with moving reference frames.

9.1.2.2. Multiphase Flow

For multiphase flows, ANSYS FLUENT solves transport equations for two types of scalars: *per phase* and *mixture*. For an arbitrary k scalar in *phase-l*, denoted by ϕ_l^k , ANSYS FLUENT solves the transport equation inside the volume occupied by *phase-l*

$$\frac{\partial \alpha_l \rho_l \phi_l^k}{\partial t} + \nabla \cdot (\alpha_l \rho_l \vec{u}_l \phi_l^k - \alpha_l \Gamma_l^k \nabla \phi_l^k) = S_l^k \quad k = 1, \dots, N \quad (9-5)$$

where α_l , ρ_l , and \vec{u}_l are the volume fraction, physical density, and velocity of *phase-l*, respectively. Γ_l^k and S_l^k are the diffusion coefficient and source term, respectively, which you will need to specify. In this case, scalar ϕ_l^k is associated only with one phase (*phase-l*) and is considered an individual field variable of *phase-l*.

The mass flux for *phase-l* is defined as

$$F_l = \int_S \alpha_l \rho_l \vec{u}_l \cdot d\vec{S} \quad (9-6)$$

If the transport variable described by scalar ϕ_l^k represents the physical field that is shared between phases, or is considered the same for each phase, then you should consider this scalar as being associated with a mixture of phases, ϕ^k . In this case, the generic transport equation for the scalar is

$$\frac{\partial \rho_m \phi^k}{\partial t} + \nabla \cdot (\rho_m \vec{u}_m \phi^k - \Gamma_m^k \nabla \phi^k) = S^k \quad k = 1, \dots, N \quad (9-7)$$

where mixture density ρ_m , mixture velocity \vec{u}_m , and mixture diffusivity for the scalar k Γ_m^k are calculated according to

$$\rho_m = \sum_l \alpha_l \rho_l \quad (9-8)$$

$$\rho_m \vec{u}_m = \sum_l \alpha_l \rho_l \vec{u}_l \quad (9-9)$$

$$F_m = \int_S \rho_m \vec{u}_m \cdot d\vec{S} \quad (9-10)$$

$$\Gamma_m^k = \sum_l \alpha_l \Gamma_l^k \quad (9-11)$$

$$S_m^k = \sum_l S_l^k \quad (9-12)$$

To calculate mixture diffusivity, you will need to specify individual diffusivities for each material associated with individual phases.

Note that if the user-defined mass flux option is activated, then mass fluxes shown in [Equation 9–6 \(p. 507\)](#) and [Equation 9–10 \(p. 508\)](#) will need to be replaced in the corresponding scalar transport equations. For more information about the theoretical background of user-defined scalar transport equations, see [User-Defined Scalar \(UDS\) Transport Equations](#) in the [Theory Guide](#).

9.1.3. Setting Up UDS Equations in ANSYS FLUENT

ANSYS FLUENT allows you to define up to 50 user-defined scalar (UDS) transport equations in your model. The general scalar transport equation, [Equation 1–8](#) in the [Theory Guide](#), is shown below with the four terms (transient, flux, diffusivity, source) that you can customize. ([Equation 9–13 \(p. 508\)](#)). You will define a UDS transport equation by setting the parameters for these four terms.

$$\underbrace{\frac{\partial \rho \phi_k}{\partial t}}_{unsteady} + \frac{\partial}{\partial x_i} \begin{pmatrix} \underbrace{F_i \phi_k}_{convection} & -\Gamma_k \underbrace{\frac{\partial \phi_k}{\partial x_i}}_{diffusion} \end{pmatrix} = \underbrace{S_{\phi_k}}_{sources} \quad k=1, \dots, N_{scalars} \quad (9-13)$$

In addition, you can set boundary conditions for the variables within cells of a fluid or solid zone for a particular scalar equation. This is done by fixing the value of ϕ_k in [Equation 9–13 \(p. 508\)](#). When ϕ_k is fixed in a given cell, the UDS scalar transport is not solved and the cell is not included when the residual sum is computed. Additionally, you can also specify custom boundary conditions in the mixture on all wall, inflow, and outflow boundaries on a per-scalar basis.

The procedures for setting up a user-defined scalar (UDS) equation for single-phase and multiphase flows are outlined below. Note that a significant difference between a UDS for a single-phase versus a multiphase application is that you will need to associate each UDS with its corresponding phase domain or mixture domain, depending on your application. If you supply UDFs for transient terms, convective

fluxes, and sources, you will need to be aware that they are directly called from the phase or mixture domains, according to the scalar association settings.

See the [UDF Manual](#) for information on using UDFs to define scalar quantities.

9.1.3.1. Single Phase Flow

- Specify the number of UDS equations you require in the [User-Defined Scalars Dialog Box \(p. 2271\) \(Figure 9.1 \(p. 509\)\)](#).

Define → User-Defined → Scalars...

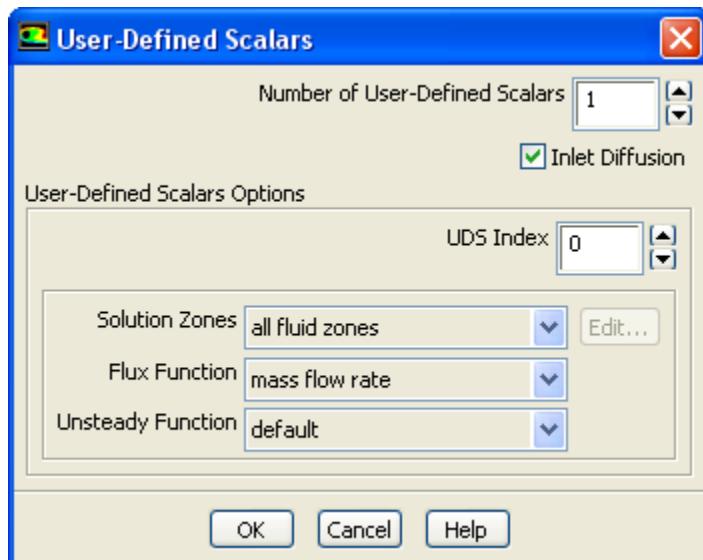

Important

The maximum number of user-defined scalar transport equations you can define is 50. ANSYS FLUENT assigns numbers to the equations starting with 0.

Important

Note that ANSYS FLUENT assigns a default name for each scalar equation (User Scalar 0, User Scalar 1, etc.). These labels will appear in graphics dialog boxes in ANSYS FLUENT. You can change them by means of a UDF. See the [UDF Manual](#) for details.

Figure 9.1 The User-Defined Scalars Dialog Box

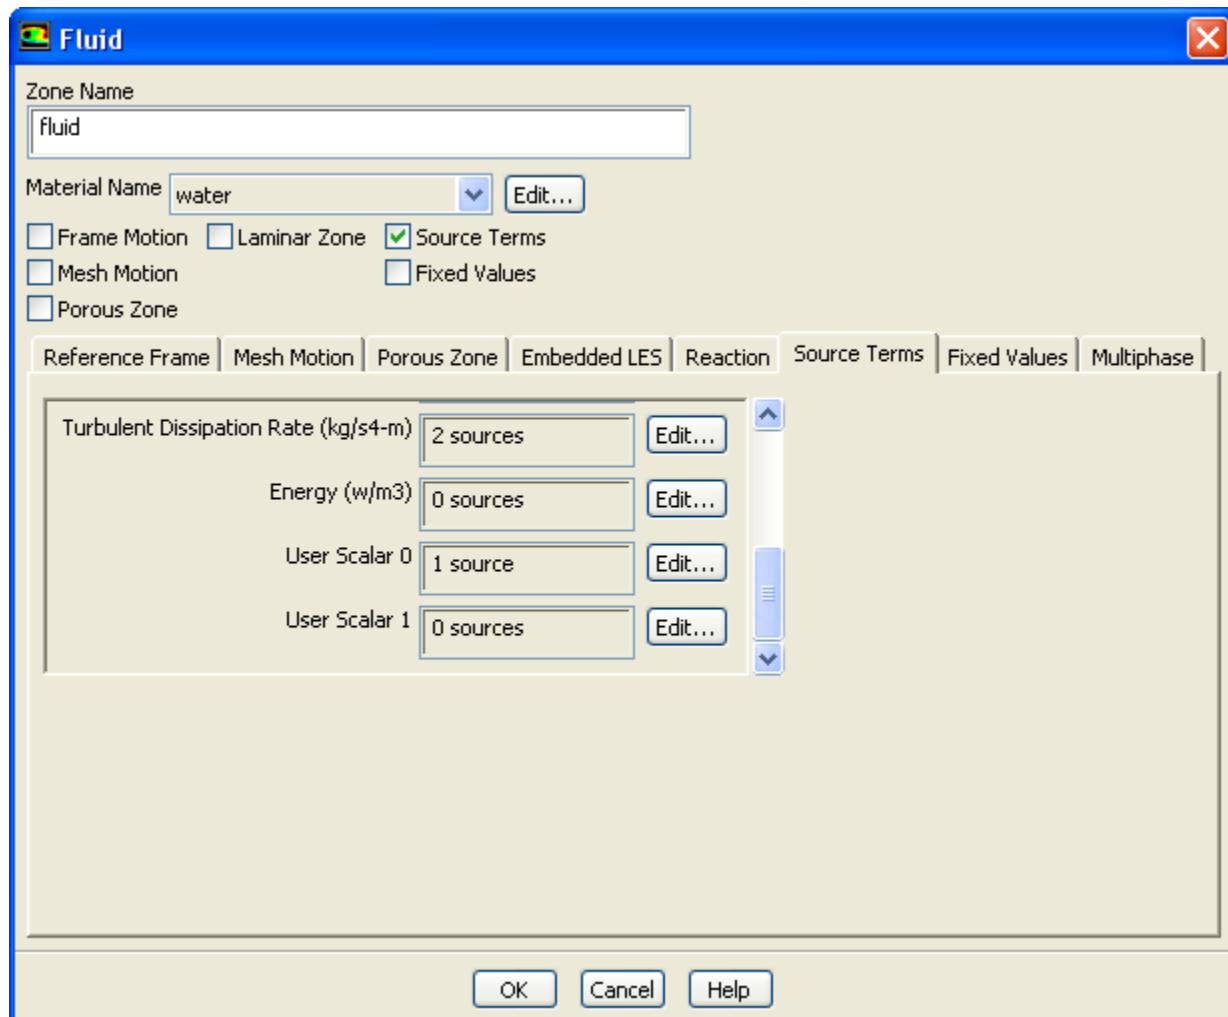

- Enable **Inlet Diffusion** if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.
- Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.
 - Specify the **Solution Zones** you want the scalar equation to be solved in as **all fluid zones**, **all solid zones**, **all zones** (fluid and solid) or **selected zones**. If you choose **selected zones**, click the **Edit** button to view the list of zones you can select.
 - Specify the **Flux Function** to be **none**, **mass flow rate**, or a user-defined function (UDF). The **Flux Function** determines how the convective flux is computed, which determines the equation that

ANSYS FLUENT solves for the user-defined scalar. Selecting **none**, **mass flow rate**, or a user-defined function results in ANSYS FLUENT solving [Equation 1–9](#), [Equation 1–10](#), or [Equation 1–11](#), respectively (in the [Theory Guide](#)). See the [UDF Manual](#) for details on flux UDFs.

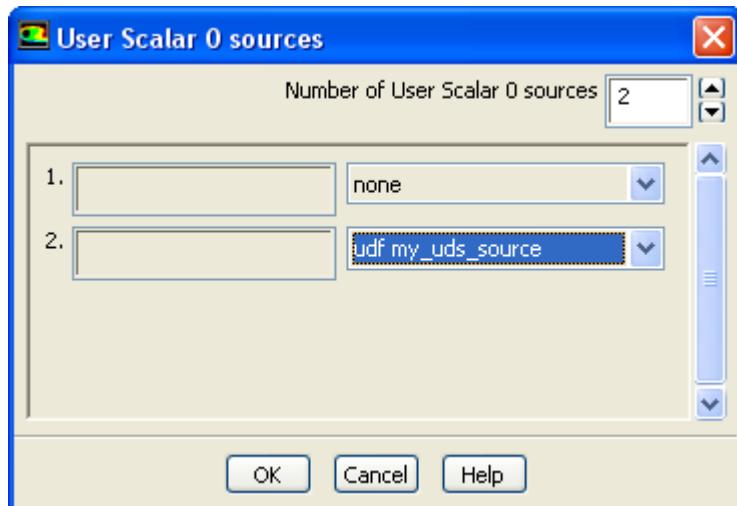

- c. Specify the **Unsteady Function** to be **none**, **default**, or a user-defined function (UDF). Select **none** for a steady state solution and **default** if you want the transient term in [Equation 1–8](#) in the [Theory Guide](#)). See the separate [UDF Manual](#) for details on unsteady UDFs.
 - d. Repeat this process for each scalar equation by incrementing the **UDS Index**.
 - e. Click **OK** when all user scalar equations have been defined.
4. To specify source term(s) for each of the N UDS equations, enable the **Source Terms** option in the **Fluid** or **Solid** dialog box ([Figure 9.2 \(p. 510\)](#)) and click the **Source Terms** tab. The source parameters will be displayed.

Cell Zone Conditions

Figure 9.2 The Fluid Dialog Box with Inputs for Source Terms for a User-Defined Scalar

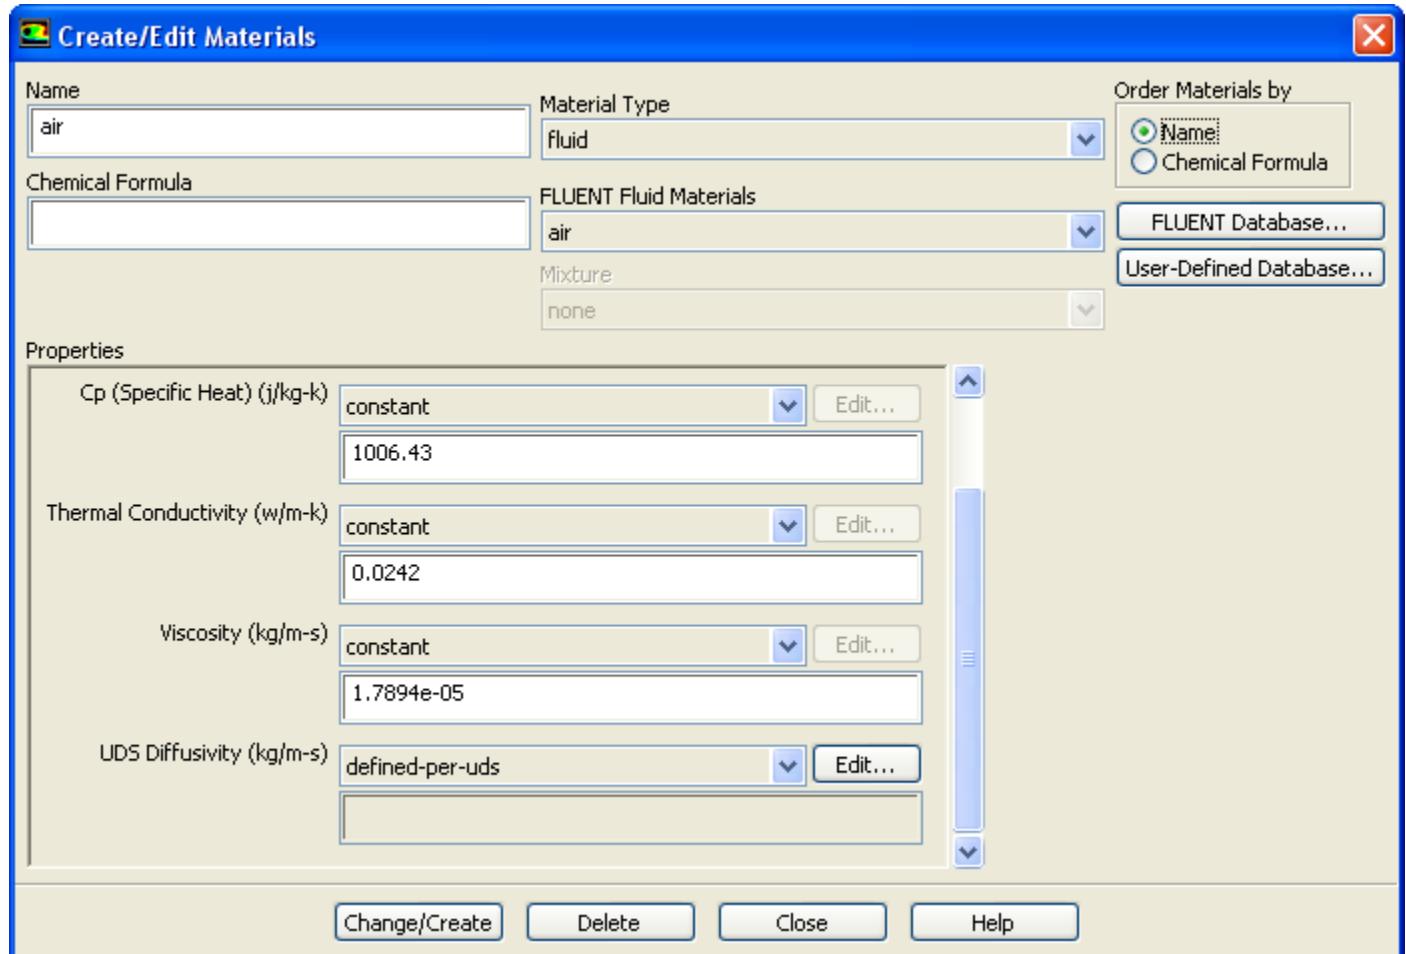

- a. Specify the number of sources you require for each scalar equation by clicking on the **Edit...** button next to the scalar name (e.g., **User Scalar 0**). This will open the **User Scalar 0 sources** dialog box ([Figure 9.3 \(p. 511\)](#)).

Figure 9.3 The User Scalar Sources Dialog Box

- b. Specify the **Number of User Scalar Sources** for the scalar equation by incrementing the counter. Based on the value you have chosen, the sources will be added to the list in the dialog box. Specify each source to be **none**, **constant**, or a user-defined function (UDF). For details on defining a UDF scalar source, see the [UDF Manual](#). Click **OK** when you have specified all scalar sources.
- 5. To specify diffusivity for each of the N UDS equations, display the [Materials Task Page \(p. 1880\)](#) ([Figure 9.4 \(p. 512\)](#)) and select either **defined-per-uds** (the default) or **user-defined** in the drop-down list for **UDS Diffusivity**.

[Materials](#) → [Create/Edit](#)

Figure 9.4 The Materials Dialog Box with Input for Diffusivity for UDS Equations

See [User-Defined Scalar \(UDS\) Diffusivity \(p. 446\)](#) for details on the different options available to you for defining diffusion coefficients.

6. To specify boundary conditions for the user-defined scalars on wall, inflow, and outflow boundaries, you can define a specific value or a specific flux for each scalar. A coupled boundary condition can be specified on two-sided walls for scalars that are to be solved in regions on both sides of the wall (i.e., scalars solved in both **fluid** and **solid** zones).

Boundary Conditions

- a. In the **UDS** tab under **User Defined Scalar Boundary Condition**, select either **Specified Flux** or **Specified Value** in the drop-down list next to each scalar (e.g., **User Scalar 0**) for a boundary wall. For interior walls, select **Coupled Boundary** if the scalars are to be solved on both sides of a two-sided wall. Note that the **Coupled Boundary** option will only show up in the drop-down list if the scalar is defined in the **fluid** and **solid** zones in the [User-Defined Scalars Dialog Box \(p. 2271\)](#).
- b. Under **User Defined Scalar Boundary Value**, enter a constant value or select a user-defined function from the drop-down list for each scalar. If you select **Specified Flux**, your input will be the value of the flux at the boundary (i.e., the negative of the term in parenthesis on the left hand side of [Equation 1–9](#) in the [Theory Guide](#)) dot [as in the dot product of] n [as in the vector, n], where n is the normal into the domain). If you select **Specified Value**, your input will be the value of the scalar itself at the boundary. See the [UDF Manual](#) for information on using UDFs for UDS boundary conditions.

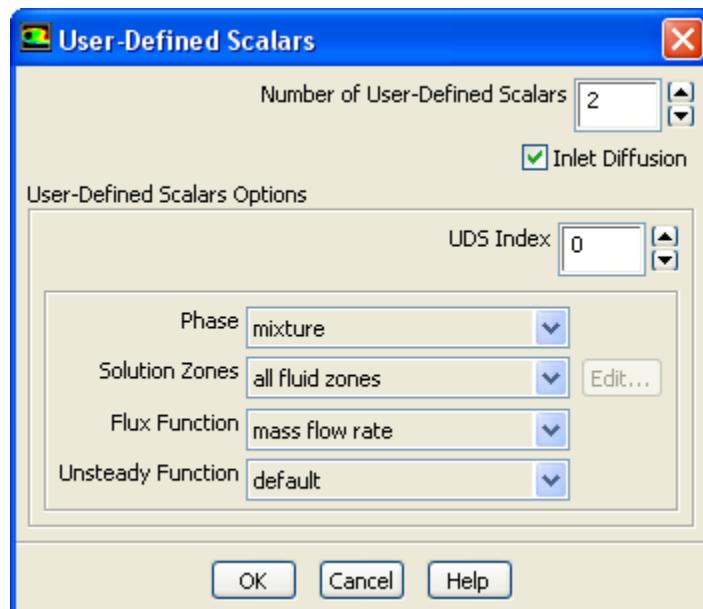

7. Set the solution parameters in the **Solution Controls** task page, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.
8. Examine the results using the usual postprocessing tools. In each postprocessing dialog box, the list of field variables will include the **User Defined Scalars...** category, which contains the value of each UDS and its diffusion coefficient (Γ_k in [Equation 1–8](#), [Equation 1–9](#), [Equation 1–10](#), or [Equation 1–11](#) in the [Theory Guide](#)):
 - **User Scalar-n**
 - **Diffusion Coef. of Scalar-n**

9.1.3.2. Multiphase Flow

1. Specify the number of scalars in the [User-Defined Scalars Dialog Box \(p. 2271\)](#) ([Figure 9.5 \(p. 513\)](#)).

Define → **User-Defined** → **Scalars...**

Figure 9.5 The User-Defined Scalars Dialog Box for a Multiphase Flow

Important

The maximum number of user-defined scalar transport equations you can define is 50. ANSYS FLUENT assigns numbers to the equations starting with 0. The default association type is set to **mixture** for all scalars.

Important

Note that ANSYS FLUENT assigns a default name for each scalar equation (**User Scalar 0**, **User Scalar 1**, etc.). These labels will appear in graphics dialog boxes in ANSYS FLUENT. You can change them by means of a UDF. See the [UDF Manual](#) for details.

2. Keep the default **Inlet Diffusion** enabled if you want to include the diffusion term in the UDS transport equation for all inflow and outflow boundaries.
3. Set the first user-defined scalar equation parameters by making sure that the **UDS Index** is set to 0.
 - a. Select the **Phase** you want the scalar equation solved in as a primary phase, secondary phase, or the mixture.
 - b. Specify the **Solution Zones** you want the scalar equation to be solved in as **all fluid zones, all solid zones, all zones** (fluid and solid) or **selected zones**. If you choose **selected zones**, click the **Edit** button to view the list of zones you can select.
 - c. Specify the **Flux Function** to **Unsteady Function** the same way as you would for a single phase flow (see above).
 - d. Repeat this process for each scalar equation by incrementing the **UDS Index**.
 - e. Click **OK** when all user scalar equations have been defined.
4. Specify source term(s) for each of the N UDS equations in the **Fluid** or **Solid** dialog box as described for a single phase flow (see above).
5. Specify boundary conditions for the user-defined scalars in the mixture on all wall, inflow, and outflow boundary as described for a single phase flow (see above).
6. Set the solution parameters, specify an initial value for each UDS (as you do for all other scalar transport equations), and calculate a solution.

9.2. Periodic Flows

Periodic flow occurs when the physical geometry of interest and the expected pattern of the flow/thermal solution have a periodically repeating nature. Two types of periodic flow can be modeled in ANSYS FLUENT. In the first type, no pressure drop occurs across the periodic planes. In the second type, a pressure drop occurs across translationally periodic boundaries, resulting in "fully-developed" or "streamwise-periodic" flow.

This section discusses streamwise-periodic flow. A description of no-pressure-drop periodic flow is provided in [Periodic Boundary Conditions \(p. 336\)](#), and a description of streamwise-periodic heat transfer is provided in [Modeling Periodic Heat Transfer \(p. 813\)](#).

Information about streamwise-periodic flow is presented in the following sections:

- [9.2.1. Overview and Limitations](#)
- [9.2.2. User Inputs for the Pressure-Based Solver](#)
- [9.2.3. User Inputs for the Density-Based Solvers](#)
- [9.2.4. Monitoring the Value of the Pressure Gradient](#)
- [9.2.5. Postprocessing for Streamwise-Periodic Flows](#)

For more information about the theoretical background of periodic flows, see [Periodic Flows](#) in the [Theory Guide](#).

9.2.1. Overview and Limitations

More information about periodic flows is presented in the following sections:

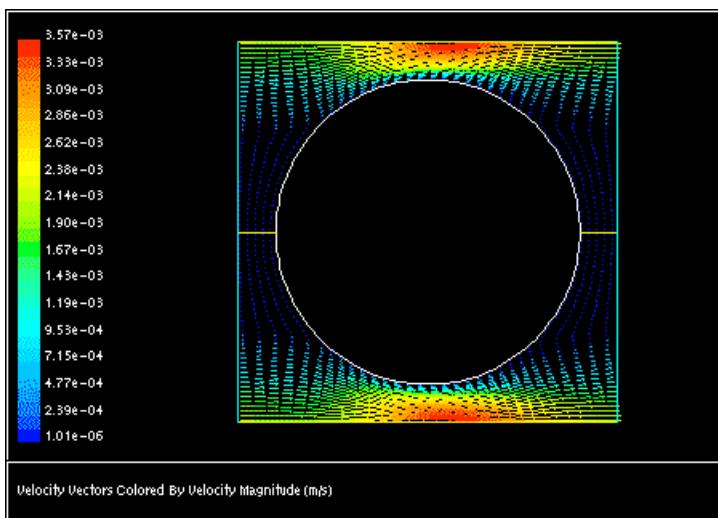

- [9.2.1.1. Overview](#)
- [9.2.1.2. Limitations for Modeling Streamwise-Periodic Flow](#)

9.2.1.1. Overview

ANSYS FLUENT provides the ability to calculate streamwise-periodic—or “fully-developed”—fluid flow. These flows are encountered in a variety of applications, including flows in compact heat exchanger channels and flows across tube banks. In such flow configurations, the geometry varies in a repeating manner along the direction of the flow, leading to a periodic fully-developed flow regime in which the flow pattern repeats in successive cycles. Other examples of streamwise-periodic flows include fully-developed flow in pipes and ducts. These periodic conditions are achieved after a sufficient entrance length, which depends on the flow Reynolds number and geometric configuration.

Streamwise-periodic flow conditions exist when the flow pattern repeats over some length L , with a constant pressure drop across each repeating module along the streamwise direction. [Figure 9.6 \(p. 515\)](#) depicts one example of a periodically repeating flow of this type which has been modeled by including a single representative module.

Figure 9.6 Example of Periodic Flow in a 2D Heat Exchanger Geometry

9.2.1.2. Limitations for Modeling Streamwise-Periodic Flow

The following limitations apply to modeling streamwise-periodic flow:

- The flow must be incompressible.
- When performing unsteady-state simulations with translational periodic boundary conditions, the specified pressure gradient is recommended.
- If one of the density-based solvers is used, you can specify only the pressure jump; for the pressure-based solver, you can specify either the pressure jump or the mass flow rate.
- No net mass addition through inlets/exits or extra source terms is allowed.
- Species can be modeled only if inlets/exits (without net mass addition) are included in the problem. Reacting flows are not permitted.
- Steady particle tracks can be modeled only if the particles have a possibility to leave the domain without generating incomplete trajectories.
- While Eulerian multiphase can be modeled with translational periodic boundary conditions, you cannot use the mass flow rate specification method. However, you can specify a constant pressure gradient.

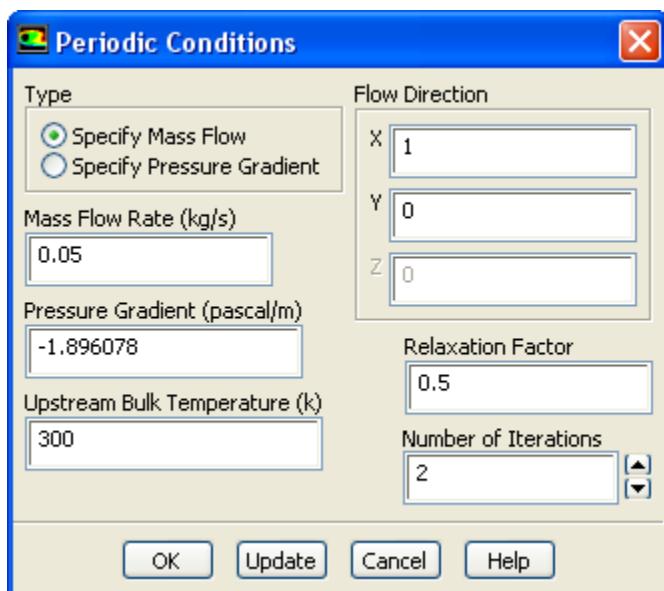

9.2.2. User Inputs for the Pressure-Based Solver

If you are using the pressure-based solver, in order to calculate a spatially periodic flow field with a specified mass flow rate or pressure derivative, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. You can specify translational periodicity in the [Periodic Conditions Dialog Box \(p. 2020\)](#), as described in [Periodic Boundary Conditions \(p. 336\)](#). (If you need to create periodic boundaries, see [Creating Conformal Periodic Zones \(p. 195\)](#).)

In the [Periodic Conditions Dialog Box \(p. 2020\)](#) which is opened from the [Boundary Conditions Task Page \(p. 1958\)](#), you will complete the following inputs after the mesh has been read into ANSYS FLUENT ([Figure 9.7 \(p. 516\)](#)):

Boundary Conditions → Periodic Conditions...

Figure 9.7 The Periodic Conditions Dialog Box

1. Select either the specified mass flow rate (**Specify Mass Flow**) option or the specified pressure gradient (**Specify Pressure Gradient**) option. For most problems, the mass flow rate across the periodic boundary will be a known quantity; for others, the mass flow rate will be unknown, but the pressure gradient (β in [Equation 1–22](#), in the [Theory Guide](#)) will be a known quantity.
2. Specify the mass flow rate and/or the pressure gradient (β in [Equation 1–22](#), in the [Theory Guide](#)):
 - If you selected the **Specify Mass Flow** option, enter the desired value for the **Mass Flow Rate**. You can also specify an initial guess for the **Pressure Gradient**, but this is not required.

Important

For axisymmetric problems, the mass flow rate is per 2π radians.

- If you selected the **Specify Pressure Gradient** option, enter the desired value for **Pressure Gradient**.

3. Define the flow direction by setting the **X,Y,Z** (or **X,Y** in 2D) point under **Flow Direction**. The flow will move in the direction of the vector pointing from the origin to the specified point. The direction vector must be parallel to the periodic translation direction or its opposite.
4. If you chose in step 1 to specify the mass flow rate, set the parameters used for the calculation of β . These parameters are described in detail below.

After completing these inputs, you can solve the periodic velocity field to convergence.

9.2.2.1. Setting Parameters for the Calculation of β

If you choose to specify the mass flow rate, ANSYS FLUENT will need to calculate the appropriate value of the pressure gradient β . You can control this calculation by specifying the **Relaxation Factor** and the **Number of Iterations**, and by supplying an initial guess for β . All of these inputs are entered in the *Periodic Conditions Dialog Box* (p. 2020).

The **Number of Iterations** sets the number of sub-iterations performed on the correction of β in the pressure correction equation. Because the value of β is not known a priori, it must be iterated on until the **Mass Flow Rate** that you have defined is achieved in the computational model. This correction of β occurs in the pressure correction step of the SIMPLE, SIMPLEC, or PISO algorithm. A correction to the current value of β is calculated based on the difference between the desired mass flow rate and the actual one. The sub-iterations referred to here are performed within the pressure correction step to improve the correction for β before the pressure correction equation is solved for the resulting pressure (and velocity) correction values. The default value of 2 sub-iterations should suffice in most problems, but can be increased to help speed convergence. The **Relaxation Factor** is an under-relaxation factor that controls convergence of this iteration process.

You can also speed up convergence of the periodic calculation by supplying an initial guess for β in the **Pressure Gradient** field. Note that the current value of β will be displayed in this field if you have performed any calculations. To update the **Pressure Gradient** field with the current value at any time, click the **Update** button.

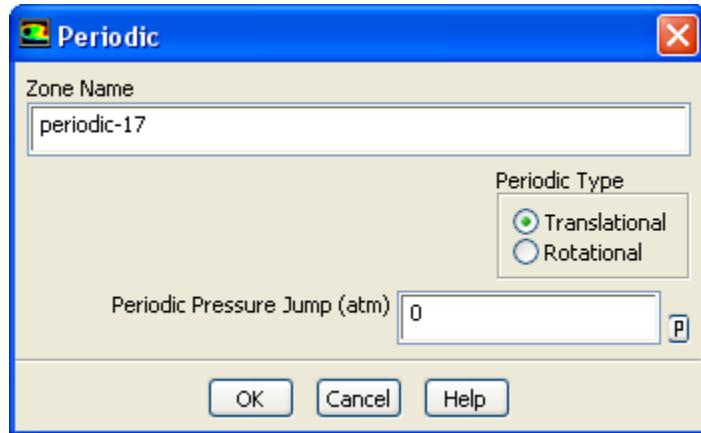

9.2.3. User Inputs for the Density-Based Solvers

If you are using one of the density-based solvers, in order to calculate a spatially periodic flow field with a specified pressure jump, you must first create a mesh with translationally periodic boundaries that are parallel to each other and equal in size. (If you need to create periodic boundaries, see *Creating Conformal Periodic Zones* (p. 195).)

Then, follow the steps below:

1. In the *Periodic Dialog Box* (p. 1988) (*Figure 9.8* (p. 518)), which is opened from the **Boundary Conditions** task page, indicate that the periodicity is **Translational** (the default).

Figure 9.8 The Periodic Dialog Box

- Also in the *Periodic Dialog Box* (p. 1988), set the **Periodic Pressure Jump** (Δp in [Equation 1–21](#) in the Theory Guide).

After completing these inputs, you can solve the periodic velocity field to convergence.

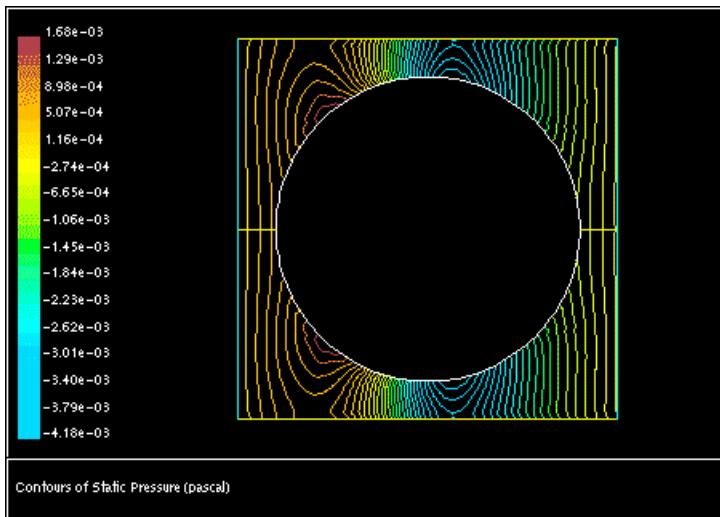

9.2.4. Monitoring the Value of the Pressure Gradient

If you have specified the mass flow rate, you can monitor the value of the pressure gradient β during the calculation using the *Statistic Monitors Dialog Box* (p. 2068). Select **per/pr-grad** as the variable to be monitored. See [Monitoring Statistics](#) (p. 1389) for details about using this feature.

9.2.5. Postprocessing for Streamwise-Periodic Flows

For streamwise-periodic flows, the velocity field should be completely periodic. If a density-based solver is used to compute the periodic flow, the pressure field reported will be the actual pressure p (which is not periodic). If the pressure-based solver is used, the pressure field reported will be the periodic pressure field \tilde{p} (\vec{r}) of [Equation 1–22](#), in the Theory Guide. [Figure 9.9](#) (p. 519) displays the periodic pressure field in the geometry of [Figure 9.6](#) (p. 515).

If you specified a mass flow rate and had ANSYS FLUENT calculate the pressure gradient, you can check the pressure gradient in the streamwise direction (β) by looking at the current value for **Pressure Gradient** in the *Periodic Conditions Dialog Box* (p. 2020).

Figure 9.9 Periodic Pressure Field Predicted for Flow in a 2D Heat Exchanger Geometry

9.3. Swirling and Rotating Flows

Many important engineering flows involve swirl or rotation and ANSYS FLUENT is well-equipped to model such flows. Swirling flows are common in combustion, with swirl introduced in burners and combustors in order to increase residence time and stabilize the flow pattern. Rotating flows are also encountered in turbomachinery, mixing tanks, and a variety of other applications.

Information about rotating and swirling flows is provided in the following subsections:

- [9.3.1. Overview of Swirling and Rotating Flows](#)
- [9.3.2. Turbulence Modeling in Swirling Flows](#)
- [9.3.3. Mesh Setup for Swirling and Rotating Flows](#)
- [9.3.4. Modeling Axisymmetric Flows with Swirl or Rotation](#)

For more information about the theoretical background of swirling and rotating flows, see [Swirling and Rotating Flows](#) in the [Theory Guide](#).

When you begin the analysis of a rotating or swirling flow, it is essential that you classify your problem into one of the following five categories of flow:

- axisymmetric flows with swirl or rotation
- fully three-dimensional swirling or rotating flows
- flows requiring a moving reference frame
- flows requiring multiple moving reference frames or mixing planes
- flows requiring sliding meshes

Modeling and solution procedures for the first two categories are presented in this section. The remaining three, which all involve “moving zones”, are discussed in [Modeling Flows with Moving Reference Frames](#) (p. 535).

9.3.1. Overview of Swirling and Rotating Flows

An overview of swirling and rotating flows is presented in the following sections:

- [9.3.1.1. Axisymmetric Flows with Swirl or Rotation](#)
- [9.3.1.2. Three-Dimensional Swirling Flows](#)

9.3.1.3. Flows Requiring a Moving Reference Frame

9.3.1.1.1. Axisymmetric Flows with Swirl or Rotation

Your problem may be axisymmetric with respect to geometry and flow conditions but still include swirl or rotation. In this case, you can model the flow in 2D (i.e., solve the axisymmetric problem) and include the prediction of the circumferential (or swirl) velocity. It is important to note that while the assumption of axisymmetry implies that there are no circumferential gradients in the flow, there may still be non-zero swirl velocities.

9.3.1.1.1.1. Momentum Conservation Equation for Swirl Velocity

The tangential momentum equation for 2D swirling flows may be written as

$$\frac{\partial}{\partial t}(\rho w) + \frac{1}{r} \frac{\partial}{\partial x}(r \rho u w) + \frac{1}{r} \frac{\partial}{\partial r}(r \rho v w) = \frac{1}{r} \frac{\partial}{\partial x} \left[r \mu \frac{\partial w}{\partial x} \right] + \frac{1}{r^2} \frac{\partial}{\partial r} \left[r^3 \mu \frac{\partial}{\partial r} \left(\frac{w}{r} \right) \right] - \rho \frac{v w}{r} \quad (9-14)$$

where x is the axial coordinate, r is the radial coordinate, u is the axial velocity, v is the radial velocity, and w is the swirl velocity.

9.3.1.2. Three-Dimensional Swirling Flows

When there are geometric changes and/or flow gradients in the circumferential direction, your swirling flow prediction requires a three-dimensional model. If you are planning a 3D ANSYS FLUENT model that includes swirl or rotation, you should be aware of the setup constraints listed in [Coordinate System Restrictions](#) (p. 521). In addition, you may wish to consider simplifications to the problem which might reduce it to an equivalent axisymmetric problem, especially for your initial modeling effort. Because of the complexity of swirling flows, an initial 2D study, in which you can quickly determine the effects of various modeling and design choices, can be very beneficial.

Important

For 3D problems involving swirl or rotation, there are no special inputs required during the problem setup and no special solution procedures. Note, however, that you may want to use the cylindrical coordinate system for defining velocity-inlet boundary condition inputs, as described in [Defining the Velocity](#) (p. 278). Also, you may find the gradual increase of the rotational speed (set as a wall or inlet boundary condition) helpful during the solution process. This is described for axisymmetric swirling flows in [Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed](#) (p. 524).

9.3.1.3. Flows Requiring a Moving Reference Frame

If your flow involves a rotating boundary which moves through the fluid (e.g., an impeller blade or a grooved or notched surface), you will need to use a moving reference frame to model the problem. Such applications are described in detail in [Introduction](#) (p. 535). If you have more than one rotating boundary (e.g., several impellers in a row), you can use multiple reference frames (described in [The Multiple Reference Frame Model](#) (p. 545)) or mixing planes (described in [The Mixing Plane Model](#) (p. 547)).

9.3.2. Turbulence Modeling in Swirling Flows

If you are modeling turbulent flow with a significant amount of swirl (e.g., cyclone flows, swirling jets), you should consider using one of ANSYS FLUENT's advanced turbulence models: the RNG k - ε model, realizable k - ε model, or Reynolds stress model. The appropriate choice depends on the strength of the swirl, which can be gauged by the swirl number. The swirl number is defined as the ratio of the axial flux of angular momentum to the axial flux of axial momentum:

$$S = \frac{\int r w \vec{v} \cdot d\vec{A}}{\bar{R} \int u \vec{v} \cdot d\vec{A}} \quad (9-15)$$

where \bar{R} is the hydraulic radius.

For flows with weak to moderate swirl ($S < 0.5$), both the RNG k - ε model and the realizable k - ε model yield appreciable improvements over the standard k - ε model. See [RNG \$k\$ - \$\varepsilon\$ Model](#) and [Realizable \$k\$ - \$\varepsilon\$ Model Swirl Modification](#) (p. 718) for details about these models.

For highly swirling flows ($S > 0.5$), the Reynolds stress model (RSM) is strongly recommended. The effects of strong turbulence anisotropy can be modeled rigorously only by the second-moment closure adopted in the RSM. See [Reynolds Stress Model \(RSM\) Steps in Using a Turbulence Model](#) (p. 696) for details about this model.

For swirling flows encountered in devices such as cyclone separators and swirl combustors, near-wall turbulence modeling is quite often a secondary issue at most. The fidelity of the predictions in these cases is mainly determined by the accuracy of the turbulence model in the core region. However, in cases where walls actively participate in the generation of swirl (i.e., where the secondary flows and vortical flows are generated by pressure gradients), non-equilibrium wall functions can often improve the predictions since they use a law of the wall for mean velocity sensitized to pressure gradients. See [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#) for additional details about near-wall treatments for turbulence.

9.3.3. Mesh Setup for Swirling and Rotating Flows

9.3.3.1. Coordinate System Restrictions

Recall that for an axisymmetric problem, the axis of rotation must be the x axis and the mesh must lie on or above the $y = 0$ line.

9.3.3.2. Mesh Sensitivity in Swirling and Rotating Flows

In addition to the setup constraint described above, you should be aware of the need for sufficient resolution in your mesh when solving flows that include swirl or rotation. Typically, rotating boundary layers may be very thin, and your ANSYS FLUENT model will require a very fine mesh near a rotating wall. In addition, swirling flows will often involve steep gradients in the circumferential velocity (e.g., near the centerline of a free-vortex type flow), and thus require a fine mesh for accurate resolution.

9.3.4. Modeling Axisymmetric Flows with Swirl or Rotation

As discussed in *Overview of Swirling and Rotating Flows* (p. 519), you can solve a 2D axisymmetric problem that includes the prediction of the circumferential or swirl velocity. The assumption of axisymmetry implies that there are no circumferential gradients in the flow, but that there may be non-zero circumferential velocities. Examples of axisymmetric flows involving swirl or rotation are depicted in *Figure 9.10* (p. 522) and *Figure 9.11* (p. 522).

Figure 9.10 Rotating Flow in a Cavity

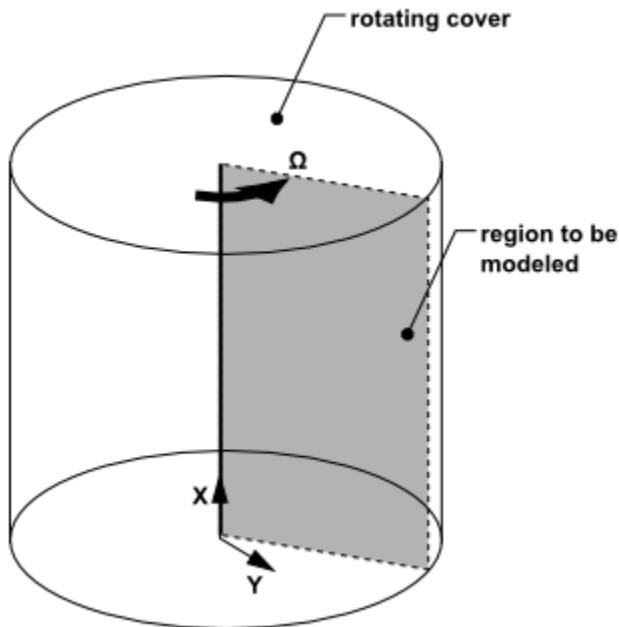

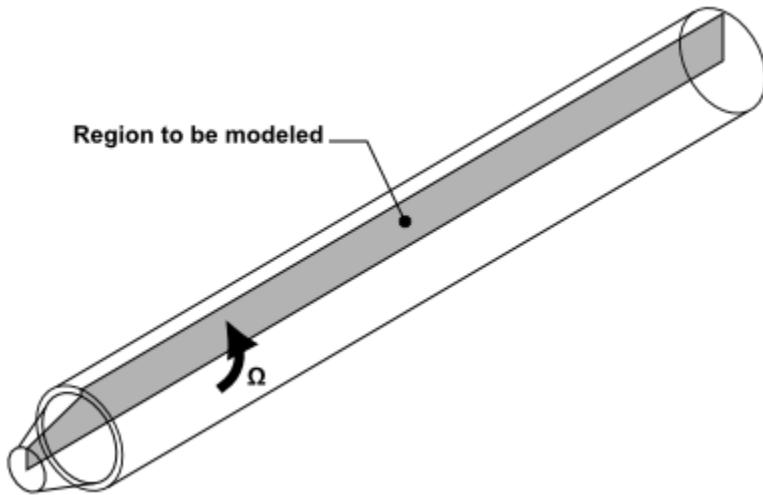

Figure 9.11 Swirling Flow in a Gas Burner

9.3.4.1. Problem Setup for Axisymmetric Swirling Flows

For axisymmetric problems, you will need to perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of axisymmetric swirl/rotation are listed here. You will need to set up the rest of the problem as usual.)

1. Activate solution of the momentum equation in the circumferential direction by turning on the **Axisymmetric Swirl** option for **Space** in the **General** task page.

2. Define the rotational or swirling component of velocity, $r\Omega$, at inlets or walls.

Important

Remember to use the axis boundary type for the axis of rotation.

The procedures for input of rotational velocities at inlets and at walls are described in detail in [Defining the Velocity \(p. 278\)](#) and [Velocity Conditions for Moving Walls \(p. 314\)](#).

9.3.4.2. Solution Strategies for Axisymmetric Swirling Flows

The difficulties associated with solving swirling and rotating flows are a result of the high degree of coupling between the momentum equations, which is introduced when the influence of the rotational terms is large. A high level of rotation introduces a large radial pressure gradient which drives the flow in the axial and radial directions. This, in turn, determines the distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and you may require special solution techniques in order to obtain a converged solution. Solution techniques that may be beneficial in swirling or rotating flow calculations include the following:

- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the **Pressure** list for **Spatial Discretization** in the [Solution Methods Task Page \(p. 2048\)](#)), which is well-suited for the steep pressure gradients involved in swirling flows.
- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.
- (Pressure-based solver only) Change the under-relaxation parameters on the velocities, perhaps to 0.3–0.5 for the radial and axial velocities and 0.8–1.0 for swirl.
- (Pressure-based solver only) Use a sequential or step-by-step solution procedure, in which some equations are temporarily left inactive (see below).
- If necessary, start the calculations using a low rotational speed or inlet swirl velocity, increasing the rotation or swirl gradually in order to reach the final desired operating condition (see below).

See [Using the Solver \(p. 1311\)](#) for details on the procedures used to make these changes to the solution parameters. More details on the step-by-step procedure and on the gradual increase of the rotational speed are provided below.

9.3.4.2.1. Step-By-Step Solution Procedures for Axisymmetric Swirling Flows

Often, flows with a high degree of swirl or rotation will be easier to solve if you use the following step-by-step solution procedure, in which only selected equations are left active in each step. This approach allows you to establish the field of angular momentum, then leave it fixed while you update the velocity field, and then finally to couple the two fields by solving all equations simultaneously.

Important

Since the density-based solvers solve all the flow equations simultaneously, the following procedure applies only to the pressure-based solver.

In this procedure, you will use the **Equations...** button in the *Solution Controls Task Page* (p. 2052) to turn individual transport equations on and off between calculations.

1. If your problem involves inflow/outflow, begin by solving the flow without rotation or swirl effects. That is, enable the **Axisymmetric** option instead of the **Axisymmetric Swirl** option in the *General Task Page* (p. 1763), and do not set any rotating boundary conditions. The resulting flow-field data can be used as a starting guess for the full problem.
2. Enable the **Axisymmetric Swirl** option and set all rotating/swirling boundary conditions.
3. Begin the prediction of the rotating/swirling flow by solving only the momentum equation describing the circumferential velocity. This is the **Swirl Velocity** listed in the **Equations** list in the *Equations Dialog Box* (p. 2054). Let the rotation “diffuse” throughout the flow field, based on your boundary condition inputs. In a turbulent flow simulation, you may also want to leave the turbulence equations active during this step. This step will establish the field of rotation throughout the domain.
4. Turn off the momentum equations describing the circumferential motion (**Swirl Velocity**). Leaving the velocity in the circumferential direction fixed, solve the momentum and continuity (pressure) equations (**Flow** in the **Equations** list in the *Equations Dialog Box* (p. 2054)) in the other coordinate directions. This step will establish the axial and radial flows that are a result of the rotation in the field. Again, if your problem involves turbulent flow, you should leave the turbulence equations active during this calculation.
5. Turn on all of the equations simultaneously to obtain a fully coupled solution. Note the under-relaxation controls suggested above.

In addition to the steps above, you may want to simplify your calculation by solving isothermal flow before adding heat transfer or by solving laminar flow before adding a turbulence model. These two methods can be used for any of the solvers (i.e., pressure-based or density-based).

9.3.4.2.2. Improving Solution Stability by Gradually Increasing the Rotational or Swirl Speed

Because the rotation or swirl defined by the boundary conditions can lead to large complex forces in the flow, your ANSYS FLUENT calculations will be less stable as the speed of rotation or degree of swirl increases. Hence, one of the most effective controls you can apply to the solution is to solve your rotating flow problem starting with a low rotational speed or swirl velocity and then slowly increase the magnitude up to the desired level. The procedure for accomplishing this is as follows:

1. Set up the problem using a low rotational speed or swirl velocity in your inputs for boundary conditions. The rotation or swirl in this first attempt might be selected as 10% of the actual operating conditions.
2. Solve the problem at these conditions, perhaps using the step-by-step solution strategy outlined above.
3. Save this initial solution data.
4. Modify your inputs (boundary conditions). Increase the speed of rotation, perhaps doubling it.
5. Restart the calculation using the solution data saved in step 3 as the initial solution for the new calculation. Save the new data.
6. Continue to increment the speed of rotation, following steps 4 and 5, until you reach the desired operating condition.

9.3.4.2.2.1. Postprocessing for Axisymmetric Swirling Flows

Reporting of results for axisymmetric swirling flows is the same as for other flows. The following additional variables are available for postprocessing when axisymmetric swirl is active:

- **Swirl Velocity** (in the **Velocity...** category)
- **Swirl-Wall Shear Stress** (in the **Wall Fluxes...** category)

9.4. Compressible Flows

Compressibility effects are encountered in gas flows at high velocity and/or in which there are large pressure variations. When the flow velocity approaches or exceeds the speed of sound of the gas or when the pressure change in the system ($\Delta p/p$) is large, the variation of the gas density with pressure has a significant impact on the flow velocity, pressure, and temperature. Compressible flows create a unique set of flow physics for which you must be aware of the special input requirements and solution techniques described in this section. [Figure 9.12 \(p. 525\)](#) and [Figure 9.13 \(p. 526\)](#) show examples of compressible flows computed using ANSYS FLUENT.

Figure 9.12 Transonic Flow in a Converging-Diverging Nozzle

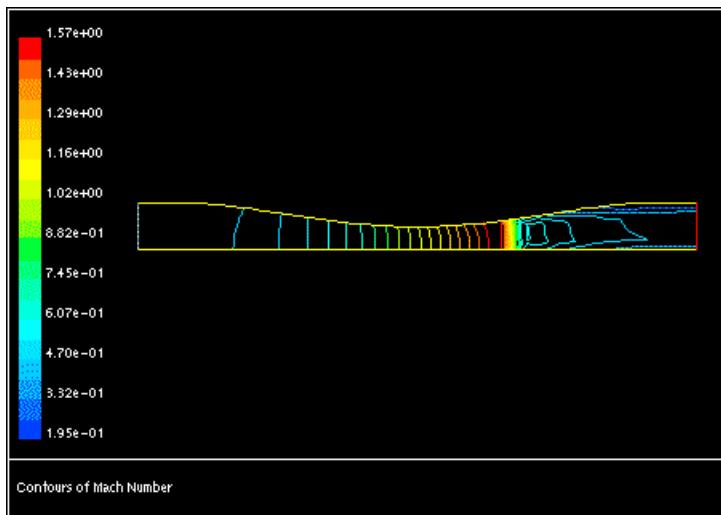

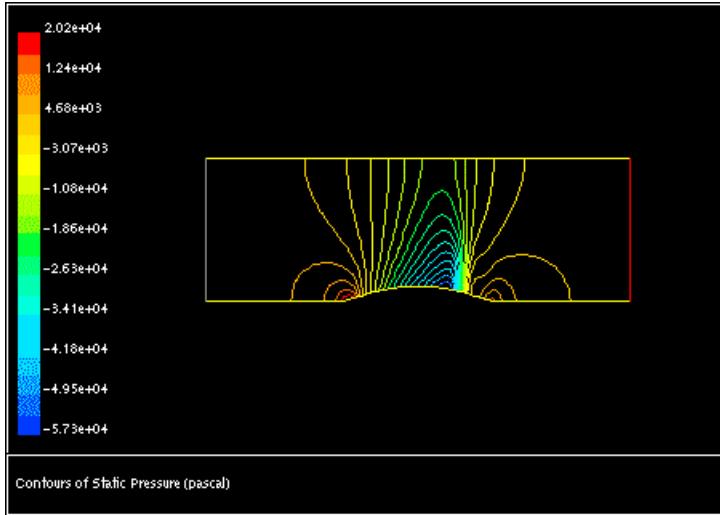

Figure 9.13 Mach 0.675 Flow Over a Bump in a 2D Channel

Information about compressible flows is provided in the following subsections:

- 9.4.1. When to Use the Compressible Flow Model
- 9.4.2. Physics of Compressible Flows
- 9.4.3. Modeling Inputs for Compressible Flows
- 9.4.4. Floating Operating Pressure
- 9.4.5. Solution Strategies for Compressible Flows
- 9.4.6. Reporting of Results for Compressible Flows

For more information about the theoretical background of compressible flows, see [Compressible Flows](#) in the [Theory Guide](#).

9.4.1. When to Use the Compressible Flow Model

Compressible flows can be characterized by the value of the Mach number:

$$M \equiv u/c \quad (9-16)$$

Here, c is the speed of sound in the gas:

$$c = \sqrt{\gamma RT} \quad (9-17)$$

and γ is the ratio of specific heats (c_p/c_v).

When the Mach number is less than 1.0, the flow is termed subsonic. At Mach numbers much less than 1.0 ($M \approx 0.1$ or so), compressibility effects are negligible and the variation of the gas density with pressure can safely be ignored in your flow modeling. As the Mach number approaches 1.0 (which is referred to as the transonic flow regime), compressibility effects become important. When the Mach number exceeds 1.0, the flow is termed supersonic, and may contain shocks and expansion fans which can impact the flow pattern significantly. ANSYS FLUENT provides a wide range of compressible flow modeling capabilities for subsonic, transonic, and supersonic flows.

9.4.2. Physics of Compressible Flows

Compressible flows are typically characterized by the total pressure p_0 and total temperature T_0 of the flow. For an ideal gas, these quantities can be related to the static pressure and temperature by the following:

$$\frac{p_0}{p} = \exp\left(\frac{\int_{T_0}^{T_0} \frac{C_p}{T} dT}{R}\right) \quad (9-18)$$

For constant C_p , [Equation 9-18 \(p. 527\)](#) reduces to

$$\begin{aligned} \frac{p_0}{p} &= \left(1 + \frac{\gamma - 1}{2} M^2\right)^{\gamma / (\gamma - 1)} \\ \frac{T_0}{T} &= 1 + \frac{\gamma - 1}{2} M^2 \end{aligned} \quad (9-19)$$

These relationships describe the variation of the static pressure and temperature in the flow as the velocity (Mach number) changes under isentropic conditions. For example, given a pressure ratio from inlet to exit (total to static), [Equation 9-19 \(p. 527\)](#) can be used to estimate the exit Mach number which would exist in a one-dimensional isentropic flow. For air, [Equation 9-19 \(p. 527\)](#) p/p_0 , of 0.5283. This choked flow condition will be established at the point of minimum flow area (e.g., in the throat of a nozzle). In the subsequent area expansion the flow may either accelerate to a supersonic flow in which the pressure will continue to drop, or return to subsonic flow conditions, decelerating with a pressure rise. If a supersonic flow is exposed to an imposed pressure increase, a shock will occur, with a sudden pressure rise and deceleration accomplished across the shock.

9.4.2.1. Basic Equations for Compressible Flows

Compressible flows are described by the standard continuity and momentum equations solved by ANSYS FLUENT, and you do not need to activate any special physical models (other than the compressible treatment of density as detailed below). The energy equation solved by ANSYS FLUENT correctly incorporates the coupling between the flow velocity and the static temperature, and should be activated whenever you are solving a compressible flow. In addition, if you are using the pressure-based solver, you should activate the viscous dissipation terms in [Equation 5-1](#) in the [Theory Guide](#), which become important in high-Mach-number flows.

9.4.2.2. The Compressible Form of the Gas Law

For compressible flows, the ideal gas law is written in the following form:

$$\rho = \frac{p_{op} + p}{\frac{R}{M_w} T} \quad (9-20)$$

where p_{op} is the operating pressure defined in the [Operating Conditions Dialog Box \(p. 1952\)](#), p is the local static pressure relative to the operating pressure, R is the universal gas constant, and M_w is the molecular weight. The temperature, T , will be computed from the energy equation.

Some compressible flow problems involve fluids that do not behave as ideal gases. For example, flow under very high-pressure conditions cannot typically be modeled accurately using the ideal-gas assumption. Therefore, the real gas model described in [Real Gas Models \(p. 471\)](#) should be used instead.

9.4.3. Modeling Inputs for Compressible Flows

To set up a compressible flow in ANSYS FLUENT, you will need to follow the steps listed below. (Only those steps relevant specifically to the setup of compressible flows are listed here. You will need to set up the rest of the problem as usual.)

1. Set the **Operating Pressure** in the [Operating Conditions Dialog Box \(p. 1952\)](#).

(You can think of p_{op} as the absolute static pressure at a point in the flow where you will define the gauge pressure p to be zero. See [Operating Pressure \(p. 468\)](#) for guidelines on setting the operating pressure. For time-dependent compressible flows, you may want to specify a floating operating pressure instead of a constant operating pressure. See [Floating Operating Pressure \(p. 529\)](#) for details.)

2. Activate solution of the energy equation in the [Energy Dialog Box \(p. 1778\)](#).

3. (Pressure-based solver only) If you are modeling turbulent flow, activate the optional viscous dissipation terms in the energy equation by turning on **Viscous Heating** in the [Viscous Model Dialog Box \(p. 1778\)](#). Note that these terms can be important in high-speed flows.

This step is not necessary if you are using one of the density-based solvers, because the density-based solvers always include the viscous dissipation terms in the energy equation.

4. Set the following items in the [Create/Edit Materials Dialog Box \(p. 1882\)](#):

- Select **ideal-gas** in the drop-down list next to **Density**.
 - Define all relevant properties (specific heat, molecular weight, thermal conductivity, etc.).
- Set cell zone conditions and boundary conditions (using the [Boundary Conditions Task Page \(p. 1958\)](#) and [Cell Zone Conditions Task Page \(p. 1940\)](#)), being sure to choose a well-posed cell zone or boundary condition combination that is appropriate for the flow regime. See below for details. Recall that all

inputs for pressure (either total pressure or static pressure) must be relative to the operating pressure, and the temperature inputs at inlets should be total (stagnation) temperatures, *not* static temperatures.

Cell Zone Conditions

Boundary Conditions

These inputs should ensure a well-posed compressible flow problem. You will also want to consider special solution parameter settings, as noted in *Solution Strategies for Compressible Flows* (p. 531), before beginning the flow calculation.

9.4.3.1. Boundary Conditions for Compressible Flows

Well-posed inlet and exit boundary conditions for compressible flow are listed below:

- For flow inlets:
 - Pressure inlet: Inlet total temperature and total pressure and, for supersonic inlets, static pressure
 - Mass flow inlet: Inlet mass flow and total temperature
- For flow exits:
 - Pressure outlet: Exit static pressure (ignored if flow is supersonic at the exit. All the information travels downstream in a supersonic region, hence the pressure at the outlet can be computed by directly extrapolating from the adjacent cell center [33] (p. 2368). Therefore, it is not meaningful to use the exit static pressure prescribed in the boundary conditions task page, and the exit static pressure is ignored).

It is important to note that your boundary condition inputs for pressure (either total pressure or static pressure) must be in terms of gauge pressure — i.e., pressure relative to the operating pressure defined in the *Operating Conditions Dialog Box* (p. 1952), as described above.

All temperature inputs at inlets should be total (stagnation) temperatures, *not* static temperatures.

9.4.4. Floating Operating Pressure

ANSYS FLUENT provides a “floating operating pressure” option to handle time-dependent compressible flows with a gradual increase in the absolute pressure in the domain. This option is desirable for slow subsonic flows with static pressure build-up, since it efficiently accounts for the slow changing of absolute pressure without using acoustic waves as the transport mechanism for the pressure build-up.

Examples of typical applications include the following:

- combustion or heating of a gas in a closed domain
- pumping of a gas into a closed domain

9.4.4.1. Limitations

The floating operating pressure option should *not* be used for transonic or incompressible flows. In addition, it cannot be used if your model includes any pressure inlet, pressure outlet, exhaust fan, inlet vent, intake fan, outlet vent, or pressure far field boundaries.

9.4.4.2. Theory

The floating operating pressure option allows ANSYS FLUENT to calculate the pressure rise (or drop) from the integral mass balance, separately from the solution of the pressure correction equation. When this option is activated, the absolute pressure at each iteration can be expressed as

$$p_{abs} = p_{op, float} + p \quad (9-21)$$

where p is the pressure relative to the reference location, which in this case is in the cell with the minimum pressure value. Thus the reference location itself is floating.

$p_{op, float}$ is referred to as the floating operating pressure, and is defined as

$$p_{op, float} = p_{op}^0 + \Delta p_{op} \quad (9-22)$$

where p_{op}^0 is the initial operating pressure and Δp_{op} is the pressure rise.

Including the pressure rise Δp_{op} in the floating operating pressure $p_{op, float}$, rather than in the pressure p , helps to prevent roundoff error. If the pressure rise were included in p , the calculation of the pressure gradient for the momentum equation would give an inexact balance due to precision limits for 32-bit real numbers.

9.4.4.3. Enabling Floating Operating Pressure

When time dependence is active, you can turn on the **Floating Operating Pressure** option in the *Operating Conditions Dialog Box* (p. 1952).

↳ **Boundary Conditions** → **Operating Conditions...**

(Note that the inputs for **Reference Pressure Location** will disappear when you enable **Floating Operating Pressure**, since these inputs are no longer relevant.)

Important

The floating operating pressure option should *not* be used for transonic flows or for incompressible flows. It is meaningful only for slow subsonic flows of ideal gases, when the characteristic time scale is much larger than the sonic time scale.

9.4.4.4. Setting the Initial Value for the Floating Operating Pressure

When the floating operating pressure option is enabled, you will need to specify a value for the **Initial Operating Pressure** in the *Solution Initialization Task Page* (p. 2088).

↳ **Solution Initialization**

This initial value is stored in the case file with all your other initial values.

9.4.4.5. Storage and Reporting of the Floating Operating Pressure

The current value of the floating operating pressure is stored in the data file. If you visit the [Operating Conditions Dialog Box \(p. 1952\)](#) after a number of time steps have been performed, the current value of the **Operating Pressure** will be displayed.

Note that the floating operating pressure will automatically be reset to the initial operating pressure if you reset the data (i.e., start over at the first iteration of the first time step).

9.4.4.6. Monitoring Absolute Pressure

You can monitor the absolute pressure during the calculation using the [Surface Monitor Dialog Box \(p. 2074\)](#) (see [Monitoring Surface Integrals \(p. 1395\)](#) for details). You can also generate graphical plots or alphanumeric reports of absolute pressure when your solution is complete. The **Absolute Pressure** variable is contained in the **Pressure...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See [Field Function Definitions \(p. 1653\)](#) for its definition.

9.4.5. Solution Strategies for Compressible Flows

The difficulties associated with solving compressible flows are a result of the high degree of coupling between the flow velocity, density, pressure, and energy. This coupling may lead to instabilities in the solution process and, therefore, may require special solution techniques in order to obtain a converged solution. In addition, the presence of shocks (discontinuities) in the flow introduces an additional stability problem during the calculation. Solution techniques that may be beneficial in compressible flow calculations include the following:

- (Pressure-based solver only) Initialize the flow to be near stagnation (i.e. velocity small but not zero, pressure to inlet total pressure, temperature to inlet total temperature). Turn off the energy equation for the first 50 iterations. Leave the energy under-relaxation at 1. Set the pressure under-relaxation to 0.4, and the momentum under-relaxation to 0.3. After the solution stabilizes and the energy equation has been turned on, increase the pressure under-relaxation to 0.7.
- Set reasonable limits for the temperature and pressure (in the [Solution Limits Dialog Box \(p. 2054\)](#)) to avoid solution divergence, especially at the start of the calculation. If ANSYS FLUENT prints messages about temperature or pressure being limited as the solution nears convergence, the high or low computed values may be physical, and you will need to change the limits to allow these values.
- If required, begin the calculations using a reduced pressure ratio at the boundaries, increasing the pressure ratio gradually in order to reach the final desired operating condition. If the Mach number is low, you can also consider starting the compressible flow calculation from an incompressible flow solution (although the incompressible flow solution can in some cases be a rather poor initial guess for the compressible calculation).
- In some cases, computing an inviscid solution as a starting point may be helpful.

See [Using the Solver \(p. 1311\)](#) for details on the procedures used to make these changes to the solution parameters.

9.4.6. Reporting of Results for Compressible Flows

You can display the results of your compressible flow calculations in the same manner that you would use for an incompressible flow. The variables listed below are of particular interest when you model compressible flow:

- **Total Temperature**

- **Total Pressure**
- **Mach Number**

These variables are contained in the variable selection drop-down list that appears in postprocessing dialog boxes. **Total Temperature** is in the **Temperature...** category, **Total Pressure** is in the **Pressure...** category, and **Mach Number** is in the **Velocity...** category. See *Field Function Definitions* (p. 1653) for their definitions.

9.5. Inviscid Flows

Inviscid flow analysis neglect the effect of viscosity on the flow and are appropriate for high-Reynolds-number applications where inertial forces tend to dominate viscous forces. One example for which an inviscid flow calculation is appropriate is an aerodynamic analysis of some high-speed projectile. In a case like this, the pressure forces on the body will dominate the viscous forces. Hence, an inviscid analysis will give you a quick estimate of the primary forces acting on the body. After the body shape has been modified to maximize the lift forces and minimize the drag forces, you can perform a viscous analysis to include the effects of the fluid viscosity and turbulent viscosity on the lift and drag forces.

Another area where inviscid flow analysis are routinely used is to provide a good initial solution for problems involving complicated flow physics and/or complicated flow geometry. In a case like this, the viscous forces are important, but in the early stages of the calculation the viscous terms in the momentum equations will be ignored. Once the calculation has been started and the residuals are decreasing, you can turn on the viscous terms (by enabling laminar or turbulent flow) and continue the solution to convergence. For some very complicated flows, this is the only way to get the calculation started.

Information about inviscid flows is provided in the following subsections:

- 9.5.1. Setting Up an Inviscid Flow Model
- 9.5.2. Solution Strategies for Inviscid Flows
- 9.5.3. Postprocessing for Inviscid Flows

For more information about the theoretical background of inviscid flows, see [Inviscid Flows](#) in the Theory Guide.

9.5.1. Setting Up an Inviscid Flow Model

For inviscid flow problems, you will need to perform the following steps during the problem setup procedure. (Only those steps relevant specifically to the setup of inviscid flow are listed here. You will need to set up the rest of the problem as usual.)

1. Activate the calculation of inviscid flow by selecting **Inviscid** in the [Viscous Model Dialog Box](#) (p. 1778).

Models → **Viscous** → **Edit...**

2. Set boundary conditions and flow properties.

Boundary Conditions

Note

Walls are assumed to be slip surfaces (the velocity is not equal to zero, unlike viscous flows) and therefore have a tangential velocity computed based on the solution of the governing equations.

 Materials

3. Solve the problem and examine the results.

9.5.2. Solution Strategies for Inviscid Flows

Since inviscid flow problems will usually involve high-speed flow, you may have to reduce the under-relaxation factors for momentum (if you are using the pressure-based solver) or reduce the Courant number (if you are using the density-based solver), in order to get the solution started. Once the flow is started and the residuals are monotonically decreasing, you can start increasing the under-relaxation factors or Courant number back up to the default values.

Modifications to the under-relaxation factors and the Courant number can be made in the [Solution Controls Task Page](#) (p. 2052).

 Solution Controls

The solution strategies for compressible flows apply also to inviscid flows. See [Solution Strategies for Compressible Flows](#) (p. 531) for details.

9.5.3. Postprocessing for Inviscid Flows

If you are interested in the lift and drag forces acting on your model, you can use the [Force Reports Dialog Box](#) (p. 2186) to compute them.

 Reports →  Forces → Set Up...

See [Forces on Boundaries](#) (p. 1640) for details.

Chapter 10: Modeling Flows with Moving Reference Frames

This chapter provides details about the moving reference frame capabilities in ANSYS FLUENT.

The information in this chapter is divided into the following sections:

- 10.1. Introduction
- 10.2. Flow in Single Moving Reference Frames (SRF)
- 10.3. Flow in Multiple Moving Reference Frames

10.1. Introduction

ANSYS FLUENT solves the equations of fluid flow and heat transfer, by default, in a stationary (or inertial) reference frame. However, there are many problems where it is advantageous to solve the equations in a moving (or non-inertial) reference frame. Such problems typically involve moving parts (such as rotating blades, impellers, and similar types of moving surfaces), and it is the flow around these moving parts that is of interest. In most cases, the moving parts render the problem unsteady when viewed from the stationary frame. With a moving reference frame, however, the flow around the moving part can (with certain restrictions) be modeled as a steady-state problem with respect to the moving frame.

ANSYS FLUENT's moving reference frame modeling capability allows you to model problems involving moving parts by allowing you to activate moving reference frames in selected cell zones. When a moving reference frame is activated, the equations of motion are modified to incorporate the additional acceleration terms which occur due to the transformation from the stationary to the moving reference frame. By solving these equations in a steady-state manner, the flow around the moving parts can be modeled.

For many problems, it may be possible to refer the entire computational domain to a single moving reference frame. This is known as the single reference frame (or SRF) approach. The use of the SRF approach is possible; provided the geometry meets certain requirements. For more complex geometries, it may not be possible to use a single reference frame. In such cases, you must break up the problem into multiple cell zones, with well-defined interfaces between the zones. The manner in which the interfaces are treated leads to two approximate, steady-state modeling methods for this class of problem: the multiple reference frame (or MRF) approach, and the mixing plane approach. These approaches will be discussed in [The Multiple Reference Frame Model \(p. 545\)](#) and [The Mixing Plane Model \(p. 547\)](#). If unsteady interaction between the stationary and moving parts is important, you can employ the sliding mesh approach to capture the transient behavior of the flow. The sliding meshing model will be discussed in [Modeling Flows Using Sliding and Dynamic Meshes \(p. 559\)](#).

The principal reason for employing a moving reference frame is to render a problem which is unsteady in the stationary (inertial) frame steady with respect to the moving frame. For a steadily moving frame (e.g., the frame speed is constant), it is possible to transform the equations of fluid motion to the moving frame such that steady-state solutions are possible. By default, ANSYS FLUENT permits the activation of a moving reference frame with a steady speed. If the speed is not constant, the transformed equations will contain additional terms (see [Relative Velocity Formulation](#) in the [Theory Guide](#)). It should also be noted that you can run an unsteady simulation in a moving reference frame with constant speed. This would be necessary if you wanted to simulate, for example, vortex shedding from a rotating

fan blade. The unsteadiness in this case is due to a natural fluid instability (vortex generation) rather than induced from interaction with a stationary component.

For more information about the equations for moving reference frames, see [Equations for a Moving Reference Frame](#) in the [Theory Guide](#).

Figure 10.1 Single Component (Blower Wheel Blade Passage)

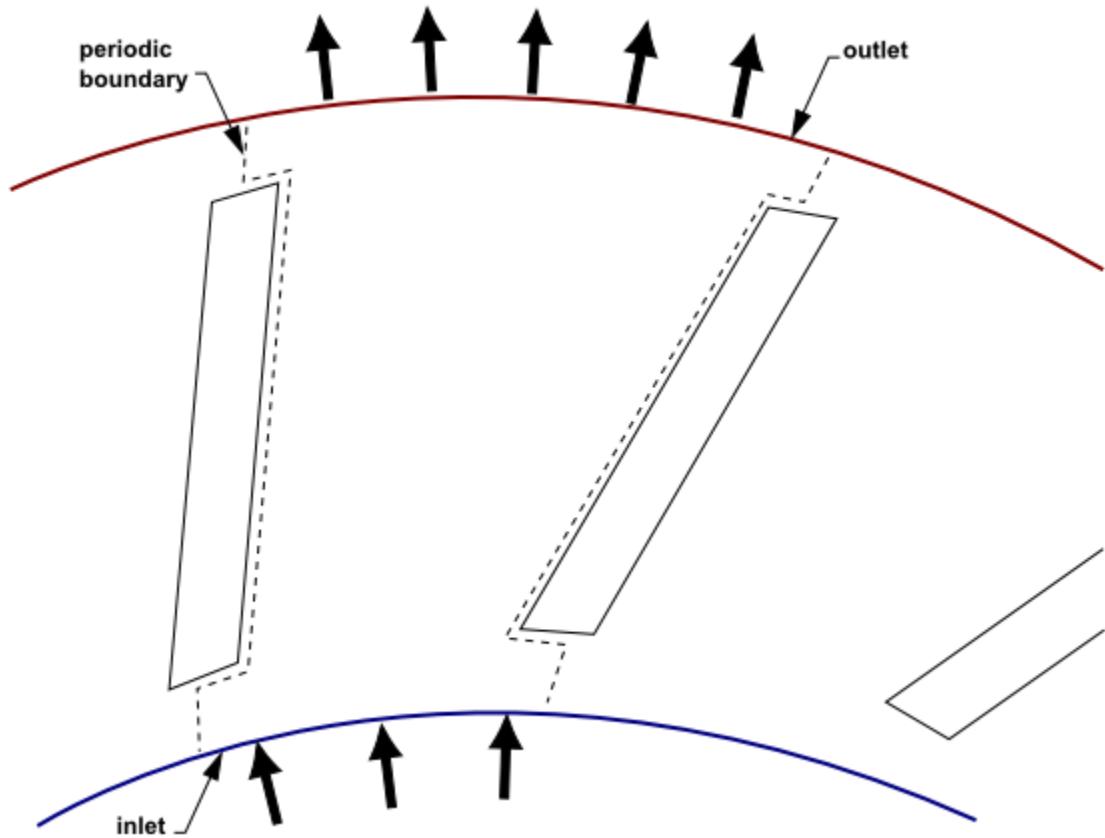

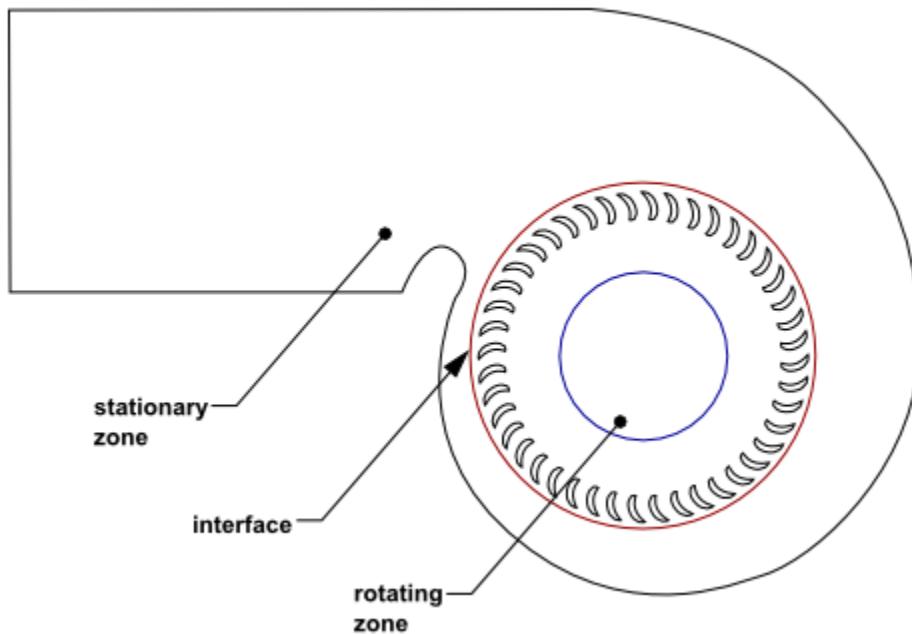

Figure 10.2 Multiple Component (Blower Wheel and Casing)

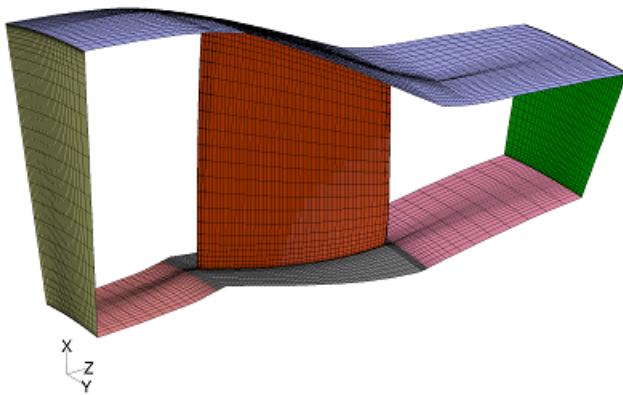

10.2. Flow in Single Moving Reference Frames (SRF)

Many problems permit the entire computational domain to be referred to a single moving reference frame (hence the name SRF modeling). In such cases, the equations given in [Equations for a Moving Reference Frame](#) are solved in all fluid cell zones. Steady-state solutions are possible in SRF models provided suitable boundary conditions are prescribed. In particular, wall boundaries must adhere to the following requirements:

- Any walls which are moving with the reference frame can assume any shape. An example would be the blade surfaces associated with a pump impeller. The no slip condition is defined in the relative frame such that the relative velocity is zero on the moving walls.
- For a rotating problem, you can define walls that are non-moving with respect to the stationary coordinate system, but these walls must be surfaces of revolution about the axis of rotation. Here the no slip condition is defined such that the absolute velocity is zero on the walls. An example of this type of boundary would be a cylindrical wind tunnel wall which surrounds a rotating propeller.

Rotationally periodic boundaries may also be used, but the surface must be periodic about the axis of rotation. As an example, it is very common to model flow through a blade row of a turbomachine by assuming the flow to be rotationally periodic and using a periodic domain about a single blade. This permits good resolution of the flow around the blade without the expense of modeling all blades in the blade row (see [Figure 10.3 \(p. 538\)](#)).

Flow boundary conditions in ANSYS FLUENT (inlets and outlets) can, in most cases, be prescribed in either the stationary or moving frames. For example, for a velocity inlet, one can specify either the relative velocity or absolute velocity, depending on which is more convenient. For additional information on these and other boundary conditions, see [Setting Up a Single Moving Reference Frame Problem \(p. 538\)](#) and [Cell Zone and Boundary Conditions \(p. 211\)](#).

Figure 10.3 Single Blade Model with Rotationally Periodic Boundaries

10.2.1. Mesh Setup for a Single Moving Reference Frame

It is important to remember the following coordinate-system constraints when you are setting up a problem involving a moving reference frame for a rotating problem:

- For 2D problems, the axis of rotation must be parallel to the z axis.
- For 2D axisymmetric problems, the axis of rotation must be the x axis.
- For 3D geometries, you should generate the mesh with a specific origin and rotational axis in mind for the rotating cell zone. Usually it is convenient to use the origin of the global coordinate system (0,0,0) for the frame origin, and either the x , y , or z axis for the rotational axis; however, ANSYS FLUENT can accommodate an arbitrary origin and rotational axis.

With 3D rotating problems, it is also important to note that if you wish to include walls which have zero velocity in the stationary frame, these walls must be a surface of revolution with respect to the axis of rotation. If the stationary walls are not surfaces of revolution, you must encapsulate the rotating parts with interface boundaries, thereby breaking your model up into multiple zones, and use either the MRF or mixing plane models for steady state solutions (see *The Multiple Reference Frame Model* (p. 545) and *The Mixing Plane Model* (p. 547)), or the sliding mesh model for unsteady interaction (see *Modeling Flows Using Sliding and Dynamic Meshes* (p. 559)).

10.2.2. Setting Up a Single Moving Reference Frame Problem

To model a problem involving a single moving reference frame, follow the steps outlined below.

1. Select the **Velocity Formulation** to be used when solving: either **Relative** or **Absolute**. (See *Choosing the Relative or Absolute Velocity Formulation* (p. 541) for details.)

General

(Note that this step is irrelevant if you are using one of the density-based solvers; these solvers always use an absolute velocity formulation.)

2. For each cell zone in the domain, specify the translational velocity of the reference frame and/or the angular velocity (ω) of the reference frame and the axis about which it rotates.

Cell Zone Conditions

- a. In the **Fluid** or **Solid** dialog box, specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** for the frame motion to define the axis of rotation.
- b. Also in the **Fluid** (*Figure 10.4 (p. 540)*) or **Solid** dialog box, enable the **Frame Motion** option and then set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity** in the expanded portion of the dialog box under the **Reference Frame** tab.

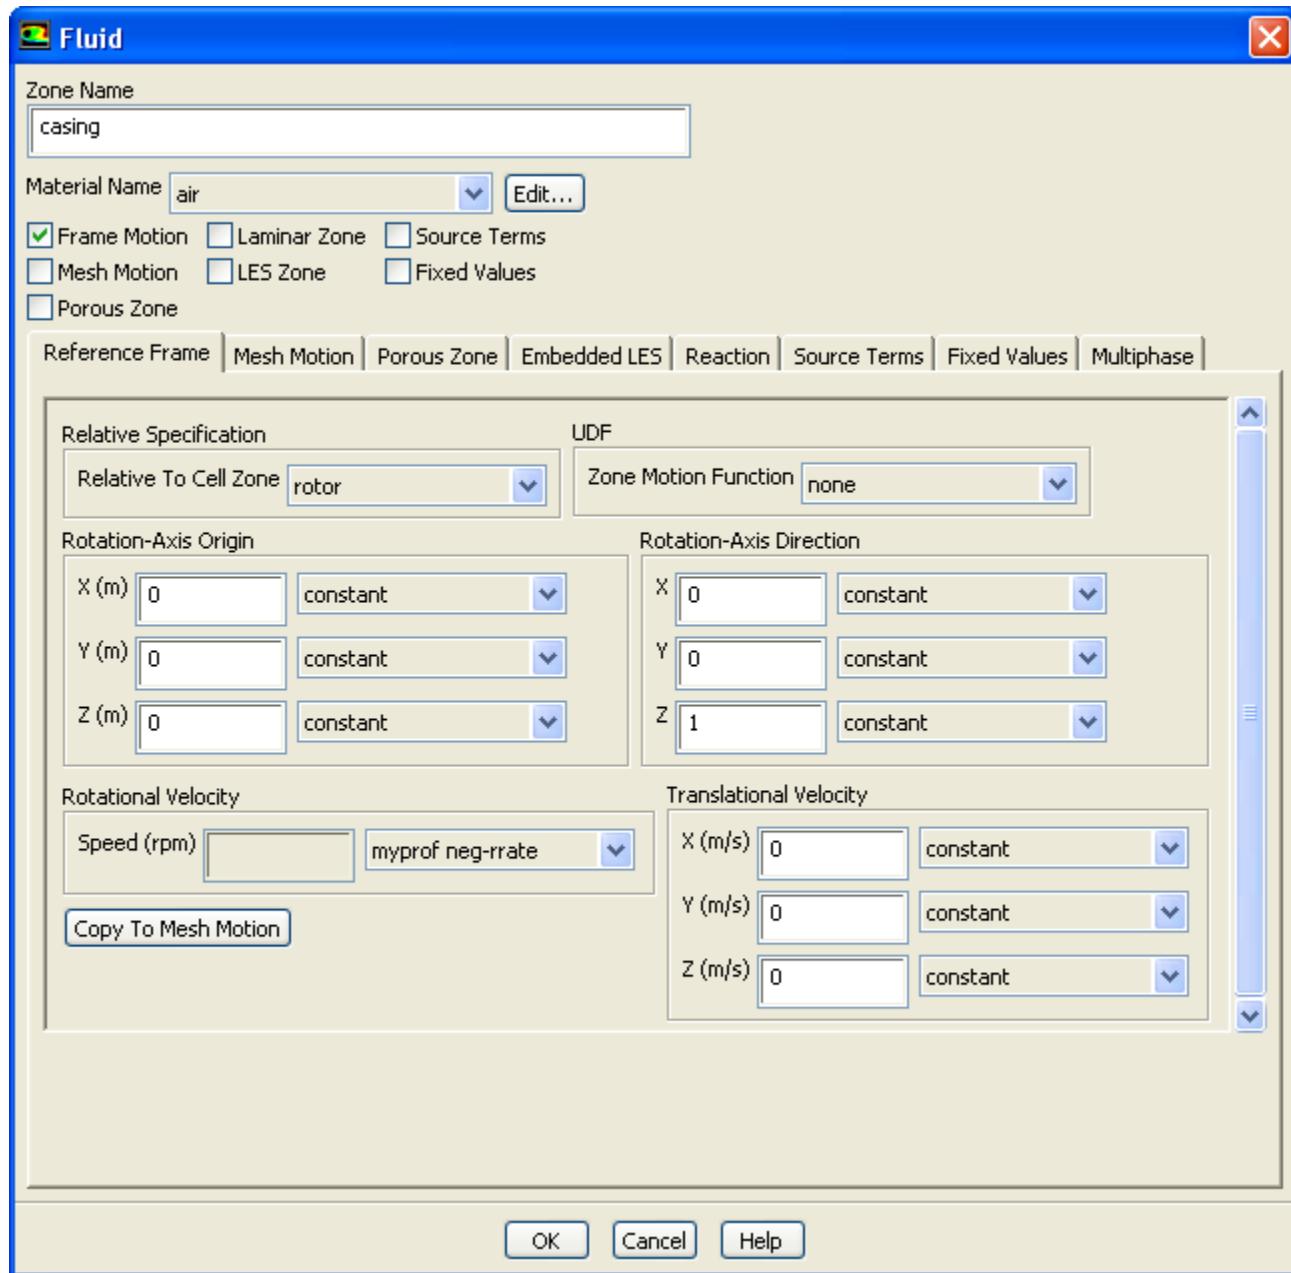

Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in *Defining Transient Cell Zone and Boundary Conditions (p. 393)*, or a UDF macro, described in [DEFINE_TRANSIENT_PROFILE](#). Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro [DEFINE_ZONE_MOTION](#). This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Note

If you decide to hook a UDF, you will no longer have access to the rotation axis origin and direction, or the velocities.

Details about these inputs are presented in [Inputs for Fluid Zones \(p. 221\)](#) and in [Inputs for Solid Zones \(p. 227\)](#). Details about the zone motion UDF can be found in [DEFINE_ZONE_MOTION](#) in the [UDF Manual](#).

- c. If you need to switch between the moving reference frame and moving mesh models, simply click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models. The variables used for the origin, axis, and velocity components, as well as for the UDF [DEFINE_ZONE_MOTION](#) will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

Figure 10.4 The Fluid Dialog Box Displaying Frame Motion Inputs

Important

For solid zones, you only need to activate the **Frame Motion** option if you intend to include the convective terms in the energy equation for the solid (Equation 5-11 in the [Theory Guide](#)). Normally, this is not required if you wish to do a conjugate heat transfer problem where the solid and fluid zones are moving together.

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the moving reference frame (i.e., relative to the velocity of the adjacent cell zone specified in step 2).

If the wall is moving at the speed of the moving frame (and hence stationary in the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the velocity of the fluid zone.

Details about these inputs are presented in *Velocity Conditions for Moving Walls* (p. 314).

4. Define the boundary conditions at the inlets, as described in *Boundary Conditions* (p. 261). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

Details about these inputs are presented in *Defining the Flow Direction* (p. 271) and *Defining the Velocity* (p. 278).

10.2.2.1. Choosing the Relative or Absolute Velocity Formulation

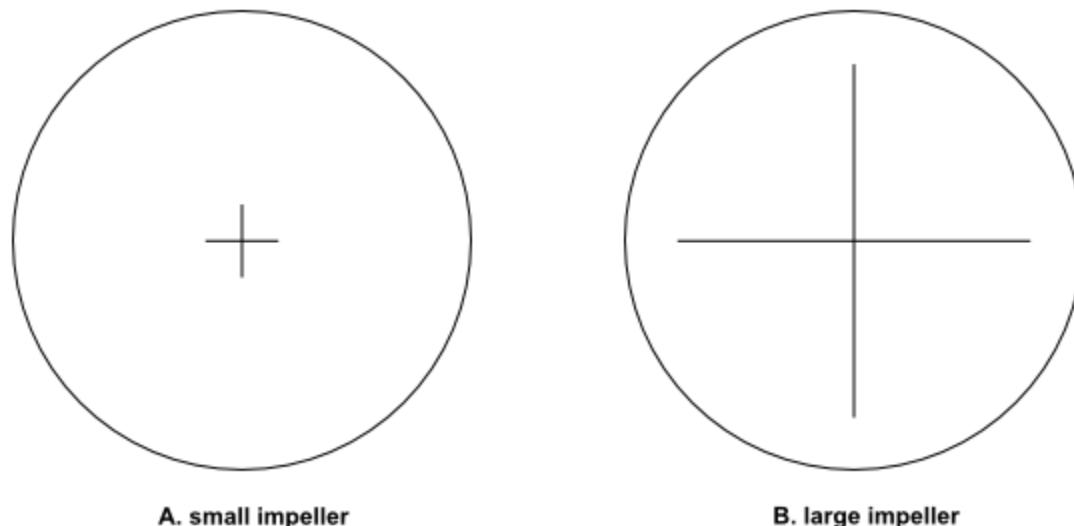

It is recommended that you use the velocity formulation that will result in most of the flow domain having the smallest velocities in that frame, thereby reducing the numerical diffusion in the solution and leading to a more accurate solution.

The absolute velocity formulation is preferred in applications where the flow in most of the domain is not moving (e.g., a fan in a large room). The relative velocity formulation is appropriate when most of the fluid in the domain is moving, as in the case of a large impeller in a mixing tank.

10.2.2.1.1. Example

A problem with stationary outer walls and a rotating impeller can be solved in a single reference frame. The example is illustrated in *Figure 10.5* (p. 541).

Figure 10.5 Geometry with the Rotating Impeller

In case A, it is expected that only the flow near the impeller would be rotating and that much of the flow away from the impeller would have a low velocity magnitude in the absolute frame. Therefore, solving using the absolute velocity formulation is recommended. In case B, most of the flow is expected

to be rotating with a velocity close to that of the impeller. Hence, the relative velocity formulation is appropriate.

In a situation between case A and case B, either of the formulations may be used.

Important

- If the velocity formulation is switched during the solution process, ANSYS FLUENT will not transform the current solution to the other frame, which can lead to large jumps in residuals. If changing the frame is necessary, it is recommended that you first reinitialize, and then solve.
- When one of the density-based solution algorithms is used, the absolute formulation is always used; the relative velocity formulation is not available in the density-based solvers.

For velocity inlets, pressure inlets, mass flow inlets, and walls, you may specify velocity in either the absolute or the relative frame, regardless of whether the absolute or relative velocity formulation is used in the computation.

For pressure outlets, the specified static pressure is independent of frame. However, when there is backflow at a pressure outlet, the specified static pressure is used as the total pressure. For calculations using the absolute velocity formulation, the specified static pressure is used as the total pressure in the absolute frame; for the relative velocity formulation, the specified static pressure is assumed to be the total pressure in the relative frame. As for the flow direction, ANSYS FLUENT assumes the absolute velocity to be normal to the pressure outlet for the absolute velocity formulation; for the relative velocity formulation, it is the relative velocity that is assumed to be normal to the pressure outlet.

10.2.3. Solution Strategies for a Single Moving Reference Frame

The difficulties associated with solving flows in moving reference frames are similar to those discussed in [Solution Strategies for Axisymmetric Swirling Flows \(p. 523\)](#). The primary issue you must confront is the high degree of coupling between the momentum equations when the influence of the rotational terms is large. A high degree of rotation introduces a large radial pressure gradient which drives the flow in the axial and radial directions, thereby setting up a distribution of the swirl or rotation in the field. This coupling may lead to instabilities in the solution process, and hence require special solution techniques to obtain a converged solution. Some techniques that may be beneficial include the following:

- (Pressure-based solver only) Consider switching the frame in which velocities are solved by changing the velocity formulation setting in the [General Task Page \(p. 1763\)](#). (See [Choosing the Relative or Absolute Velocity Formulation \(p. 541\)](#) for details.)
- (Pressure-based segregated solver only) Use the PRESTO! scheme (enabled in the [Solution Methods Task Page \(p. 2048\)](#)), which is well-suited for the steep pressure gradients involved in rotating flows.
- Ensure that the mesh is sufficiently refined to resolve large gradients in pressure and swirl velocity.
- (Pressure-based, segregated solver only) Reduce the under-relaxation factors for the velocities, perhaps to 0.3–0.5 or lower, if necessary.
- Begin the calculations using a low rotational speed, increasing the rotational speed gradually in order to reach the final desired operating condition.

See [Using the Solver \(p. 1311\)](#) for details on the procedures used to make these changes to the solution parameters.

10.2.3.1. Gradual Increase of the Rotational Speed to Improve Solution Stability

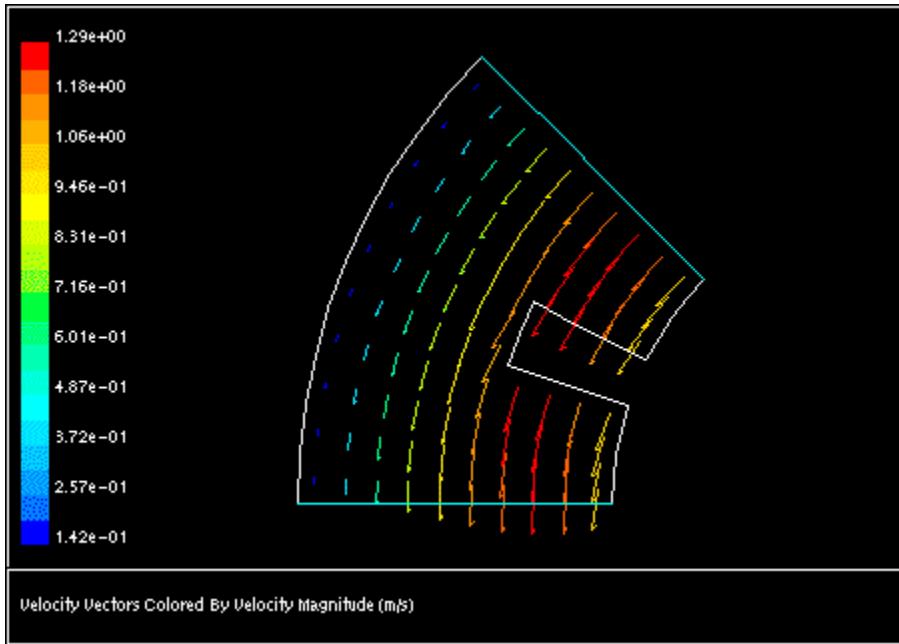

Because the rotation of the reference frame and the rotation defined via boundary conditions can lead to large complex forces in the flow, your ANSYS FLUENT calculations may be less stable as the speed of rotation (and hence the magnitude of these forces) increases. One of the most effective controls you can exert on the solution is to start with a low rotational speed and then slowly increase the rotation up to the desired level. The procedure you use to accomplish this is as follows:

1. Set up the problem using a low rotational speed in your inputs for boundary conditions and for the angular velocity of the reference frame. The rotational speed in this first attempt might be selected as 10% of the actual operating condition.
2. Solve the problem at these conditions.
3. Save this initial solution data.
4. Modify your inputs (i.e., boundary conditions and angular velocity of the reference frame). Increase the speed of rotation, perhaps doubling it.
5. Restart or continue the calculation using the solution data saved in Step 3 as the initial guess for the new calculation. Save the new data.
6. Continue to increment the rotational speed, following Steps 4 and 5, until you reach the desired operating condition.

10.2.4. Postprocessing for a Single Moving Reference Frame

When you solve a problem in a moving reference frame, you can plot or report both absolute and relative velocities. For all velocity parameters (e.g., **Velocity Magnitude** and **Mach Number**), corresponding relative values will be available for postprocessing (e.g., **Relative Velocity Magnitude** and **Relative Mach Number**). These variables are contained in the **Velocity...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (e.g., **Relative Total Pressure**, **Relative Total Temperature**, **Rothalpy**).

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select **Relative Velocity** in the **Vectors of** drop-down list in the [Vectors Dialog Box \(p. 2123\)](#) to plot vectors in the moving frame. If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing **Relative Velocity Magnitude** in the **Color by** list); by default they will be colored by absolute velocity magnitude. [Figure 10.6 \(p. 544\)](#) and [Figure 10.7 \(p. 544\)](#) show absolute and relative velocity vectors in a moving domain with a stationary outer wall.

Figure 10.6 Absolute Velocity Vectors**Figure 10.7 Relative Velocity Vectors**

10.3. Flow in Multiple Moving Reference Frames

Many problems involve multiple moving parts or contain stationary surfaces which are not surfaces of revolution (and therefore cannot be used with the Single Reference Frame modeling approach). For these problems, you must break up the model into multiple fluid/solid cell zones, with interface boundaries separating the zones. Zones which contain the moving components can then be solved using the moving reference frame equations ([Equations for a Moving Reference Frame](#) in the [Theory Guide](#)), whereas stationary zones can be solved with the stationary frame equations. The manner in

which the equations are treated at the interface lead to two approaches which are supported in ANSYS FLUENT:

- Multiple Moving Reference Frames
 - Multiple Reference Frame Model (MRF)
 - Mixing Plane Model (MPM)
- Sliding Mesh Model (SMM)

Both the MRF and mixing plane approaches are steady-state approximations, and differ primarily in the manner in which conditions at the interfaces are treated. These approaches will be discussed in the sections below. The sliding mesh model approach is, on the other hand, inherently unsteady due to the motion of the mesh with time. This approach is discussed in *[Modeling Flows Using Sliding and Dynamic Meshes](#)* (p. 559).

For additional information, please see the following sections:

- 10.3.1.The Multiple Reference Frame Model
- 10.3.2.The Mixing Plane Model
- 10.3.3.Mesh Setup for a Multiple Moving Reference Frame
- 10.3.4.Setting Up a Multiple Moving Reference Frame Problem
- 10.3.5.Solution Strategies for MRF and Mixing Plane Problems
- 10.3.6.Postprocessing for MRF and Mixing Plane Problems

10.3.1. The Multiple Reference Frame Model

Additional information about the MRF model is presented in the following sections:

- 10.3.1.1.Overview
- 10.3.1.2.Limitations

10.3.1.1. Overview

The MRF model [48] (p. 2369) is, perhaps, the simplest of the two approaches for multiple zones. It is a steady-state approximation in which individual cell zones can be assigned different rotational and/or translational speeds. The flow in each moving cell zone is solved using the moving reference frame equations (see *[Introduction](#)* (p. 535)). If the zone is stationary ($\omega = 0$), the equations reduce to their stationary forms. At the interfaces between cell zones, a local reference frame transformation is performed to enable flow variables in one zone to be used to calculate fluxes at the boundary of the adjacent zone. For more information about the MRF interface formulation, see *[The MRF Interface Formulation](#)* in the *[Theory Guide](#)*.

It should be noted that the MRF approach does not account for the relative motion of a moving zone with respect to adjacent zones (which may be moving or stationary); the mesh remains fixed for the computation. This is analogous to freezing the motion of the moving part in a specific position and observing the instantaneous flowfield with the rotor in that position. Hence, the MRF is often referred to as the “frozen rotor approach.”

While the MRF approach is clearly an approximation, it can provide a reasonable model of the flow for many applications. For example, the MRF model can be used for turbomachinery applications in which rotor-stator interaction is relatively weak, and the flow is relatively uncomplicated at the interface between the moving and stationary zones. In mixing tanks, for example, since the impeller-baffle interactions are relatively weak, large-scale transient effects are not present and the MRF model can be used.

Another potential use of the MRF model is to compute a flow field that can be used as an initial condition for a transient sliding mesh calculation. This eliminates the need for a startup calculation. The multiple reference frame model should not be used, however, if it is necessary to actually simulate the transients that may occur in strong rotor-stator interactions, the sliding mesh model alone should be used (see [Modeling Flows Using Sliding and Dynamic Meshes](#) (p. 559)).

For more information about and examples of multiple moving reference frames, see [The Multiple Reference Frame Model](#) in the [Theory Guide](#).

10.3.1.2. Limitations

The following limitations exist when using the MRF approach:

- The interfaces separating a moving region from adjacent regions must be oriented such that the component of the frame velocity normal to the boundary is zero. This means that for a translationally moving frame, the moving zone's boundaries must be parallel to the translational velocity vector. For rotating problems, the interfaces must be surfaces of revolution about the axis of rotation defined for the fluid zone. For the example shown [Figure 2.4: "Geometry with One Rotating Impeller"](#) (in the [Theory Guide](#)), this requires the dashed boundary to be circular (not square or any other shape).
- Strictly speaking, the use of multiple reference frames is meaningful only for steady flow. However, ANSYS FLUENT will allow you to solve an unsteady flow when multiple reference frames are being used. In this case, unsteady terms (as described in [Temporal Discretization](#) in the [Theory Guide](#)) are added to all the governing transport equations. You should carefully consider whether this will yield meaningful results for your application, because, for unsteady flows, a sliding mesh calculation will generally yield more meaningful results than an MRF calculation.
- Particle trajectories and pathlines drawn by ANSYS FLUENT use the velocity relative to the cell zone motion. For massless particles, the resulting pathlines follow the streamlines based on relative velocity. For particles with mass, however, the particle tracks displayed are meaningless. Similarly, coupled discrete-phase calculations are meaningless.

An alternative approach for particle tracking and coupled discrete-phase calculations with multiple reference frames is to track particles based on absolute velocity instead of relative velocity. To make this change, use the `define/models/dpm/options/track-in-absolute-frame` text command. Note, that the results may strongly depend on the location of walls inside the multiple reference frame. The particle injection velocities (specified in the [Set Injection Properties Dialog Box](#) (p. 2255)) are defined relative to the frame of reference in which the particles are tracked. By default, the injection velocities are specified relative to the local reference frame. If you enable the `track-in-absolute-frame` option, the injection velocities are specified relative to the absolute frame.

- You cannot accurately model axisymmetric swirl in the presence of multiple reference frames using the relative velocity formulation. This is because the current implementation does not apply the transformation used in [Equation 2–16](#) (in the [Theory Guide](#)) to the swirl velocity derivatives. For this situation, the absolute velocity formulation should be used.
- Translational and rotational velocities are assumed to be constant (time varying ω, v_t are not allowed).
- The relative velocity formulation cannot be used in combination with the MRF and mixture models. (For details, see [Mixture Model Theory](#) in the [Theory Guide](#)). For such cases, use the absolute velocity formulation instead.
- You must not have a single interface between reference frames where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (i.e., the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and

the other that is a standard fluid-fluid interface. See [Using a Non-Conformal Mesh in ANSYS FLUENT \(p. 170\)](#) for the steps involved in setting up a coupled interface.

Important

You can switch from the MRF model to the sliding mesh model for a more robust and accurate solution, by using the `mesh/modify-zones/mrf-to-sliding-mesh` text command.

See [Using Sliding Meshes \(p. 564\)](#) for details on how to make this change in the fluid's boundary conditions. Currently, this switch is not possible when running in parallel or for non-conformal interfaces.

10.3.2. The Mixing Plane Model

The mixing plane model in ANSYS FLUENT provides an alternative to the multiple reference frame and sliding mesh models for simulating flow through domains with one or more regions in relative motion.

Additional information about the mixing plane model is presented in the following sections:

[10.3.2.1. Overview](#)

[10.3.2.2. Limitations](#)

10.3.2.1. Overview

As discussed in [The Multiple Reference Frame Model \(p. 545\)](#), the MRF model is applicable when the flow at the interface between adjacent moving/stationary zones is nearly uniform ("mixed out"). If the flow at this interface is not uniform, the MRF model may not provide a physically meaningful solution. The sliding mesh model (see [Modeling Flows Using Sliding and Dynamic Meshes \(p. 559\)](#)) may be appropriate for such cases, but in many situations it is not practical to employ a sliding mesh. For example, in a multistage turbomachine, if the number of blades is different for each blade row, a large number of blade passages is required in order to maintain circumferential periodicity. Moreover, sliding mesh calculations are necessarily unsteady, and thus require significantly more computation to achieve a final, time-periodic solution. For situations where using the sliding mesh model is not feasible, the mixing plane model can be a cost-effective alternative.

In the mixing plane approach, each fluid zone is treated as a steady-state problem. Flow-field data from adjacent zones are passed as boundary conditions that are spatially averaged or "mixed" at the mixing plane interface. This mixing removes any unsteadiness that would arise due to circumferential variations in the passage-to-passage flow field (e.g., wakes, shock waves, separated flow), thus yielding a steady-state result. Despite the simplifications inherent in the mixing plane model, the resulting solutions can provide reasonable approximations of the time-averaged flow field.

10.3.2.2. Limitations

Note the following limitations of the mixing plane model:

- The LES turbulence model cannot be used with the mixing plane model.
- The models for species transport and combustion cannot be used with the mixing plane model.
- The VOF multiphase model cannot be used with the mixing plane model.
- The discrete phase model cannot be used with the mixing plane model for coupled flows. Non-coupled computations can be done, but you should note that the particles leave the domain of the mixing plane.

You can find more information about the following topics in the Theory Guide:

Rotor and Stator Domains
The Mixing Plane Concept
Choosing an Averaging Method
Mixing Plane Algorithm of ANSYS FLUENT
Mass Conservation
Swirl Conservation
Total Enthalpy Conservation

10.3.3. Mesh Setup for a Multiple Moving Reference Frame

Two mesh setup methods are available. Choose the method that is appropriate for your model, noting the restrictions in [Limitations](#) (p. 546).

- If the boundary between two zones that are in different reference frames is conformal (i.e., the mesh node locations are identical at the boundary where the two zones meet), you can simply create the mesh as usual, with all cell zones contained in the same mesh file. A different cell zone should exist for each portion of the domain that is modeled in a different reference frame. Use an *interior* zone for the boundary between reference frames.
- If the boundary between two zones that are in different reference frames is non-conformal (i.e., the mesh node locations are *not* identical at the boundary where the two zones meet), follow the non-conformal mesh setup procedure described in [Using a Non-Conformal Mesh in ANSYS FLUENT](#) (p. 170).

10.3.4. Setting Up a Multiple Moving Reference Frame Problem

To learn more about setting up a multiple reference frame problem, see the following sections:

- [10.3.4.1. Setting Up Multiple Reference Frames](#)
- [10.3.4.2. Setting Up the Mixing Plane Model](#)

10.3.4.1. Setting Up Multiple Reference Frames

To model a problem involving multiple reference frames, perform the following:

Important

The mesh-setup constraints for a moving reference frame listed in [Mesh Setup for a Single Moving Reference Frame](#) (p. 538) apply to multiple reference frames as well.

1. Select the **Velocity Formulation** to be used in the [General Task Page](#) (p. 1763): either **Absolute** or **Relative**. (For details, see [Choosing the Relative or Absolute Velocity Formulation](#) (p. 541).)

General

(Note that this step is irrelevant if you are using one of the density-based solution algorithms; these algorithms always use an absolute velocity formulation.)

2. For each cell zone in the domain, specify its translational velocity and/or its angular velocity (ω) and the axis about which it rotates.

Cell Zones Conditions

- a. If the zone is moving, or if you plan to specify cylindrical velocity or flow-direction components at inlets to the zone, you will need to define the axis of rotation of the frame of reference. In the **Fluid** or **Solid** dialog box, specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** under the **Reference Frame** tab.
- b. In the **Fluid** (*Figure 10.4 (p. 540)*) or **Solid** dialog box, enable the **Frame Motion** option. Set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity** in the expanded portion of the dialog box under the **Reference Frame** tab.

Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in *Defining Transient Cell Zone and Boundary Conditions (p. 393)*, or a UDF macro, described in `DEFINE_TRANSIENT_PROFILE`. Specifying the individual velocities as either a profile or a UDF allows you to specify a specific input of the frame motion individually. However, you can also specify the frame motion inputs via a single user-defined function that uses the UDF macro `DEFINE_ZONE_MOTION`. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Note

If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

Details about these inputs are presented in *Inputs for Fluid Zones (p. 221)* and in *Inputs for Solid Zones (p. 227)*. Details about the zone motion UDF can be found in `DEFINE_ZONE_MOTION` in the **UDF Manual**.

- c. To switch between the MRF and moving mesh models, click the **Copy To Mesh Motion** for zones with a moving frame of reference and **Copy to Frame Motion** for zones with moving meshes to transfer motion variables, such as the axes, frame origin, and velocity components between the two models.

The variables used for the origin, axis, and velocity components, as well as for the UDF `DEFINE_ZONE_MOTION` will be copied. This is particularly useful if you are doing a steady-state MRF simulation to obtain an initial solution for a transient Moving Mesh simulation in a turbomachine.

3. Define the velocity boundary conditions at walls. You can choose to define either an absolute velocity or a velocity relative to the velocity of the adjacent cell zone specified in step 2.

If the wall is moving at the speed of the moving frame (and hence stationary relative to the moving frame), it is convenient to specify a relative angular velocity of zero. Likewise, a wall that is stationary in the non-moving frame of reference should be given a velocity of zero in the absolute reference frame. Specifying the wall velocities in this manner obviates the need to modify these inputs later if a change is made in the rotational velocity of the fluid zone.

An example for which you would specify a relative velocity is as follows: If an impeller is defined as **wall-3** and the fluid region within the impeller's radius is defined as **fluid-5**, you would need to specify the angular velocity and axis of rotation for **fluid-5** and then assign **wall-3** a relative velocity of 0. If you later wanted to model a different angular velocity for the impeller, you would need to change only the angular velocity of the fluid region; you would not need to modify the wall velocity conditions.

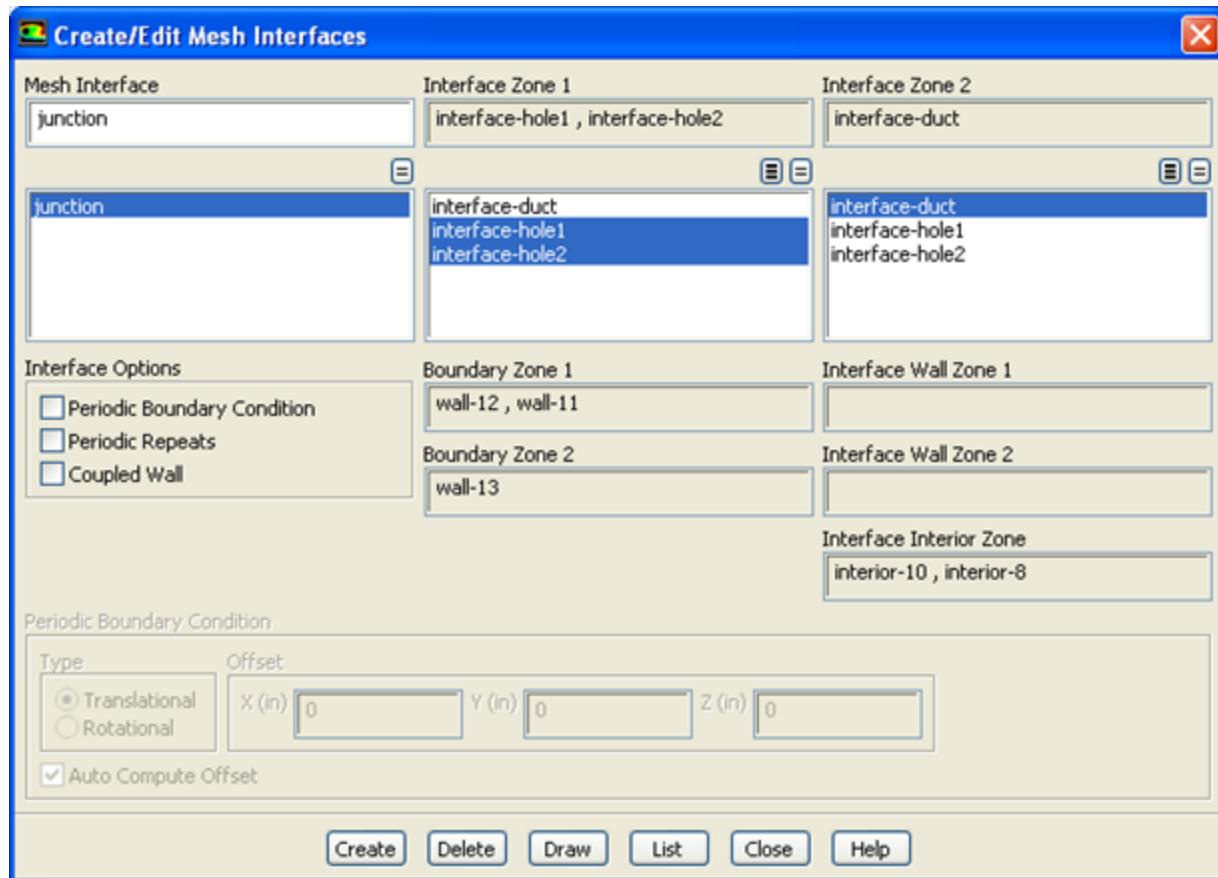

Details about these inputs are presented in [Velocity Conditions for Moving Walls \(p. 314\)](#).

- Define the boundary conditions at the inlets, as described in [Boundary Conditions \(p. 261\)](#). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). Likewise, the total pressure and flow direction can be prescribed in absolute or relative frames for pressure inlets.

Details about these inputs are presented in [Defining the Flow Direction \(p. 271\)](#) and [Defining the Velocity \(p. 278\)](#).

- Define the mesh interfaces in the [Create/Edit Mesh Interfaces Dialog Box \(p. 2022\)](#) ([Figure 11.10 \(p. 567\)](#)).

Mesh Interfaces → Create/Edit...

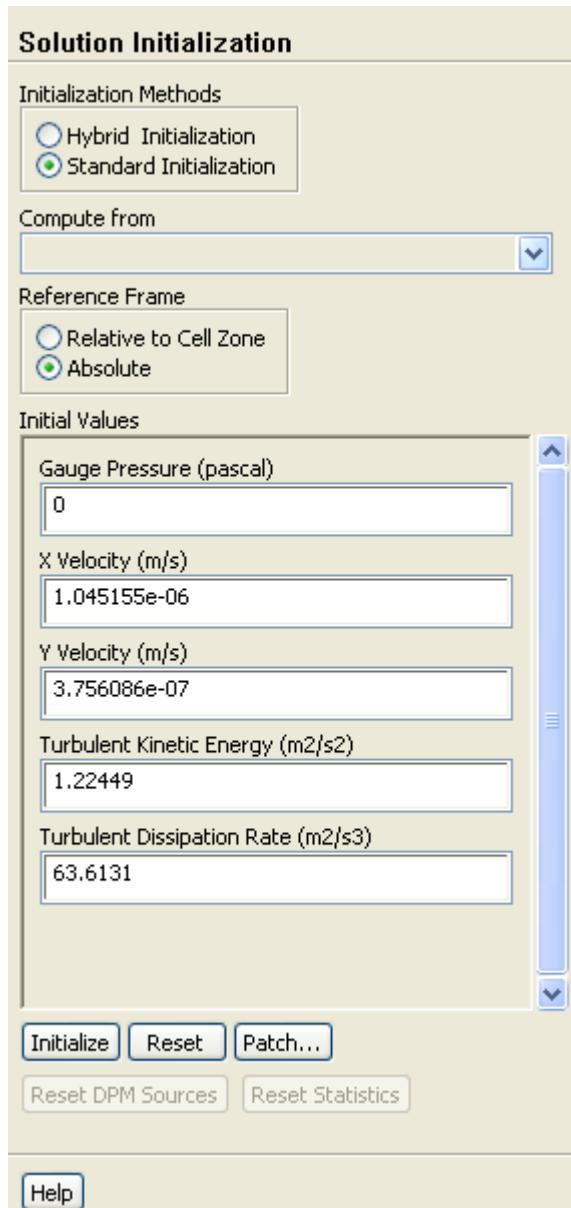

To learn how to use the **Create/Edit Mesh Interfaces** dialog box, see [Using a Non-Conformal Mesh in ANSYS FLUENT \(p. 170\)](#).

- Initialize the solution using an absolute frame of reference ([Figure 10.8 \(p. 551\)](#)).

Solution Initialize

Select the **Absolute** option under **Reference Frame**. If the **Relative to Cell Zone** option is selected, the initial flow field can contain discontinuities, which can cause convergence problems in the first few iterations.

Figure 10.8 The Solution Initialization Task Page for Moving Reference Frames

10.3.4.2. Setting Up the Mixing Plane Model

The model inputs for mixing planes are presented in this section. Only those steps relevant specifically to the setup of a mixing plane problem are listed here. Note that the use of wall and periodic boundaries in a mixing plane model is consistent with their use when the model is not active.

1. Select the **Absolute** or **Relative Velocity Formulation** in the [General Task Page](#) (p. 1763), when the pressure-based solver is enabled.

Important

When the density-based solver is enabled, only the **Absolute Velocity Formulation** can be used with the mixing plane model.

2. For each cell zone in the domain, specify its angular velocity (ω) and the axis about which it rotates.

 **Cell Zones Conditions**

- a. If the zone is rotating, or if you plan to specify cylindrical-velocity or flow-direction components at inlets to the zone, you will need to define the axis of rotation for the frame of reference. In the **Fluid** dialog box or [Solid Dialog Box \(p. 1949\)](#), specify the **Rotation-Axis Origin** and **Rotation-Axis Direction** under the **Reference Frame** tab.
- b. In the **Fluid** ([Figure 10.4 \(p. 540\)](#)) or **Solid** dialog box, enable the **Frame Motion** option and then set the **Speed** under **Rotational Velocity** and/or the **X**, **Y**, and **Z** components of the **Translational Velocity** in the expanded portion of the dialog box under the **Reference Frame** tab.

Important

It is important to define the axis of rotation for the cell zones on *both* sides of the mixing plane interface, including the stationary zone.

3. Define the velocity boundary conditions at walls, as described in step 3 of [Setting Up Multiple Reference Frames \(p. 548\)](#).
4. Define the boundary conditions at the inlets, as described in [Boundary Conditions \(p. 261\)](#). For velocity inlets, you can choose to define either absolute velocities or velocities relative to the motion of the adjacent cell zone (specified in step 2). For pressure inlets and mass flow inlets, the specification of the flow direction and total pressure will always be absolute, because the absolute velocity formulation is always used for mixing plane calculations. For a mass flow inlet, you do not need to specify the mass flow rate or mass flux. ANSYS FLUENT will automatically select the **Mass Flux with Average Mass Flux** specification method and set the correct values when you create the mixing plane, as described in [More About Mass Flux and Average Mass Flux \(p. 285\)](#).

Details about these inputs are presented in [Defining the Flow Direction \(p. 271\)](#), [Defining the Velocity \(p. 278\)](#), and [Inputs at Mass Flow Inlet Boundaries \(p. 283\)](#).

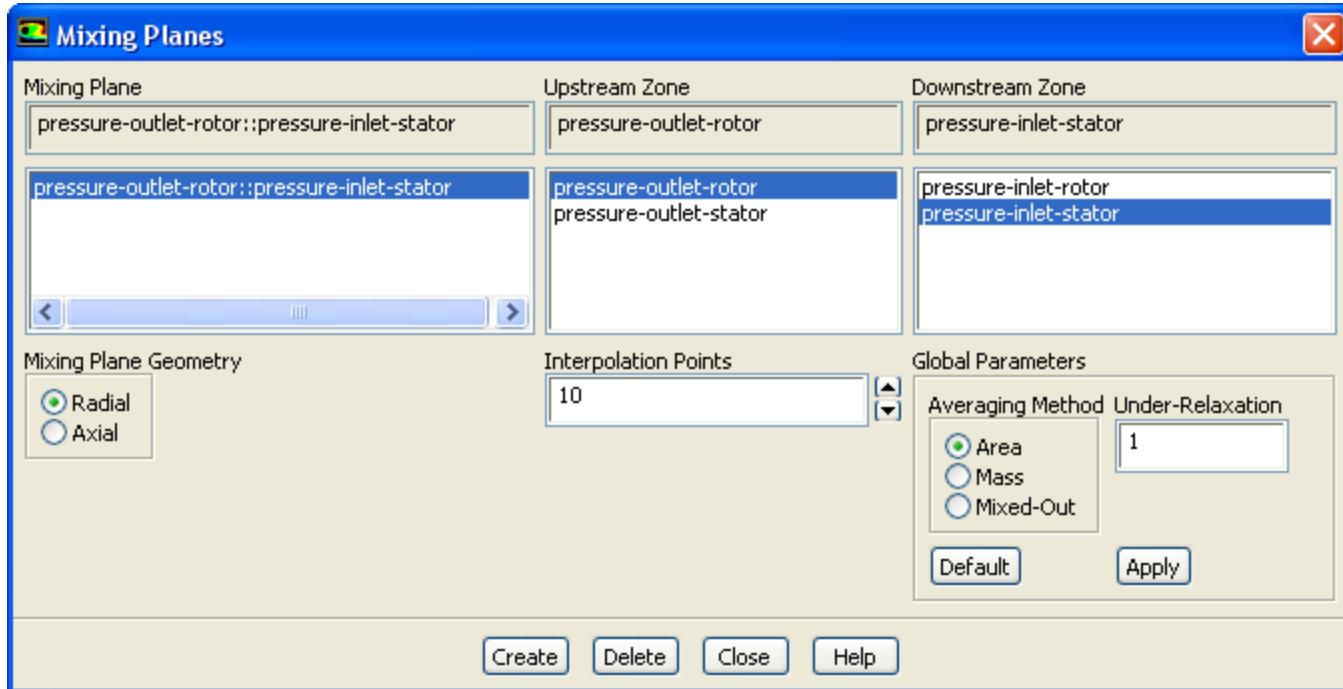

Important

Note that the outlet boundary zone at the mixing plane interface must be defined as a pressure outlet, and the inlet boundary zone at the mixing plane interface must be defined as either a velocity inlet (incompressible flow only), a pressure inlet, or a mass flow inlet. The overall inlet and exit boundary conditions can be any suitable combination permitted by the solver (e.g., velocity inlet, pressure inlet, or mass flow inlet; pressure outlet). Keep in mind, however, that if mass conservation across the mixing plane is important, you need to use a mass flow inlet as the downstream boundary; strict mass conservation is *not* maintained across the mixing plane when you use a velocity inlet or pressure inlet.

5. Define the mixing planes in the [Mixing Planes Dialog Box \(p. 2250\)](#) ([Figure 10.9 \(p. 553\)](#)).

Define → Mixing Planes...

Figure 10.9 The Mixing Planes Dialog Box

- Specify the two zones that comprise the mixing plane by selecting an upstream zone in the **Upstream Zone** list and a downstream zone in the **Downstream Zone** list. It is essential that the correct pairs be chosen from these lists (i.e., that the boundary zones selected lie on the mixing plane interface). You can check this by displaying the mesh.

↳ General → Display...

- (3D only) Indicate the geometry of the mixing plane interface by choosing one of the options under **Mixing Plane Geometry**.

A **Radial** geometry signifies that information at the mixing plane interface is to be circumferentially averaged into profiles that vary in the radial direction, e.g., $p(r)$, $T(r)$. This is the case for axial-flow machines, for example.

An **Axial** geometry signifies that circumferentially averaged profiles are to be constructed that vary in the axial direction, e.g., $p(x)$, $T(x)$. This is the situation for a radial-flow device.

Important

Note that the radial direction is normal to the rotation axis for the fluid zone and the axial direction is parallel to the rotation axis.

- (3D only) Set the number of **Interpolation Points**. This is the number of radial or axial locations used in constructing the boundary profiles for circumferential averaging. You should choose a number that approximately corresponds to the resolution of the surface mesh in the radial or

axial direction. Note that while you can use more points if you wish, the resolution of the boundary profile will only be as fine as the resolution of the surface mesh itself.

In 2D the flow data is averaged over the entire interface to create a profile consisting of a single data point. For this reason you do not need to set the number of **Interpolation Points** or select a **Mixing Plane Geometry** in 2D.

- d. Set the **Global Parameters** for the mixing plane.
 - i. Select the **Averaging Method**. The **Area** averaging method is the default method. For detailed information about each of the **Area**, **Mass**, or **Mixed-Out** options, see [Choosing an Averaging Method](#) in the [Theory Guide](#).
 - ii. Set the **Under-Relaxation** parameter. It is sometimes desirable to under-relax the changes in boundary values at mixing planes as these may change very rapidly during the early iterations of the solution and cause the calculation to diverge. The changes can be relaxed by specifying an under-relaxation less than 1. The new boundary profile values are then computed using

$$\phi_{new} = \phi_{old} + \alpha (\phi_{calculated} - \phi_{old}) \quad (10-1)$$

where α is the under-relaxation factor. Once the flow field is established, the value of α can be increased.

- iii. Click **Apply** to set the **Global Parameters**. If the **Default** button is visible to the right of the **Apply** button, clicking the **Default** button will return **Global Parameters** back to their default values. The **Default** button will then change to be a **Reset** button. Clicking the **Reset** button will change the **Global Parameters** back to the values that were last applied.
- e. Click **Create** to create a new mixing plane. ANSYS FLUENT will name the mixing plane by combining the names of the zones selected as the **Upstream Zone** and **Downstream Zone** and enter the new mixing plane in the **Mixing Plane** list.

If you create an incorrect mixing plane, you can select it in the **Mixing Plane** list and click the **Delete** button to delete it.

10.3.4.2.1. Modeling Options

There are two options available for use with the mixing plane model: a fixed pressure level for incompressible flows, and the swirl conservation described in [Swirl Conservation](#) in the [Theory Guide](#).

10.3.4.2.1.1. Fixing the Pressure Level for an Incompressible Flow

For certain turbomachinery configurations, such as a torque converter, there is no fixed-pressure boundary when the mixing plane model is used. The mixing plane model is usually used to model the three interfaces that connect the components of the torque converter. In this configuration, the pressure is no longer fixed. As a result, the pressure may float unbounded, making it difficult to obtain a converged solution.

To resolve this problem, ANSYS FLUENT offers an option for fixing the pressure level. When this option is enabled, ANSYS FLUENT will adjust the gauge pressure field after each iteration by subtracting from it the pressure value in the cell closest to the **Reference Pressure Location** in the [Operating Conditions Dialog Box](#) (p. 1952).

Important

This option is available only for incompressible flows calculated using the pressure-based solver.

To enable the fixed pressure option, use the `fix-pressure-level` text command:

```
define → mixing-planes → set → fix-pressure-level
```

10.3.4.2.1.2. Conserving Swirl Across the Mixing Plane

Conservation of swirl is important for applications such as torque converters ([Swirl Conservation](#) in the [Theory Guide](#)). If you want to enable swirl conservation across the mixing plane, you can use the commands in the `conserve-swirl` text menu:

```
define → mixing-planes → set → conserve-swirl
```

To turn on swirl conservation, use the `enable?` text command. Once the option is turned on, you can ask the solver to report information about the swirl conservation during the calculation. If you turn on `verbosity?`, ANSYS FLUENT will report for every iteration the zone ID for the zone on which the swirl conservation is active, the upstream and downstream swirl integration per zone area, and the ratio of upstream to downstream swirl integration before and after the correction.

To obtain a report of the swirl integration at every pressure inlet, pressure outlet, velocity inlet, and mass flow inlet in the domain, use the `report-swirl-integration` command. You can use this information to determine the torque acting on each component of the turbomachinery according to [Equation 2-22](#) (in the [Theory Guide](#)).

10.3.4.2.1.3. Conserving Total Enthalpy Across the Mixing Plane

One of the options available in the mixing plane model is to conserve total enthalpy across the mixing plane. This is a desirable feature because global parameters such as efficiency are directly related to the change in total enthalpy across a blade row or stage.

The procedure for ensuring conservation of total enthalpy simply involves adjusting the downstream total temperature profile such that the integrated total enthalpy matches the upstream integrated total enthalpy.

If you want to enable total enthalpy conservation, you can use the commands in the `conserve-total-enthalpy` text menu:

```
define → mixing-planes → set → conserve-total-enthalpy
```

To turn on total enthalpy conservation, use the `enable?` text command. Once the option is turned on, you can ask the solver to report information about the total enthalpy conservation during the calculation. If you turn on `verbosity?`, ANSYS FLUENT will report at every iteration the zone ID for the zone on which the total enthalpy conservation is active, the upstream and downstream heat flux, and the ratio of upstream to downstream heat flux.

10.3.5. Solution Strategies for MRF and Mixing Plane Problems

10.3.5.1. MRF Model

For multiple moving reference frames, follow the guidelines presented in *Solution Strategies for a Single Moving Reference Frame* (p. 542) for a single moving reference frame. Keep in mind that with multiple zones, the possibility exists of interaction between moving and stationary components. This will manifest itself as poor or oscillatory convergence. In such cases, it is strongly recommend that the sliding mesh approach be used to compute the flowfield in order to resolve the unsteady interactions.

10.3.5.2. Mixing Plane Model

It should be emphasized that the mixing plane model is a reasonable approximation so long as there is no significant reverse flow in the vicinity of the mixing plane. If significant reverse flow occurs, the mixing plane will not be a satisfactory model of the actual flow. In a numerical simulation, reverse flow often occurs during the early stages of the computation even though the flow at convergence is not reversed. Therefore, it is helpful in these situations to first obtain a provisional solution using *fixed* conditions at the rotor-stator interface. The mixing plane model can then be enabled and the solution run to convergence.

If you are using the mass or mixed-out averaging method and you are experiencing convergence problems in the presence of severe reverse flow, initialize your solution using the default area-averaging method, then switch to mass or mixed-out averaging after the reverse flow dies out.

Under-relaxing the changes in the mixing plane boundary values can also help in troublesome situations. In many cases, setting the under-relaxation factor to a value less than 1 can be helpful. Once the flow field is established, you can gradually increase the under-relaxation factor.

10.3.6. Postprocessing for MRF and Mixing Plane Problems

When you solve a problem using the multiple reference frame or mixing plane model, you can plot or report both absolute and relative velocities. For all velocity parameters (e.g., **Velocity Magnitude** and **Mach Number**), corresponding relative values will be available for postprocessing (e.g., **Relative Velocity Magnitude** and **Relative Mach Number**). These variables are contained in the **Velocity...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Relative values are also available for postprocessing of total pressure, total temperature, and any other parameters that include a dynamic contribution dependent on the reference frame (e.g., **Relative Total Pressure**, **Relative Total Temperature**).

Important

Relative velocities are relative to the translational/rotational velocity of the “reference zone” (specified in the **Reference Values** task page (see *Reference Values Task Page* (p. 2046))). The velocity of the reference zone is the velocity defined in the *Fluid Dialog Box* (p. 1942) for that zone.

When plotting velocity vectors, you can choose to plot vectors in the absolute frame (the default), or you can select **Relative Velocity** in the **Vectors of** drop-down list in the *Vectors Dialog Box* (p. 2123) to plot vectors relative to the translational/rotational velocity of the “reference zone” (specified in the *Reference Values Task Page* (p. 2046)). If you plot relative velocity vectors, you might want to color the vectors by relative velocity magnitude (by choosing **Relative Velocity Magnitude** in the **Color by** list); by default they will be colored by absolute velocity magnitude.

You can also generate a plot of circumferential averages in ANSYS FLUENT. This allows you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS FLUENT computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see [XY Plots of Circumferential Averages \(p. 1596\)](#).

For details about turbomachinery-specific postprocessing features see [Turbomachinery Postprocessing \(p. 1605\)](#).

Chapter 11: Modeling Flows Using Sliding and Dynamic Meshes

This chapter describes the setup and use of the sliding and dynamic mesh models in ANSYS FLUENT. To learn more about the theory of sliding meshes in ANSYS FLUENT, see [Sliding Mesh Theory](#) in the [Theory Guide](#). For more information about the theory behind dynamic meshes in ANSYS FLUENT, see [Dynamic Mesh Theory](#) in the [Theory Guide](#).

Understanding and using the sliding and deforming mesh models is presented in the following sections:

- 11.1. Introduction
- 11.2. Sliding Mesh Examples
- 11.3. The Sliding Mesh Technique
- 11.4. Sliding Mesh Interface Shapes
- 11.5. Using Sliding Meshes
- 11.6. Using Dynamic Meshes

11.1. Introduction

The sliding mesh model allows you to set up a problem in which separate zones move relative to each other. The motion can be translational or rotational. The relative motion of stationary and moving components (e.g., in a rotating machine) will give rise to transient interactions. Often, the transient solution that is sought in a sliding mesh simulation is time-periodic. That is, the transient solution repeats with a period related to the speeds of the moving domains.

The dynamic mesh model allows you to move the boundaries of a cell zone relative to other boundaries of the zone, and to adjust the mesh accordingly. The boundaries can move rigidly with respect to each other (i.e., linear or rotational motion), and/or deform.

When deciding whether to use a sliding mesh versus a dynamic mesh, consider the following:

- Many problems could be solved by either approach.
- If the problem does not involve mesh deformation, the sliding mesh model is recommended, as it is simpler and more efficient.
- The dynamic mesh method must be used if the mesh is deforming, or if the mesh motion is a function of the solution (e.g., the six degree of freedom solver).

For examples of typical sliding mesh and dynamic mesh problems, see [Introduction](#) in the [Theory Guide](#).

11.2. Sliding Mesh Examples

When a time-accurate solution (rather than a time-averaged solution) for rotor-stator interaction is desired, you must use the sliding mesh model to compute the unsteady flow field. The sliding mesh model is the most accurate method for simulating flows in multiple moving reference frames, but also the most computationally demanding.

Most often, the unsteady solution that is sought in a sliding mesh simulation is time-periodic. That is, the unsteady solution repeats with a period related to the speeds of the moving domains. However, you can model other types of transients, including translating sliding mesh zones (e.g., two cars or trains

passing in a tunnel, as shown in [Figure 11.1 \(p. 560\)](#)). Note that the sliding mesh can be modeled using periodic boundaries ([Figure 11.2 \(p. 560\)](#)) or a circular/cylindrical interface ([Figure 11.3 \(p. 561\)](#)).

Figure 11.1 Two Passing Trains in a Tunnel

Figure 11.2 Rotor-Stator Interaction (Stationary Guide Vanes with Rotating Blades)

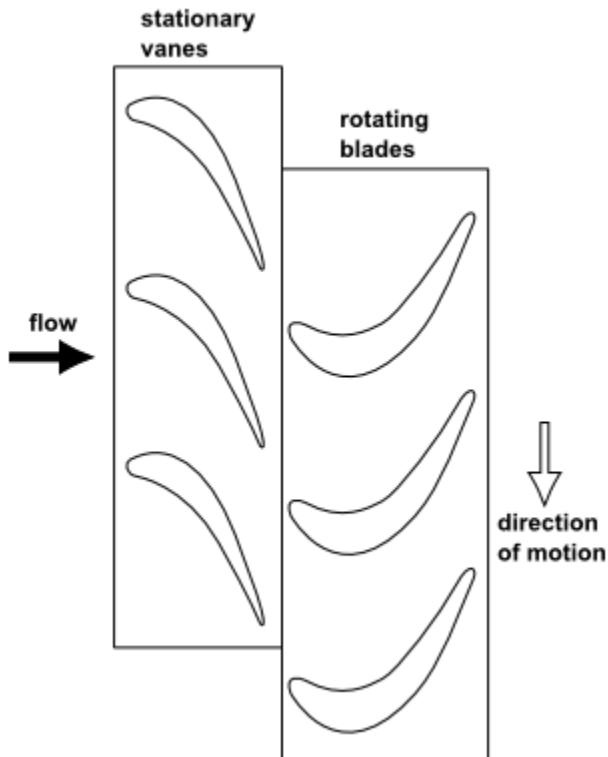

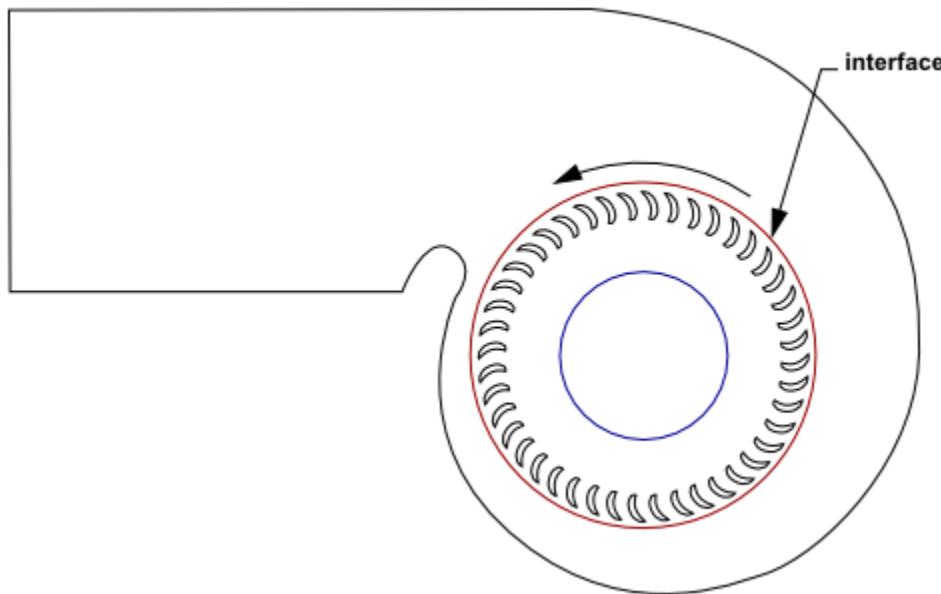

Figure 11.3 Blower

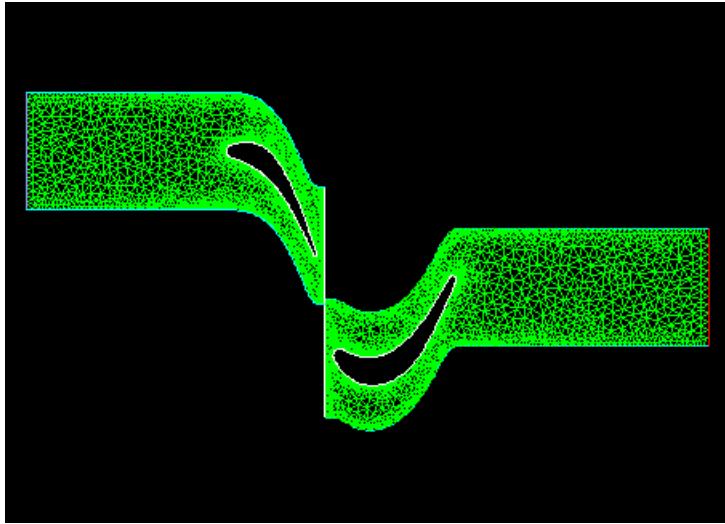

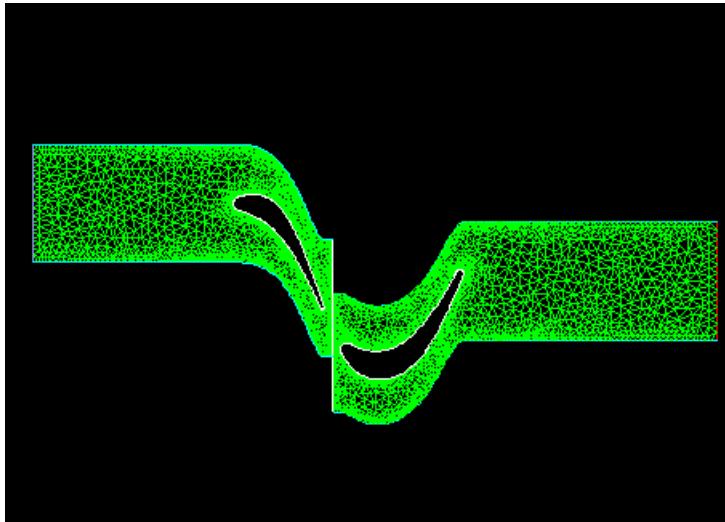

Note that for flow situations where there is no interaction between stationary and moving parts (e.g., when there is only a rotor), it is not necessary to use a sliding mesh, and the moving reference frame model is recommended. (See [Flow in a Moving Reference Frame](#) for details.) If you are interested in a steady approximation of the interaction, you may use the multiple reference frame model or the mixing plane model, as described in [The Multiple Reference Frame Model](#) and [The Mixing Plane Model](#) in the Theory Guide.

11.3. The Sliding Mesh Technique

In the sliding mesh technique, two or more cell zones are used. (If you generate the mesh in each zone independently, you will need to merge the mesh files prior to starting the calculation, as described in [Reading Multiple Mesh/Case/Data Files](#) in the User's Guide.) Each cell zone is bounded by at least one "interface zone" where it meets the opposing cell zone. The interface zones of adjacent cell zones are associated with one another to form a "mesh interface." The two cell zones will move relative to each other along the mesh interface.

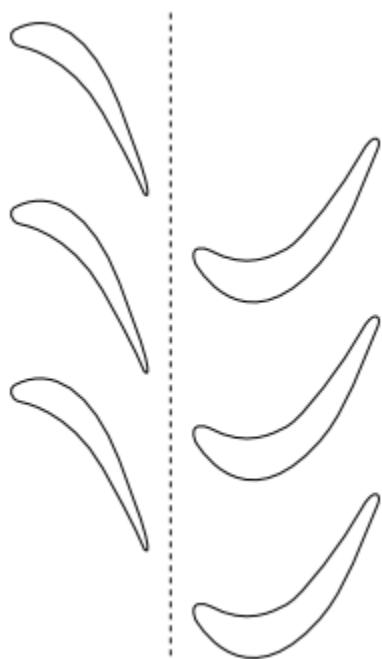

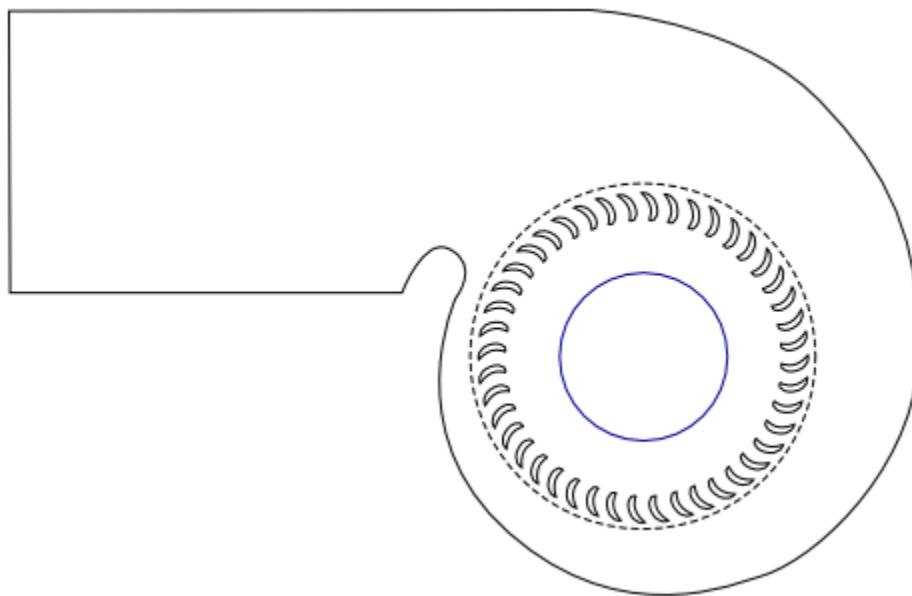

During the calculation, the cell zones slide (i.e., rotate or translate) relative to one another along the mesh interface in discrete steps. [Figure 11.4 \(p. 562\)](#) and [Figure 11.5 \(p. 562\)](#) show the initial position of two meshes and their positions after some translation has occurred. Note that all non-conformal interfaces will be automatically updated (if necessary) by ANSYS FLUENT when the mesh is updated.

As the rotation or translation takes place, node alignment along the mesh interface is not required. Since the flow is inherently unsteady, a time-dependent solution procedure is required.

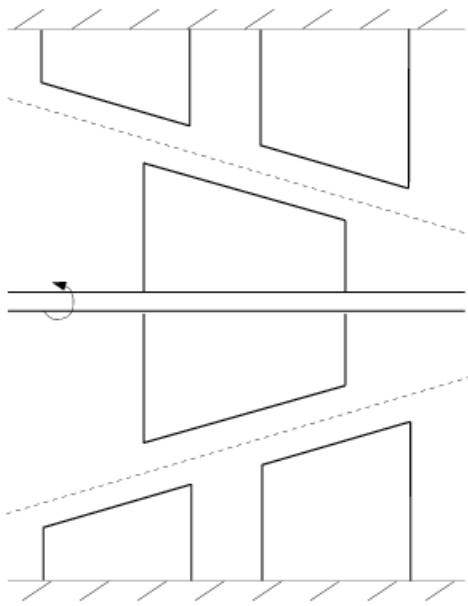

Figure 11.4 Initial Position of the Meshes**Figure 11.5 Rotor Mesh Slides with Respect to the Stator**

11.4. Sliding Mesh Interface Shapes

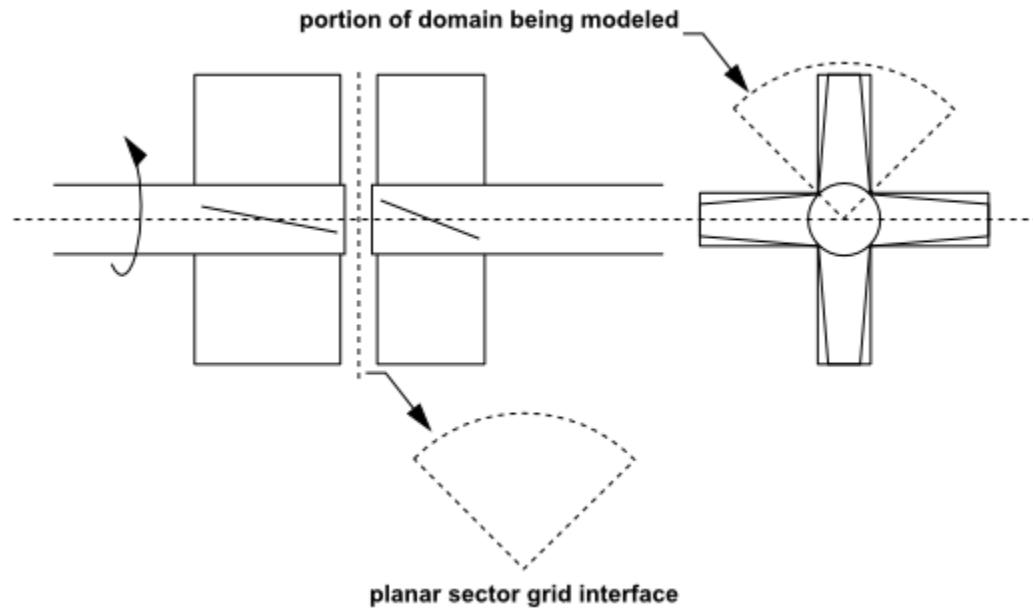

The mesh interface and the associated interface zones can be any shape, provided that the two interface boundaries are based on the same geometry. [Figure 11.6 \(p. 563\)](#) shows an example with a linear mesh interface and [Figure 11.7 \(p. 563\)](#) shows a circular-arc mesh interface. (In both figures, the mesh interface is designated by a dashed line.)

Figure 11.6 2D Linear Mesh Interface**Figure 11.7 2D Circular-Arc Mesh Interface**

If *Figure 11.6* (p. 563) was extruded to 3D, the resulting sliding interface would be a planar rectangle; if *Figure 11.7* (p. 563) was extruded to 3D, the resulting interface would be a cylinder. *Figure 11.8* (p. 564) shows an example that would use a conical mesh interface. (The slanted, dashed lines represent the intersection of the conical interface with a 2D plane.)

Figure 11.8 3D Conical Mesh Interface

For an axial rotor/stator configuration, in which the rotating and stationary parts are aligned axially instead of being concentric (see [Figure 11.9 \(p. 564\)](#)), the interface will be a planar sector. This planar sector is a cross-section of the domain perpendicular to the axis of rotation at a position along the axis between the rotor and the stator.

Figure 11.9 3D Planar-Sector Mesh Interface

11.5. Using Sliding Meshes

This section describes how to use sliding meshes, including restrictions and constraints, problem setup, solution strategies, and postprocessing.

11.5.1. Requirements and Constraints

11.5.2. Setting Up the Sliding Mesh Problem

11.5.3. Solution Strategies for Sliding Meshes

11.5.4. Postprocessing for Sliding Meshes

11.5.1. Requirements and Constraints

Before beginning the problem setup in ANSYS FLUENT, be sure that the mesh you have created meets the following requirements:

- The mesh must have a different cell zone for each portion of the domain that is sliding at a different speed.
- The mesh interface must be situated such that there is no motion normal to it.
- The mesh interface can be any shape (including a non-planar surface, in 3D), provided that the two interface boundaries are based on the same geometry. If there are sharp features in the mesh (e.g., 90-degree angles), it is especially important that both sides of the interface closely follow that feature.
- If you create a single mesh with multiple cell zones, you must be sure that each cell zone has a distinct face zone on the sliding boundary. The face zones for two adjacent cell zones will have the same position and shape, but one will correspond to one cell zone and one to the other. (Note that it is also possible to create a separate mesh file for each of the cell zones, and then merge them as described in [Reading Multiple Mesh/Case/Data Files \(p. 158\)](#).)
- If you are modeling a rotor/stator geometry using periodicity, the periodic angle of the mesh around the rotor blade(s) must be the same as that of the mesh around the stationary vane(s).
- All periodic zones must be correctly oriented (either rotational or translational) before you create the mesh interface.
- Note the following limitations if you want to use the periodic repeats option as part of the mesh interface:
 - The edges of the second interface zone must be offset from the corresponding edges of the first interface zone by a uniform amount (either a uniform translational displacement or a uniform rotation angle).
 - Some portion of the two interface zones must overlap (i.e., be spatially coincident).
 - The non-overlapping portions of the interface zones must have identical shape and dimensions at all times during the mesh motion.
 - One pair of conformal periodic zones must be adjacent to each of the interface zones. For example, when you calculate just one channel and blade of a fan, turbine, etc., you must have conformal periodics on either side of the interface threads. This will not work with non-conformal periodics.

Note that for 3D cases, you cannot have more than one pair of conformal periodic zones adjacent to each of the interface zones.

- You must not have a single sliding mesh interface where part of the interface is made up of a coupled two-sided wall, while another part is not coupled (i.e., the normal interface treatment). In such cases, you must break the interface up into two interfaces: one that is a coupled interface, and the other that is a standard fluid-fluid interface. See [Using a Non-Conformal Mesh in ANSYS FLUENT \(p. 170\)](#) for information about creating coupled interfaces.

For details about these restrictions and general information about how the sliding mesh model works in ANSYS FLUENT, see [The Sliding Mesh Technique \(p. 561\)](#).

11.5.2. Setting Up the Sliding Mesh Problem

The steps for setting up a sliding mesh problem are listed below. (Note that this procedure includes only those steps necessary for the sliding mesh model itself; you will need to set up other models, boundary conditions, etc. as usual.)

1. Enable the appropriate option for modeling transient flow in the [General Task Page \(p. 1763\)](#). (See [Performing Time-Dependent Calculations \(p. 1365\)](#) for details about the transient modeling capabilities in ANSYS FLUENT.)

General

2. Set the cell zone conditions for the sliding motion:

Cell Zones Conditions

In the [Solid Dialog Box \(p. 1949\)](#) or [Fluid Dialog Box \(p. 1942\)](#) of each moving fluid or solid zone, enable the **Mesh Motion** option and set the translational and/or rotational velocity under the **Mesh Motion** tab. (Note that a solid zone cannot move at a different speed than an adjacent fluid zone.)

Important

Note that simultaneous translation and rotation can be modeled only if the rotation axis and the translation direction are the same (i.e., the origin is fixed).

Note that the speed can be specified as a constant value or a transient profile. The transient profile may be in a file format, as described in [Defining Transient Cell Zone and Boundary Conditions \(p. 393\)](#), or a UDF macro, described in [DEFINE_TRANSIENT_PROFILE](#) in the [UDF Manual](#). Specifying the individual velocities as either a profile or a UDF allows you to specify a single component of the frame motion individually. However, you can also specify the frame motion using a user-defined function. This may prove to be quite convenient if you are modeling a more complicated motion of the moving reference frame, where the hooking of many different user-defined functions or profiles can be cumbersome.

Note

If you decide to hook a UDF, then you will no longer have access to the rotation axis origin and direction, or the velocities.

3. Set the boundary conditions for the sliding motion:

Boundary Conditions

Change the zone **Type** of the interface zones of adjacent cell zones to **interface** in the [Boundary Conditions Task Page \(p. 1958\)](#).

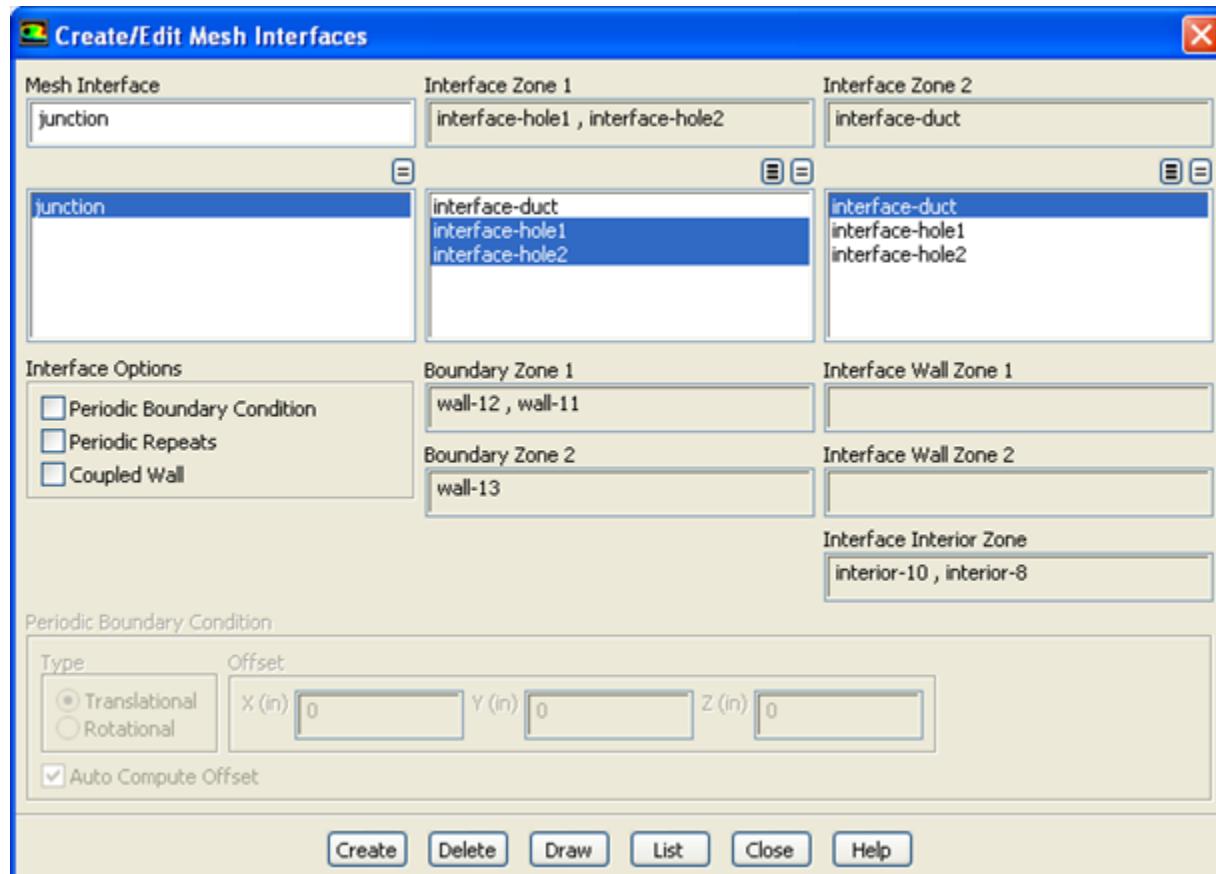

By default, the velocity of a wall is set to zero relative to the motion of the adjacent mesh. For walls bounding a moving mesh this results in a “no-slip” condition in the reference frame of the mesh. Therefore, you need not modify the wall velocity boundary conditions unless the wall is stationary in the absolute frame, and therefore moving in the relative frame. See [Velocity Conditions for Moving Walls \(p. 314\)](#) for details about wall motion.

See [Cell Zone and Boundary Conditions \(p. 211\)](#) for details about inputting cell zone and boundary conditions.

- Define the mesh interfaces in the [Create/Edit Mesh Interfaces Dialog Box \(p. 2022\) \(Figure 11.10 \(p. 567\)\)](#).

Mesh Interfaces → **Create/Edit...**

Figure 11.10 The Create/Edit Mesh Interfaces Dialog Box

- Enter a name for the interface in the **Mesh Interface** field.
- Specify the two interface zones that comprise the mesh interface by selecting one or more zones in the **Interface Zone 1** list and one or more zones in the **Interface Zone 2** list. (The order does not matter.)
- Enable the desired **Interface Options**, if appropriate. There are two options relevant for sliding meshes:
 - Enable **Periodic Repeats** when each of the two cell zones has a single pair of conformal periodics adjacent to the interface (see [Figure 6.31 \(p. 166\)](#)). This option is typically used when simulating the interface between a rotor and stator. See [Non-Conformal Meshes \(p. 162\)](#) for further details.

Important

Periodic Repeats is not a valid option when more than one zone is selected in each **Interface Zone**.

- Enable **Coupled Wall** if you would like to model a thermally coupled wall between two fluid zones that share a sliding mesh interface.
-

Important

Note that the following interfaces are coupled by default:

- the interface between a solid zone and fluid zone
- the interface between a solid zone and solid zone

Therefore, no action is required in the *Create/Edit Mesh Interfaces Dialog Box* (p. 2022) to set up such interfaces.

- d. Click **Create** to create a new mesh interface.

For non-periodic interfaces, ANSYS FLUENT will create boundary zones for the interface, which will appear under **Boundary Zone 1** and **Boundary Zone 2**. You can use the *Boundary Conditions Task Page* (p. 1958) to change them to another zone type (e.g., pressure far-field, symmetry, pressure outlet).

If you have enabled the **Coupled Wall** option, ANSYS FLUENT will also create wall interface zones, which will appear under **Interface Wall Zone 1** and **Interface Wall Zone 2**.

If you create an incorrect mesh interface, you can select it in the **Mesh Interface** list and click the **Delete** button to delete it. (Any boundary zones that were created when the interface was created will also be deleted.)

After a **Mesh Interface** is defined, you can select the appropriate mesh interface and click the **Draw** button to display the zones under **Interface Zone 1** and **Interface Zone 2** together as defined by the **Mesh Interface**. This is particularly useful if you want to check the location of the interface zones prior to setting up a mesh interface.

5. Preview the mesh motion using the **Zone Motion** dialog box, which can be opened from the **Run Calculation** task page.

Run Calculation → Preview Mesh Motion...

For details about using the **Zone Motion** dialog box, see *Previewing the Dynamic Mesh* (p. 661).

Important

When you have completed the problem setup, you should save an initial case file so that you can easily return to the original mesh position (i.e., the positions before any sliding occurs). The mesh position is stored in the case file, so case files that you save at different times during the transient calculation will contain meshes at different positions.

Important

If you desire to go from an MRF model setup to a sliding mesh setup, use the following text command:

```
mesh → modify-zones → mrf-to-sliding-mesh
```

To successfully switch from an MRF to a sliding mesh, you must provide the ID of the fluid zone. ANSYS FLUENT identifies all the zones belonging to this fluid zone, as well as fluid zones shared in the domain. ANSYS FLUENT then splits these zones into walls, after which the walls are slit converted to interfaces. ANSYS FLUENT then changes the cell zone condition of the fluid zone to **Moving Mesh** in the *Fluid Dialog Box* (p. 1942). Note that the interface between the cells zones should be an interior boundary. You do not need to do this if you have already created a mesh interface. The sliding mesh solution tends to be more robust than the MRF solution.

11.5.3. Solution Strategies for Sliding Meshes

You will begin the sliding mesh calculation by initializing the solution (as described in *Initializing the Entire Flow Field Using Standard Initialization* (p. 1349)) and then specifying the time step size and number of time steps in the *Run Calculation Task Page* (p. 2107), as for any other transient calculation. (See *Performing Time-Dependent Calculations* (p. 1365) for details about time-dependent solutions.) Note that the time step size in the initial case file is saved without clicking **Calculate**. ANSYS FLUENT will iterate on the current time step solution until satisfactory residual reduction is achieved, or the maximum number of iterations per time step is reached. When it advances to the next time step, the cell and wall zones will automatically be moved according to the specified translational or rotational velocities (as discussed in the previous section). The new interface-zone intersections will be computed automatically, and resultant interior/periodic/external boundary zones will be updated.

Note that you can run the MRF case using mesh interfaces with an appreciable loss of accuracy, doing so makes it easier to later on convert to a sliding mesh.

Note

The sliding mesh can be initialized with an MRF solution (rather using Standard or Hybrid initializations).

It is recommended that you preview the sliding mesh motion (as described in *Previewing the Dynamic Mesh* (p. 661)) before beginning your calculation. This can catch problems with the motion specification(s) before you begin the CFD calculation. Remember to save the case and initial data files before doing a mesh preview since the mesh position is altered once you do the preview. You can reread the initial condition case/data files to get back to the original mesh position.

11.5.3.1. Saving Case and Data Files

ANSYS FLUENT's automatic saving of case and data files (see *Automatic Saving of Case and Data Files* (p. 68)) can be used with the sliding mesh model. This provides a convenient way for you to save results at successive time steps for later postprocessing.

Important

You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh's original position to restart the solution if desired.

Important

If you are planning to solve your sliding mesh model in several stages, whereby you run the calculation for some period of time, save case and data files, exit ANSYS FLUENT, start a new ANSYS FLUENT session, read the case and data files, continue the calculation for some time, save case and data files, exit ANSYS FLUENT, and so on, there may be some distortion in the mesh with each subsequent continuation of the calculation. To avoid this problem, you can delete the mesh interface before saving the case file, and then create it again after you read the case file into a new ANSYS FLUENT session.

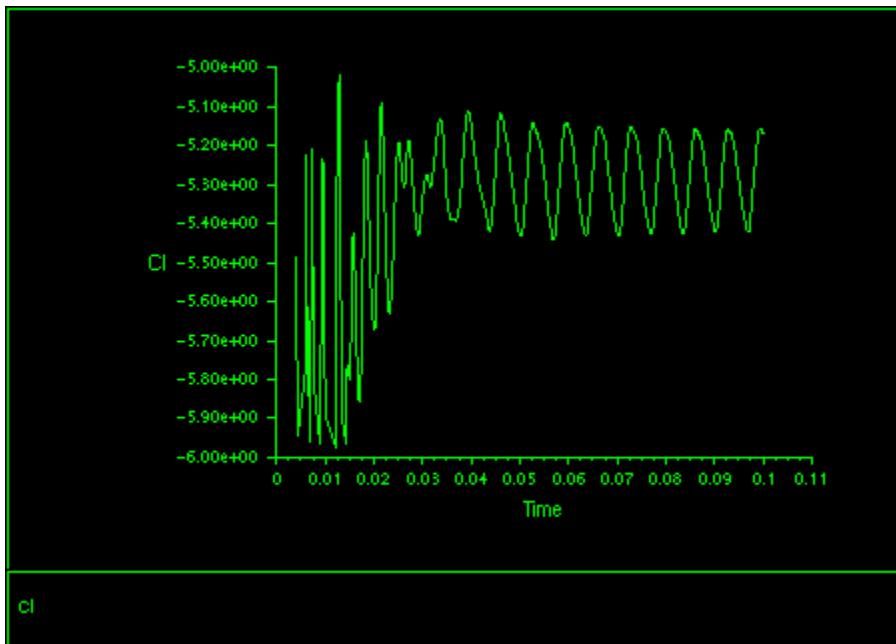

11.5.3.2. Time-Periodic Solutions

For some problems (e.g., rotor-stator interactions), you may be interested in a time-periodic solution. That is, the startup transient behavior may not be of interest to you. Once this startup phase has passed, the flow will start to exhibit time-periodic behavior. If T is the period of unsteadiness, then for some flow property ϕ at a given point in the flow field:

$$\phi(t) = \phi(t + NT) \quad (N = 1, 2, 3, \dots) \quad (11-1)$$

For rotating problems, the period (in seconds) can be calculated by dividing the sector angle of the domain (in radians) by the rotor speed (in radians/sec): $T = \theta/\Omega$. For 2D rotor-stator problems, $T = P/v_b$, where P is the pitch and v_b is the blade speed. The number of time steps in a period can be determined by dividing the time period by the time step size. When the solution field does not change from one period to the next (for example, if the change is less than 5%), a time-periodic solution has been reached.

To determine how the solution changes from one period to the next, you will need to compare the solution at some point in the flow field over two periods. For example, if the time period is 10 seconds, you can compare the solution at a given point after 22 seconds with the solution after 32 seconds to see if a time-periodic solution has been reached. If not, you can continue the calculation for another period and compare the solutions after 32 and 42 seconds, and so on until you see little or no change from one period to the next. You can also track global quantities, such as lift and drag coefficients and mass flow, in the same manner. [Figure 11.11 \(p. 571\)](#) shows a lift coefficient plot for a time-periodic solution.

Figure 11.11 Lift Coefficient Plot for a Time-Periodic Solution

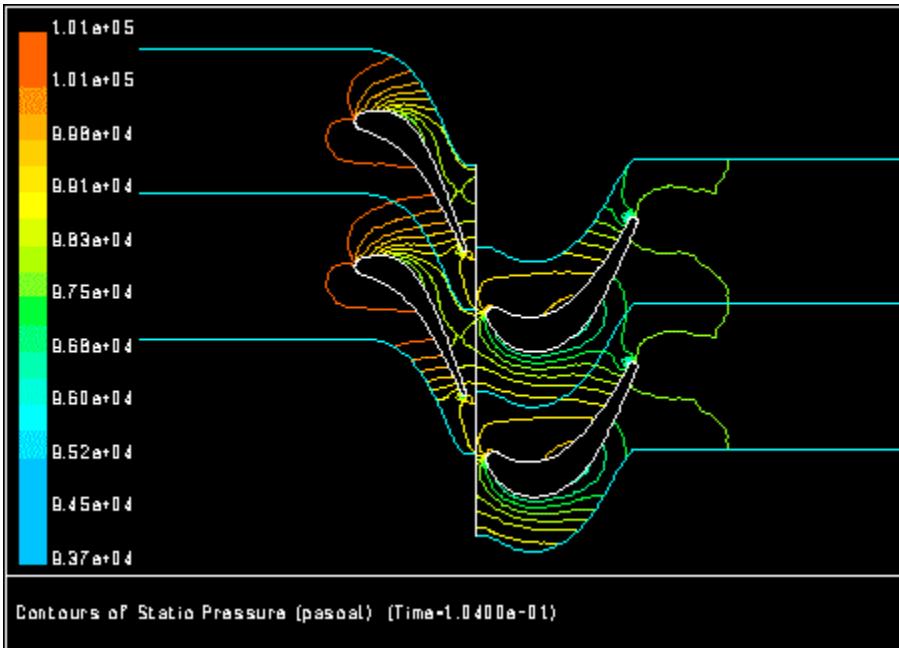

The final time-periodic solution is independent of the time steps taken during the initial stages of the solution procedure. You can therefore define “large” time steps in the initial stages of the calculation, since you are not interested in a time-accurate solution for the startup phase of the flow. Starting out with large time steps will allow the solution to become time-periodic more quickly. As the solution becomes time-periodic, however, you should reduce the time step in order to achieve a time-accurate result.

Important

If you are solving with second-order time accuracy, the temporal accuracy of the solution will be affected if you change the time step during the calculation. You may start out with larger time steps, but you should not change the time step by more than 20% during the solution process. You should not change the time step at all during the last several periods to ensure that the solution has approached a time-periodic state.

11.5.4. Postprocessing for Sliding Meshes

Postprocessing for sliding mesh problems is the same as for other transient problems. You will read in the case and data file for the time of interest and display and report results as usual. For spatially-periodic problems, you may want to use periodic repeats (set in the [Views Dialog Box \(p. 2157\)](#), as described in [Modifying the View \(p. 1554\)](#)) to display the geometry. [Figure 11.12 \(p. 572\)](#) shows the flow field for the rotor-stator example in [Figure 11.4 \(p. 562\)](#) at one instant in time, using 1 periodic repeat.

Figure 11.12 Contours of Static Pressure for the Rotor-Stator Example

When displaying velocity vectors, note that absolute velocities (i.e., velocities in the inertial, or laboratory, reference frame) are displayed by default. You may also choose to display relative velocities by selecting **Relative Velocity** in the **Vectors** drop-down list in the [Vectors Dialog Box \(p. 2123\)](#). In this case, velocities relative to the translational/rotational velocity of the “reference zone” (specified in the [Reference Values Task Page \(p. 2046\)](#)) will be displayed. (The velocity of the reference zone is the velocity defined in the [Fluid Dialog Box \(p. 1942\)](#) for that zone.)

Note that you cannot create zone surfaces for the intersection boundaries (i.e., the interior/periodic/external zones created from the intersection of the interface zones). You may instead create zone surfaces for the interface zones. Data displayed on these surfaces will be “one-sided.” That is, nodes on the interface zones will “see” only the cells on one side of the mesh interface, and slight discontinuities may appear when you plot contour lines across the interface. Note also that, for non-planar interface shapes in 3D, you may see small gaps in your plots of filled contours. These discontinuities and gaps are only graphical in nature. The solution does not have these discontinuities or gaps. To eliminate these discontinuities for postprocessing purposes only, you can use the `define/mesh-interfaces/enforce-continuity-after-bc?` text command, which will ensure that continuity will take precedence over the boundary condition.

You can also generate a plot of circumferential averages in ANSYS FLUENT. This allows you to find the average value of a quantity at several different radial or axial positions in your model. ANSYS FLUENT computes the average of the quantity over a specified circumferential area, and then plots the average against the radial or axial coordinate. For more information on generating XY plots of circumferential averages, see [XY Plots of Circumferential Averages \(p. 1596\)](#).

Sliding mesh results can be analyzed by employing the time averaging (or RMS averaging) option (**Data Sampling for Time Statistics**) in the **Run Calculation** task page. This will compute time averages for velocity, pressure, temperature, and turbulence. You need to plan ahead since you have to engage the time averaging after the solution has become time-periodic and run for at least one period of the oscillating flow field.

11.6. Using Dynamic Meshes

The steps for setting up a dynamic mesh problem are listed below. (Note that this procedure includes only those steps necessary for the dynamic mesh model itself; you will need to set up other models, cell zone conditions, boundary conditions, etc. as usual.)

1. Enable the appropriate option for modeling transient or steady flow in the [General Task Page](#) (p. 1763).

General

If your problem involves a steady flow, see [Steady-State Dynamic Mesh Applications](#) (p. 663) for important considerations.

2. Set cell zone conditions and boundary conditions as required in the [Cell Zone Conditions Task Page](#) (p. 1940) and [Boundary Conditions Task Page](#) (p. 1958).

Cell Zone Conditions

Boundary Conditions

See [Cell Zone and Boundary Conditions](#) (p. 211) for information about inputting conditions. The wall velocity is set up automatically when the motion attribute is set for wall zones, so you will not specify wall motion in the **Wall** dialog box.

3. Enable the dynamic mesh model, and specify related parameters in the [Dynamic Mesh Task Page](#) (p. 2024).

Dynamic Mesh → Dynamic Mesh

See [Setting Dynamic Mesh Modeling Parameters](#) (p. 574) for details.

4. Create the dynamic zones for your model, using the [Dynamic Mesh Zones Dialog Box](#) (p. 2037).

Dynamic Mesh → Create/Edit...

See [Specifying the Motion of Dynamic Zones](#) (p. 645) for details.

5. You can display the motion of the moving zones with prescribed motion to verify the simulation setup.

Dynamic Mesh → Display Zone Motion...

See [Previewing the Dynamic Mesh](#) (p. 661) for details.

6. If it is a transient simulation, define the events that will occur during the calculation.

Dynamic Mesh → Events...

See [Defining Dynamic Mesh Events](#) (p. 637) for details.

7. Save the case and data.

File → Write → Case & Data...

8. Preview your dynamic mesh setup (when the motion is a prescribed motion). See [Steady-State Dynamic Mesh Applications](#) (p. 663) for previewing your steady-state dynamic mesh motion and refer to [Previewing the Dynamic Mesh](#) (p. 661) for details.

 **Dynamic Mesh → Preview Mesh Motion...**

9. Specify the pressure-velocity coupling scheme. For transient flow calculations, the PISO algorithm is recommended, as it is the most efficient for such cases (see [PISO \(p. 1322\)](#) for details).
10. Use the automatic saving feature to specify the file name and frequency with which case and data files should be saved during the solution process.

 **Calculation Activities → Edit... (Autosave Every)**

See [Automatic Saving of Case and Data Files \(p. 68\)](#) for details about the use of this feature. This provides a convenient way for you to save results at successive time steps for later postprocessing.

Important

You must save a case file each time you save a data file because the mesh position is stored in the case file. Since the mesh position changes with each time step, reading data for a given time step will require the case file at that time step so that the mesh will be in the proper position. You should also save your initial case file so that you can easily return to the mesh's original position to restart the solution if desired.

11. (optional) If you want to create a graphical animation of the mesh over time during the solution procedure, you can use the [Calculation Activities Task Page \(p. 2093\)](#) to set up the graphical displays that you want to use in the animation. See [Animating the Solution \(p. 1409\)](#) for details.

For additional information, please see the following sections:

- [11.6.1. Setting Dynamic Mesh Modeling Parameters](#)
- [11.6.2. Dynamic Mesh Update Methods](#)
- [11.6.3. In-Cylinder Settings](#)
- [11.6.4. Six DOF Solver Settings](#)
- [11.6.5. Implicit Update Settings](#)
- [11.6.6. Defining Dynamic Mesh Events](#)
- [11.6.7. Specifying the Motion of Dynamic Zones](#)
- [11.6.8. Previewing the Dynamic Mesh](#)
- [11.6.9. Steady-State Dynamic Mesh Applications](#)

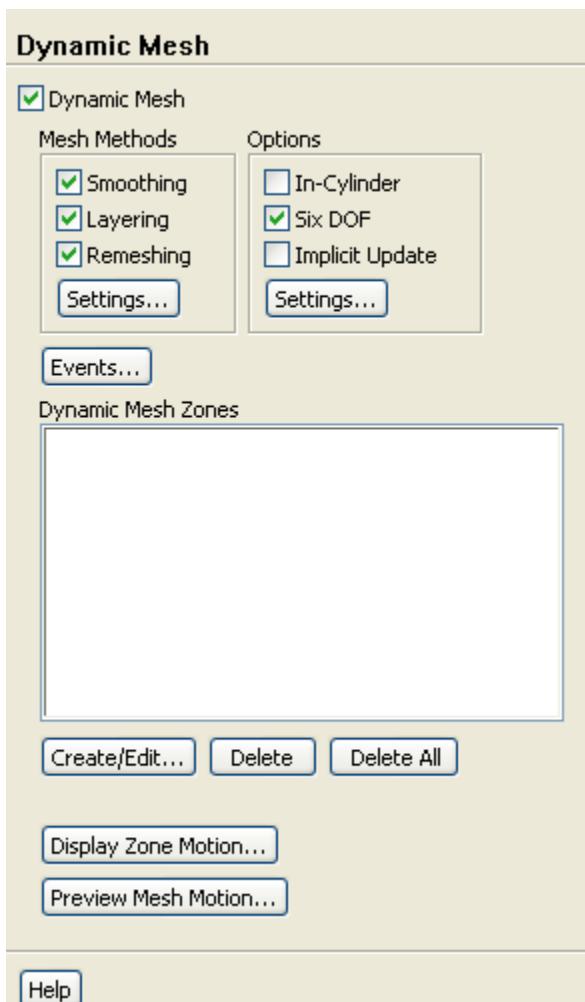

11.6.1. Setting Dynamic Mesh Modeling Parameters

To enable the dynamic mesh model, enable **Dynamic Mesh** in the [Dynamic Mesh Task Page \(p. 2024\)](#) ([Figure 11.13 \(p. 575\)](#)).

 **Dynamic Mesh → Dynamic Mesh**

Then, enable the appropriate options in the **Options** group box. If you are modeling in-cylinder motion, enable the **In-Cylinder** option. If you are going to use the six degrees of freedom solver, then enable the **Six DOF** option. If you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step), then enable the **Implicit Update** option. More information about these options and the related settings can be found in [In-Cylinder Settings \(p. 618\)](#), [Six DOF Solver Settings \(p. 633\)](#), and [Implicit Update Settings \(p. 635\)](#), respectively.

Next, you will need to select the appropriate mesh update methods in the **Mesh Methods** group box, and set the associated parameters, if relevant. See [Dynamic Mesh Update Methods \(p. 575\)](#) for details.

Figure 11.13 The Dynamic Mesh Task Page

11.6.2. Dynamic Mesh Update Methods

Three groups of mesh motion methods are available in ANSYS FLUENT to update the volume mesh in the deforming regions subject to the motion defined at the boundaries:

- *[Smoothing Methods \(p. 575\)](#)*
- *[Dynamic Layering \(p. 591\)](#)*
- *[Remeshing Methods \(p. 595\)](#)*

Note that you can use ANSYS FLUENT's dynamic mesh models in conjunction with hanging node adaption, with the exception of dynamic layering and face remeshing. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the [Theory Guide](#).

Details on how to set up the various dynamic mesh update methods are provided in the sections that follow.

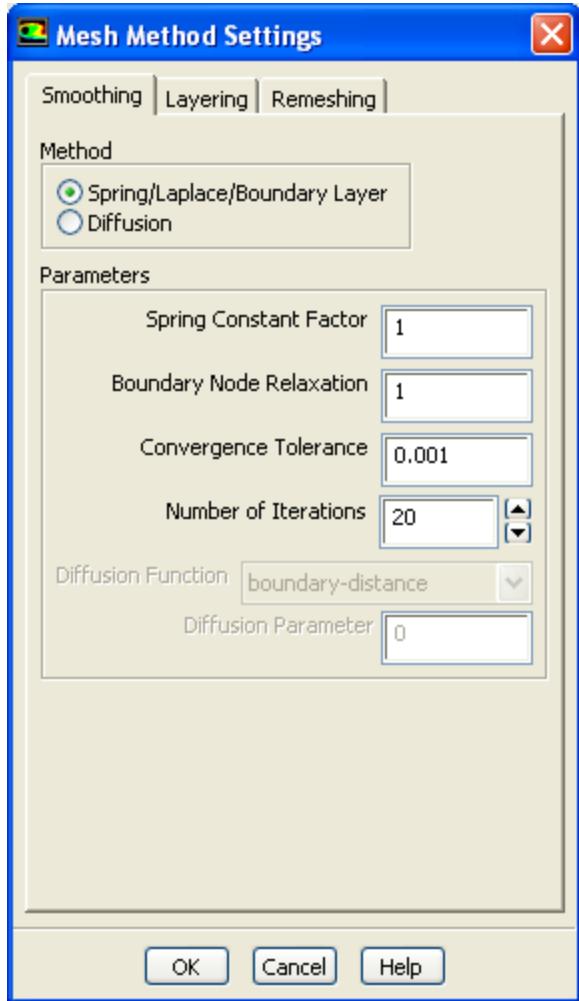

11.6.2.1. Smoothing Methods

To enable smoothing, perform the following steps:

1. Enable the **Smoothing** option in the **Mesh Methods** group box of the [Dynamic Mesh Task Page \(p. 2024\)](#).

2. Click the **Settings...** button to open the **Mesh Method Settings** dialog box.

Figure 11.14 The Smoothing Tab of the Mesh Method Settings Dialog Box

3. If you want spring-based smoothing, select **Spring/Laplace/Boundary Layer** from the **Method** list and define the settings in the **Parameters** group box, which are described in *Spring-Based Smoothing* (p. 577).
4. If you want diffusion-based smoothing (described in *Diffusion-Based Smoothing* (p. 581)):
 - a. Select **Diffusion** from the **Method** list .
 - b. Make a selection from the **Diffusion Function** drop-down list, to indicate whether you want the diffusion coefficient to be a function of the **boundary-distance** or the **cell-volume**. These functions and suggested values for the **Diffusion Parameter** are described in *Diffusivity Based on Boundary Distance* (p. 583) and *Diffusivity Based on Cell Volume* (p. 585).
5. If you plan to apply the 2.5D remeshing method, perform the following steps to set up Laplacian smoothing (as described in *Laplacian Smoothing Method* (p. 586)).
 - a. Select **Spring/Laplace/Boundary Layer** from the **Method** list
 - b. Define only the **Boundary Node Relaxation** and **Number of Iterations** in the **Parameters** group box (the other settings are not relevant).
6. If you plan to apply the boundary layer smoothing method (as described in *Boundary Layer Smoothing Method* (p. 587)), select **Spring/Laplace/Boundary Layer** from the **Method** list.

11.6.2.1.1. Spring-Based Smoothing

For spring-based smoothing, the edges between any two mesh nodes are idealized as a network of interconnected springs. The initial spacings of the edges before any boundary motion constitute the equilibrium state of the mesh. A displacement at a given boundary node will generate a force proportional to the displacement along all the springs connected to the node. Using Hook's Law, the force on a mesh node can be written as

$$\vec{F}_i = \sum_j^{n_i} k_{ij} (\Delta \vec{x}_j - \Delta \vec{x}_i) \quad (11-2)$$

where $\Delta \vec{x}_i$ and $\Delta \vec{x}_j$ are the displacements of node i and its neighbor j , n_i is the number of neighboring nodes connected to node i , and k_{ij} is the spring constant (or stiffness) between node i and its neighbor j . The spring constant for the edge connecting nodes i and j is defined as

$$k_{ij} = \frac{1}{\sqrt{|\vec{x}_i - \vec{x}_j|}} \quad (11-3)$$

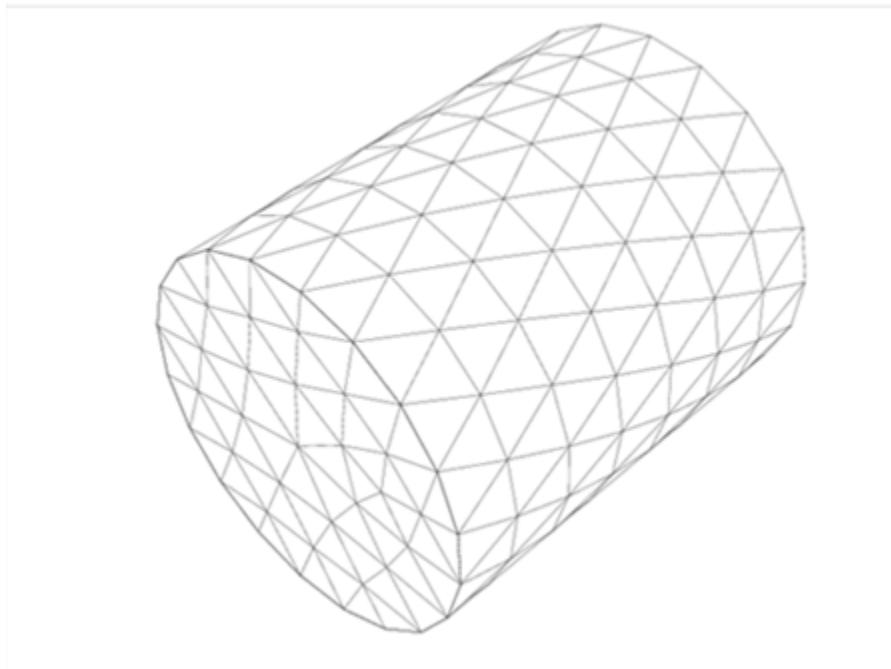

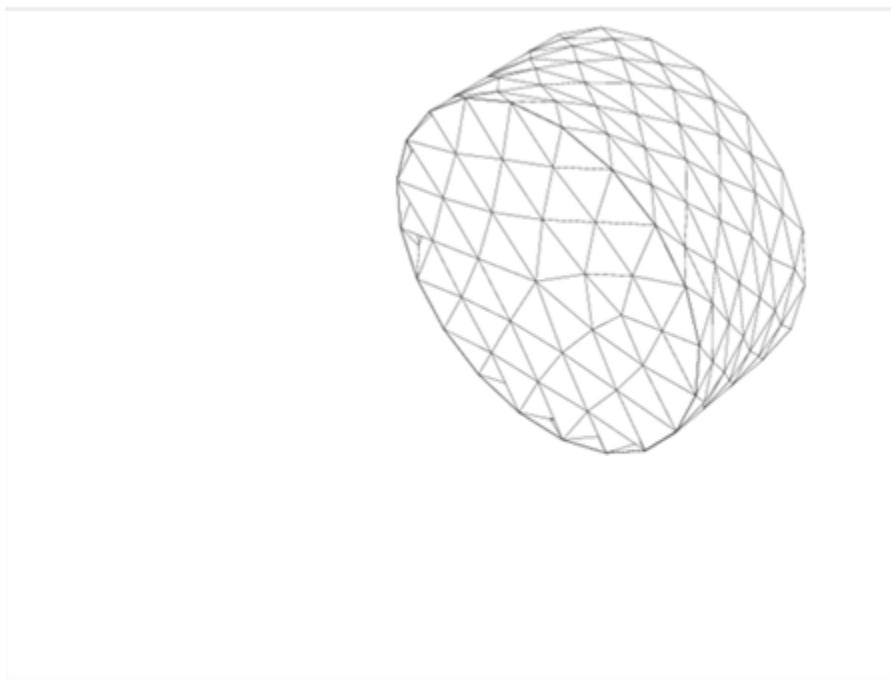

At equilibrium, the net force on a node due to all the springs connected to the node must be zero. This condition results in an iterative equation such that

$$\Delta \vec{x}_i^{m+1} = \frac{\sum_j^{n_i} k_{ij} \Delta \vec{x}_j^m}{\sum_j^{n_i} k_{ij}} \quad (11-4)$$

Since displacements are known at the boundaries (after boundary node positions have been updated), [Equation 11-4 \(p. 577\)](#) is solved using a Jacobi sweep on all interior nodes. At convergence, the positions are updated such that

$$\vec{x}_i^{n+1} = \vec{x}_i^n + \Delta \vec{x}_i^m, \text{converged} \quad (11-5)$$

where $n+1$ and n are used to denote the positions at the next time step and the current time step, respectively. The spring-based smoothing is shown in [Figure 11.15 \(p. 578\)](#) and [Figure 11.16 \(p. 578\)](#) for a cylindrical cell zone where one end of the cylinder is moving.

Figure 11.15 Spring-Based Smoothing on Interior Nodes: Start**Figure 11.16 Spring-Based Smoothing on Interior Nodes: End**

You can control the spring stiffness by adjusting the value of the **Spring Constant Factor** between 0 and 1. A value of 0 indicates that there is no damping on the springs, and boundary node displacements have more influence on the motion of the interior nodes. A value of 1 imposes the default level of damping on the interior node displacements as determined by solving [Equation 11–4](#) (p. 577).

The effect of the **Spring Constant Factor** is illustrated in [Figure 11.17](#) (p. 579) and [Figure 11.18](#) (p. 579), which show the trailing edge of a NACA-0012 airfoil after a counter-clockwise rotation of 2.3° and the mesh is smoothed using the spring-based smoother but limited to 20 iterations. Degenerate cells ([Figure](#)

11.17 (p. 579)) are created with the default value of 1 for the **Spring Constant Factor**. However, the original mesh distribution (*Figure 11.18 (p. 579)*) is recovered if the **Spring Constant Factor** is set to 0 (i.e., no damping on the displacement of nodes on the airfoil surface).

Figure 11.17 Effect of a Spring Constant Factor of 1 on Interior Node Motion

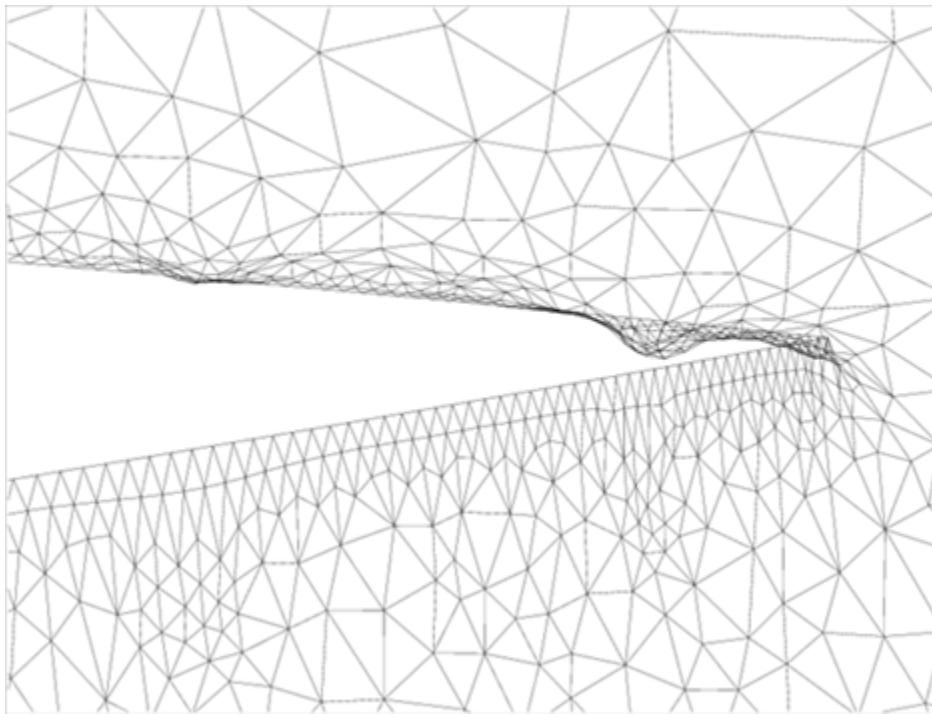

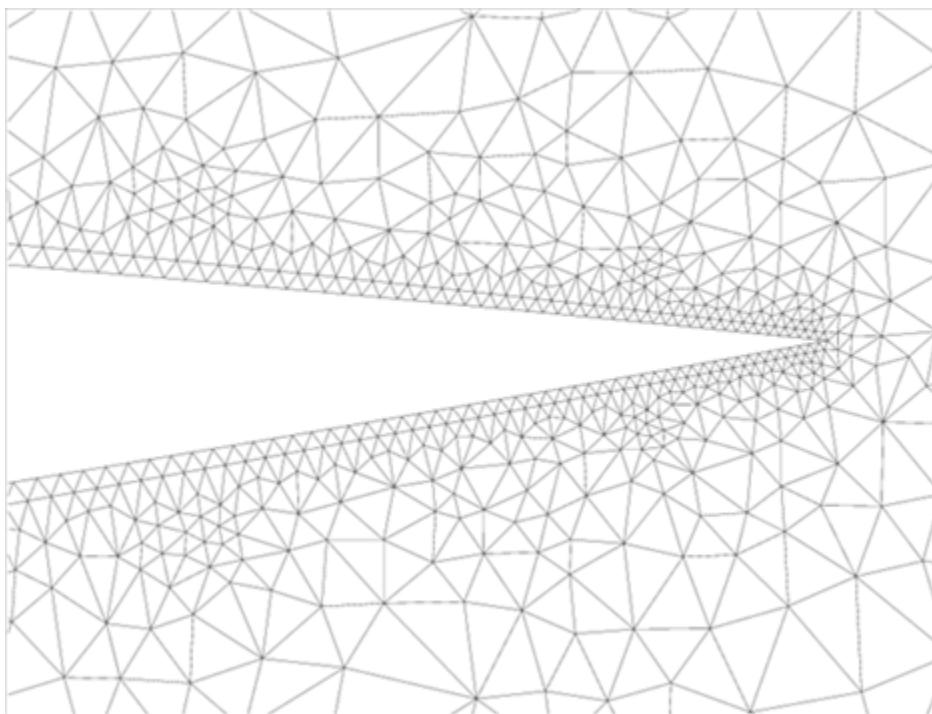

Figure 11.18 Effect of a Spring Constant Factor of 0 on Interior Node Motion

If your model contains deforming boundary zones, you can use the **Boundary Node Relaxation** to control how the node positions on the deforming boundaries are updated. On deforming boundaries, the node positions are updated such that

$$\vec{x}^{n+1} = \vec{x}^n + \beta \Delta \vec{x}_{\text{spring}}^{m,\text{converged}} \quad (11-6)$$

where β is the **Boundary Node Relaxation**. A value of 0 prevents deforming boundary nodes from moving (equivalent to turning off smoothing on deforming boundary zones) and a value of 1 indicates no under-relaxation.

You can control the solution of [Equation 11-4 \(p. 577\)](#) using the values of **Convergence Tolerance** and **Number of Iterations**. ANSYS FLUENT solves [Equation 11-4 \(p. 577\)](#) iteratively during each time step until one of the following criteria is met:

- The specified number of iterations has been performed.
- The solution is converged for that time step:

$$\left(\frac{\Delta \vec{x}_{\text{rms}}^m}{\Delta \vec{x}_{\text{rms}}^1} \right) < \text{convergence tolerance} \quad (11-7)$$

where $\Delta \vec{x}_{\text{rms}}^1$ is the interior and deforming nodes RMS displacement at the first iteration.

11.6.2.1.1.1. Applicability of the Spring-Based Smoothing Method

You can use the spring-based smoothing method to update any cell or face zone whose boundary is moving or deforming.

For non-tetrahedral cell zones (non-triangular in 2D), the spring-based method is recommended when the following conditions are met:

- The boundary of the cell zone moves predominantly in one direction (i.e., no excessive anisotropic stretching or compression of the cell zone).
- The motion is predominantly normal to the boundary zone.

If these conditions are not met, the resulting cells may have high skewness values, since not all possible combinations of node pairs in non-tetrahedral cells (or non-triangular in 2D) are idealized as springs. Polyhedral cells are particularly likely to become highly skewed with spring-based smoothing (regardless of whether the previous conditions are met), and so the diffusion-based smoothing method is generally recommended for polyhedra (see [Diffusion-Based Smoothing \(p. 581\)](#)).

By default, spring-based smoothing is disabled for cell zones that are not entirely comprised of either triangular or tetrahedral cells. If you want to use spring-based smoothing on all cell shapes, you can turn on the model for these zones using the `spring-on-all-shapes?` text interface command:

```
define → dynamic-mesh → controls → smoothing-parameters → spring-on-all-
shapes?
```

If you have mixed element zones and you do not want spring-based smoothing on all cell shapes, you can enable spring-based smoothing on only the triangular or tetrahedral cells using the `spring-on-deformable-shapes?` text interface command:

```
define → dynamic-mesh → controls → smoothing-parameters → spring-on-deformable-shapes?
```

11.6.2.1.2. Diffusion-Based Smoothing

For diffusion-based smoothing, the mesh motion is governed by the diffusion equation

$$\nabla \cdot (\gamma \nabla \vec{u}) = 0 \quad (11-8)$$

where \vec{u} is the mesh displacement velocity. The boundary conditions for [Equation 11-8 \(p. 581\)](#) are obtained from the user prescribed or computed (Six DOF) boundary motion. On deforming boundaries, the boundary conditions are such that the mesh motion is tangent to the boundary (that is, the normal velocity component vanishes). The Laplace equation [Equation 11-8 \(p. 581\)](#) then describes how the prescribed boundary motion diffuses into the interior of the deforming mesh.

The diffusion coefficient γ in [Equation 11-8 \(p. 581\)](#) can be used to control how the boundary motion affects the interior mesh motion. A constant coefficient means that the boundary motion diffuses uniformly throughout the mesh. With a nonuniform diffusion coefficient, mesh nodes in regions with high diffusivity tend to move together (that is, with less relative motion).

In FLUENT, two different formulations are available for the diffusion coefficient γ . The first formulation allows you to have the diffusion coefficient be a function of the boundary distance, and is of the form

$$\gamma = \frac{1}{d^\alpha} \quad (11-9)$$

where d is a normalized boundary distance. The second formulation allows you to have the diffusion coefficient be a function of the cell volume, and is of the form

$$\gamma = \frac{1}{V^\alpha} \quad (11-10)$$

where V is the normalized cell volume. In both [Equation 11-9 \(p. 581\)](#) and [Equation 11-10 \(p. 581\)](#), $\alpha \geq 0$ is a user input parameter. See [Diffusivity Based on Boundary Distance \(p. 583\)](#) and [Diffusivity Based on Cell Volume \(p. 585\)](#) for information about defining the diffusion coefficient.

The vector [Equation 11-8 \(p. 581\)](#) is discretized using ANSYS FLUENT's standard finite volume method, and the resulting matrix is solved iteratively using the algebraic multigrid (AMG) solver. The cell centered solution for the displacement velocity \vec{u} is interpolated onto the nodes using inverse distance weighted averaging, and the node positions are updated according to

$$\vec{x}_{new} = \vec{x}_{old} + \vec{u} \Delta t \quad (11-11)$$

Computationally, diffusion-based smoothing is generally more costly than spring-based smoothing. But it tends to produce better quality meshes than spring-based smoothing and often allows larger

boundary deformations before breaking down. [Figure 11.19 \(p. 582\)](#) and [Figure 11.20 \(p. 582\)](#) show a mesh before and after rotating the boundary by 45 degrees, using diffusion-based smoothing. With spring-based smoothing, the same mesh shows degenerated cells after a rotation of 40 degrees ([Figure 11.21 \(p. 583\)](#)).

Figure 11.19 The Initial Mesh

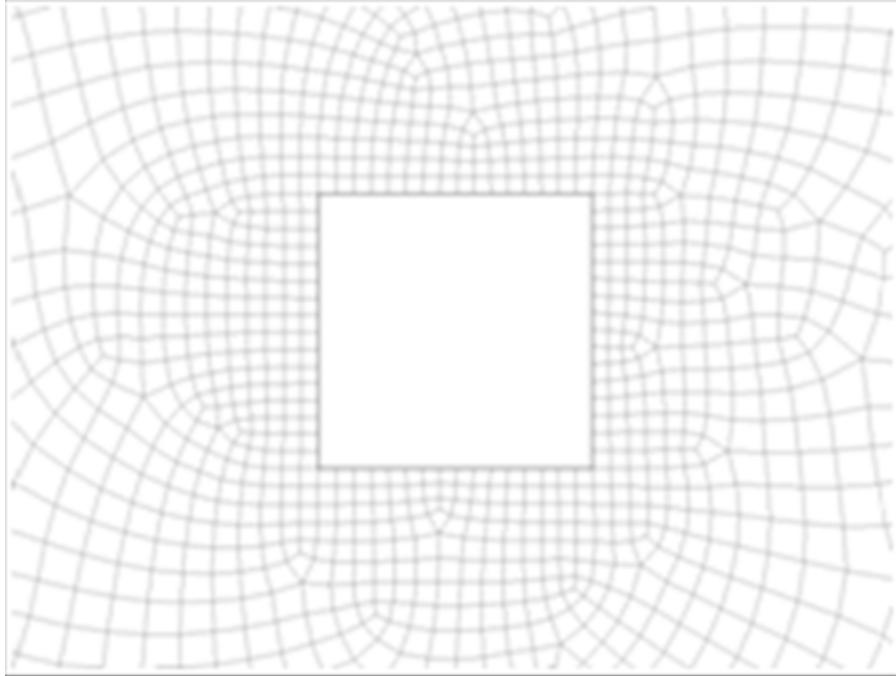

Figure 11.20 Valid Mesh After 45 Degree Rotation Using Diffusion-Based Smoothing

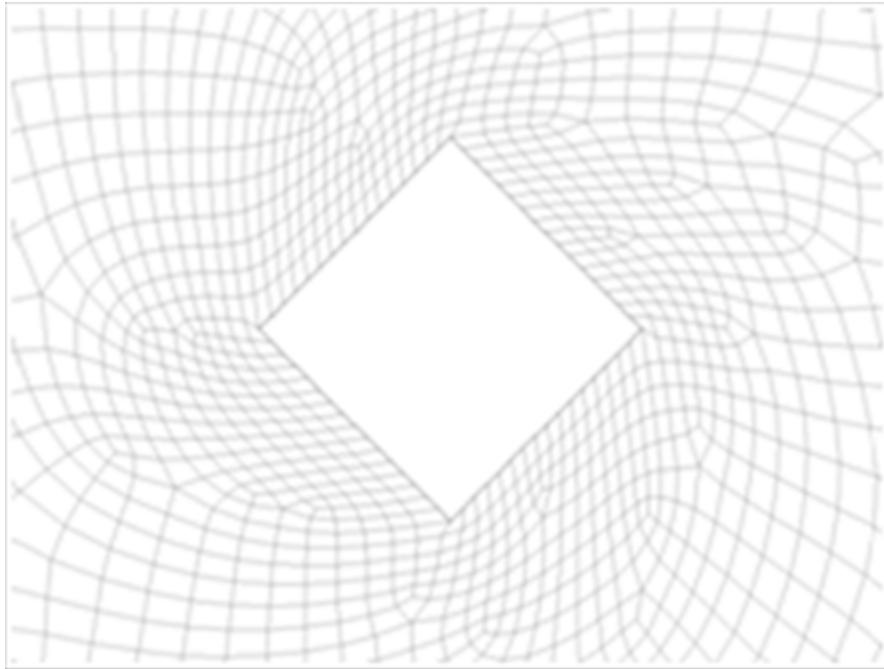

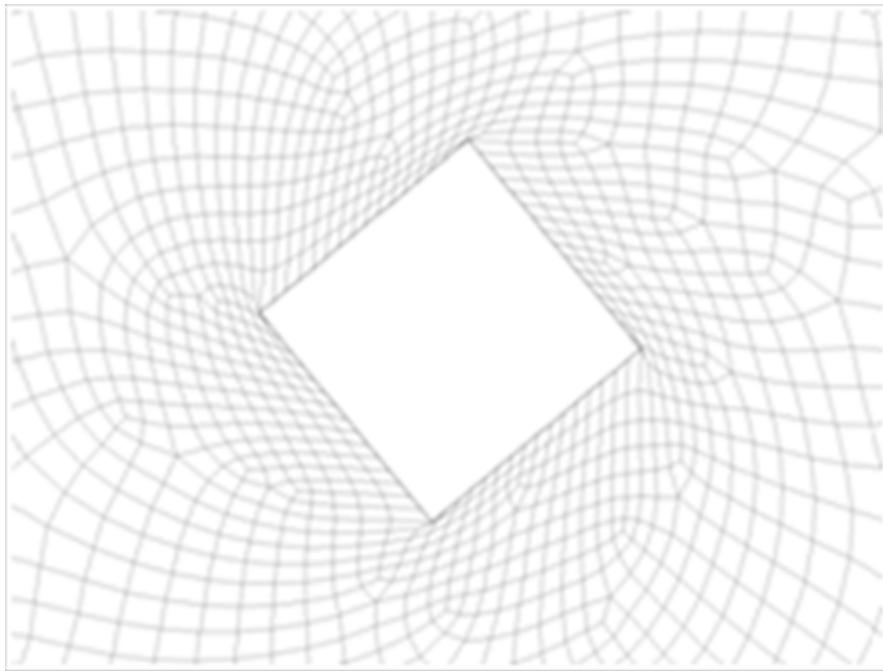

Figure 11.21 Degenerated Mesh After 40 Degree Rotation Using Spring-Based Smoothing

It should be noted that with diffusion-based smoothing the interior mesh motion is governed by the solution to [Equation 11-8 \(p. 581\)](#) and the prescribed boundary motion, and not by mesh irregularities. Poor quality elements or mesh defects are not smoothed out by this method, but rather move together with the pre-computed (at the begin of each mesh update) displacement velocity \vec{u} .

It is also worth noting that the nature of the diffusion equation is such that the resulting solution (i.e., the displacement velocity \vec{u}) depends on the dimensionality of the problem and the type of boundary motion prescribed. To illustrate the impact of the type of boundary motion, consider the goal of boundary-distance-based diffusion ([Equation 11-9 \(p. 581\)](#)): to control which parts of the mesh absorb the boundary motion, so that you can preserve the mesh in the vicinity of the moving boundary (at the expense of the interior of the mesh). For more translational (piston-type) boundary motions, you can preserve a reasonably “thick” region of the mesh adjacent to the boundary (i.e., multiple layers of cells); for rotational boundary motions, the rate of decay for the solution as you move away from the boundary is such that it can be difficult to preserve even a “thin” region. For this reason, mesh smoothing can handle translational boundary motions generally much better than rotational motions.

Although it should in most cases not be necessary, the accuracy of the solution to the diffusion equation governing the mesh motion can be controlled by selecting the maximum number of iterations, `max-iter` (by default 20), and the relative residual tolerance, `relative-convergence-tolerance` (by default 1.0e-4), in the text interface:

```
define → dynamic-mesh → controls → smoothing-parameters → max-iter
```

```
define → dynamic-mesh → controls → smoothing-parameters → relative-conver-
gence-tolerance
```

11.6.2.1.2.1. Diffusivity Based on Boundary Distance

Using boundary-distance-based diffusion ([Equation 11-9 \(p. 581\)](#)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of boundary distance. Decreasing the diffusivity away from the moving boundary causes those regions to absorb more of the mesh motion, and

better preserves the mesh quality near the moving boundary. This is particularly helpful for a moving boundary that has pronounced geometrical features (such as sharp corners) along with a prescribed motion that is predominantly rotational.

You can manipulate the diffusion coefficient γ (in [Equation 11–9 \(p. 581\)](#)) primarily by adjusting the **Diffusion Parameter** α . A range of 0 to 2 has been shown to be of practical use. A value of 0 (the default value) specifies that $\gamma = 1$ and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of α preserve larger regions of the mesh near the moving boundary, and cause the regions away from the moving boundary to absorb more of the motion.

The following two figures illustrate the effect of the **Diffusion Parameter** α on the resulting mesh for a translational (piston-type) boundary motion, when the diffusivity is based on the boundary distance. In this example, an initially uniformly meshed square domain is deformed by moving the left boundary to the right.

Figure 11.22 Effect of Diffusion Parameter of 0 on Interior Node Motion

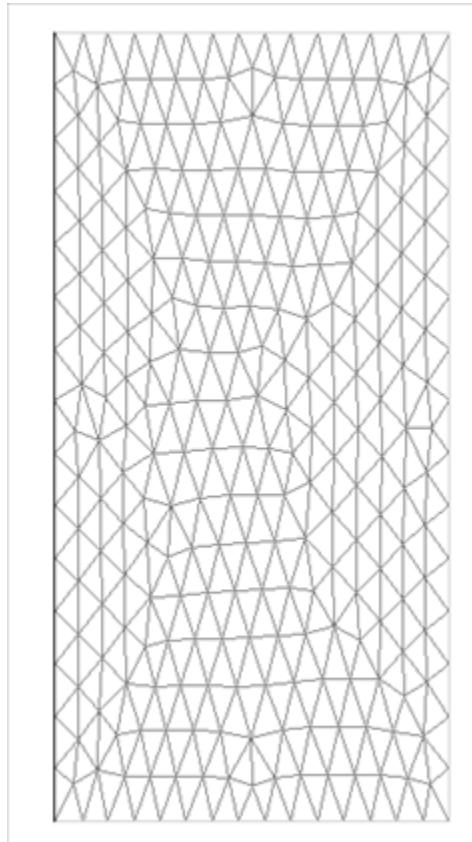

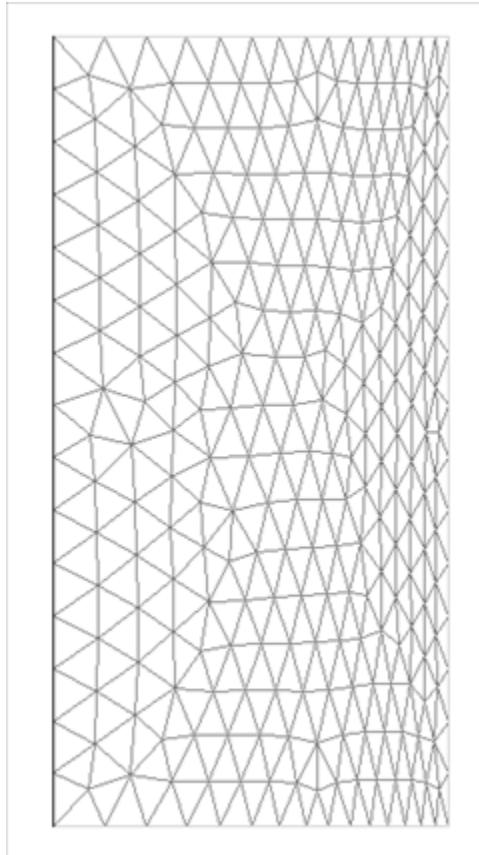

Figure 11.23 Effect of Diffusion Parameter of 1 on Interior Node Motion

For rotational boundary motions, a value of 1.5 for the **Diffusion Parameter** α is recommended as a good starting point.

Two different methods are available for the evaluation of the boundary distance d if boundary-distance-based diffusion is used. By default, FLUENT uses the “standard” boundary distance in [Equation 11–9 \(p. 581\)](#), which is the normalized distance to the nearest wall boundary; note that none of the other boundary types (e.g., inlets, outlets, symmetry, and periodic boundaries) are considered. This method is the same as that which is used to evaluate the boundary distance for turbulence models. An example of this method is shown in [Figure 11.23 \(p. 585\)](#), where only the left and right boundaries are walls. You have the option of using a “generalized” boundary distance instead, which is the normalized distance to the nearest boundary that is not declared as deforming, regardless of type. Both methods use the largest distance found in all deforming cell zones to normalize the value.

You can specify that the generalized boundary distance is used via the following text command:

```
define → dynamic-mesh → controls → smoothing-parameters → boundary-distance-method
```

If the generalized boundary distance is used, an additional scalar equation for the boundary distance d will be solved as part of the solution of [Equation 11–8 \(p. 581\)](#).

11.6.2.1.2.2. Diffusivity Based on Cell Volume

Using cell-volume-based diffusion ([Equation 11–10 \(p. 581\)](#)) allows you to control how the boundary motion diffuses into the interior of the domain as a function of cell size. Decreasing the diffusivity in

larger cells causes those cells to absorb more of mesh motion and thus better preserves the cell quality of smaller cells.

You can manipulate the diffusion coefficient γ (in [Equation 11–9 \(p. 581\)](#)) by adjusting the **Diffusion Parameter** α . A value of 0 (the default value) specifies that $\gamma = 1$ and yields a uniform diffusion of the boundary motion throughout the mesh. Higher values of α result in larger cells absorbing more of the motion than smaller cells.

Note that the cell volume used in [Equation 11–10 \(p. 581\)](#) is the local cell volume, normalized by the average cell volume of all deforming cell zones.

11.6.2.1.2.3. Applicability of the Diffusion-Based Smoothing Method

Diffusion-based mesh smoothing is an alternative method to spring-based smoothing. It is by default available for all element types, and you can use it to update any cell zone whose boundaries are moving or deforming.

Diffusion-based smoothing is computationally more expensive than spring-based smoothing, but likely results in better mesh quality (especially for non-tetrahedral / non-triangular cell zones, and for polyhedral cells in particular) and generally allows for larger boundary deformations before breaking down.

Similar to spring-based smoothing, diffusion-based mesh smoothing can handle translational boundary deformations much better than rotational motions.

Diffusion-based smoothing is not compatible with the boundary layer smoothing method or the face region remeshing method. For more information about these methods, see [Boundary Layer Smoothing Method \(p. 587\)](#) and [Face Region Remeshing Method \(p. 606\)](#).

11.6.2.1.3. Laplacian Smoothing Method

Laplacian smoothing is the most commonly used and the simplest mesh smoothing method. This method adjusts the location of each mesh vertex to the geometric center of its neighboring vertices. This method is computationally inexpensive but it does not guarantee an improvement on mesh quality, since repositioning a vertex by Laplacian smoothing can result in poor quality elements. To overcome this problem, ANSYS FLUENT only relocates the vertex to the geometric center of its neighboring vertices if and only if there is an improvement in the mesh quality (i.e., the skewness has been improved).

This improved Laplacian smoothing can be enabled on deforming boundaries only (i.e., the zone with triangular elements in 3D and zones with linear elements in 2D). The computation of the node positions works as follows:

$$\overline{\vec{x}}_i^m = \frac{\sum_j^{n_i} \vec{x}_j^m}{n_i} \quad (11-12)$$

where $\overline{\vec{x}}_i^m$ is the averaged node position of node i at iteration m , \vec{x}_j^m is the node position of neighbor node of \vec{x}_i^m at iteration m , and n_i is the number nodes neighboring node i . The new node position \vec{x}_i^{m+1} is then computed as follows:

$$\vec{x}_i^{m+1} = \vec{x}_i^m (1 - \beta) + \overline{\vec{x}_i^m} \beta \quad (11-13)$$

where β is the boundary node relaxation factor.

This update only happens if the maximum skewness of all faces adjacent to \vec{x}_i^{m+1} is improved in comparison to \vec{x}_i^m .

For details on applying Laplacian smoothing to either a cell zone (with 2.5D remeshing) or a face zone, see [Smoothing Methods \(p. 575\)](#) or [Deforming Motion \(p. 652\)](#), respectively. Note that the **Boundary Node Relaxation** is used differently by ANSYS FLUENT when the 2.5D remeshing method model is enabled. On deforming boundaries, the node positions are updated such that

$$\vec{x}^{n+1} = \vec{x}^n + \beta \Delta \vec{x}_{Laplacian}^m \quad (11-14)$$

11.6.2.1.4. Boundary Layer Smoothing Method

The boundary layer smoothing method is used to deform the boundary layer mesh during a moving-deforming mesh simulation. For cases that apply mesh motion (either **Rigid Body** or **User-Defined**) to a face zone with adjacent boundary layers, the boundary layer can be made to deform according to the mesh motion that is applied to the face zone. This smoothing method preserves the height of each boundary layer and can be applied to boundary layer zones of all mesh types (i.e., wedges/prisms and hexahedra in 3D, quadrilaterals in 2D).

Consider the example below, where a UDF of the form `DEFINE_GRID_MOTION` provides the moving-deforming mesh model with the locations of the nodes located on the compliant strip on an idealized airfoil. The node motion varies sinusoidally ([Figure 11.26 \(p. 590\)](#) and [Figure 11.27 \(p. 591\)](#)), both in time and space as seen by the deformation of the face zone and the respective boundary layer. A deforming flag is set on the adjacent cell zone, such that the cells adjacent to the deforming wall will also be deformed, in order to avoid skewness. Compare the initial mesh ([Figure 11.24 \(p. 588\)](#)) prior to applying the mesh motion with the mesh in which the boundary layer has been deformed ([Figure 11.26 \(p. 590\)](#)).

Figure 11.24 The Mesh Prior to Applying Boundary Layer Smoothing

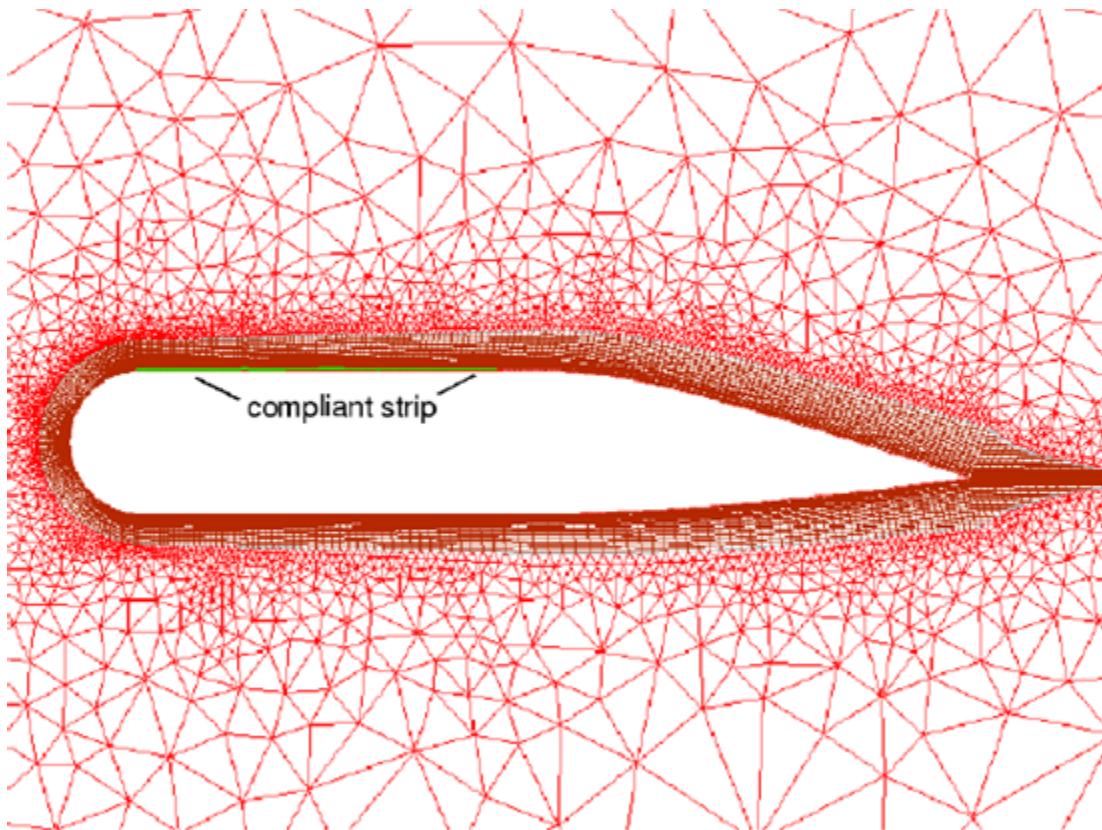

Figure 11.25 Zooming into the Mesh of the Compliant Strip Prior to Applying Boundary Layer Smoothing

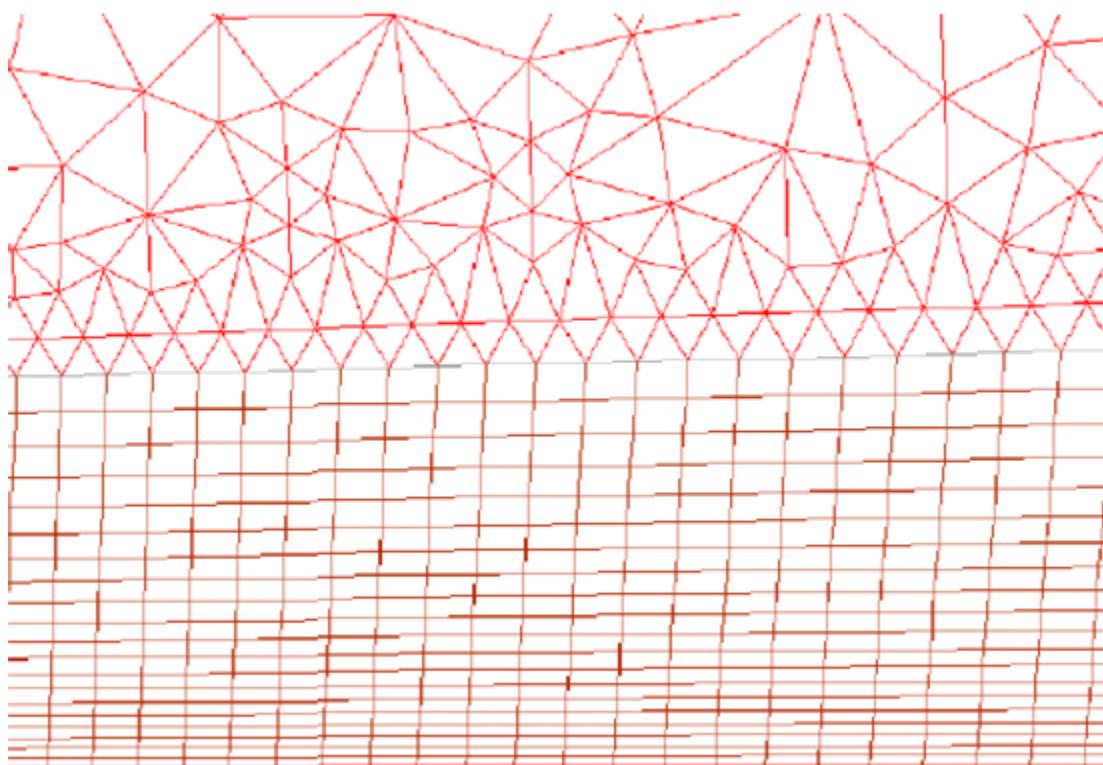

Figure 11.26 The Mesh After Applying Boundary Layer Smoothing

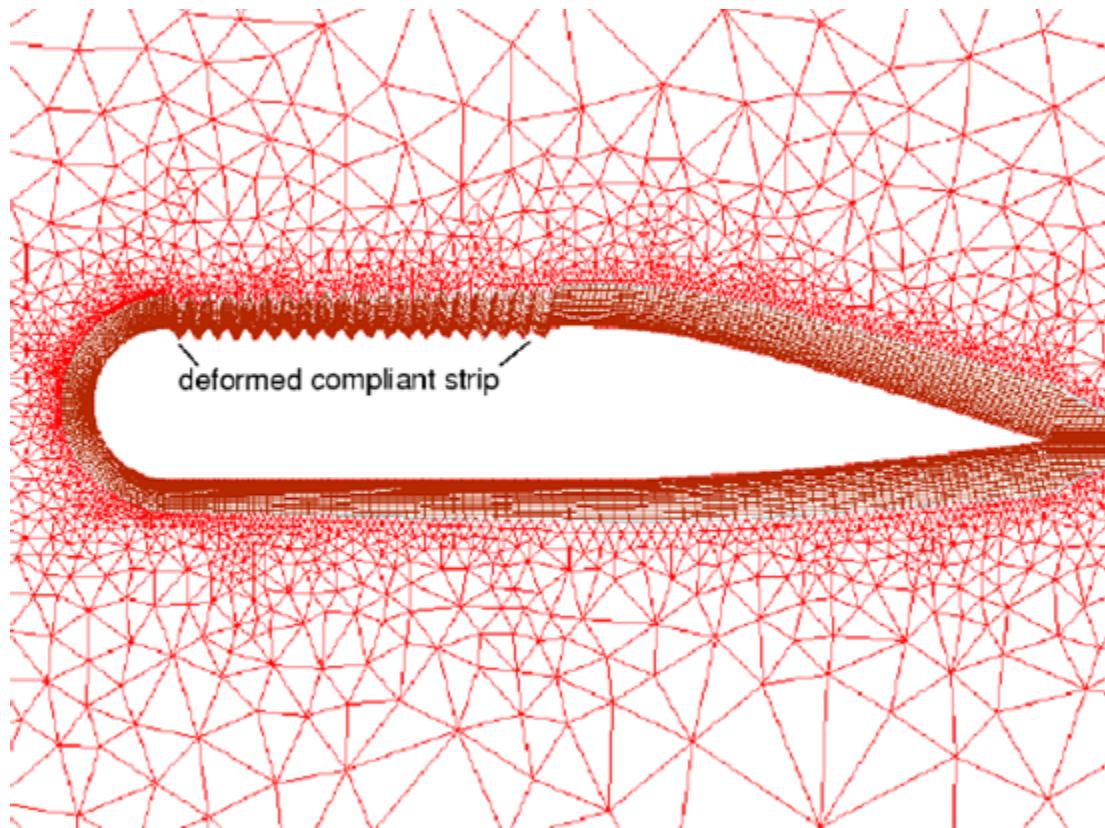

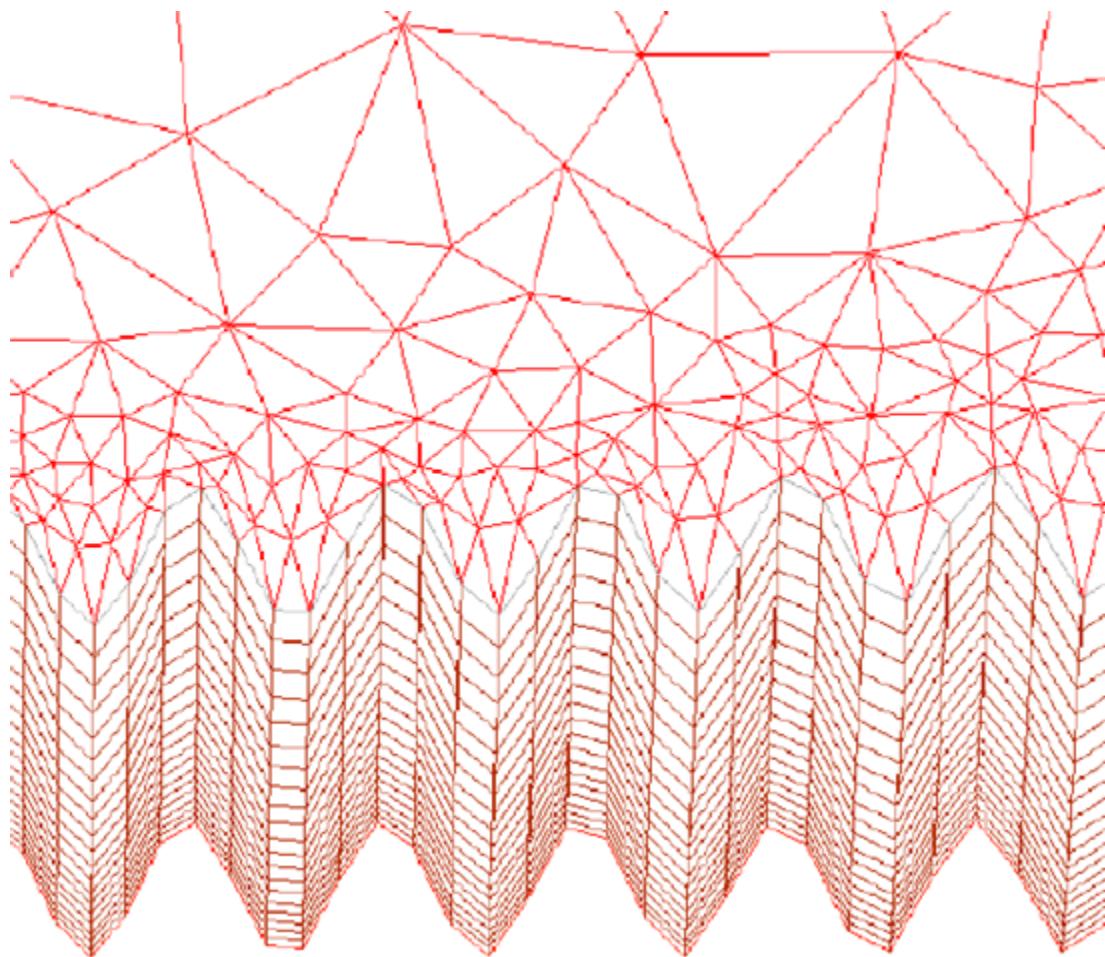

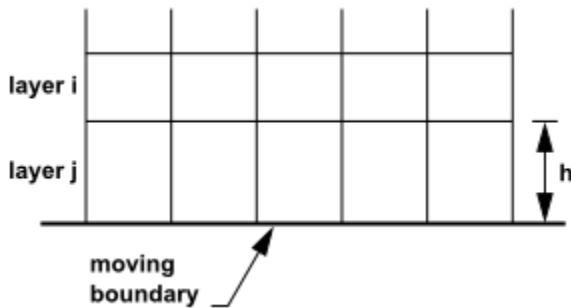

Figure 11.27 Zooming into the Deformed Boundary Layer of the Compliant Strip

See [Smoothing Methods \(p. 575\)](#) and [Specifying Boundary Layer Deformation Smoothing \(p. 657\)](#) for details about enabling smoothing and defining a moving and deforming boundary layer, respectively. Note that boundary layer smoothing is compatible with spring-based smoothing, but not with diffusion-based smoothing. Also note that the boundary layer smoothing method will work whether or not you have segregated the boundary layer elements into a separate cell zone.

11.6.2.2. Dynamic Layering

In prismatic (hexahedral and/or wedge) mesh zones, you can use dynamic layering to add or remove layers of cells adjacent to a moving boundary, based on the height of the layer adjacent to the moving surface. The dynamic mesh model in ANSYS FLUENT allows you to specify an ideal layer height on each moving boundary. The layer of cells adjacent to the moving boundary (layer j in [Figure 11.28 \(p. 592\)](#)) is split or merged with the layer of cells next to it (layer i in [Figure 11.28 \(p. 592\)](#)) based on the height (h) of the cells in layer j .

Figure 11.28 Dynamic Layering

If the cells in layer j are expanding, the cell heights are allowed to increase until

$$h_{min} > (1 + \alpha_s) h_{ideal} \quad (11-15)$$

where h_{min} is the minimum cell height of cell layer j , h_{ideal} is the ideal cell height, and α_s is the layer split factor. Note that ANSYS FLUENT allows you to define h_{ideal} as either a constant value or a value that varies as a function of time or crank angle. When the condition in [Equation 11-15 \(p. 592\)](#) is met, the cells are split based on the specified layering option. This option can be height based or ratio based.

With the height-based option, the cells are split to create a layer of cells with constant height h_{ideal} and a layer of cells of height $h - h_{ideal}$. With the ratio-based option, the cells are split such that locally, the ratio of the new cell heights is exactly α_s everywhere. [Figure 11.29 \(p. 592\)](#) and [Figure 11.30 \(p. 593\)](#) show the result of splitting a layer of cells above a valve geometry using the height-based and ratio-based option.

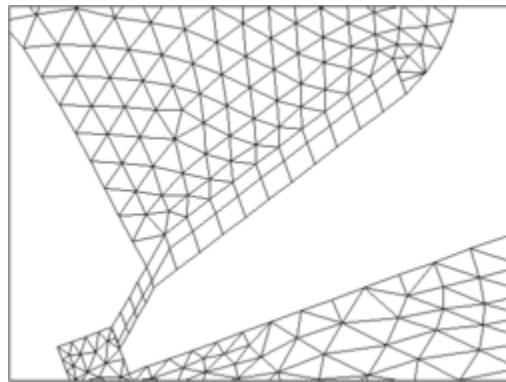

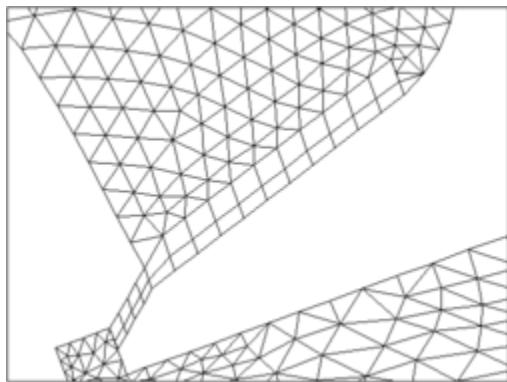

Figure 11.29 Results of Splitting Layer with the Height-Based Option

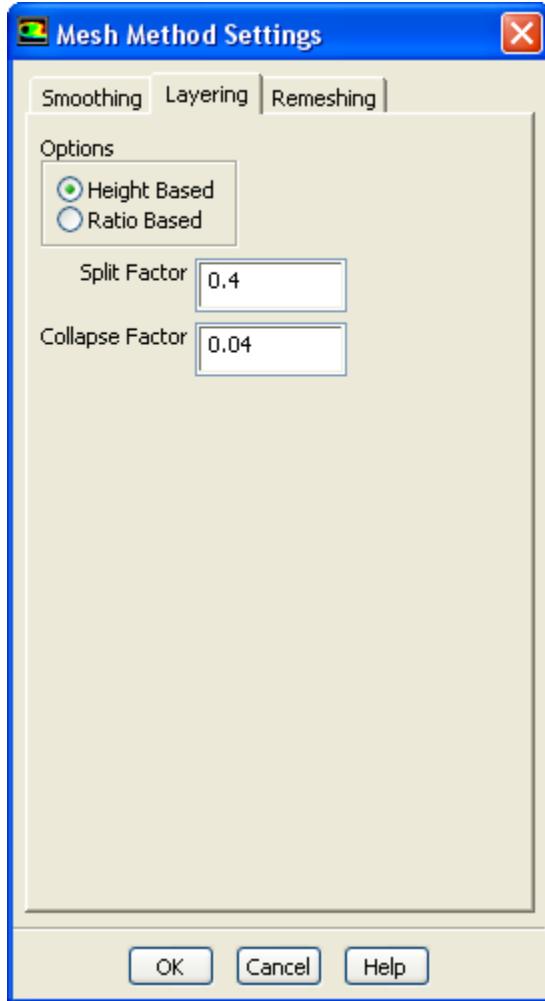

Figure 11.30 Results of Splitting Layer with the Ratio-Based Option

If the cells in layer j are being compressed, they can be compressed until

$$h_{min} < \alpha_c h_{ideal} \quad (11-16)$$

where α_c is the layer collapse factor. When this condition is met, the compressed layer of cells is merged into the layer of cells above the compressed layer; i.e., the cells in layer j are merged with those in layer i .

To enable dynamic layering, enable the **Layering** option under **Mesh Methods** in the *Dynamic Mesh Task Page* (p. 2024) (*Figure 11.31* (p. 594)). The layering control is specified in the **Layering** tab which can be displayed by clicking **Settings...**

Figure 11.31 The Layering Tab in the Mesh Method Settings Dialog Box

You can control how a cell layer is split by specifying either **Height Based** or **Ratio Based** under **Options**. Note that for **Height Based**, the height of the cells in a particular new layer will be constant, but you can choose to have this height vary from layer to layer as a function of time or crank angle when you specify the **Cell Height** in the **Dynamic Mesh Zones** dialog box (see [Specifying the Motion of Dynamic Zones \(p. 645\)](#) for further details).

The **Split Factor** and **Collapse Factor** (α_s in [Equation 11–15 \(p. 592\)](#) and α_c in [Equation 11–16 \(p. 593\)](#), respectively) are the factors that determine when a layer of cells (hexahedra or wedges in 3D, or quadrilaterals in 2D) that is next to a moving boundary is split or merged with the adjacent cell layer, respectively.

11.6.2.2.1. Applicability of the Dynamic Layering Method

You can use the dynamic layering method to split or merge cells adjacent to any moving boundary provided the following conditions are met:

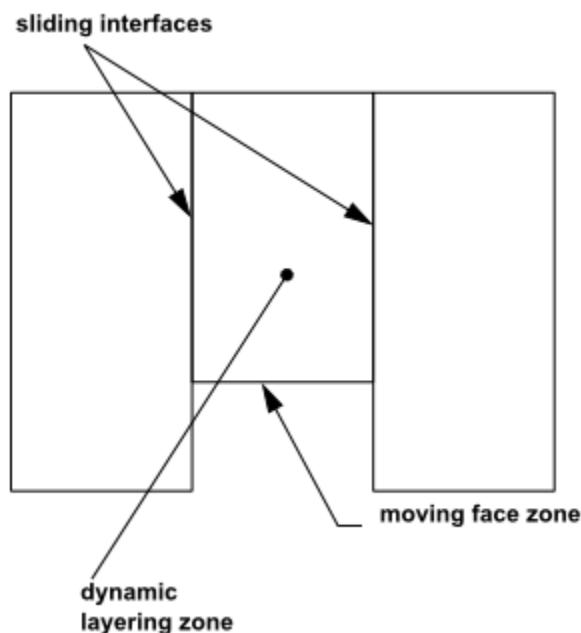

- All cells adjacent to the moving face zone are either wedges or hexahedra (quadrilaterals in 2D) even though the cell zone may contain mixed cell shapes.
- The cell layers must be completely bounded by one-sided face zones, except when sliding interfaces are used (see [Applicability of the Face Region Remeshing Method \(p. 609\)](#)).

- If the bounding face zones are two-sided walls, you must split the wall and wall-shadow pair and use the coupled sliding interface option to couple the two adjacent cell zones.
- Note that you cannot use the dynamic layering method in conjunction with hanging node adaption. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the [Theory Guide](#).

If the moving boundary is an internal zone, cells on both sides (possibly with different ideal cell layer heights) of the internal zone are considered for dynamic layering.

If you want to use dynamic layering on cells adjacent to a moving wall that do not span from boundary to boundary, you must separate those cells which are involved in the dynamic layering and use the sliding interfaces capability in ANSYS FLUENT to transition from the deforming cells to the adjacent non-deforming cells (see [Figure 11.32 \(p. 595\)](#)). For a moving interior face, the zones must be separated such that they are either expanding or collapsing on the same side. No one zone can consist of both expanding and collapsing layers.

Figure 11.32 Use of Sliding Interfaces to Transition Between Adjacent Cell Zones and the Dynamic Layering Cell Zone

11.6.2.3. Remeshing Methods

On zones with a triangular or tetrahedral mesh, the spring-based smoothing method (described in [Spring-Based Smoothing \(p. 577\)](#)) is normally used. When the boundary displacement is large compared to the local cell sizes, the cell quality can deteriorate or the cells can become degenerate. This will invalidate the mesh (e.g., result in negative cell volumes) and consequently, will lead to convergence problems when the solution is updated to the next time step.

To circumvent this problem, ANSYS FLUENT agglomerates cells that violate the skewness or size criteria and locally remeshes the agglomerated cells or faces. If the new cells or faces satisfy the skewness criterion, the mesh is locally updated with the new cells (with the solution interpolated from the old cells). Otherwise, the new cells are discarded.

ANSYS FLUENT includes several remeshing methods that include local cell remeshing, zone remeshing, local face remeshing (for 3D flows only), face region remeshing, CutCell zone remeshing (for 3D flows

only), and 2.5D surface remeshing (for 3D flows only). The remeshing methods are suitable for particular kinds of cell types:

- The local cell and local face remeshing methods only affect the triangular and tetrahedral cell types in the mesh (i.e., in mixed cell zones, the non-triangular/tetrahedral cells are skipped).
- The zone remeshing method replaces all cell types with triangular tetrahedral cells (in 2D and 3D domains, respectively), and can remesh and produce wedge/prism cells in 3D boundary layer meshes.
- The face region remeshing method is applied to triangular cells in 2D, and tetrahedral cells in 3D. In 3D domains, the face region remeshing method can also remesh and produce wedge/prism cells in 3D boundary layer meshes.
- The CutCell zone remeshing method works for all cell types.
- The 2.5D remeshing method only works on hexagonal meshes or wedge/prism cells extruded from triangular surface elements.

To enable remeshing methods, enable the **Remeshing** option under **Mesh Methods** in the *Dynamic Mesh Task Page (p. 2024)* (*Figure 11.13 (p. 575)*). Click the **Settings...** button to open the **Mesh Method Settings** dialog box, where you can specify the remeshing method and parameters in the **Remeshing** tab (*Figure 11.33 (p. 597)*).

You can view the vital statistics of your mesh by clicking the **Mesh Scale Info...** button at the bottom of the *Mesh Method Settings Dialog Box (p. 2026)*. This dialog box displays the *Mesh Scale Info Dialog Box (p. 2029)* where you can view the minimum and maximum length scale values as well as the maximum cell and face skewness values.

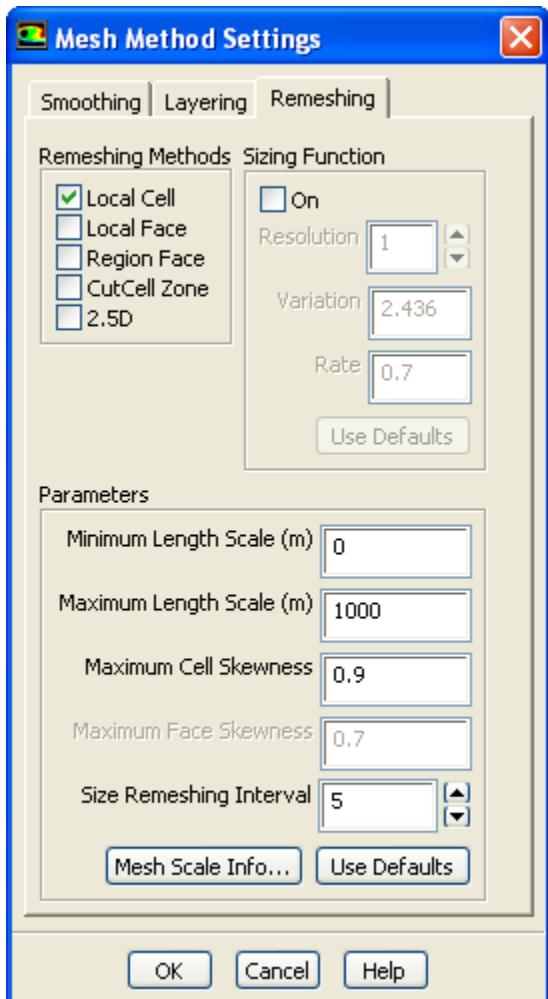

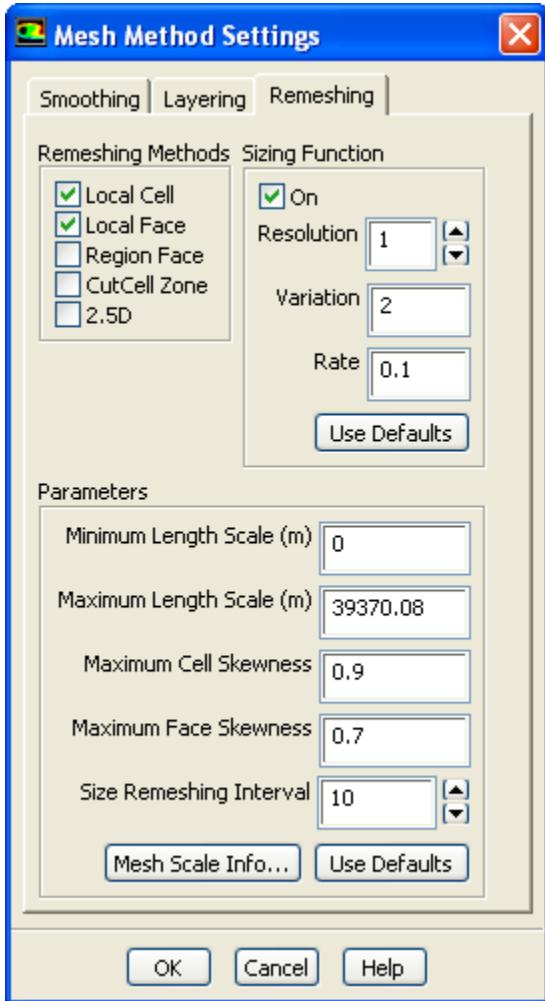

Figure 11.33 The Remeshing Tab in the Mesh Method Settings Dialog Box

Figure 11.34 The Remeshing Tab in the Mesh Method Settings Dialog Box Using the Sizing Function Option

11.6.2.3.1. Local Remeshing Method

Using the local remeshing method (i.e., local cell remeshing, with or without local face remeshing), ANSYS FLUENT marks cells based on cell skewness and minimum and maximum length scales as well as an optional sizing function.

ANSYS FLUENT evaluates each cell and marks it for remeshing if it meets one or more of the following criteria:

- It has a skewness that is greater than a specified maximum skewness.
- It is smaller than a specified minimum length scale.
- It is larger than a specified maximum length scale.
- Its height does not meet the specified length scale (at moving face zones, e.g., above a moving piston).

If local remeshing is not able to reduce the maximum cell skewness sufficiently, then the cell zone remeshing method is used to automatically remesh all of the cells in the cell zone, as well as the faces of all adjacent deforming dynamic face zones (see [Cell Zone Remeshing Method \(p. 605\)](#) for details). The maximum allowable cell skewness is set to be 0.98 by default. The cell zone remeshing method gives

the mesher more flexibility to create a new mesh of better quality than the local cell remeshing method. The automatic remeshing of cell zones can be disabled using the following text command:

```
define → dynamic-mesh → controls → remeshing-parameter → zone-remeshing
```

11.6.2.3.1.1. Local Cell Remeshing Method

As previously mentioned, in local cell remeshing, ANSYS FLUENT agglomerates cells based on skewness, size, and height (adjacent moving face zones) prior to the movement of the boundary. The size criteria are specified with **Minimum Length Scale** and **Maximum Length Scale**. Cells with length scales below the minimum length scale and above the maximum length scale are marked for remeshing. The value of **Maximum Cell Skewness** indicates the desired skewness of the mesh. By default, the **Maximum Cell Skewness** is set to 0.9 for 3D simulations and 0.7 for 2D simulations. Cells with skewness above the maximum skewness are marked for remeshing.

The marking of cells based on skewness is done at every time step when the local remeshing method is enabled. However, marking based on size and height is performed between the specified **Size Remeshing Interval** since the change in cell size distribution is typically small over one time step.

By default, ANSYS FLUENT replaces the agglomerated cells only if the quality of the remeshed cells has improved.

11.6.2.3.1.2. Local Face Remeshing Method

The local face remeshing method only applies to 3D geometries. Using this method, ANSYS FLUENT marks the faces (and the adjacent cells) on the deforming boundaries based on the face skewness. This method allows you to remesh locally at deforming boundaries; however, you are not able to remesh across multiple face zones.

Enable the **Local Face** remeshing option and set the **Maximum Face Skewness** to a specific value. In addition, you should enable the **Remeshing** option in the **Meshing Options** tab of the *Dynamic Mesh Zones Dialog Box* (p. 2037) for a deforming zone type (see *Deforming Motion* (p. 652)).

11.6.2.3.1.2.1. Applicability of the Local Face Remeshing Method

If you define deforming face zones in your model and you use local face remeshing in the adjacent cell zone, the faces on the deforming face zone can be remeshed only if the following conditions are met:

- The faces are triangular.
- The faces do not exist across zones or features.
- Note that you cannot use the local face remeshing method in conjunction with hanging node adaption. For more information on hanging node adaption, see *Hanging Node Adaption* in the *Theory Guide*.

11.6.2.3.1.3. Local Remeshing Based on Size Functions

Instead of marking cells based on minimum and maximum length scales, ANSYS FLUENT also marks cells based on the size distribution generated by the sizing function if the **Sizing Function** option is enabled.

Cells can be marked using size functions only with the following remeshing methods:

- local cell remeshing
- 2.5D surface remeshing (as described in *2.5D Surface Remeshing Method* (p. 613))

Figure 11.36 (p. 600) demonstrates the advantages of using size functions for local remeshing.

Figure 11.35 Mesh at the End of a Dynamic Mesh Simulation Without Size Functions

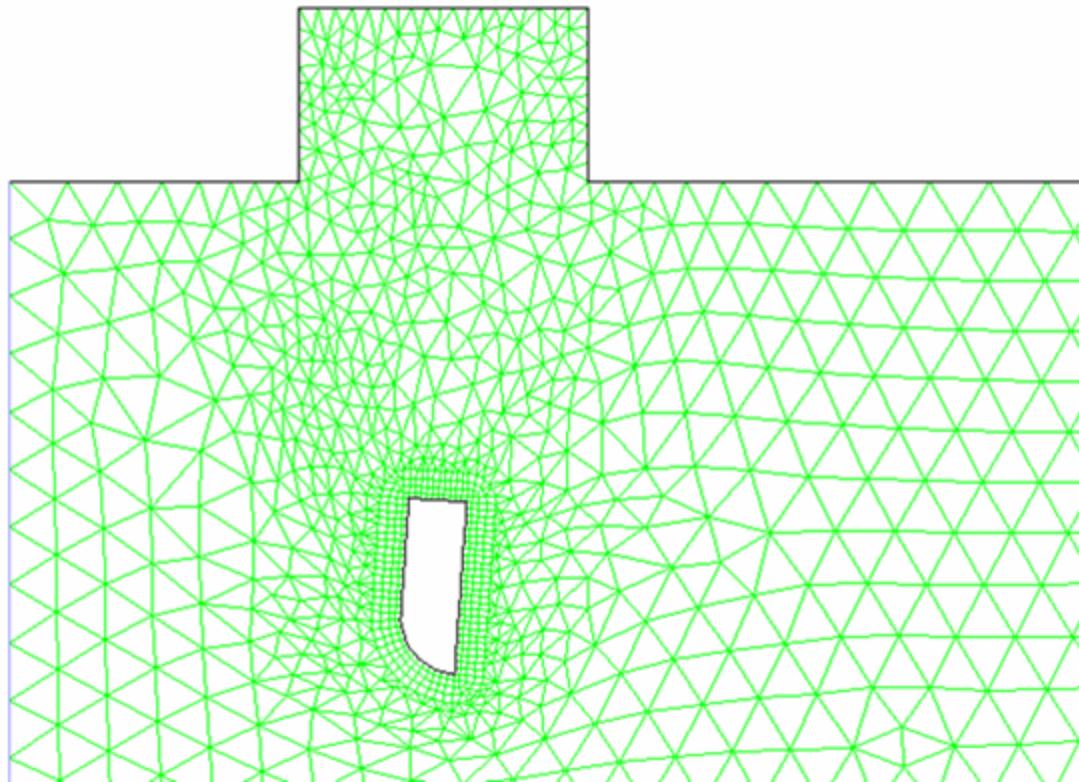

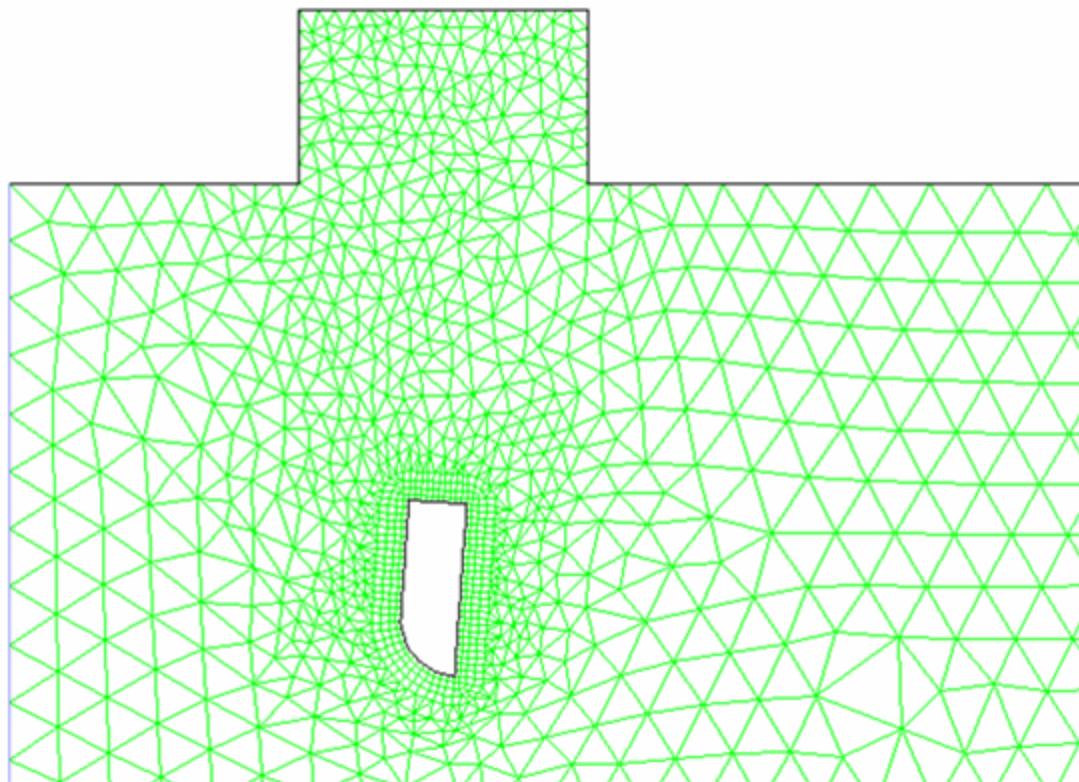

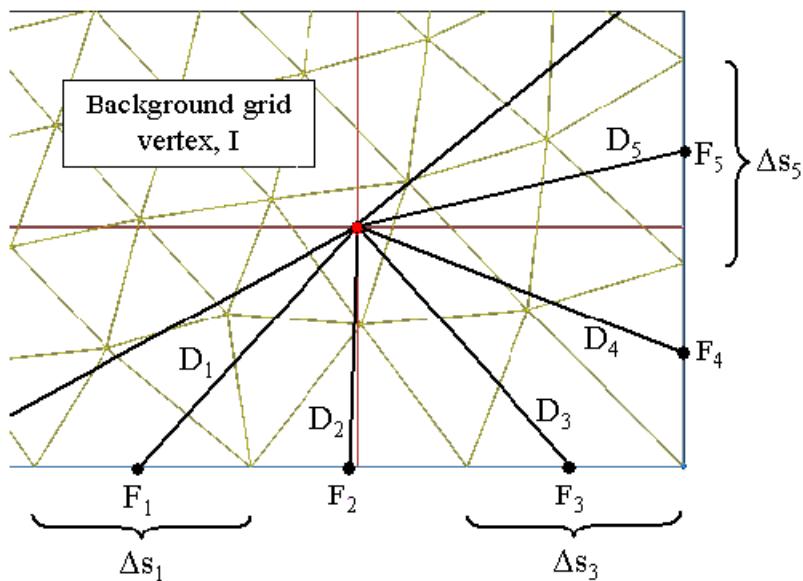

Figure 11.36 Mesh at the End of a Dynamic Mesh Simulation With Size Functions

In determining the sizing function, ANSYS FLUENT draws a bounding box around the zone that is approximately twice the size of the zone, and locates the shortest feature length within each fluid zone. ANSYS FLUENT then subdivides the bounding box based on the shortest feature length and the **Size Function Resolution** that you specify. This allows ANSYS FLUENT to create a background mesh.

You control the resolution of the background mesh and a background mesh is created for each fluid zone. The shortest feature length is determined by shrinking a second box around the object, and then selecting the shortest edge on that box. The size function is evaluated at the vertex of each individual background mesh.

Figure 11.37 Size Function Determination at Background Mesh Vertex I

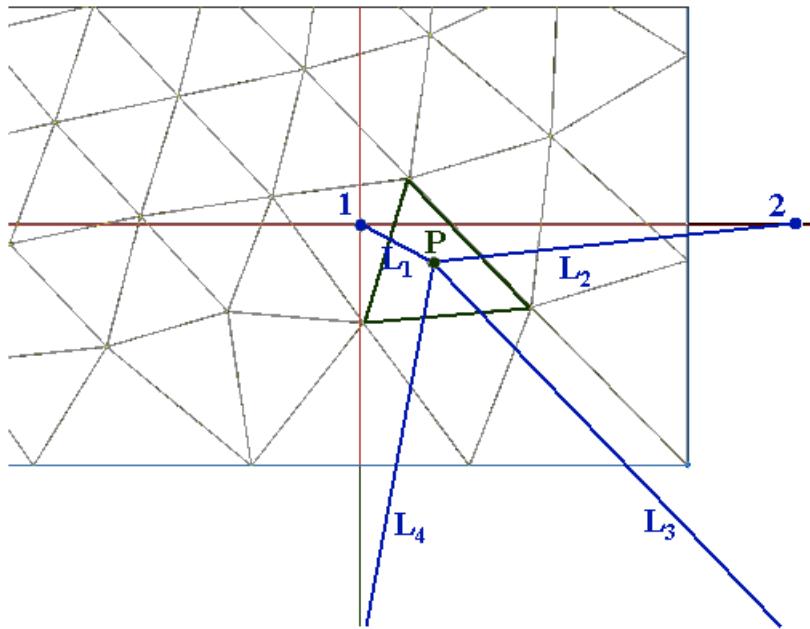

As seen in [Figure 11.37 \(p. 601\)](#), the local value of the size function SF_I is defined by

$$SF_I = \left(\frac{\sum \frac{1}{D_J} \Delta s_J}{\sum \frac{1}{D_J}} \right) \quad (11-17)$$

where D_J is the distance from vertex I on the background mesh to the centroid of boundary cell J and Δs_J is the mesh size (length) of boundary cell J .

The size function is then smoothed using Laplacian smoothing. ANSYS FLUENT then interpolates the value of the size function by calculating the distance L_I from a given cell centroid P to the background mesh vertices that surround the cell (see [Figure 11.38 \(p. 602\)](#)). The intermediate value of the size function $size_b$ at the centroid is computed from

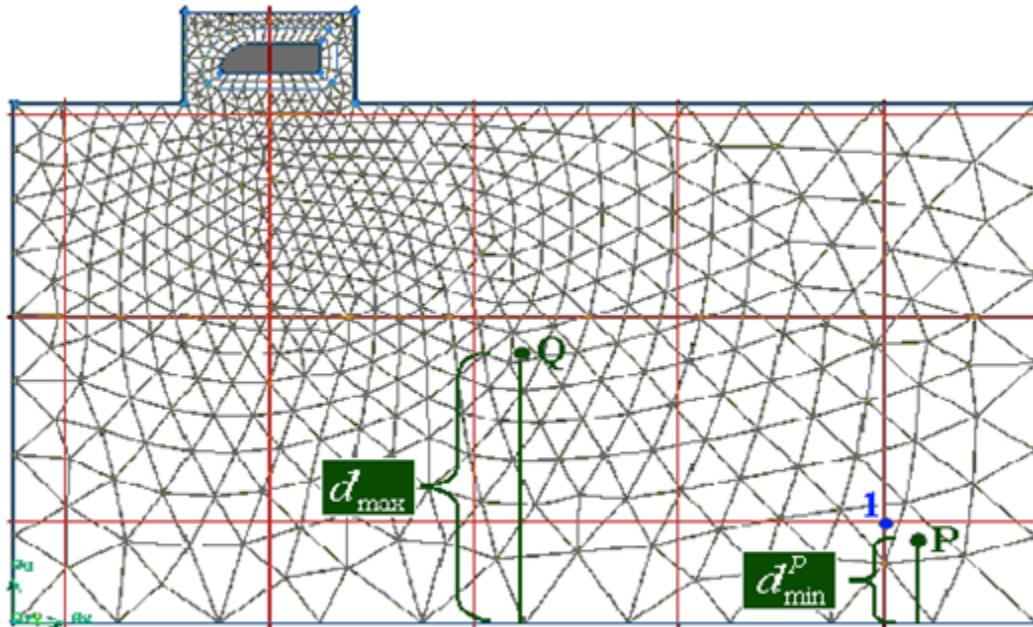

$$size_b = \left(\frac{\sum SF_I \frac{1}{L_I}}{\sum \frac{1}{L_I}} \right) \quad (11-18)$$

Figure 11.38 Interpolating the Value of the Size Function

Next, a single point Q is located within the domain (see *Figure 11.39* (p. 603)) that has the largest distance d_{max} to the nearest boundary to it. The normalized distance d_b for the given centroid P is given by

$$d_b = \frac{d_{min}^P}{d_{max}} \quad (11-19)$$

Figure 11.39 Determining the Normalized Distance

Using the parameters α and β (the **Size Function Variation** and the **Size Function Rate**, respectively), you can write the final value $size_P$ of the size function at point P as

$$size_P = size_b \times \left(1 + \alpha \times d_b^P + 2\beta \right) = size_b \times \gamma \quad (11-20)$$

where $size_b$ is the intermediate value of the size function at the cell centroid.

Note that α is the size function *variation*. Positive values mean that the cell size increases as you move away from the boundary. Since the maximum value of d_b is one, the maximum cell size becomes

$$size_{P,max} = size_b \times (1 + \alpha) = size_b \times \gamma_{max} \quad (11-21)$$

thus, α is really a measure of the maximum cell size.

The factor γ is computed from

$$\gamma = 1 + \alpha d_b^{1+2\beta} \quad \text{if } \alpha > 0 \quad (11-22)$$

$$\gamma = 1 + \alpha d_b^{\frac{1}{1-\beta}} \quad \text{if } \alpha < 0 \quad (11-23)$$

You can use **Size Function Variation** (or α) to control how large or small an interior cell can be with respect to its closest boundary cell. α ranges from -1 to ∞ ; an α value of 0.5 indicates that the interior cell size can be, at most, 1.5 the size of the closest boundary cell. Conversely, an α value of -0.5 indicates that the cell size interior of the boundary can be half of that at the closest boundary cell. A value of 0 indicates a constant size distribution away from the boundary.

You can use **Size Function Rate** (or β) to control how rapidly the cell size varies from the boundary. The value of β should be specified such that $-0.99 < \beta < +0.99$. A positive value indicates a slower transition from the boundary to the specified **Size Function Variation** value. Conversely, a negative value indicates a faster transition from the boundary to the **Size Function Variation** value. A value of 0 indicates a linear variation of cell size away from the boundary.

You can also control the resolution of the sizing function with **Size Function Resolution**. The resolution determines the size of the background bins used to evaluate the size distribution with respect to the shortest feature length of the current mesh. By default, the **Size Function Resolution** is 3 in 2D problems, and 1 in 3D problems.

A set of default values (based on the current mesh) is automatically generated if you click **Use Defaults**.

In summary, the sizing function is a distance-weighted average of all mesh sizes on all boundary faces (both stationary and moving boundaries). The sizing function is based on the sizes of the boundary cells, with the size computed from the cell volume by assuming a perfect (equilateral) triangle in 2D and a perfect tetrahedron in 3D. You can control the size distribution by specifying the **Size Function Variation** and the **Size Function Rate**. If you have enabled the **Sizing Function** option, ANSYS FLUENT will agglomerate a cell if

$$\text{size} \notin \left[\frac{4}{5}\gamma \text{size}_b, \frac{5}{4}\gamma \text{size}_b \right] \quad (11-24)$$

where γ is a factor defined by [Equation 11-22 \(p. 604\)](#) and [Equation 11-23 \(p. 604\)](#).

Note that the size function is only used for marking cells *before* remeshing. The size function is not used to govern the size of the cell during remeshing.

For steady-state applications (see [Steady-State Dynamic Mesh Applications \(p. 663\)](#)), you can instruct ANSYS FLUENT to perform a second round of cell marking and agglomeration after the boundary has moved, based on skewness criteria. The intent is to further improve the mesh quality through additional local remeshing. This optional feature works in conjunction with the [Dynamic Mesh Task Page \(p. 2024\)](#) ([Figure 11.33 \(p. 597\)](#)), and operates according to the skewness parameters you set in this dialog box. The size function parameters are not considered during this additional remeshing. Note that enabling this option will increase the time required to update the mesh during the solution.

Important

Additional local remeshing after the boundary has moved is not available for transient dynamic mesh applications, as the resulting numerical method would no longer be conservative.

When you use the **Sizing Function** remeshing option (see [Figure 11.34 \(p. 598\)](#)), you can control three parameters that govern the size function. You can specify the **Size Function Resolution**, the **Size Function Variation**, and the **Size Function Rate** or you can return to ANSYS FLUENT's default values by using the **Use Defaults** button.

The size function **Resolution** controls the density of the background mesh (see [Local Remeshing Based on Size Functions \(p. 599\)](#)). By default, it is equivalent to 3 in 2D simulations and 1 in 3D simulations.

The size function **Variation** corresponds to α in [Equation 11–20 \(p. 603\)](#). It is the measure of the maximum permissible cell size and it ranges from $-1 < \alpha < +\infty$.

The size function **Rate** corresponds to β in [Equation 11–20 \(p. 603\)](#). It is the measure of the rate of growth of the cell size, and it ranges from $-0.99 < \beta < 0.99$. A value of 0 implies linear growth, whereas higher values imply a slower growth near the boundary with faster growth as one moves toward the interior.

Note

To employ additional local remeshing, first make sure that you have enabled the **Remeshing** option in the [Dynamic Mesh Task Page \(p. 2024\)](#).

You can also use the following text command:

```
define → dynamic-mesh → controls → remeshing-parameter → remeshing-after-moving?
```

Finally, type yes to the question, optional remeshing after moving the mesh?

11.6.2.3.2. Cell Zone Remeshing Method

The cell zone remeshing method allows for the remeshing of the complete cell zone, and provides the option to also remesh the faces of all adjacent deforming dynamic face zones. This remeshing method is enabled by default when local cell remeshing is enabled, and is performed automatically if the local cell remeshing does not produce an acceptable mesh (see [Local Remeshing Method \(p. 598\)](#) for the acceptability criteria). Cell zone remeshing can also be manually invoked, using the following text command:

```
define → dynamic-mesh → actions → remesh-cell-zone
```

The cell zone remeshing method is available for triangular cells in 2D meshes and tetrahedral cells in 3D meshes. For 3D meshes, the method also allows the remeshing of wedge/prism layers at boundaries. The detection of the wedge/prism layers (as well as the prism height distribution and number of layers) is automatically performed by default, and allows for different prism parameters on each boundary zone. You can manually specify the parameters by entering non-zero values for first height, growth rate, and number of layers via the text commands available in the define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters menu, although generally it is not necessary to do this. When you enter them manually, the prism parameters are global: they apply to every prism layer detected in the remeshing zone.

Note that it is necessary to enable the dynamic mesh model and the remeshing method in order to attain access to the prism layer controls, even if the cell zone is remeshed manually and not as part of a dynamic mesh update.

11.6.2.3.2.1. Limitations of the Cell Zone Remeshing Method

Zone remeshing has the following limitations:

- Only triangular, tetrahedral, and wedge/prism cell types (when the wedge/prism cells are part of a 3D boundary layer mesh) are remeshed.
- Zones with hanging nodes cannot be remeshed.
- In parallel, the zone remeshing will automatically migrate all elements to be remeshed to a single CPU. Consequently, the machine memory will limit the size of the zone that can be remeshed.

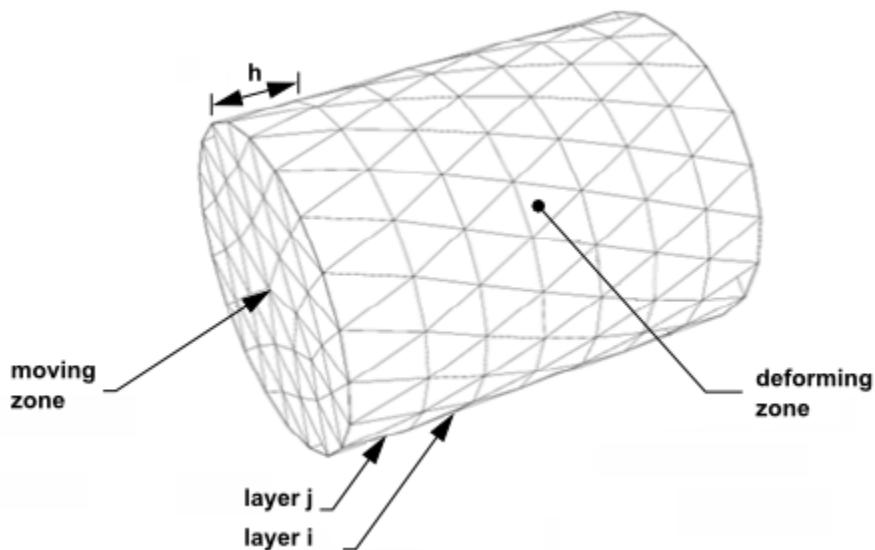

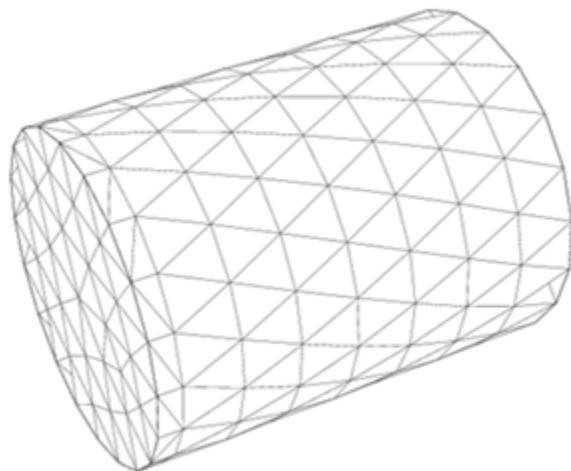

11.6.2.3.3. Face Region Remeshing Method

The face region remeshing method allows for the remeshing of those triangular faces (in 3D meshes) and linear faces (in 2D meshes) that are on a deforming face zone and adjacent to a moving face zone (see layer j in [Figure 11.40 \(p. 607\)](#)). ANSYS FLUENT marks the faces based on minimum and maximum length scales, and then remeshes the faces and the associated cells to produce a very regular mesh on the deforming boundary. Although primarily designed for in-cylinder type configurations, where the remeshing region is located where cylinder walls meet the moving piston, face region remeshing can be used for all applications where a moving dynamic zone abuts deforming dynamic face zones.

For 3D simulations, ANSYS FLUENT allows face region remeshing with symmetric boundary conditions and across multiple face zones. The remeshing can preserve features not only between the different deforming face zones, but also within a face zone. For more information on feature preservation, see [Feature Detection \(p. 617\)](#). ANSYS FLUENT also allows face region remeshing of tetrahedral cell zones which contain wedge/prism layers, as described in the section that follows.

To begin marking the faces for face region remeshing, ANSYS FLUENT identifies the nodes at the intersection of a moving dynamic zone and the adjacent deforming zones. ANSYS FLUENT then analyzes the height of the faces on the deforming zones that are in the range of the identified nodes, and then remeshes the faces depending on the specified maximum or minimum length scale.

Consider the simple tetrahedral mesh of a cylinder that has a moving end wall (see [Figure 11.40 \(p. 607\)](#)). The faces that are subject to remeshing are in layer j of the side wall. If the faces in layer j are expanding, the expansion continues until the height h reaches the maximum length scale, and then the layer is remeshed to form 2 layers of elements (see [Figure 11.41 \(p. 607\)](#)). Conversely, if the faces of layer j are contracting, the contraction continues until h reaches the minimum length scale, and then layer j and the neighboring layer of faces (layer i) on the deforming zone are remeshed to form a single layer.

Figure 11.40 Expanding Cylinder Before Region Face Remeshing**Figure 11.41 Expanding Cylinder After Region Face Remeshing**

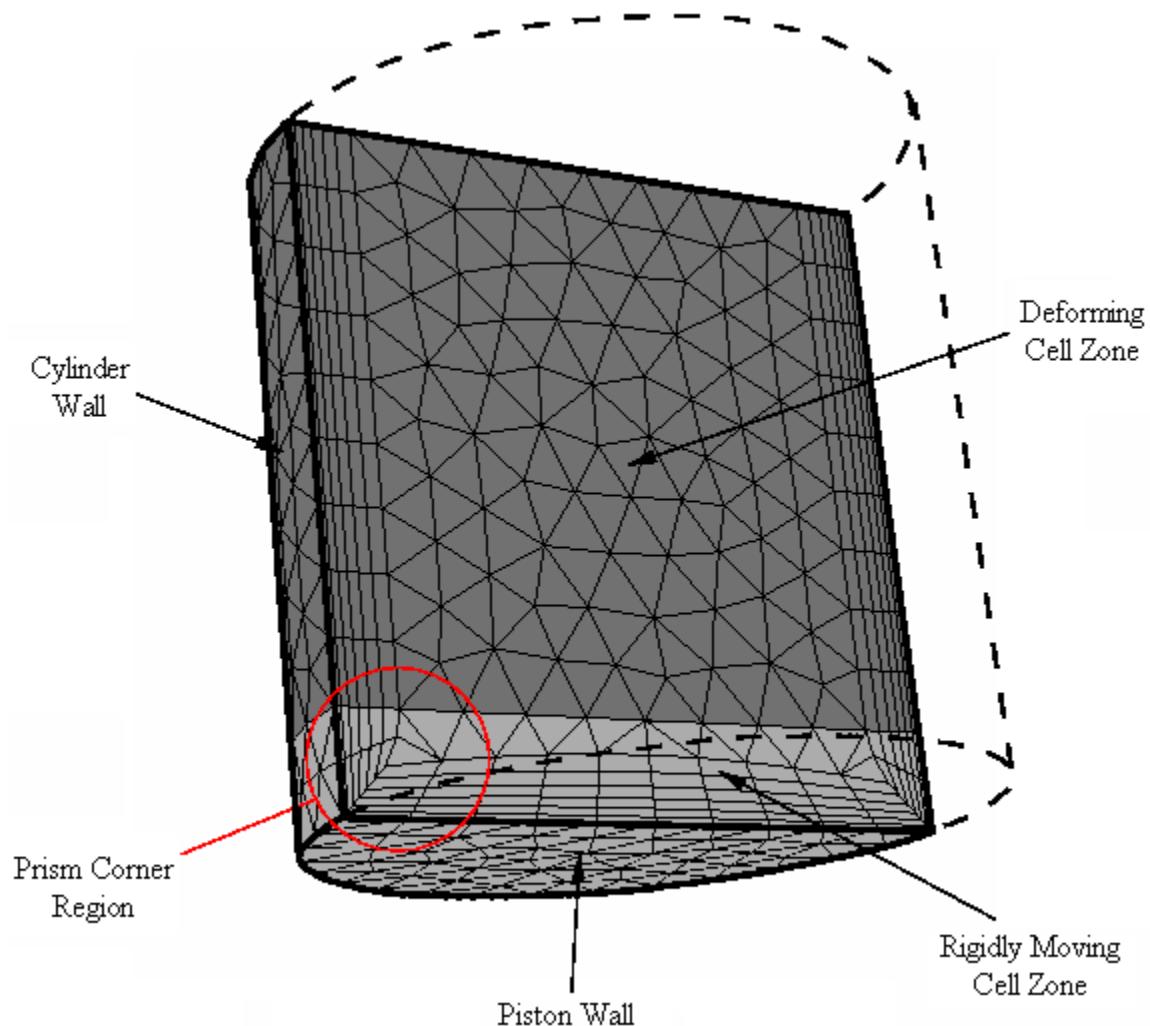

11.6.2.3.3.1. Face Region Remeshing with Prism Layers

In 3D simulations, the face region remeshing method can be applied on meshes that have wedge/prism layers along the deforming face zones. When remeshing the faces on the deforming face zones, the associated prismatic cells are remeshed as well. The prism parameters are based on the existing mesh by default; you have the option of manually setting these parameters, as described later in this section.

If the motion of the face zone is large compared to the height of the adjacent deforming face zones, it is recommended that you decompose the mesh volume in such a way as to create a dynamic cell zone that moves as a rigid body in between the moving face zone and the deforming dynamic cell

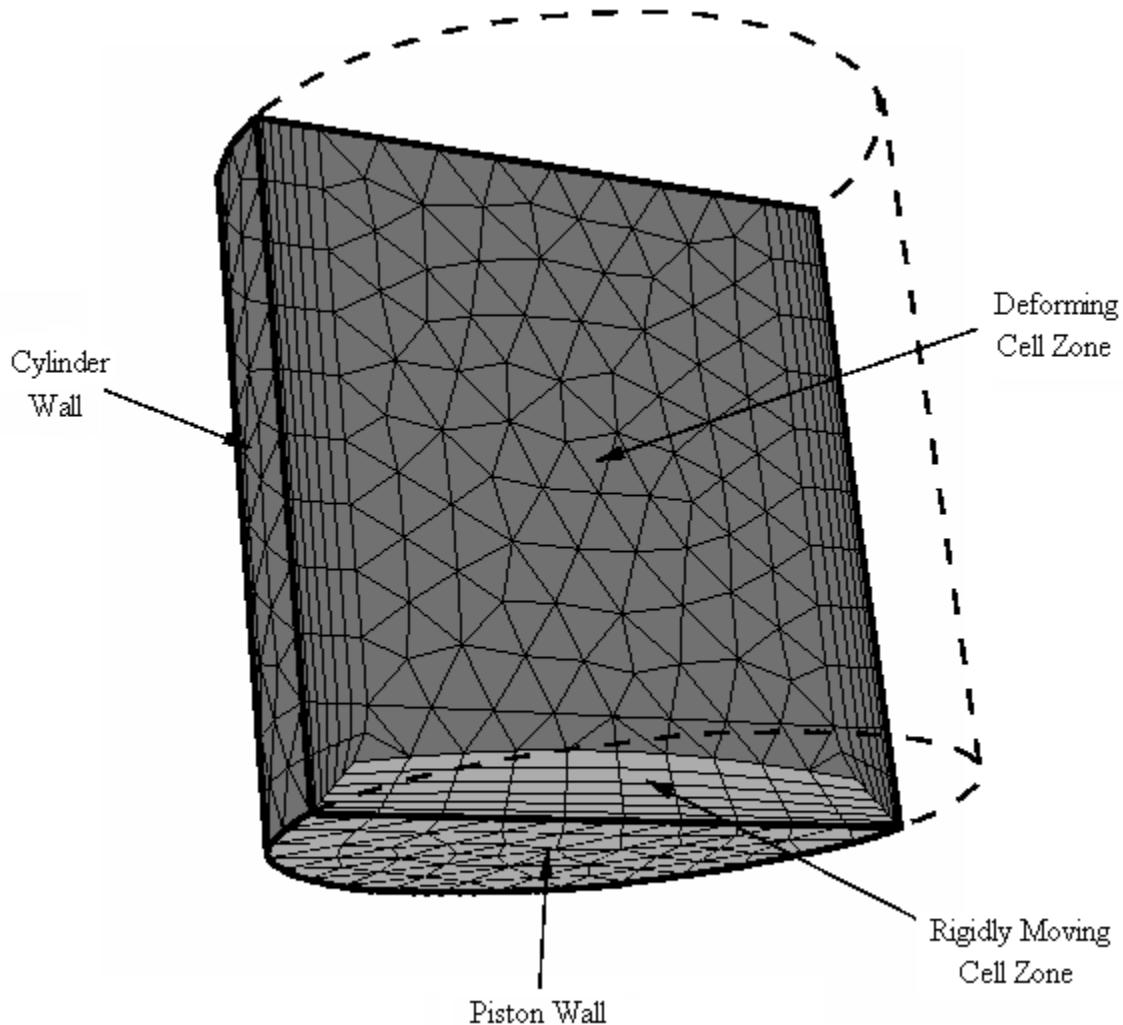

zone on which face region remeshing is applied. Consider [Figure 11.42 \(p. 608\)](#), which displays only half of an in-cylinder mesh. The rigidly moving cell zone encapsulates the prism layers on the moving piston so that the layers are not remeshed, and thus the risk of generating degenerate cells during the mesh motion update is reduced.

Figure 11.42 Volume Decomposition for Prism Layers

It is preferable (and even mandatory, if the mesh is a half model with a symmetry plane) to decompose the volume such that the “corner” region of the prism layers (shown in the previous figure) exists entirely within the rigidly moving zone. This allows for the largest deformations without risking degenerate elements, because the prism normals of the remeshed cells are uniformly perpendicular to the faces undergoing remeshing.

If the range of motion does not allow you to encapsulate the entire corner region of the prism layers in a rigidly moving zone, it is recommended that you encapsulate the “base” of the prism layers (shown in [Figure 11.43 \(p. 609\)](#)) and move these cells with a rigid body motion. Although this is less ideal than encapsulating the corner region, it does reduce the risk of degenerate mesh elements.

Figure 11.43 Volume Decomposition for the Base of the Prism Layers

For piston-type applications that contain prism layers, a reasonable rule of thumb is that you should decompose the mesh volume if the piston motion is more than half the cylinder height. If you decide not to decompose the volume at all, you must at the very least enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab of the **Dynamic Mesh Zone** dialog box when setting up the moving face zone (see [Rigid Body Motion \(p. 649\)](#) for details). In any case, it is recommended that you always preview the mesh motion over the complete simulation time, to make sure that you will have a valid mesh at each time step.

The prism layer parameters (i.e., element height, growth rate, and number of layers) are extracted automatically from the mesh and do not generally require your input. To prevent the prism parameters from drifting due to repeated remeshing, the prism parameters for first height, growth rate, and number of layers can be entered manually, using the text commands available in the `define/dynamic-mesh/controls/remeshing-parameters/prism-layer-parameters` menu.

11.6.2.3.3.2. Applicability of the Face Region Remeshing Method

Note the following limitations associated with face region remeshing:

- You can use the face region remeshing method only in cell zones that contain triangular cells (in 2D) or tetrahedral cells, with or without prism layers (in 3D). For 3D meshes, the faces on the deforming boundaries that border the moving face must all be triangular.
- The face region remeshing method is not compatible with diffusion-based smoothing. For more information about diffusion-based smoothing, see [Diffusion-Based Smoothing \(p. 581\)](#).
- You cannot use the face region remeshing method in conjunction with hanging node adaption. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the [Theory Guide](#).

11.6.2.3.4. CutCell Zone Remeshing Method

The CutCell zone remeshing method is available to remesh a complete cell zone (including all boundary zones of the remeshed cell thread). This method is available for 3D simulations only. The existing volume mesh is replaced by a predominantly Cartesian mesh. When used as part of a transient simulation, the remeshing occurs at predefined intervals and whenever the mesh quality in the cell zone is deemed poor. Examples of meshes before and after CutCell zone remeshing are shown in [Figure 11.44 \(p. 610\)](#) and [Figure 11.45 \(p. 611\)](#), respectively.

Figure 11.44 Unstructured Tetrahedral Mesh Before CutCell Zone Remeshing

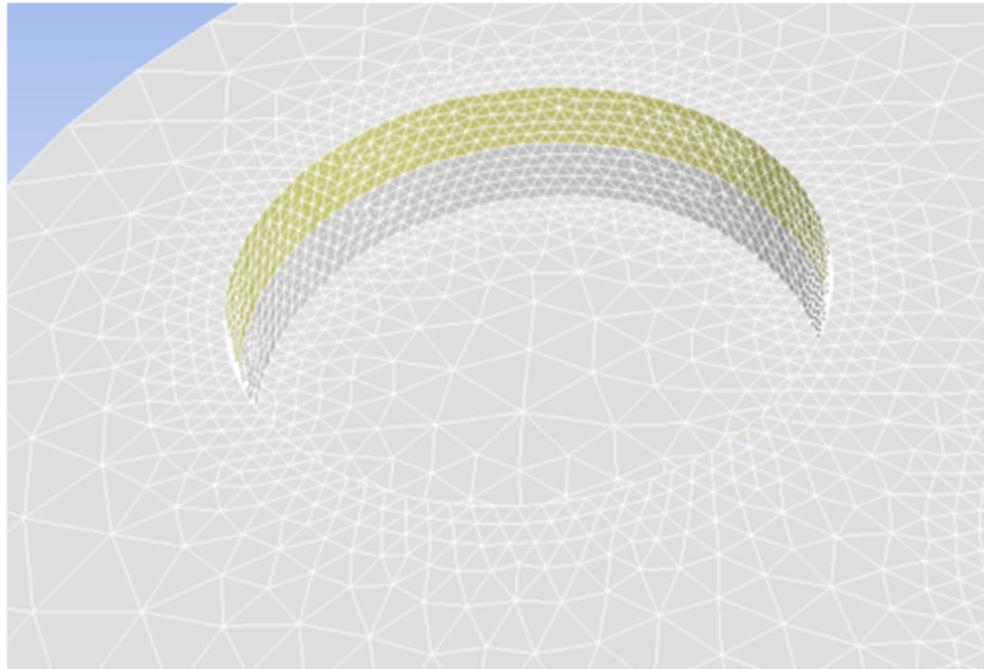

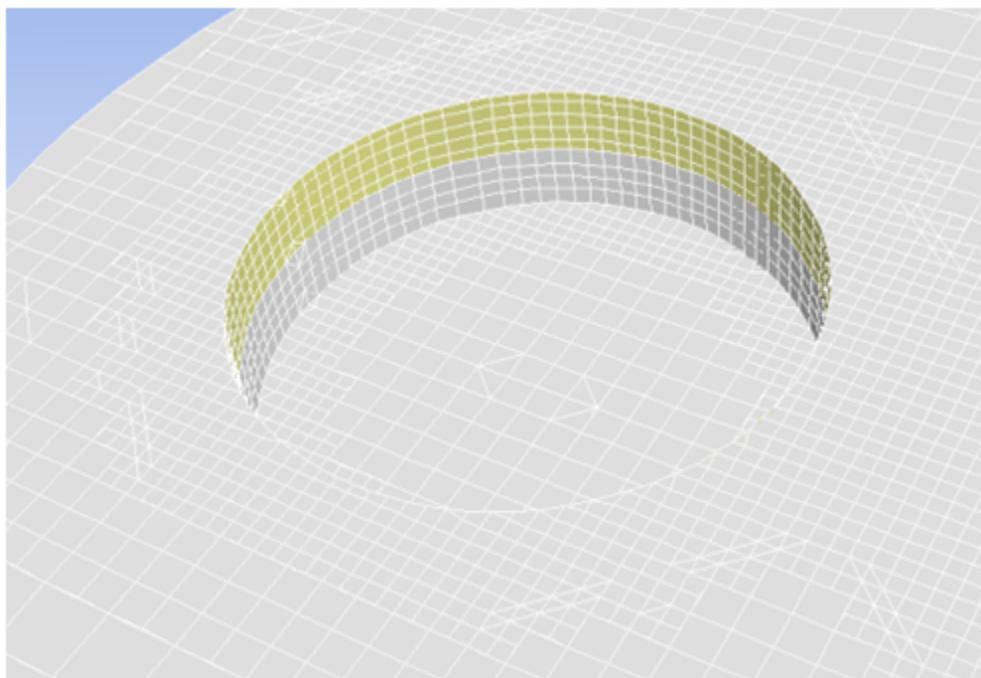

Figure 11.45 Mesh After CutCell Zone Remeshing

During CutCell zone remeshing, a uniform Cartesian grid is locally refined using size functions, in order to resolve the initial mesh with sufficient accuracy. The resulting mesh consists mostly of hexahedral elements, which reduces the cell count compared to unstructured tetrahedral meshing. Additional element types are used near the boundaries to closely resolve complex shapes. The remeshing takes place at regular intervals, or whenever the mesh quality deteriorates due to mesh motion.

The CutCell zone remeshing method not only replaces the volume mesh, it also replaces the complete surface mesh of the remeshed cell zone. Consequently, this method can only be used to remesh cell zones which are either stand-alone zones or are only connected to other cell zones through non-conformal interfaces.

The **CutCell Zone** remeshing method option is available in the **Remeshing Methods** group box. Note that the **CutCell Zone** remeshing method does not use any of the parameters specified in the **Mesh Method Settings** dialog box. The parameters used to control **CutCell Zone** remeshing are specified in the **Dynamic Mesh Zones** dialog box when setting up the zone and boundaries.

For more information about CutCell meshes, see the TGrid User's Guide.

11.6.2.3.4.1. Applicability of the CutCell Zone Remeshing Method

The CutCell zone remeshing method can be applied to cell zones, with the following limitations:

- The case must be 3D.
- The cell zone cannot be conformally connected to other cell zones; that is, a CutCell zone needs to be a stand-alone cell zone, or can only be connected to another zone through a non-conformal interface. In the latter case, the non-conformal interface is cleared before the remeshing and automatically recreated after the remeshing.

Note that the CutCell zone remeshing method can be applied to cell zones that contain adapted cells.

In parallel, all cells of the remeshed zone will be automatically migrated to and remeshed on a single CPU. Consequently, the machine memory will limit the size of the zone that can be remeshed. The mesh is automatically repartitioned after the remeshing.

In addition to the limitations listed previously, you should also note the following with regard to CutCell zone remeshing:

- Internal coupled walls, such as baffles, are discarded during the remeshing. The method is designed to primarily remesh cell zones with a single interior zone.
- Interior jump boundary condition zones (e.g., fans, porous jumps), are discarded during the remeshing.
- Conformal periodic boundary conditions are not maintained after the remeshing. Any existing conformal periodic boundaries on the zone being remeshed should slit and replaced with non-conformal periodic boundaries.
- If the zone being remeshed contains multiple interior zones prior to the remeshing, all interior zones will be collected into a single interior zone during the CutCell zone remeshing.

11.6.2.3.4.2. Using the CutCell Zone Remeshing Method

In order to apply CutCell zone remeshing to a cell zone, begin by enabling the **CutCell Zone** option in the **Remeshing Methods** group box in the **Remeshing** tab of the **Mesh Method Settings** dialog box (see [Figure 11.33 \(p. 597\)](#)). Next, use the **Dynamic Mesh Zones** dialog box to create a deforming dynamic zone for the cell zone (see [Deforming Motion \(p. 652\)](#)). Then enable **CutCell** in the **Remeshing Option** group box and enter the relevant remeshing parameters, including: the maximum mesh size for the Cartesian cells; the global size function growth rate; and the minimum orthogonal quality and remeshing interval to control the remeshing frequency.

ANSYS FLUENT allows you to specify either a soft or a mesh-based size function to control how the Cartesian mesh increases in size from the boundary toward the interior of the cell zone. For the soft size function, you specify a maximum mesh size for each boundary zone of the CutCell cell zone. When you use the mesh-based size function, ANSYS FLUENT analyzes the existing mesh to evaluate the necessary mesh refinement at the boundary. See step 4. of [Stationary Zones \(p. 646\)](#) for more information about these size functions. You have control over the size function types and parameters by defining the boundary zones as dynamic zones. If no boundary zone adjacent to the CutCell zone is defined as a dynamic zone, ANSYS FLUENT will automatically apply mesh-based size functions to each CutCell boundary zone and use the global growth rate entered for the cell zone to control the remeshing.

Note that the size functions used by the CutCell zone remeshing method are unrelated to the size function used for local cell remeshing (as described in [Local Remeshing Based on Size Functions \(p. 599\)](#)).

The cells that contain hanging nodes / edges as a result of the CutCell zone remeshing are automatically converted to polyhedral cells. See [Limitations \(p. 156\)](#) for details about limitations associated with polyhedral cells.

It is recommended that you first manually apply the CutCell zone remeshing method (as described in the section that follows) before using it as part of a transient simulation, as this allows you to evaluate if your remeshing parameters are suitable before running a calculation that is computationally expensive.

11.6.2.3.4.3. Applying the CutCell Zone Remeshing Method Manually

Although the CutCell zone remeshing method is primarily intended as an automatic remeshing method during dynamic mesh updates, you can also manually create a CutCell mesh (i.e., you can remesh without running a calculation) by using the following text command:

```
define → dynamic-mesh → actions → remesh-cell-zone-cutcell
```

You will be prompted to enter the global parameters for the CutCell zone remeshing. If no dynamic zones are set up in your case, ANSYS FLUENT will use the global parameters you enter and apply mesh-based size functions to each boundary of the CutCell zone. If the case is set up as a dynamic mesh case, manual remeshing will use the information specified on each CutCell boundary zone. During manual CutCell zone remeshing, the global parameters are taken from the text interface input, and the global parameters specified on the CutCell cell zone are ignored.

When executing manual remeshing through the `remesh-cell-zone-cutcell` text command, you will be prompted to specify whether topology warnings should be ignored. If you do not ignore the topology warnings, ANSYS FLUENT will analyze the zone being remeshed and report any interior face zones that will get discarded during the remeshing. If the zone being remeshed has periodic boundary zones, you will also be prompted to either abort the remeshing process or slit the periodics in order to proceed.

You will also be prompted to specify whether the cells that contain hanging nodes / edges as a result of the CutCell zone remeshing should be converted to polyhedral cells. See [Limitations \(p. 156\)](#) for details about limitations associated with polyhedral cells. By default, all hanging node cells are converted to polyhedral cells.

11.6.2.3.5. 2.5D Surface Remeshing Method

The 2.5D surface remeshing method only applies to extruded 3D geometries and is similar to local remeshing in two dimensions on a triangular surface mesh (not a mixed zone). Faces on a deforming boundary are marked for remeshing based on face skewness, minimum and maximum length scale; the 2.5D remeshing method also gives you the option of marking cells using size functions, as described in [Local Remeshing Based on Size Functions \(p. 599\)](#).

Figure 11.46 Close-Up of 2.5D Extruded Flow Meter Pump Geometry Before Remeshing and Laplacian Smoothing

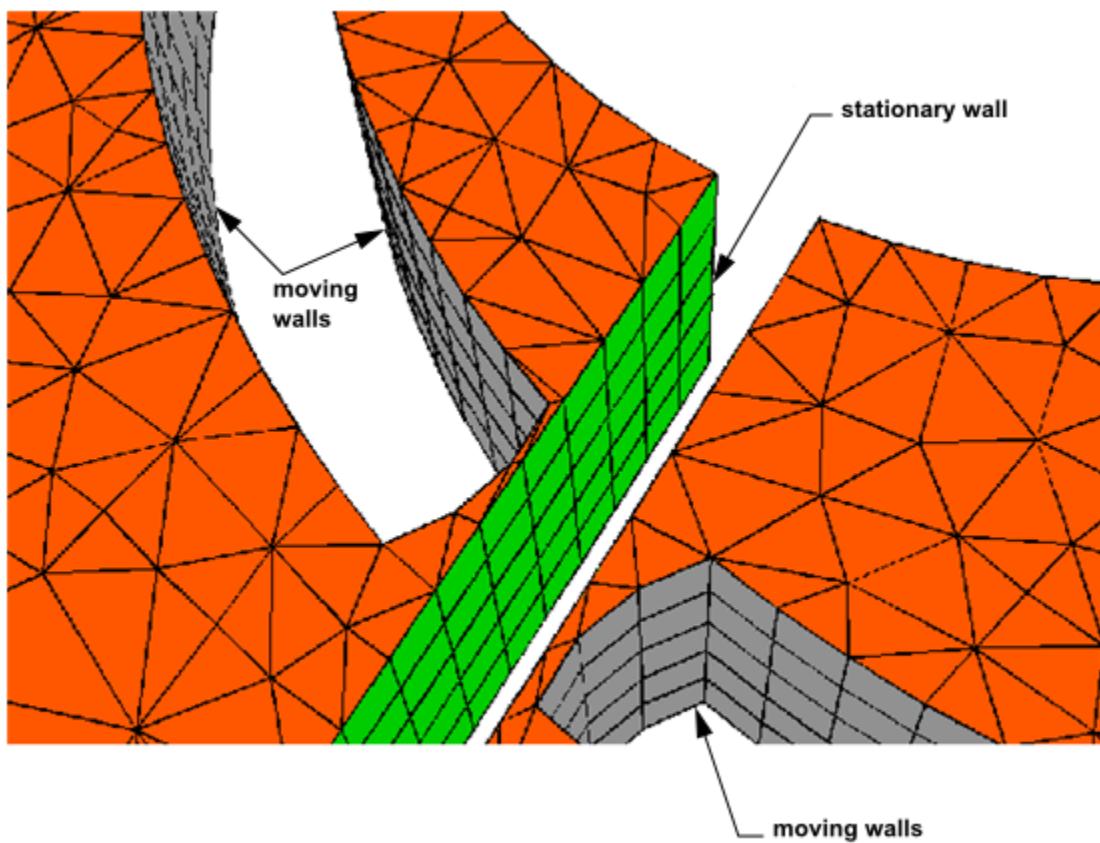

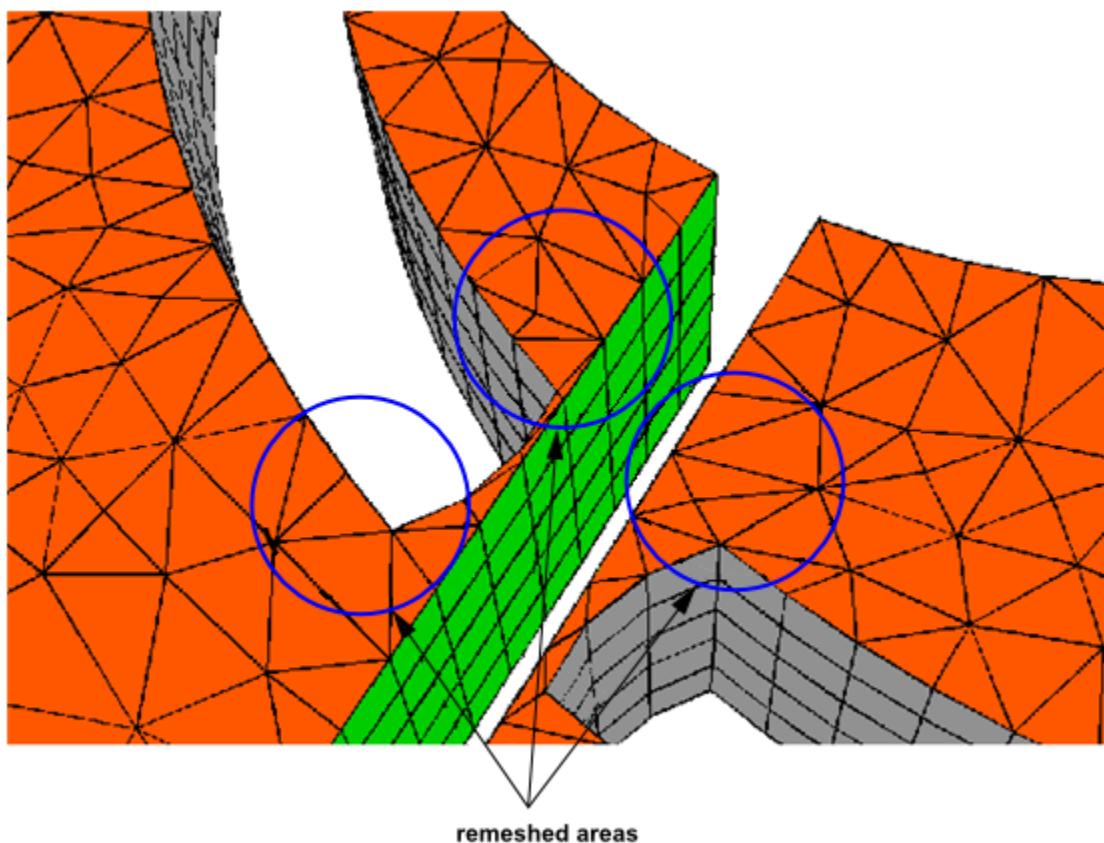

Figure 11.47 Close-Up of 2.5D Extruded Flow Meter Pump Geometry After Remeshing and Laplacian Smoothing

11.6.2.3.5.1. Applicability of the 2.5D Surface Remeshing Method

The following applies to the 2.5D surface remeshing method:

- Triangular faces get remeshed based on marking.
- Extruded prisms get remeshed based on the remeshing of the triangular face. Only extruded regions get remeshed, not mixed regions.
- Note that you cannot use the 2.5D surface remeshing method in conjunction with hanging node adaption. For more information on hanging node adaption, see [Hanging Node Adaption](#) in the [Theory Guide](#).
- In the extruded/coopered mesh, area zone changes are not allowed. In such cases, make sure that the face zones at the extruded mesh area do not change from the top to the bottom. For more information about the 2.5D model, see [Using the 2.5D Model](#) (p. 615).
- Periodics are not supported at the extruded zones.

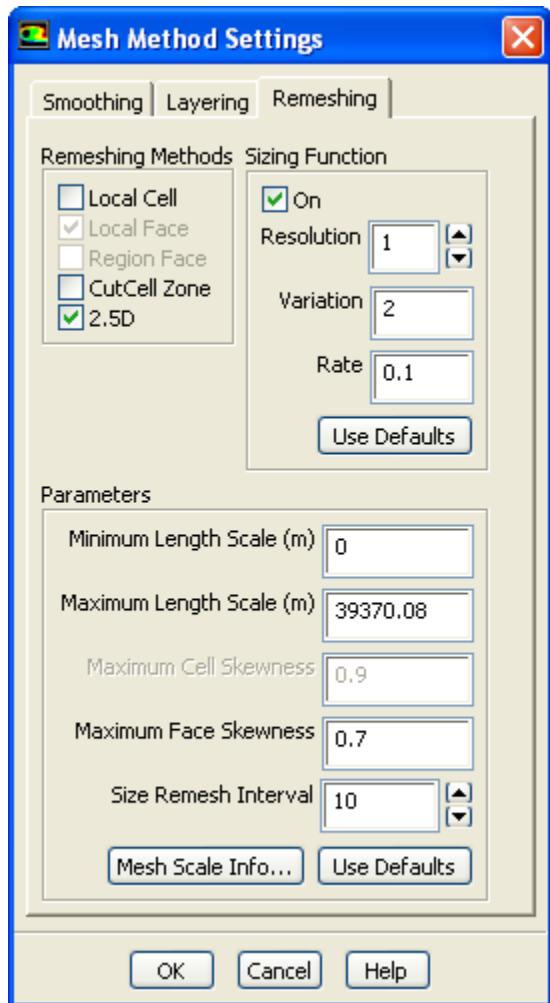

11.6.2.3.5.2. Using the 2.5D Model

For 3D simulations only, you can select the **2.5D** model under the **Remeshing** tab in the [Mesh Method Settings Dialog Box](#) (p. 2026). This model allows for a specific subset of remeshing techniques.

The 2.5D mesh essentially is a 2D triangular mesh which is expanded, or extruded, along the normal axis of the specific dynamic zone that you are interested in modeling. The triangular surface mesh is remeshed and smoothed on one side, and the changes are then extruded to the opposite side. Rigid body motion is applied to the moving face zones, while the triangular extrusion surface is assigned to

a deforming zone with remeshing and smoothing enabled. The opposite side of the triangular mesh is assigned to be a deforming zone as well, with only smoothing enabled, as in [Figure 11.49 \(p. 617\)](#).

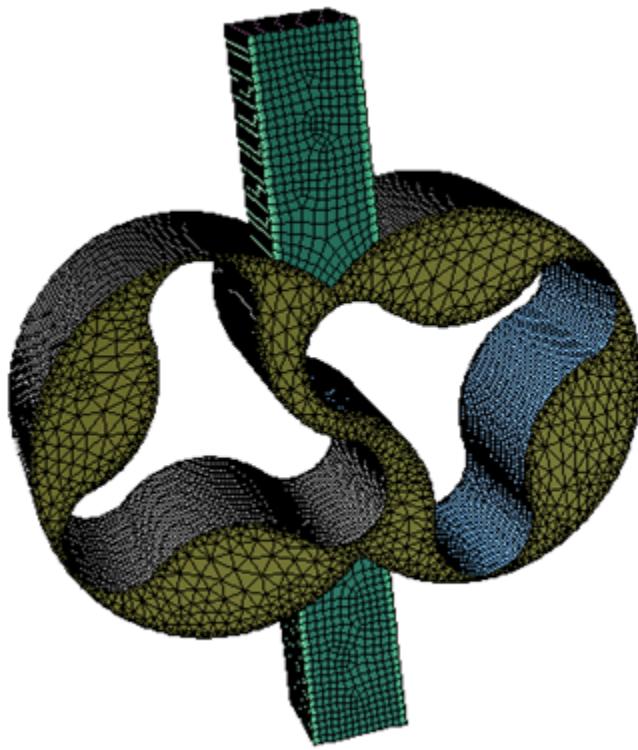

Figure 11.48 The Remeshing Tab for the 2.5D Model

For more information on setting smoothing and remeshing parameters, see [Dynamic Mesh Update Methods \(p. 575\)](#).

The 2.5D model only applies to mappable (i.e., extrudable) mesh geometries such as pumps, as in [Figure 11.49 \(p. 617\)](#). Only the aspects of the geometry that represent the “moving parts” need to be extruded in the mesh.

Figure 11.49 2.5D Extruded Gear Pump Geometry

Important

You must only apply smoothing to the opposite side of the extruded mesh, since ANSYS FLUENT requires the geometry information for the dynamic zone. ANSYS FLUENT projects the nodes back to its geometry after the extrusion. Without this geometry information, the dynamic zones tends to lose its integrity.

Important

In parallel, a partition method that partitions perpendicular to the extrusion surface should be used. For example, if the normal of the extrusion surface points in the x-direction then Cartesian-Y or Cartesian-Z would be the perfect partition methods.

The 2.5D model is used in combination with a `DEFINE_GRID_MOTION` UDF. (See [Hooking `DEFINE_GRID_MOTION` UDFs](#) in the [UDF Manual](#) for information about hooking this UDF.)

This UDF is associated with the extrusion surface that is adjacent to the cell zone, in turn applying the same deformation to the entire cell zone. This approach is particularly useful when modeling gear pumps that are predominantly extruded hexahedral meshes. For more information about this UDF, contact your support engineer.

11.6.2.3.6. Feature Detection

For 3D simulations, ANSYS FLUENT allows you to preserve features on deforming zones not only between the different face zones, but also within a face zone.

In the **Geometry Definition** tab of the [Dynamic Mesh Zones Dialog Box \(p. 2037\)](#), for any geometry definition, you can indicate whether you want to include features of a specific angle by selecting **Include Features** under **Feature Detection** and setting the **Feature Angle** (the zonal feature angle α) in degrees. If the angle β between adjacent faces is bigger than the specified angle, then the feature is recognized (i.e., $\cos(\beta) < \cos(\alpha)$).

11.6.2.3.6.1. Applicability of Feature Detection

The following items are applicable for use with feature detection:

- Feature remeshing is only possible with face region remeshing.
- Features are preserved by local face remeshing, i.e., there is no local face remeshing across features.
- Smoothing methods preserve features, i.e., nodes at feature edges are not allowed to be smoothed.

11.6.2.4. Volume Mesh Update Procedure

The volume mesh is updated automatically based on the methods described in [Dynamic Mesh Update Methods \(p. 575\)](#). ANSYS FLUENT decides which method to use for a particular zone based on which model is enabled and the shape of the cells in the zone. For example, if the boundaries of a tetrahedral cell zone are moving, and unless the zone has been set up for CutCell zone remeshing, the spring-based or diffusion-based smoothing and local remeshing methods will be used to update the volume mesh in this zone. If the zone consists of prismatic (hexahedral and/or wedge) cells, then the dynamic layer method will be used to determine where and when to insert and remove cell layers. On extruded prism zones, the 2.5D surface meshing method will be used.

Depending on which model is enabled, ANSYS FLUENT automatically determines which method to use by visiting the adjacent cell zones and setting appropriate flags for the volume mesh update methods to be used. If you specify the motion for a cell zone, ANSYS FLUENT will visit all of the neighboring cell zones and set the flags appropriately. If you specify the motion of a boundary zone, ANSYS FLUENT will analyze only the adjacent cell zones. If a cell zone does not have any moving boundaries, then no volume mesh update method will be applied to the zone.

Important

Note that as a result of the remeshing procedures, updated meshes may be slightly different when dynamic meshes are used in parallel ANSYS FLUENT, and therefore very small differences may arise in the solutions.

Important

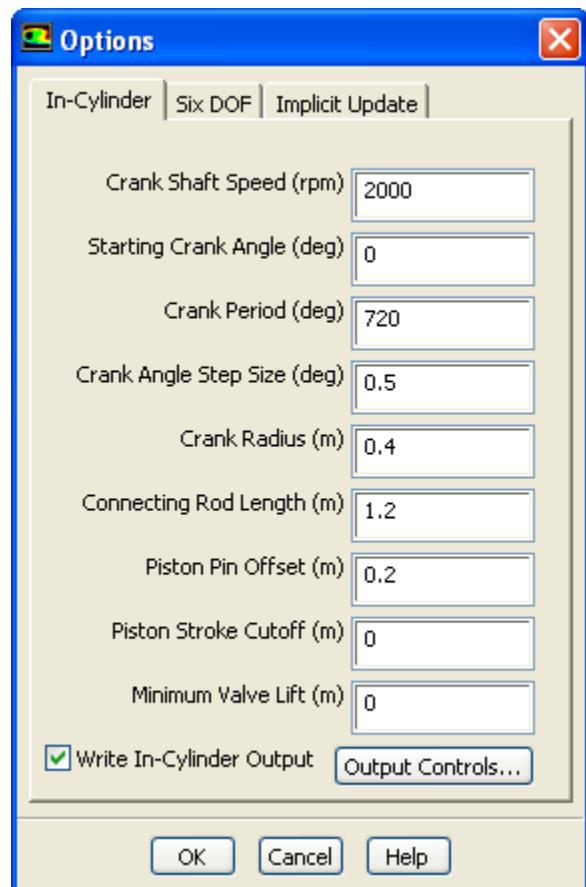

Note that if your dynamic mesh model consists of numerous shell conduction zones, the mesh update may be very time consuming because all shells are deleted and recreated during the mesh update.

11.6.3. In-Cylinder Settings

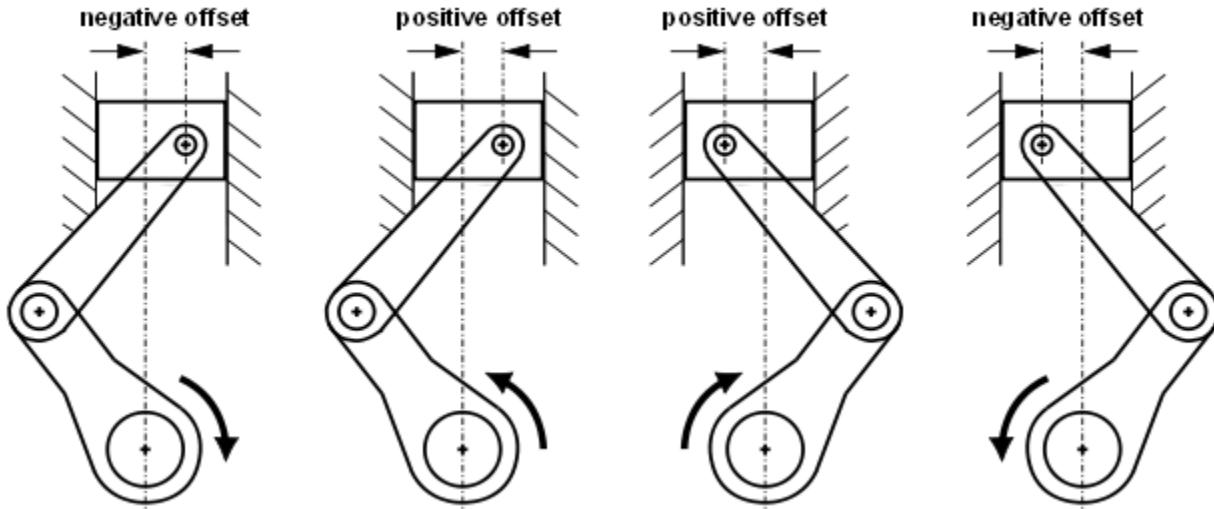

You can enable the **In-Cylinder** option in the [Dynamic Mesh Task Page \(p. 2024\)](#) ([Figure 11.13 \(p. 575\)](#)) for transient problems. Then click the **Settings...** button in the **Options** group box to open the [Options Dialog Box \(p. 2030\)](#). Click the **In-Cylinder** tab and specify the **Crank Shaft Speed**, the **Starting Crank Angle**, and the **Crank Period**, which are used to convert between flow time and crank angle. You must

also specify the time step to use for advancing the solution in terms of crank angle in **Crank Angle Step Size**. By default, ANSYS FLUENT assumes a **Crank Angle Step Size** of 0.5 degrees.

Figure 11.50 The In-Cylinder Tab of the Options Dialog Box

ANSYS FLUENT provides a built-in function that can define the location of the piston as a function of crank angle. This function is named ****piston-full****, and is selected from the **Motion/UDF Profile** drop-down list in the **Dynamic Mesh Zones** dialog box as part of rigid body motion (see [Rigid Body Motion \(p. 649\)](#) for details). If you plan to specify the piston motion using this function, you need to specify the **Crank Radius** (i.e., the distance between the crank center and the center of the crank pin) and the **Connecting Rod Length**. You also have the option of entering a value for the **Piston Pin Offset** for cases when the piston pin is offset perpendicularly from the plane defined by the crank shaft axis and the direction of motion of the piston. The sign of this offset can be positive or negative, and is determined based on the geometry and the direction of rotation of the crank shaft (as shown in [Figure 11.51 \(p. 620\)](#)).

Figure 11.51 Determining the Sign of the Piston Pin Offset

When the ****piston-full**** function is used, the piston location is calculated according to the following equation:

$$p_s = \sqrt{(r_c + L)^2 - x_{\text{offset}}^2} - r_c \cos(\theta_c) - \sqrt{L^2 - (r_c \sin(\theta_c) + x_{\text{offset}})^2} \quad (11-25)$$

where p_s is the piston location, r_c the crank radius, L is the connecting rod length, x_{offset} is the piston pin offset, and θ_c is the current crank angle.

The piston location p_s is always 0 at top-dead-center (TDC), that is, when the crank pin is perfectly aligned between the piston pin and the center of rotation of the crank shaft. TDC occurs when the crank angle is 0° when there is no piston pin offset, and prior to the crank angle reaching 0° when there is a positive piston pin offset. The piston location is a positive value at bottom-dead-center (BDC), that is, when the crank shaft is perfectly aligned between the piston pin and the crank pin. The value of p_s at BDC is equal to $2r_c$ when there is no piston pin offset, and greater than $2r_c$ when there is a non-zero piston pin offset (positive or negative).

The current crank angle θ_c is calculated from

$$\theta_c = \theta_s + t\Omega_{\text{shaft}} \quad (11-26)$$

where θ_s is the **Starting Crank Angle** and Ω_{shaft} is the **Crank Shaft Speed**.

The **Piston Stroke Cutoff** and **Minimum Valve Lift** values are used to control the actual values of the valve lift and piston stroke such that

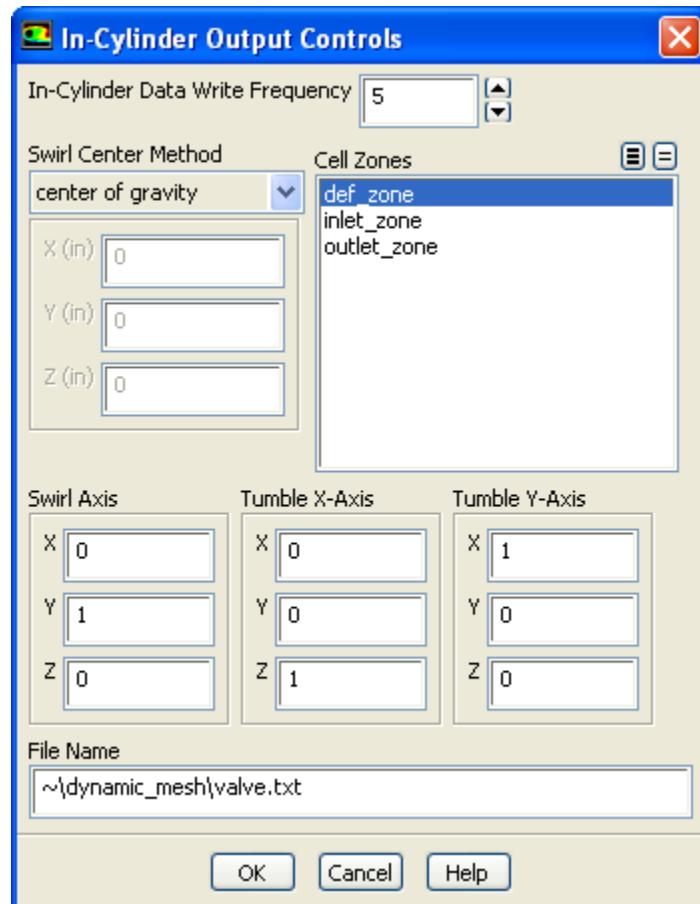

$$v_{lift} = \max(v_{lift}^c, v_{lift}^{min})$$

$$p_s = \min(p_s^c, p_s^{min})$$
(11-27)

where v_{lift}^c is the valve lift computed from the appropriate valve profiles, v_{lift}^{min} is the **Minimum Valve Lift**, p_s^c is the stroke calculated from [Equation 11-25 \(p. 620\)](#), and p_s^{min} is the **Piston Stroke Cutoff**. (See [Defining Motion/Geometry Attributes of Mesh Zones \(p. 627\)](#) on how the **Piston Stroke Cutoff** is used to control the onset of layering in the cylinder chamber.)

Enable the **Write In-Cylinder Output** option then click the **Output Controls...** button if you want to specify specific output parameters. The [In-Cylinder Output Controls Dialog Box \(p. 2032\)](#) will open, where you can specify various quantities needed for the calculation of swirl and tumble along with the frequency of writing the output to the chosen file. Swirl is used to describe circulation about the cylinder axis. Tumble flow circulates around an axis perpendicular to the cylinder axis, orthogonal to swirl flow.

Figure 11.52 The In-Cylinder Output Controls Dialog Box

The following list describes the [In-Cylinder Output Controls Dialog Box \(p. 2032\)](#).

In-Cylinder Data Write Frequency

is an integer entry specifying the interval in number of time-steps. Make sure that a value other than 0 is used for the frequency, in order to allow you to complete your setup.

Swirl Center Method

is a drop-down list which allows you to select the method to calculate the swirl center. The list contains **center of gravity** and **fixed**, with **center of gravity** being the default value.

center of gravity

option calculates the swirl center inside the code and is used as the center of gravity of the chosen cell zones.

fixed

option enables you to specify a swirl center in the entries below the drop-down list.

In addition to these two options, you can chose to use your own compiled UDF to calculate the swirl center.

For details on using a dynamic mesh UDF, see the [UDF Manual](#) for information on user-defined functions.

Cell Zones

is a list which displays the names of all existing cell zones in the case files. You can select only the zones relevant for the swirl and tumble calculations.

Swirl Axis

specifies the swirl axis with three entries for the directional components. By default, **X, Y, Z = 0, 1, 0**.

Tumble X-Axis

specifies the directional components of **Tumble X-Axis** in **X, Y, Z** directions. By default, **X, Y, Z = 0, 0, 1**.
1. This applies only in 3D.

Tumble Y-Axis

specifies the directional components of **Tumble Y-Axis** in **X, Y, Z** directions. By default, **X, Y, Z = 1, 0, 0**.
0. This applies only in 3D.

File Name

specifies the name of the **In-Cylinder** output file. By default, the file name contains the name of the case file appended with a **.txt** extension.

The **In-Cylinder** specific output controls can also be controlled using the TUI as follows:

```
Go to
define/dynamic-mesh/controls/in-cylinder-output?
Enable in-cylinder output?[no] yes
Output Write Frequency[0] 10
Cell zone name/id(1)[()] 2
Cell zone name/id(1)[()]
File Name['/nfs/devvault/data9/ic-sp-output.txt']
Swirl Center Method: (fixed cg user-defined)
Option[cg]
Swirl Axis x[0]
Swirl Axis y[1]
Swirl Axis z[0]
Tumble X-Axis x[0]
Tumble X-Axis y[0]
Tumble X-Axis z[1]
Tumble Y-Axis x[1]
Tumble Y-Axis y[0]
Tumble Y-Axis z[0]
```

If you select **fixed** as the choice at **Swirl Center Method** then you will be prompted to enter the swirl center as follows:

```
Swirl Center(x) (mm) [0]
Swirl Center(y) (mm) [0]
Swirl Center(z) (mm) [0]
```

If a swirl center method UDF has been compiled already and loaded into UDF then you can choose **user-defined** as the swirl center method option, in such a case the following is the sequence of prompts.

```
Swirl Center UDF[] swirl_udf::libudf
```

If the name of the UDF library is **libudf** then you can omit this and enter in the swirl center UDF[]swirl_udf, otherwise the name of the UDF followed by the UDF library name with symbol:: in between, should be entered.

By filling up the various entries that are needed in the *In-Cylinder Output Controls Dialog Box* (p. 2032) and pressing the **OK** button, the swirl and tumble calculations will be written at the chosen frequency to the chosen file while doing the solution run. Details of the quantities written to the file are as follows:

CA = Crank Angle

m = Mass of the entire fluid contained in the selected cell zones

L = Angular momentum vector of fluid mass contained in selected cell zones with respect to the swirl center

$|\vec{L}|$ = Magnitude of angular momentum of fluid

\vec{s} = Swirl Axis

\vec{tx} = Tumble X-Axis

\vec{ty} = Tumble Y-Axis

I_{sa} = Moment of inertia of the fluid mass about Swirl axis

I_{tx} = Moment of inertia of the fluid mass about Tumble X-Axis

I_{ty} = Moment of inertia of the fluid mass about Tumble Y-Axis

· = Dot product between two vectors

Altogether, the previous quantities are combined to yield eight columns of data in the output file, as shown in the figure that follows:

Figure 11.53 Sample Output File Showing Various Quantities

CA	(L · sa)	(L · tx)	(L · ty)	L	I _{sa}	I _{tx}	I _{ty}

11.6.3.1. Using the In-Cylinder Option

This section describes the problem setup procedure for an in-cylinder dynamic mesh simulation.

11.6.3.1.1. Overview

Consider the 2D in-cylinder example shown in [Figure 11.54 \(p. 624\)](#) for a typical pent-roof engine.

Figure 11.54 A 2D In-Cylinder Geometry

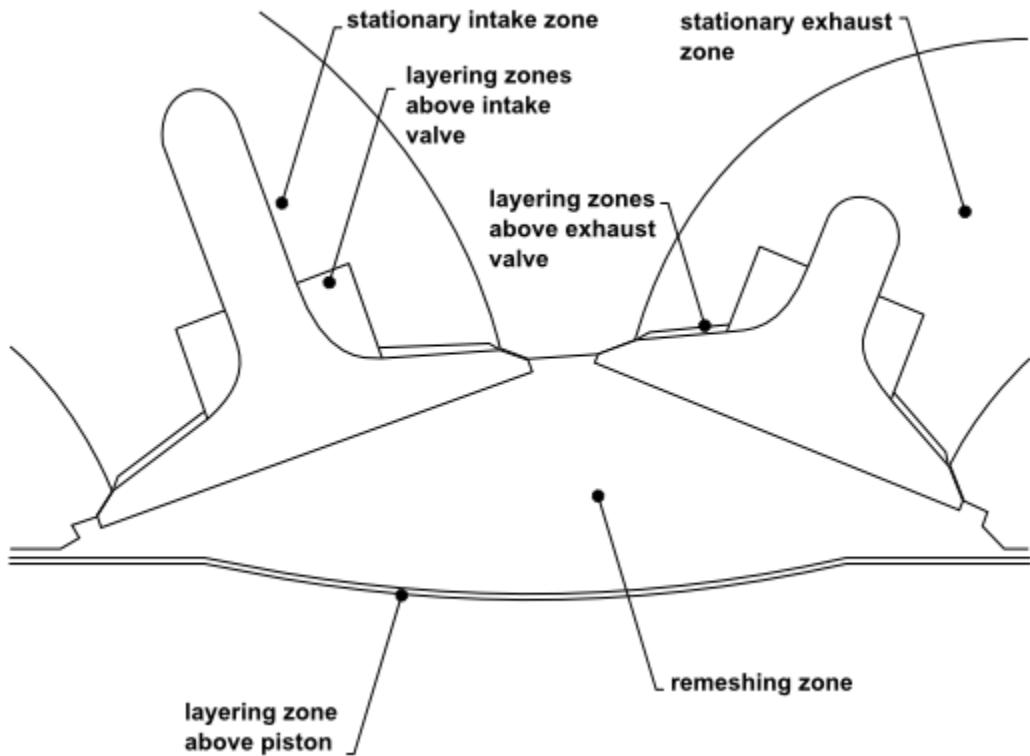

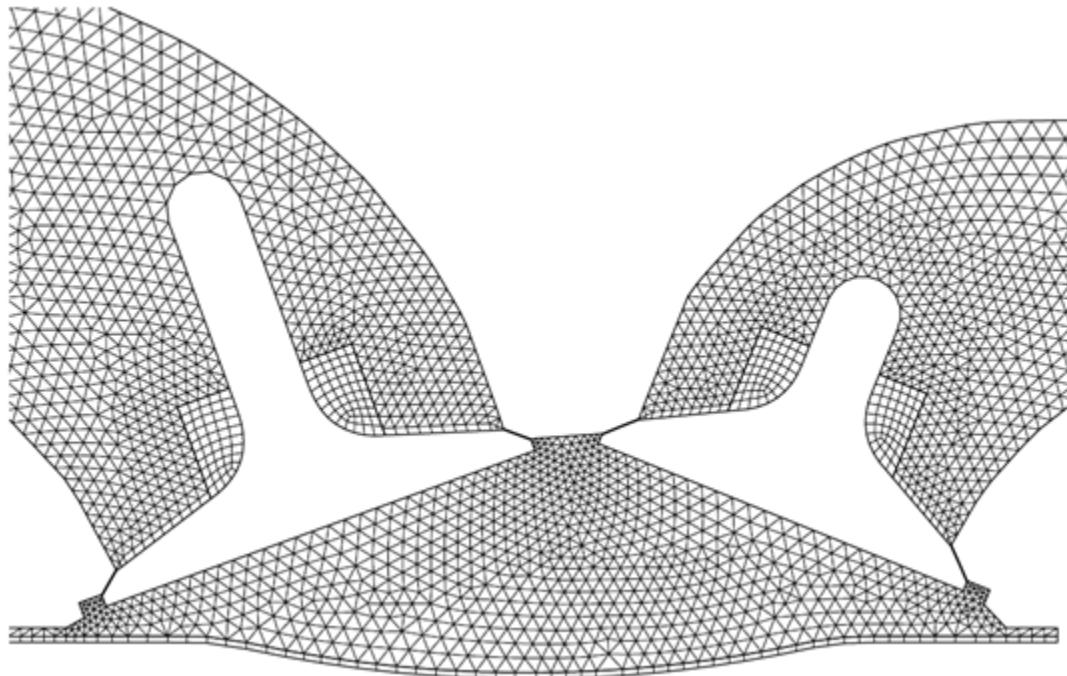

In setting up the dynamic mesh model for an in-cylinder problem, you need to consider the following issues:

- how to provide the proper mesh topology for the volume mesh update methods (smoothing, dynamic layering, and local or zonal remeshing)
- how to define the motion attributes and geometry for the valve and piston surfaces
- how to address the opening and closing of the intake and exhaust valves
- how to specify the sequence of events that controls the in-cylinder simulation

11.6.3.1.2. Defining the Mesh Topology

ANSYS FLUENT requires that you provide an initial volume mesh with the appropriate mesh topology such that the various mesh update methods described in [Dynamic Mesh Update Methods \(p. 575\)](#) can be used to automatically update the dynamic mesh. However, ANSYS FLUENT does not require you to set up all in-cylinder problems using the same mesh topology. When you generate the mesh for your in-cylinder problem, you need to consider the various mesh regions that you can identify as moving, deforming, or stationary, and generate these mesh regions with the appropriate cell shape.

The mesh topology for the example problem in [Figure 11.54 \(p. 624\)](#) is shown in [Figure 11.55 \(p. 625\)](#), and the corresponding volume mesh is shown in [Figure 11.56 \(p. 625\)](#).

Figure 11.55 Mesh Topology Showing the Various Mesh Regions**Figure 11.56 Mesh Associated With the Chosen Topology**

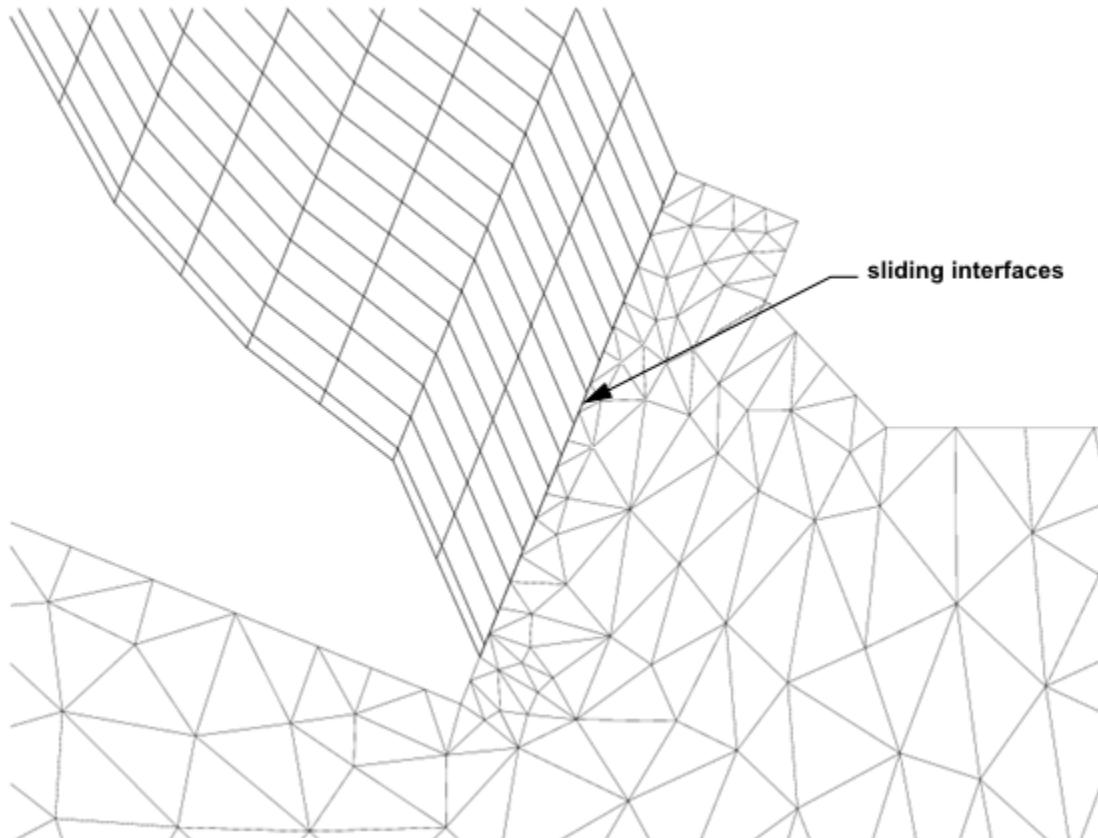

Because of the rectilinear motion of the moving surfaces, you can use dynamic layering zones to represent the mesh regions swept out by the moving surfaces. These regions are the regions above the top surfaces of the intake and exhaust valves and above the piston head surface, and must be meshed with quadrilateral or hexahedral cells (as required by the dynamic layering method).

For the chamber region, you need to define a remeshing zone (triangular cells) to accommodate the various positions of the valves in the course of the simulation. In this region, the motion of the boundaries (valves and piston surfaces) is propagated to the interior nodes using the spring-based or diffusion-based smoothing method. If the cell quality violates any of the remeshing criteria that you have specified, ANSYS FLUENT will automatically agglomerate these cells and remesh them. Furthermore, ANSYS FLUENT will also remesh the deforming faces (based on the minimum and maximum length scale that you have specified) on the cylinder walls as well as those on the sliding interfaces used to connect the chamber cell zone to the layering zones above the valve surfaces.

For the intake and exhaust port regions, you can use either triangular or quadrilateral cell zones because these zones are not moving or deforming. ANSYS FLUENT will automatically mark these regions as stationary zones and will not apply any mesh motion method on these cell zones.

The dynamic layering regions above the piston and valves are conformal with the adjacent cell zone in the chamber and ports, respectively, so you do not have to use sliding interfaces to connect these cell zones together. However, you need to use sliding interfaces to connect the dynamic layering regions above the valves and the remeshing region in the chamber. This is shown in [Figure 11.57 \(p. 626\)](#) with the exhaust valve almost at full extension. Notice that cells on the chamber side of the interface zone are remeshed (i.e., split or merged) as the interface zone opens and closes because of the motion of the exhaust valve.

Figure 11.57 The Use of Sliding Interfaces to Connect the Exhaust Valve Layering Zone to the Remeshing Zone

11.6.3.1.3. Defining Motion/Geometry Attributes of Mesh Zones

As the piston moves down from the TDC to the BDC position, you need to expand the remeshing region such that it can accommodate the valves when they are fully extended. To accomplish this, you need to specify the dynamic layering zone adjacent to the piston surface to move with the piston until some specified distance from the TDC position. Beyond this cutoff distance, the motion of the layering zone is stopped and the piston wall is allowed to continue to the BDC position. Because there is relative motion between the piston head surface and the now non-moving dynamic layering zone, cell layers will be added when the ideal layer height criteria is violated. [Figure 11.58 \(p. 627\)](#) to [Figure 11.63 \(p. 630\)](#) show the sequence of meshes before and after the onset of cell layering when the motion in the layering zone above the piston surface is stopped (shown with $\Delta\theta = 5^\circ$).

Figure 11.58 Mesh Sequence 1

Figure 11.59 Mesh Sequence 2

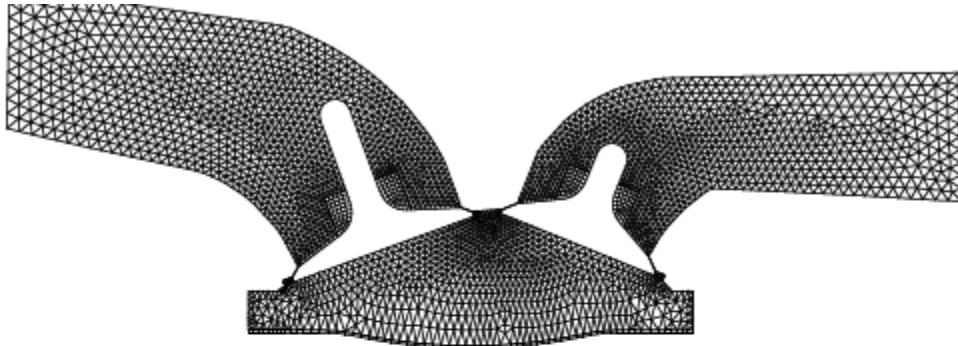

Figure 11.60 Mesh Sequence 3

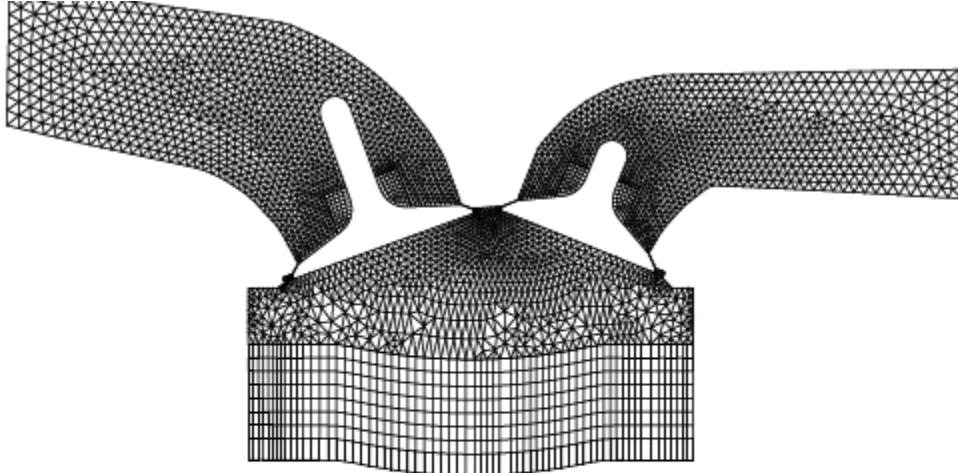

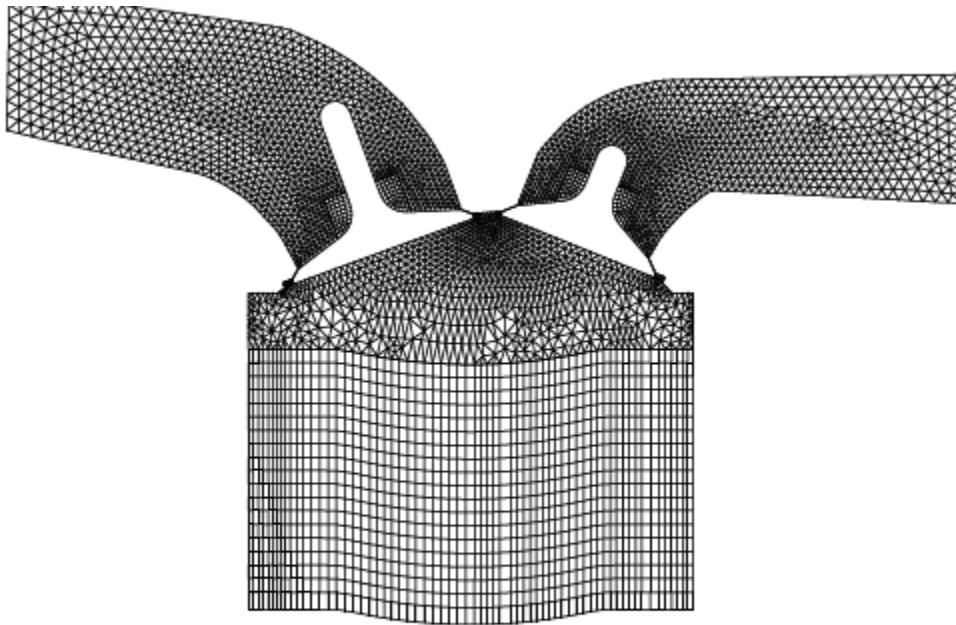

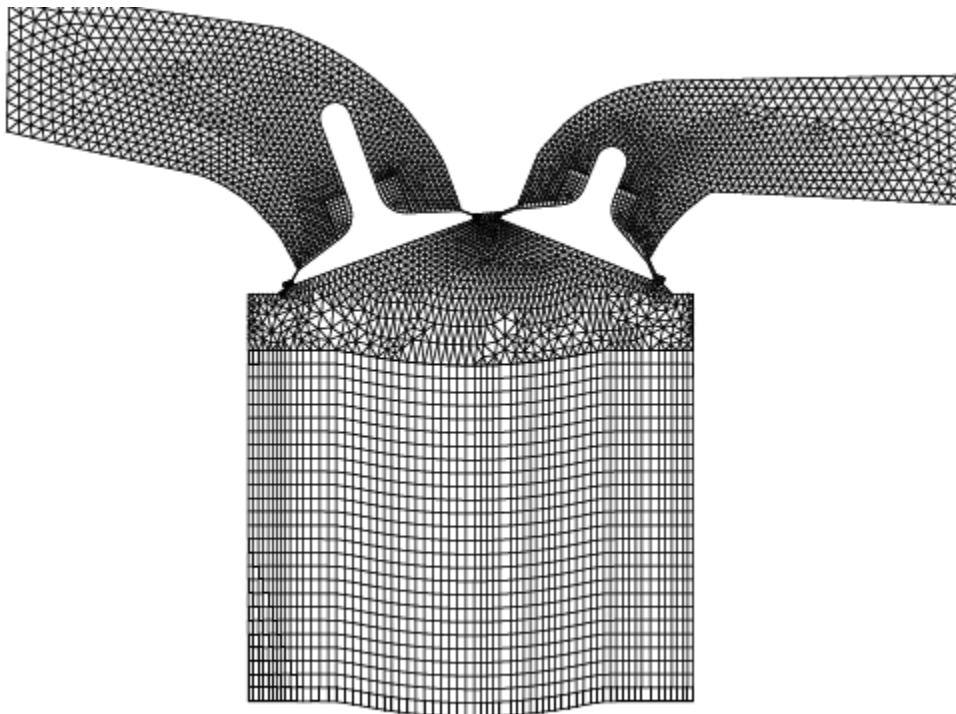

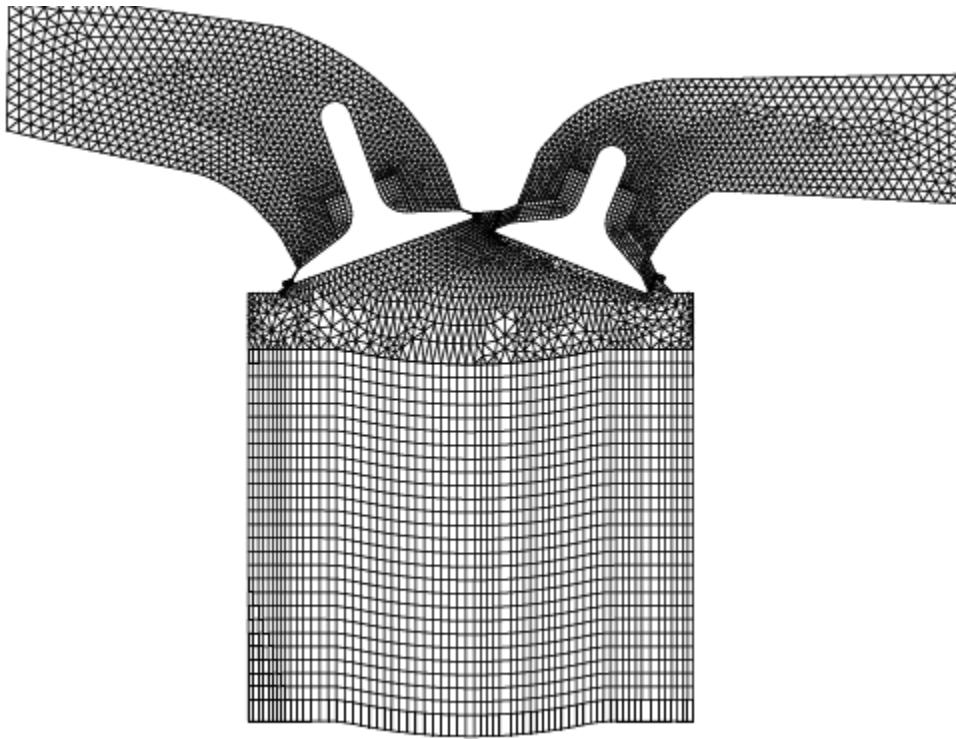

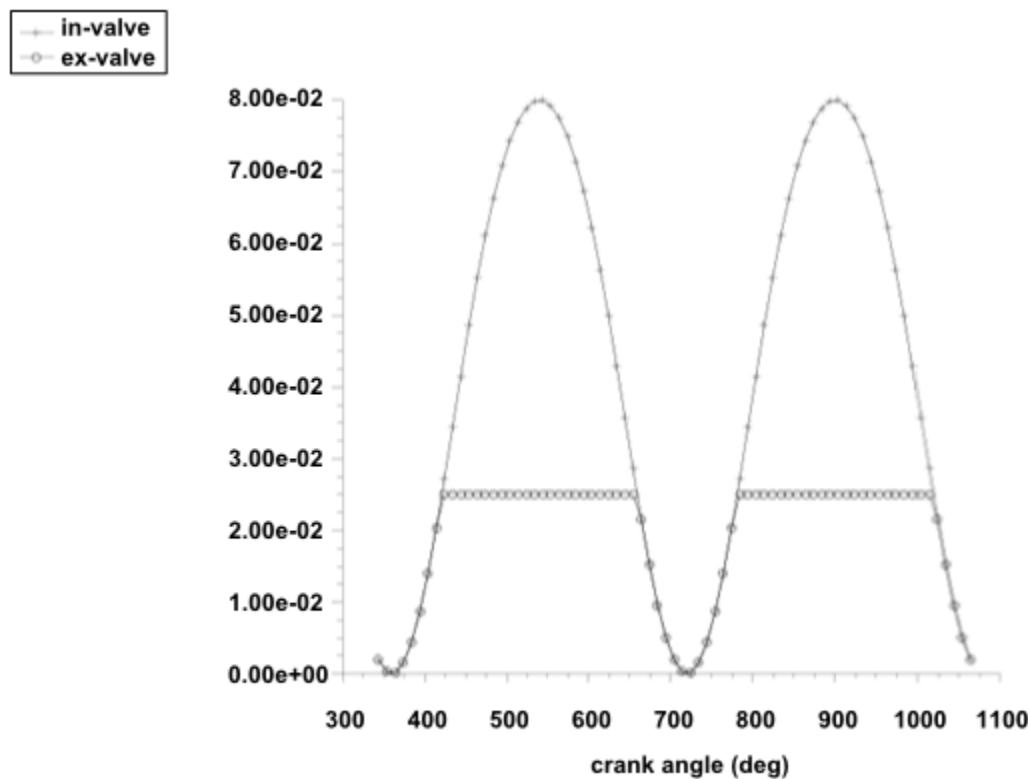

Figure 11.61 Mesh Sequence 4**Figure 11.62 Mesh Sequence 5**

Figure 11.63 Mesh Sequence 6

ANSYS FLUENT provides built-in functions to handle the full piston motion and the limited piston motion for the dynamic layering zone above the piston surface. When you define the motion attribute of the dynamic layering zone above the piston surface, you need to use the limited piston motion function (****piston-limit**** in the **Motion UDF/Profile** field in the *Dynamic Mesh Zones Dialog Box* (p. 2037)). Note that you must define the parameters used by these functions before you can use them. In the current example, the crank radius is 40 mm and the connecting rod length is 140 mm. The piston stroke cutoff is assumed to happen at 25 mm from TDC position. The lift as a function of crank angle between 344° and 1064° is shown in *Figure 11.64* (p. 631) for both limited and full piston motion.

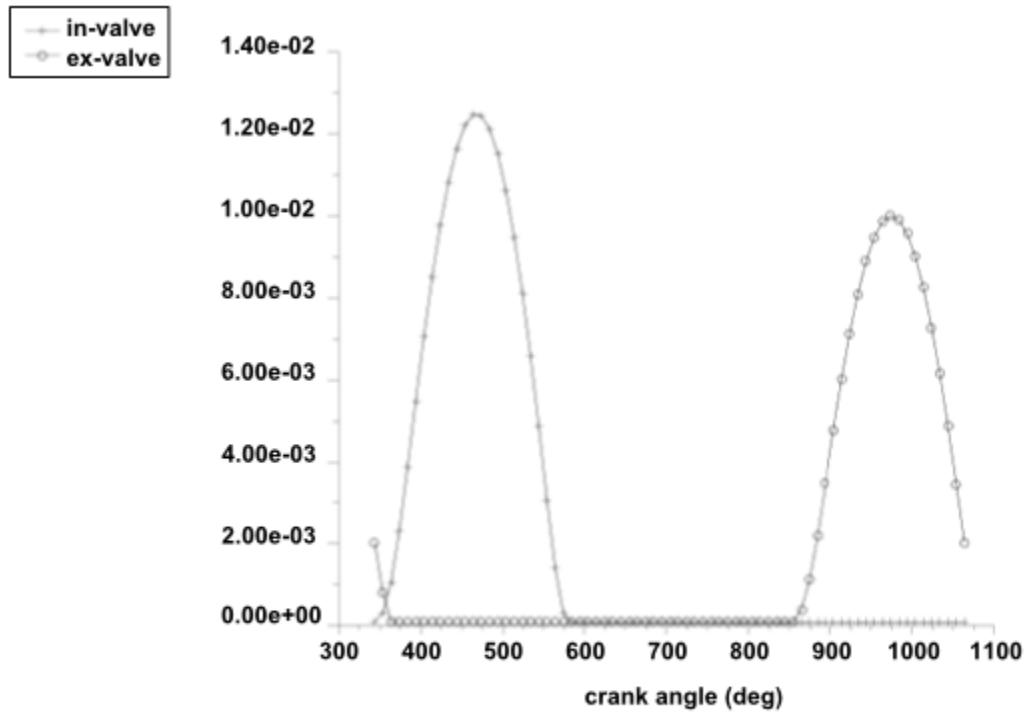

Figure 11.64 Piston Position (m) as a Function of Crank Angle (deg)

To define the motion of the valves, you need to use profiles that describe the variation of valve lift with crank angle. ANSYS FLUENT expects certain profile fields to be used to define the lift and the crank angle. For example, consider the following simplified profile definition:

```
((ex-valve 5 point)
(angle 0 180 270 360 720)
(lift 0.05 0.05 1.8 0.05 0.05))

((in-valve 5 point)
(angle 0 355 440 540 720)
(lift 0.05 0.05 2.0 0.05 0.05))
```

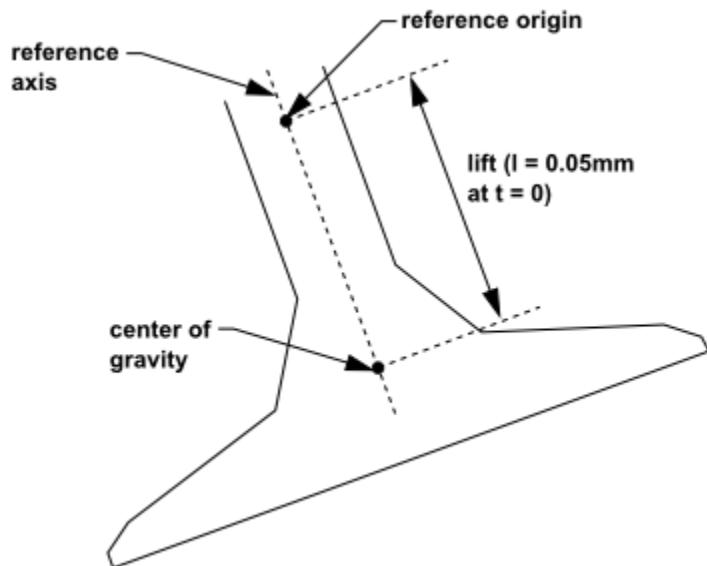

ANSYS FLUENT expects the angle and lift fields to define the crank angle and lift variations, respectively. The angle must be specified in degrees and the lift values must be in meters. The actual valve lift profiles that you will use for the current example are shown in [Figure 11.65](#) (p. 632). Notice that there is an overlapped period where both the intake and exhaust valves are open.

Figure 11.65 Intake and Exhaust Valve Lift (m) as a Function of Crank Angle (deg)

The valve lift profiles and the built-in functions will describe how each surface moves as a function of crank angle with respect to some reference point. For example, the valve lift is zero when the valve is fully closed and the valve lift is maximum when it is fully open. In order to move the surfaces, ANSYS FLUENT requires that you specify the direction of motion for each surface. ANSYS FLUENT will then update the "center of gravity" of each surface such that

$$\vec{x} = \vec{x}_{ref} - l \vec{e}_{axis} \quad (11-28)$$

where \vec{x}_{ref} is some reference position, \vec{e}_{axis} is the unit vector in the direction of motion, and l is either the valve or the piston distance with respect to the reference position \vec{x}_{ref} . Note that the unit vector of the direction of motion is specified to point in the negative direction. For example, the correct intake valve axis for this example is $(-0.3421, 0.9397)$, as shown in [Figure 11.66 \(p. 633\)](#).

Figure 11.66 Definition of Valve Zone Attributes (Intake Valve)

11.6.3.1.4. Defining Valve Opening and Closure

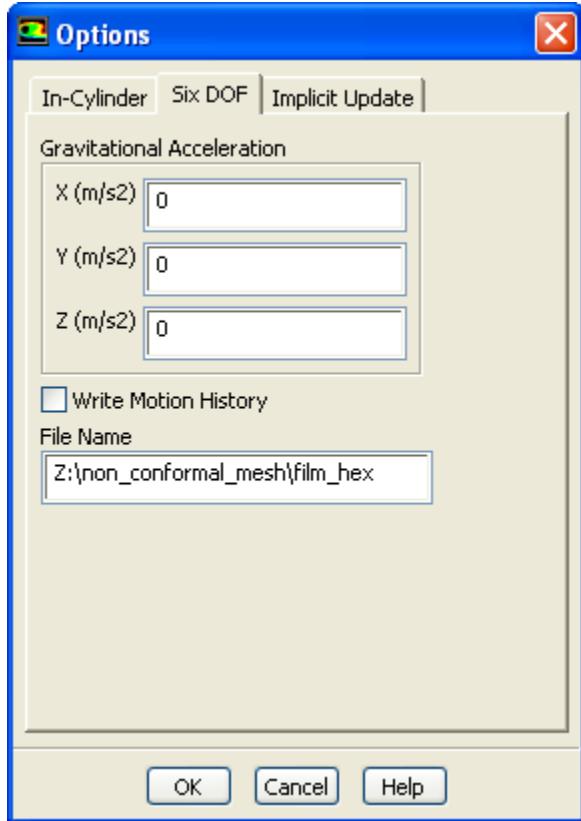

ANSYS FLUENT assumes that once you have set up the mesh topology, the mesh topology is unchanged throughout the entire simulation. Therefore, ANSYS FLUENT does not allow you to completely close the valves such that the cells between the valve and the valve seat become degenerate (flat cells) when these surfaces come in contact (removing these flat cells would require the creation of new boundary face zones). To prevent the collapse, you need to define a minimum valve lift and ANSYS FLUENT will automatically stop the motion of the valve when the valve lift is smaller than the minimum valve lift value. The minimum valve lift value can be specified in the **In-Cylinder** tab of the *Options Dialog Box* (p. 2030). For the current example, a minimum valve lift value of 0.1 mm is assumed.

When the valve position is smaller than the minimum valve lift value, it is normal practice to assume that the valve is closed. The actual closing of the valves is accomplished by deleting the sliding interfaces that connect the chamber cell zone to the dynamic layering zones on the valves. The interface zones are then converted to walls to close off the "gaps" between the valves and the valve seats.

The valve opening is achieved by the reverse process. When the valve lift has reached beyond the minimum valve lift value, the valve is assumed to be open and you can redefine the sliding interfaces such that the chamber zone is now connected to the dynamic layering zones above the valves.

11.6.4. Six DOF Solver Settings

To use the six degree of freedom solver for your transient dynamic mesh simulation, select **Six DOF** under **Options** in the *Dynamic Mesh Task Page* (p. 2024) (*Figure 11.13* (p. 575)) and click the **Settings...** button. The **Options** dialog box will open, where you can click the **Six DOF** tab (*Figure 11.67* (p. 634)).

Figure 11.67 The Six DOF Tab of the Options Dialog Box

You can specify the gravitational acceleration in the x , y , and z directions either in this dialog box, or in the **Operating Conditions** dialog box. Note that you can also keep track of an object's motion history by selecting the check box next to **Write Motion History**. A single motion history file will be generated for each moving object which can be used to display zone motion for postprocessing your results. Enter the file name in the **File Name** text entry box and click **OK** ([Figure 11.67 \(p. 634\)](#)).

11.6.4.1. Using the Six DOF Solver

ANSYS FLUENT's six degree of freedom (six DOF) solver computes external forces and moments such as aerodynamic and gravitational forces and moments on an object. These forces are computed by numerical integration of pressure and shear stress over the object's surfaces. Additional load forces can be added (e.g., injector forces, thrust (propulsive) forces, moments produced by a coil spring, etc.). This technique, along with the ANSYS FLUENT solver and the use of dynamic meshes, can be readily applied to many useful applications, such as store separation [\[77\] \(p. 2371\)](#), [\[84\] \(p. 2371\)](#). Note that if the mesh motion of your six DOF simulation depends on the fluid flow, it is beneficial to also enable implicit mesh updating (as described in [Implicit Update Settings \(p. 635\)](#)).

11.6.4.1.1. Setting Rigid Body Motion Attributes for the Six DOF Solver

When the **Six DOF** solver is enabled, you need to provide additional information for rigid body dynamic zones. For instance, you must use a user-defined function to define the six degrees of freedom parameters, and you must set the velocity and angular velocity for the center of gravity. For each moving object, exactly one user-defined function has to be defined, no matter how many zones there are for each object. For more information about the **Six DOF** solver settings in the [Dynamic Mesh Zones Dialog Box \(p. 2037\)](#) or rigid body motion, see [Rigid Body Motion \(p. 649\)](#).

Note that you can also keep track of an object's motion history using the **Motion Attributes** tab.

The commands in this tab generate a single motion history file for each moving object which can be used to display zone motion for postprocessing your results. For more information on zone motion, see *Previewing the Dynamic Mesh* (p. 661).

11.6.5. Implicit Update Settings

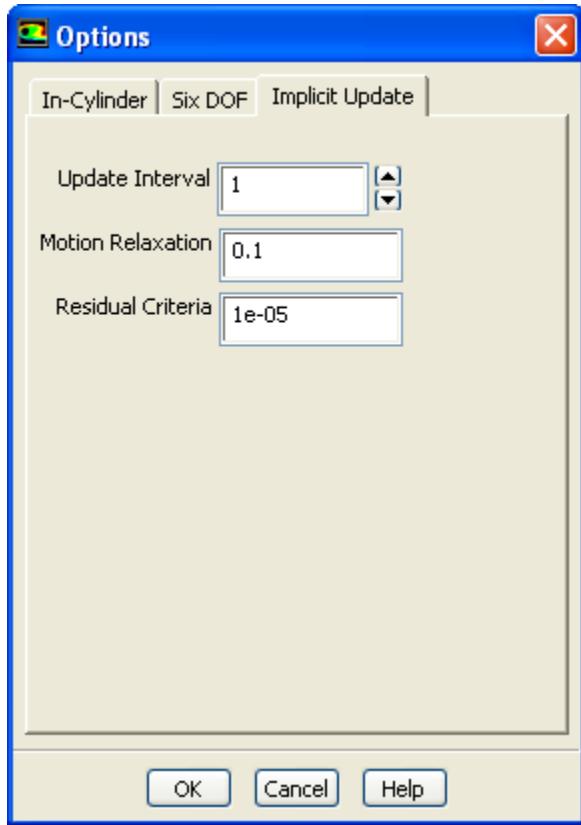

For transient problems, you can enable implicit mesh updating when you want to have the dynamic mesh updated during a time step (as opposed to just at the beginning of a time step). This capability is beneficial only for applications in which the mesh motion depends on the flow field (e.g., cases that use the six DOF solver or involve fluid-structure interaction). For such applications, having the mesh motion updated within the time step based on the converging flow solution results in a stronger coupling between the flow solution and the mesh motion, and leads to a more robust solver run. Implicit mesh updating allows you to run simulations that otherwise could not be solved or would require an unreasonably small time step.

Note that implicit mesh updating cannot be used with the following:

- the density-based solver when **Explicit** is selected from the **Transient Formulation** drop-down menu in the **Solution Methods** task page
- steady state solutions
- in-cylinder applications

To enable implicit mesh updating, perform the following steps:

1. Enable **Implicit Update** in the **Options** group box of the *Dynamic Mesh Task Page* (p. 2024) (*Figure 11.13* (p. 575)).
2. Click the **Settings...** button to open the *Options Dialog Box* (p. 2030).

Figure 11.68 The Implicit Update Tab of the Options Dialog Box

Click the **Implicit Update** tab and enter values for the settings.

- Enter a value for **Update Interval**, in order to specify the frequency in iterations at which the mesh will be updated within a time step.
- Enter a value (within the range of 0 to 1) for **Motion Relaxation**, in order to define the relaxation of the motion (i.e., displacement of the nodes) during the mesh update. The relaxation of the displacements is defined by the following equation:

$$x_k = \omega (x_{computed,k}) + (1 - \omega) x_{k-1} \quad (11-29)$$

where x_k is the node position at iteration k (within a time step), $x_{computed,k}$ is the computed node position (based on the flow field), and ω is the motion relaxation.

- Enter a value for **Residual Criteria**, in order to set the relative residual threshold that is used to check the motion convergence. The residual criteria is applied to a relative residual. ANSYS FLUENT scales the difference between the motion in iteration k and iteration $k - 1$ by the motion computed at the beginning of the time step. If this relative motion difference is smaller than the residual criteria, the mesh motion is considered converged.
- If you are using a UDF to compute the motion, make sure that the UDF uses the current flow field during each call to compute the motion (i.e., no previously stored information should be used). This is necessary, as the UDF will be called each time the mesh is updated — which can be several times within a time step, depending on what you entered for the **Update Interval**.
- After you run the simulation, make sure that the motion (and consequently, the solution) is properly converged. If the motion requires more iterations to converge than the flow field, a

warning will be displayed in the console during the iteration process. Note that the maximum number of iterations per time step (defined in the **Run Calculation** task page) is respected by the mesh motion convergence check.

11.6.6. Defining Dynamic Mesh Events

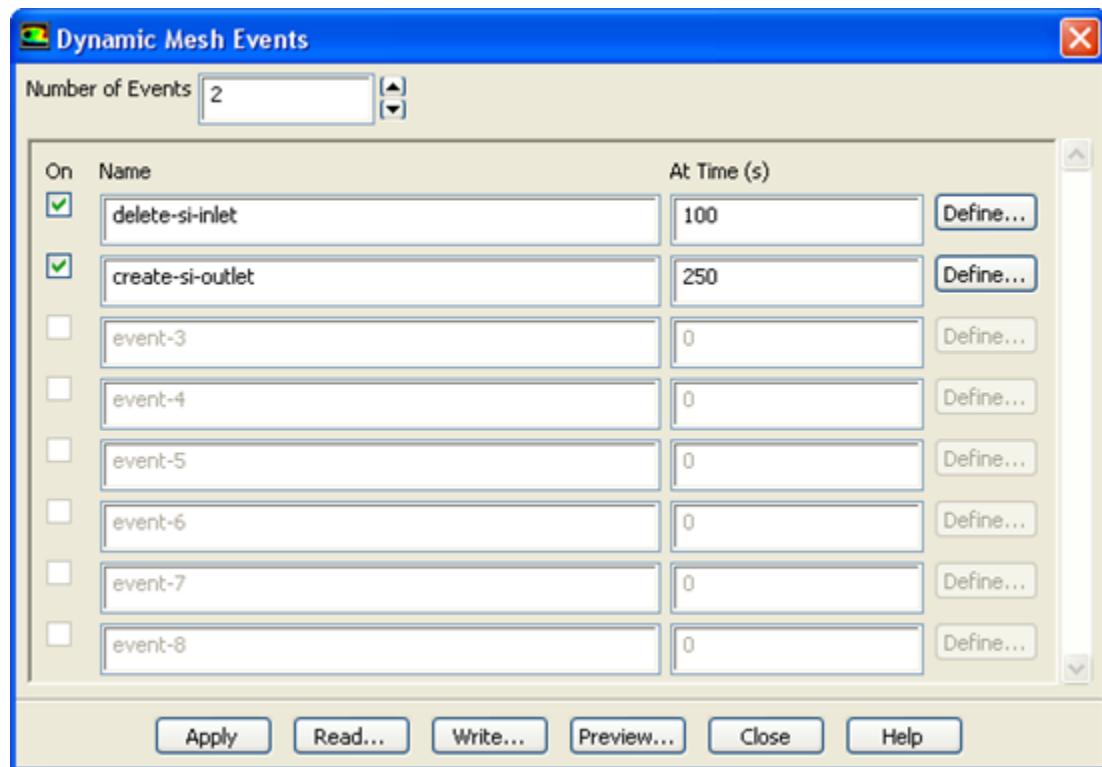

If you are simulating a transient flow, you can use the events in ANSYS FLUENT to control the timing of specific events during the course of the simulation. With in-cylinder flows for example, you may want to open the exhaust valve (represented by a pair of deforming sliding interfaces) by creating an event to create the sliding interfaces at some crank angle. You can also use dynamic mesh events to control when to suspend the motion of a face or cell zone by creating the appropriate events based on the crank angle or time. Note that in-cylinder flows are crank angle-based, whereas all other flows are time-based.

11.6.6.1. Procedure for Defining Events

You can define the events using the *Dynamic Mesh Events Dialog Box* (p. 2034) (*Figure 11.69* (p. 637)).

Figure 11.69 The Dynamic Mesh Events Dialog Box

The procedure for defining events is as follows:

1. Increase the **Number of Events** value to the number of events you wish to specify. As this value is increased, additional event entries in the dialog box will become editable.
2. Enable the check box next to the first event and enter a name for the event under the **Name** heading.
3. Specify either the time or the crank angle at which you want the event to occur.

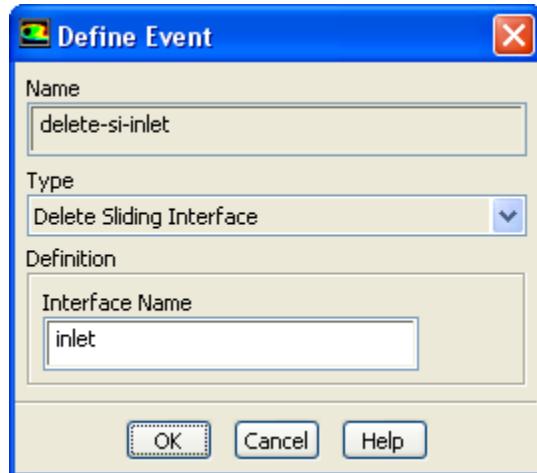

For in-cylinder flows, specify the crank angle at which you want the event to occur under **At Crank Angle**.

For non-in-cylinder flows, specify the time (in seconds) at which you want the event to occur under **At Time**.

It is not necessary to specify the events in order of increasing time or crank angle, but it may be easier to keep track of events if you specify them in the order of increasing time or angle.

- Click the **Define...** button to open the *Define Event Dialog Box* (p. 2035) (*Figure 11.70* (p. 638)).

Figure 11.70 The Define Event Dialog Box

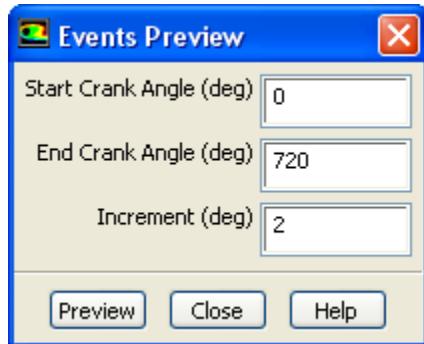

- In the *Define Event Dialog Box* (p. 2035), choose the type of event by selecting **Change Zone Type**, **Copy Zone BC**, **Activate Cell Zone**, **Deactivate Cell Zone**, **Create Sliding Interface**, **Delete Sliding Interface**, **Change Motion Attribute**, **Change Time Step Size**, **Change Under-Relaxation Factors**, **Insert Boundary Zone Layer**, **Remove Boundary Zone Layer**, **Insert Interior Zone Layer**, **Remove Interior Zone Layer**, **Insert Cell Layer**, **Remove Cell Layer**, **Execute Command**, or **Replace Mesh** in the **Type** drop-down list. These event types and their definitions are described later in this section.
- Repeat steps 2–5 for the other events, if relevant.
- Click **Apply** in the *Dynamic Mesh Events Dialog Box* (p. 2034) after you finish defining all events.
- To play the events to check that they are defined correctly, click the **Preview...** button in the *Dynamic Mesh Events Dialog Box* (p. 2034). This displays the *Events Preview Dialog Box* (p. 2037).

For in-cylinder flows, you use the *Events Preview Dialog Box* (p. 2037) (*Figure 11.71* (p. 639)), to enter the crank angles at which you want to start and end the playback in the **Start Crank Angle** and **End Crank Angle** fields, respectively.

For non-in-cylinder flows, you use the *Events Preview Dialog Box* (p. 2037) to enter the time at which you want to start and end the playback in the **Start Time** and **End Time** fields, respectively.

Specify the size of the step to take during the playback in the **Increment** field. Click **Preview** to play back the events. ANSYS FLUENT will play the events at the time (or crank angle in the case of in-cylinder flows) specified for each event and report when each event occurs in the text (console) window.

Figure 11.71 The Events Preview Dialog Box for In-Cylinder Flows

For in-cylinder simulations, you need to specify the events for one complete engine cycle. In the subsequent cycles, the events are executed whenever

$$\theta_{event} = \theta_c \pm n\theta_{period} \quad (11-30)$$

where θ_{event} is the event crank angle, θ_c is the current crank angle calculated from [Equation 11-26 \(p. 620\)](#), θ_{period} is the crank angle period for one cycle, and n is some integer.

As an example, for in-cylinder simulations, you are not required to specify the event crank angle to correspond exactly to the current crank angle calculated from [Equation 11-26 \(p. 620\)](#). ANSYS FLUENT will execute an event if the current crank angle is between $\pm 0.5 \Delta\theta$ where $\Delta\theta$ is the equivalent change in crank angle for the time step. For example, if the event preview is executed between crank angle of 340° and 1060° (crank period is 720°) using an increment of 1° , ANSYS FLUENT will report the following in the text window.

```
Execute Event: open-in-valve-left (defined at: 353.10, current angle: 353.00)
Execute Event: open-in-valve-right (defined at: 353.00, current angle: 353.00)
Execute Event: close-ex-valve-right (defined at: 355.60, current angle: 356.00)
Execute Event: close-ex-valve-left (defined at: 357.80, current angle: 358.00)
Execute Event: close-in-valve-left (defined at: 571.60, current angle: 572.00)
Execute Event: close-in-valve-right (defined at: 571.80, current angle: 572.00)
Execute Event: open-ex-valve-right (defined at: 137.10, current angle: 857.00)
Execute Event: open-ex-valve-left (defined at: 139.00, current angle: 859.00)
```

Notice that events defined at 137.10° and 139° are executed at 857° and 859° , respectively, because they satisfy the condition of [Equation 11-30 \(p. 639\)](#).

11.6.6.2. Defining Events for In-Cylinder Applications

ANSYS FLUENT will automatically limit the valve lift values depending on the specified minimum valve lift value. However, the conversion of the sliding interface zones to walls (and vice versa) is accomplished via the in-cylinder events (see [Defining Dynamic Mesh Events \(p. 637\)](#)). For example, if the exhaust valve closes at -5° before TDC position, you must define a **Delete Sliding Interface** event at the crank angle of -5° . You need to define similar events for the intake valve opening (using the **Create Sliding Interface** event), the intake valve closing (**Delete Sliding Interface** event), and the exhaust valve opening (**Create Sliding Interface** event) at the respective crank angles.

For the current example, the exhaust valve is assumed to be open between 131° and 371° and the intake valve is open between 345° and 584° .

11.6.6.2.1. Events

Each of the available events is described below.

11.6.6.2.2. Changing the Zone Type

You can change the type of a zone to be a wall, or an interface, interior, fluid, or solid zone during your simulation. To change the type of a zone, select **Change Zone Type** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#) ([Figure 11.70 \(p. 638\)](#)). Select the zone(s) that you want to change in the **Zone** list, and then select the new zone type in the **New Zone Type** drop-down list.

11.6.6.2.3. Copying Zone Boundary Conditions

You can copy boundary conditions from one zone to other zones during your simulation. If, for example, you have changed an inlet zone to type wall with the **Change Zone Type** event, you can set the boundary conditions of the new zone type by simply copying the boundary conditions from a known zone with the corresponding zone type.

To copy boundary conditions from one zone to another, select **Copy Zone BC** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#) ([Figure 11.70 \(p. 638\)](#)). In the **From Zone** drop-down list, select the zone that has the conditions you want to copy. In the **To Zone(s)** list, select the zone or zones to which you want to copy the conditions.

ANSYS FLUENT will set *all* of the boundary conditions for the zones selected in the **To Zone(s)** list to be the same as the conditions for the zone selected in the **From Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

Note that you cannot copy conditions from external walls to internal (i.e., two-sided) walls, or vice versa, if the energy equation is being solved, since the thermal conditions for external and internal walls are different.

11.6.6.2.4. Activating a Cell Zone

To activate a cell zone, select **Activate Cell Zone** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#) ([Figure 11.70 \(p. 638\)](#)), then select the zone that you want to activate in the **Zone(s)** list. For more information, see [Replacing, Deleting, Deactivating, and Activating Zones \(p. 198\)](#).

11.6.6.2.5. Deactivating a Cell Zone

To deactivate a cell zone, select **Deactivate Cell Zone** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#) ([Figure 11.70 \(p. 638\)](#)), then select the zone that you want to deactivate in the **Zone(s)** list.

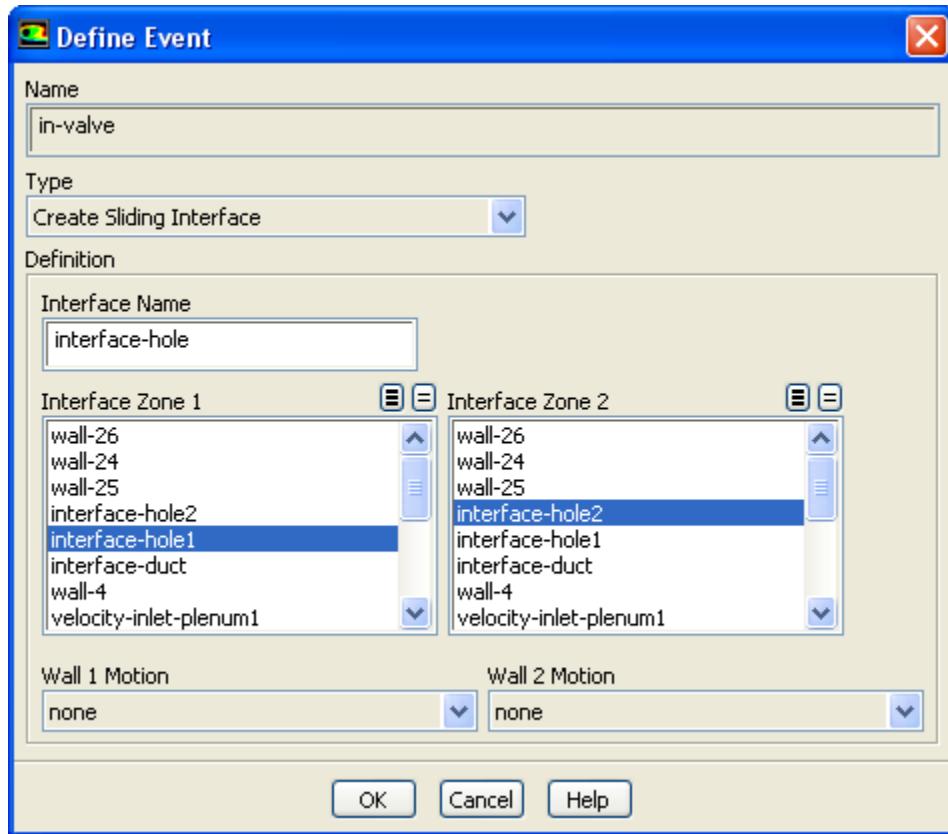

Only deactivated zones can be activated. When a zone is deactivated, ANSYS FLUENT skips the zone during the calculations. For more information, see [Replacing, Deleting, Deactivating, and Activating Zones \(p. 198\)](#).

11.6.6.2.6. Creating a Sliding Interface

To create a sliding interface during your simulation, select **Create Sliding Interface** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#) ([Figure 11.72 \(p. 641\)](#)). Enter a name for the sliding interface in the **Interface Name** field. Select the zones on either side of the interface in the **Interface Zone 1** and **Interface Zone 2** drop-down lists.

You have the option to select any number of zones listed under each of the interface zones. ANSYS FLUENT calculates intersections between all possible combinations of the left and right side of the interfaces, allowing you more flexibility in terms of creating zones and defining the interfaces.

Figure 11.72 The Define Event Dialog Box for the Creating Sliding Interface Option

Important

If ANSYS FLUENT finds another interface with the same name as defined in the event, then the old interface will be deleted and a new one created as defined in the dynamic mesh event.

If the interface zones that you selected above do not overlap each other completely, the non-overlapped regions on each interface zones are put into separate wall zones by ANSYS FLUENT. If these wall zones (i.e., non-overlapped regions) have motion attributes associated with them, their motion can only be specified by copying the motion from another dynamic zone by selecting the appropriate dynamic zones in the **Wall 1 Motion** and **Wall 2 Motion** drop-down lists, respectively.

Note that you don't have to change the boundary type from wall to interface. When the **Create Sliding Interface** event is executed, ANSYS FLUENT will automatically change the boundary type of the face zones selected in **Interface Zone 1** and **Interface Zone 2** to type interface before the sliding interface is created.

11.6.6.2.7. Deleting a Sliding Interface

To delete a sliding interface that has been created earlier in your in-cylinder simulation, select **Delete Sliding Interface** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035) (*Figure 11.70* (p. 638)). Enter the name of the sliding interface to be deleted in the **Interface Name** field.

As with the **Create Sliding Interface** event, ANSYS FLUENT will automatically change the corresponding interface zones to wall. However, you may want to use the **Copy Zone BC** event to set any boundary conditions that are not the default conditions that ANSYS FLUENT assumes.

11.6.6.2.8. Changing the Motion Attribute of a Dynamic Zone

To change the motion attribute of a dynamic zone during your in-cylinder calculation, select **Change Motion Attribute** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035) (*Figure 11.70* (p. 638)). Select the **Attribute** (**slide**, **moving**, or **remesh**) and set the appropriate **Status** (**enable** or **disable**). Select the corresponding dynamic zones for which you want to change the motion attributes in the **Dynamic Zones** list.

The **slide** attribute is used to enable or disable smoothing of nodes on selected deforming face zones, the **moving** attribute is used to suspend the motion of selected moving zones, and the **remesh** attribute is used to enable and disable face remeshing on selected deforming face zones.

11.6.6.2.9. Changing the Time Step

To change the time step at some point during the simulation, select **Change Time Step Size** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035). Specify the new physical time step size by entering the new **Time Step Size** in seconds.

For in-cylinder simulations, specify the new physical time step by entering the new **Crank Angle Step Size** value in degrees. The physical time step is calculated from

$$\Delta t = \frac{\Delta\theta_c}{6\Omega_{shaft}} \quad (11-31)$$

where the unit of Ω_{shaft} is assumed to be in RPM.

11.6.6.2.10. Changing the Under-Relaxation Factor

To change one or more under-relaxation factors, select **Change Under-Relaxation Factor** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035) (*Figure 11.70* (p. 638)). Select the under-relaxation factor that you wish to change, and assign a new value to it in the **Under-Relaxation Factors** list. For more information on setting under-relaxation factors, see *Setting Under-Relaxation Factors* (p. 1323).

11.6.6.2.11. Inserting a Boundary Zone Layer

To insert a new cell zone layer as a separate cell zone adjacent to a boundary, select **Insert Boundary Zone Layer** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035). Specify the **Base Dynamic Zone**, from which the layer of cells is to be created, and the **Side Dynamic Zone**, which represents the deforming face zone adjacent to the **Base Dynamic Zone** before the layer is inserted. The new cell zone will inherit the boundary conditions of the cell zone adjacent to the **Base Dynamic Zone** before the layer is inserted.

Note that a new cell layer can be inserted only from a one-sided **Base Dynamic Zone**. You cannot insert a new cell layer from an interior face zone.

[Figure 11.73 \(p. 643\)](#) and [Figure 11.74 \(p. 643\)](#) illustrate the insertion of a boundary zone layer. In both figures, the circular face at the top of the cylinder is the base dynamic zone.

Figure 11.73 Boundary Zone Before Insertion

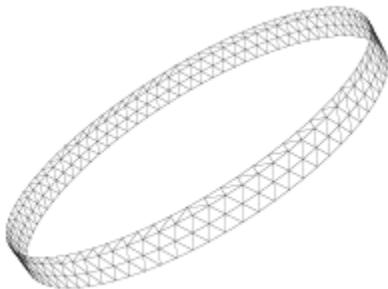

Figure 11.74 Boundary Zone After Insertion

11.6.6.2.12. Removing a Boundary Zone Layer

To remove the cell zone layer inserted using the **Insert Boundary Zone Layer** event, select **Remove Boundary Zone Layer** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#). Specify the same **Base Dynamic Zone** that you used when you defined the insert boundary layer event.

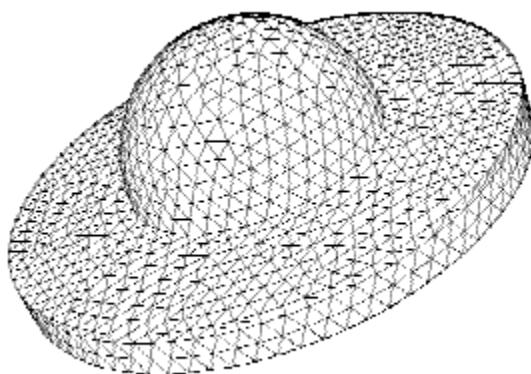

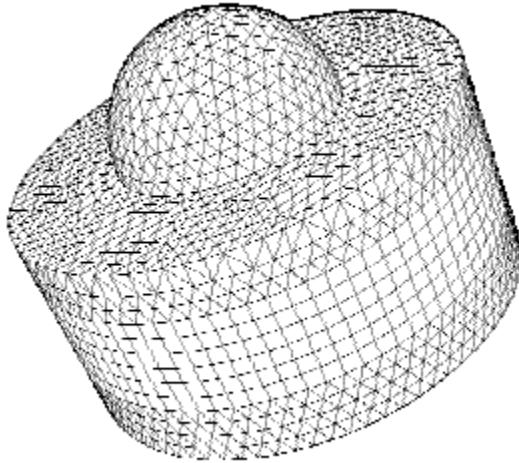

Note that a cell layer can be removed only from a one-sided **Base Dynamic Zone**.

11.6.6.2.13. Inserting an Interior Zone Layer

To insert a new zone layer as a separate cell zone adjacent to the internal side of a boundary, select **Insert Interior Zone Layer** in the **Type** drop-down list in the [Define Event Dialog Box \(p. 2035\)](#). Specify the **Base Dynamic Zone** and the **Side Dynamic Zone** as described in the **Insert Boundary Zone Layer** event. You also need to specify the names of the new interior face zones (**Internal Zone 1 Name** and **Internal Zone 2 Name**) that will be created after the cell zone layer is created by ANSYS FLUENT.

ANSYS FLUENT inserts the interior cell layer by splitting the cell zone adjacent to the **Base Dynamic Zone** with a plane. The position of the plane and the normal direction of the plane are implicitly defined by the cylinder origin and cylinder axis of the **Side Dynamic Zone**.

[Figure 11.75 \(p. 644\)](#) and [Figure 11.76 \(p. 644\)](#) illustrate the insertion of an interior zone layer.

Figure 11.75 Interior Zone Before Insertion**Figure 11.76 Interior Zone After Insertion**

11.6.6.2.14. Removing an Interior Zone Layer

To remove the zone layer inserted using the **Insert Interior Zone Layer** event, select **Remove Interior Zone Layer** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035). Specify the same **Internal Zone 1 Name** and **Internal Zone 2 Name** that you used to define the **Insert Interior Zone Layer** event.

11.6.6.2.15. Inserting a Cell Layer

To manually insert a new cell layer to the existing cell zone, select **Insert Cell Layer** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035). Specify the **Adjacent Dynamic Face Zone** and the **Direction Parameter**. This can only work on zones that are suited for layering (see *Applicability of the Dynamic Layering Method* (p. 594)).

11.6.6.2.16. Removing a Cell Layer

To manually remove a cell layer from an existing cell zone, select **Remove Cell Layer** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035). Specify the **Adjacent Dynamic Face Zone** and the

Direction Parameter. This can only work on zones that are suited for layering (see *Applicability of the Dynamic Layering Method* (p. 594)).

11.6.6.2.17. Executing a Command

To execute a command, select **Execute Command** in the **Type** drop-down list in the *Define Event Dialog Box* (p. 2035) (*Figure 11.70* (p. 638)). A command can be a series of text or Scheme commands, or a macro you have defined (or will define) using the *Define Macro Dialog Box* (p. 2103) (see *Defining Macros* (p. 1402)). Enter the series of commands or the name of the macro in the **Command** text-entry box.

Important

If the command to be executed involves saving a file, see *Saving Files During the Calculation* (p. 1404) for important information.

11.6.6.2.18. Replacing the Mesh

To replace the mesh and interpolate existing data onto the new mesh during your simulation, select **Replace Mesh** from the **Type** drop-down list in the **Define Event** dialog box (*Figure 11.70* (p. 638)). Then, specify the replacement mesh under **Mesh File**. Enable **Interpolate Data Across Zones** if necessary (see *Replacing the Mesh* (p. 202) for details).

11.6.6.2.19. Resetting Inert EGR

To convert burnt gases at the end of the cycle to inert for the next cycle, select **Inert EGR Reset** from the **Type** drop-down list in the **Define Event** dialog box (*Figure 11.70* (p. 638)). Specify the **Zone(s)**. This event is only applicable to and available for the partially premixed combustion model. For further details, see *Resetting Inert EGR* (p. 945).

11.6.6.3. Exporting and Importing Events

If you want to save the events you have defined to a file, click **Write...** in the *Dynamic Mesh Events Dialog Box* (p. 2034) and specify the **Event File** in *The Select File Dialog Box* (p. 33).

To read the events back into ANSYS FLUENT, click **Read...** in the *Dynamic Mesh Events Dialog Box* (p. 2034) and specify the **Event File** in *The Select File Dialog Box* (p. 33).

11.6.7. Specifying the Motion of Dynamic Zones

You need to define the motion of the dynamic zones in your model. If the zone is a rigid body, you can use a profile or user-defined function (UDF) to define the motion of the rigid body or use the six DOF solver. If the zone is a deforming zone, you can define the geometry and the parameters that control the face or zone remeshing, if applicable. For a zone that is deforming and moving at the same time, you can use a user-defined function to define the geometry and motion of the zone as they change with time.

11.6.7.1. General Procedure

You will specify the motion of the dynamic zones in your model using the **Dynamic Mesh Zones** dialog box

Details about specifying different types of motion are provided in this section.

11.6.7.1.1. Creating a Dynamic Zone

When you have completed the specification of a dynamic zone, click **Create** in the *Dynamic Mesh Zones Dialog Box* (p. 2037) to complete the specification and add the zone to the **Dynamic Mesh Zones** list.

11.6.7.1.2. Modifying a Dynamic Zone

If you want to make a change to the specification of a dynamic zone, select the zone in the **Dynamic Mesh Zones** list, change the specification, and then click **Create** in the *Dynamic Mesh Zones Dialog Box* (p. 2037) to update the specification.

11.6.7.1.3. Checking the Center of Gravity

If a dynamic zone has solid body motion, you can view its current position and orientation of the center of gravity (with respect to initial data) by selecting the zone in the **Dynamic Mesh Zones** list and viewing the values under **Center of Gravity Location** and **Center of Gravity Orientation**.

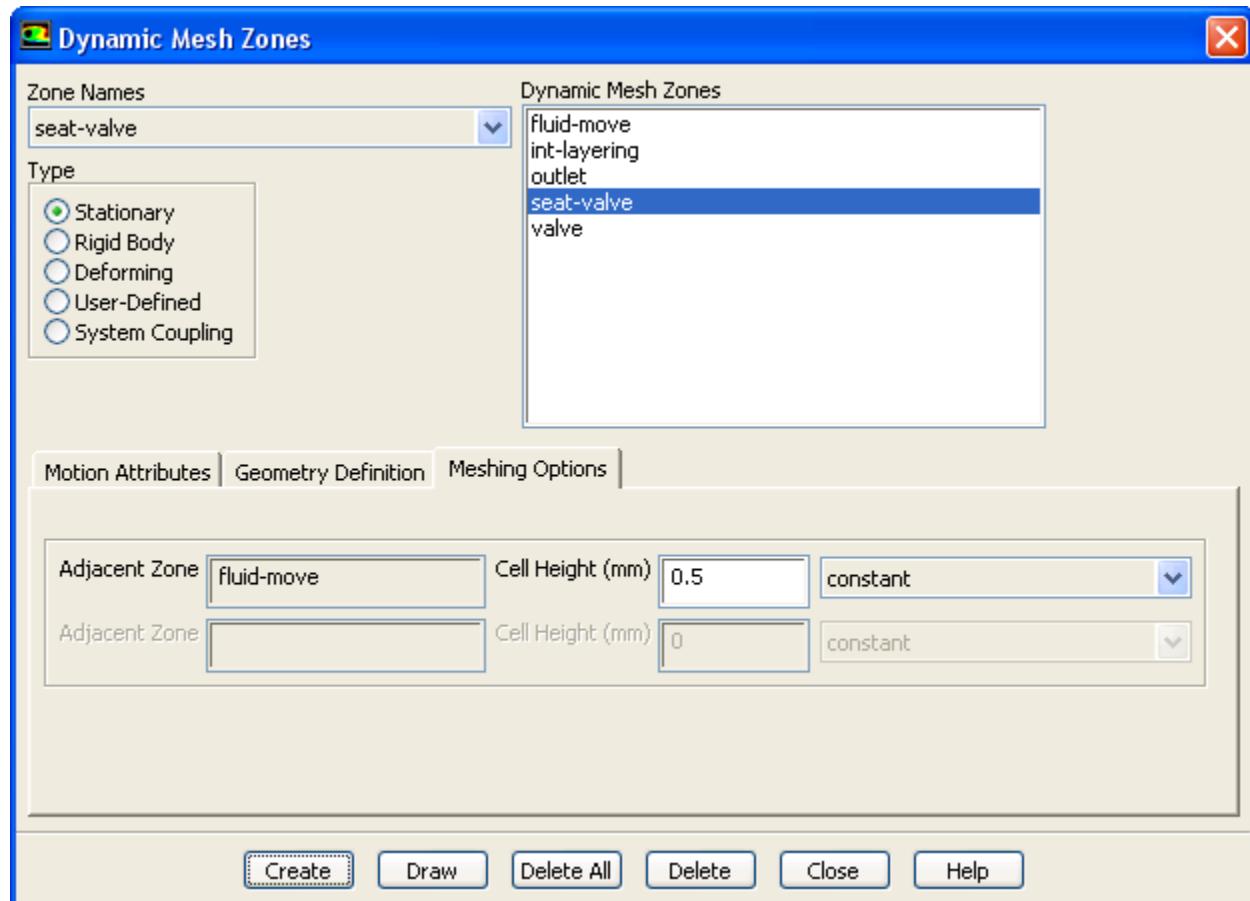

11.6.7.1.4. Deleting a Dynamic Zone

To delete a dynamic zone that you have specified, select the zone in the **Dynamic Mesh Zones** list, and click **Delete** or **Delete All**. The zone or zones will be removed from the **Dynamic Mesh Zones** list.

11.6.7.2. Stationary Zones

By default, if no motion (moving or deforming) attributes are assigned to a face or cell zone, then the zone is not considered when updating the mesh to the next time step. However, there are cases where an explicit declaration of a stationary zone is required. For example, if a cell zone is assigned some solid body motion, the positions of all nodes belonging to the cell zone will be updated even though some of the nodes may also be part of a non-moving boundary zone. An explicit declaration of a stationary zone excludes the nodes on these zones when updating the node positions.

Figure 11.77 The Dynamic Mesh Zones Dialog Box for a Stationary Zone

To define a stationary zone in your model, follow the steps below.

1. Select the stationary zone in the **Zone Names** drop-down list.
2. Select **Stationary** under **Type**.
3. If the stationary zone is a face zone that is not a boundary of a CutCell dynamic cell zone, then define the **Cell Height** in the **Meshing Options** tab for any **Adjacent Zone** that is involved in local remeshing or dynamic layering. The **Cell Height** specifies the ideal height (h_{ideal}) in [Equation 11-15 \(p. 592\)](#) and [Equation 11-16 \(p. 593\)](#) of the adjacent cells. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a `DEFINE_DYNAMIC_ZONE_PROPERTY` UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS FLUENT, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

Refer to the [UDF Manual](#) for information about UDFs.

4. If the stationary zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab. See [Figure 11.78 \(p. 648\)](#) for an example of the **Dynamic Mesh Zones** dialog box with the **Meshing Options** tab as it appears for CutCell boundary zones. (The

same meshing input is required at all CutCell boundary zones, whether the motion type is stationary, rigid body, deforming, user-defined, or system coupling.)

Two different size functions are available to control the local mesh refinement:

- soft size function

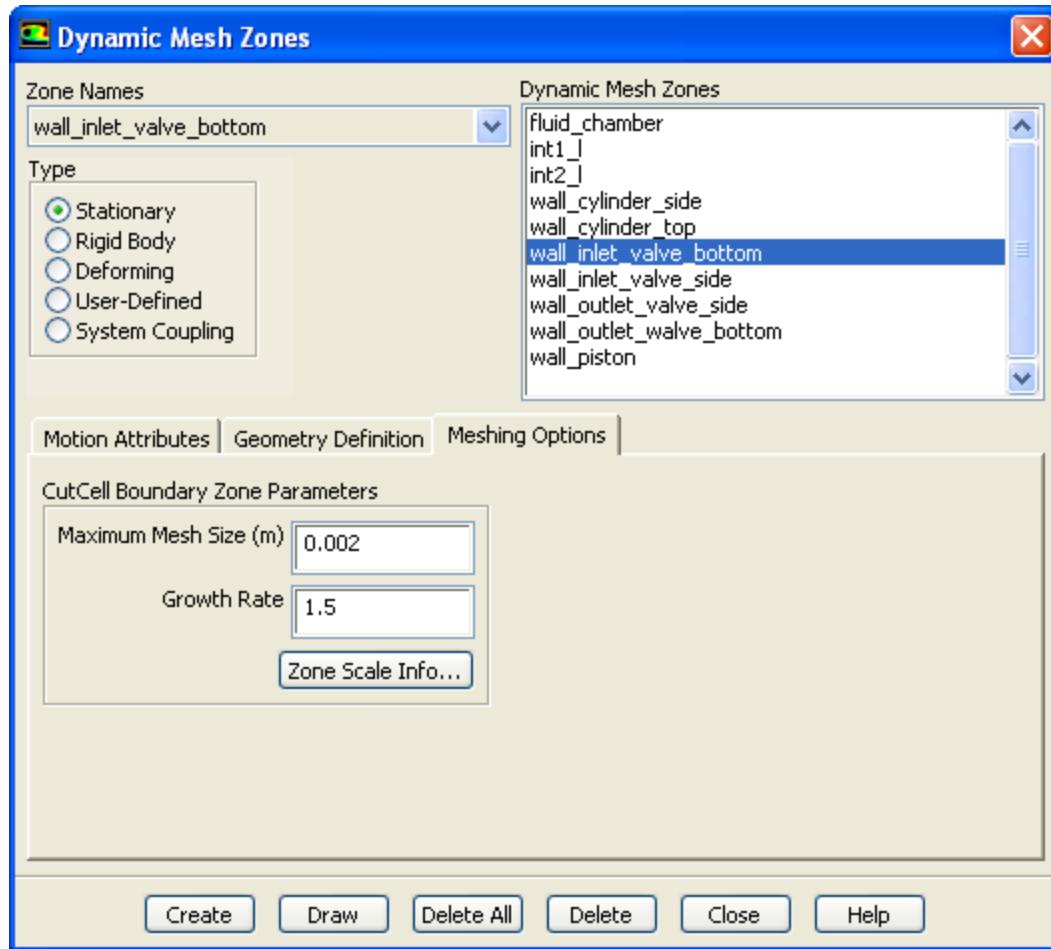

For this size function, the Cartesian mesh is locally refined such that the resulting mesh size is smaller or equal to the **Maximum Mesh Size** specified.

- mesh-based size function

For this size function, the Cartesian mesh is locally refined such that the resulting mesh size is locally of the same size as the input mesh provided.

The switch between using the soft or the mesh-based size function depends on the value entered for the **Maximum Mesh Size**. A value of 0 specifies that the mesh-based size function is used. If a positive value is entered, then the soft size-function is used and the value entered locally limits the mesh size. The **Growth Rate** controls the rate at which the Cartesian mesh grows away from the boundary. The maximum Cartesian mesh size obtained in the cell zone is always controlled by the specified **Maximum Mesh Size** for the CutCell cell zone.

Figure 11.78 The Dynamic Mesh Zones Dialog Box for a CutCell Boundary Zone

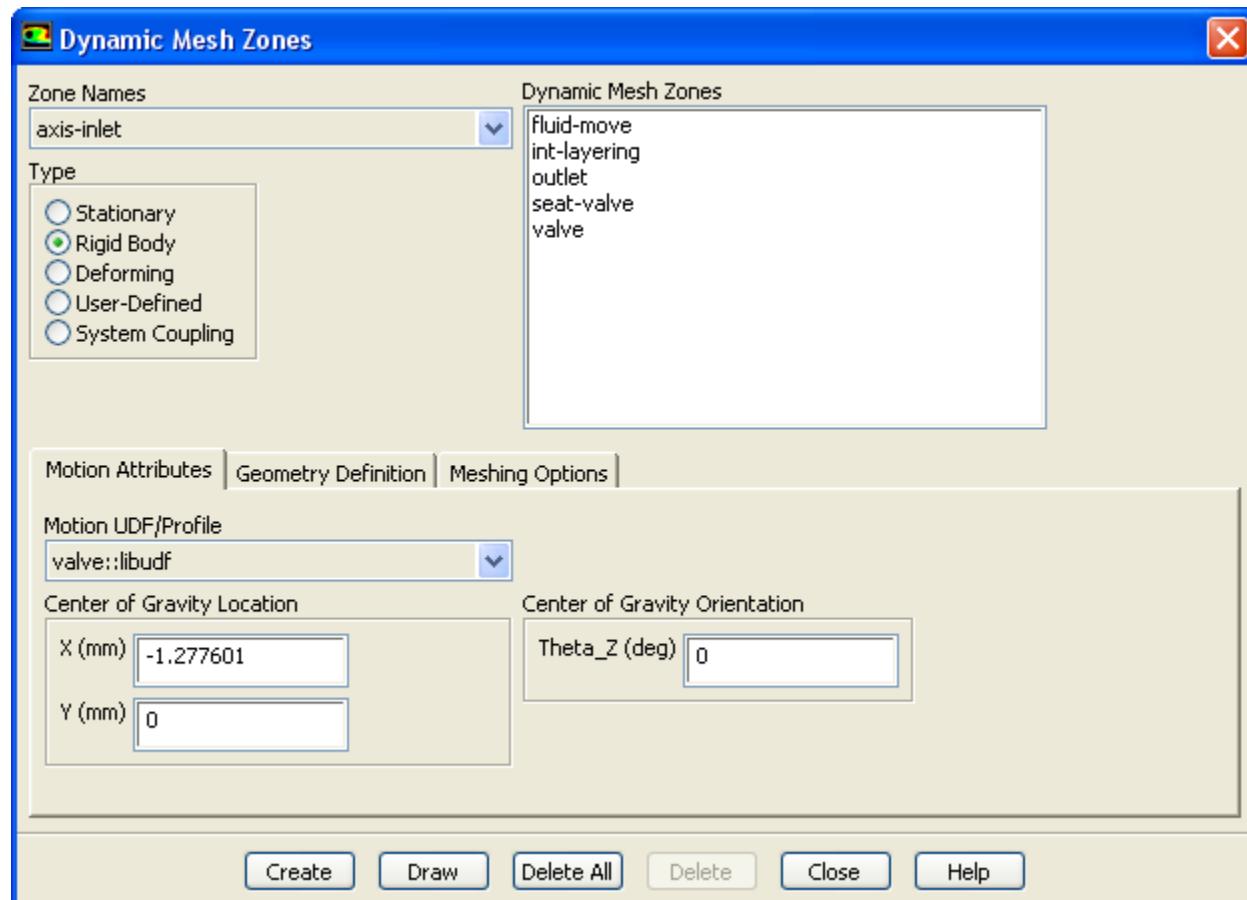

You can view the vital statistics of your zone by clicking on the **Zone Scale Info...** button. This opens the [Zone Scale Info Dialog Box \(p. 2043\)](#), where you can view the minimum, maximum, and average length scale values, as well as the maximum skewness value.

5. Click **Create**.

11.6.7.3. Rigid Body Motion

To define a rigid-body zone in your model, follow the steps below.

Figure 11.79 The Dynamic Mesh Zones Dialog Box for a Rigid Body Motion

1. Select the rigid body zone in the **Zone Names** drop-down list.
2. Select the **Rigid Body** option under **Type**.
3. If you want to specify the motion of the rigid body zone using a profile or user-defined function, then select a profile or user-defined function from the **Motion UDF/Profile** drop-down list in the **Motion Attributes** tab. See [Profiles \(p. 382\)](#) and [Solid-Body Kinematics \(p. 658\)](#) for information on profiles, and see the [UDF Manual](#) for information on user-defined functions.
4. If you selected the **In-Cylinder** option in the [Dynamic Mesh Task Page \(p. 2024\)](#), ANSYS FLUENT provides built-in functions in the **Motion UDF/Profile** drop-down list that can be useful for defining the rigid body motion of a piston. If you would like the motion of the piston to be a function of crank angle (i.e., governed by [Equation 11–25 \(p. 620\)](#)), then you should select ****piston-full****. For further information, see [In-Cylinder Settings \(p. 618\)](#).
5. If you want to use the **Six DOF** solver option, then select the appropriate UDF from the **Six DOF UDF** drop-down list in the **Motion Attributes** tab (see [Figure 11.80 \(p. 651\)](#)). Note that you should

make sure that **On** is enabled under **Six DOF Options** to ensure that the Six DOF solver is being used. See the [UDF Manual](#) for information on user-defined functions. For more information about the six DOF solver, see [Using the Six DOF Solver \(p. 634\)](#).

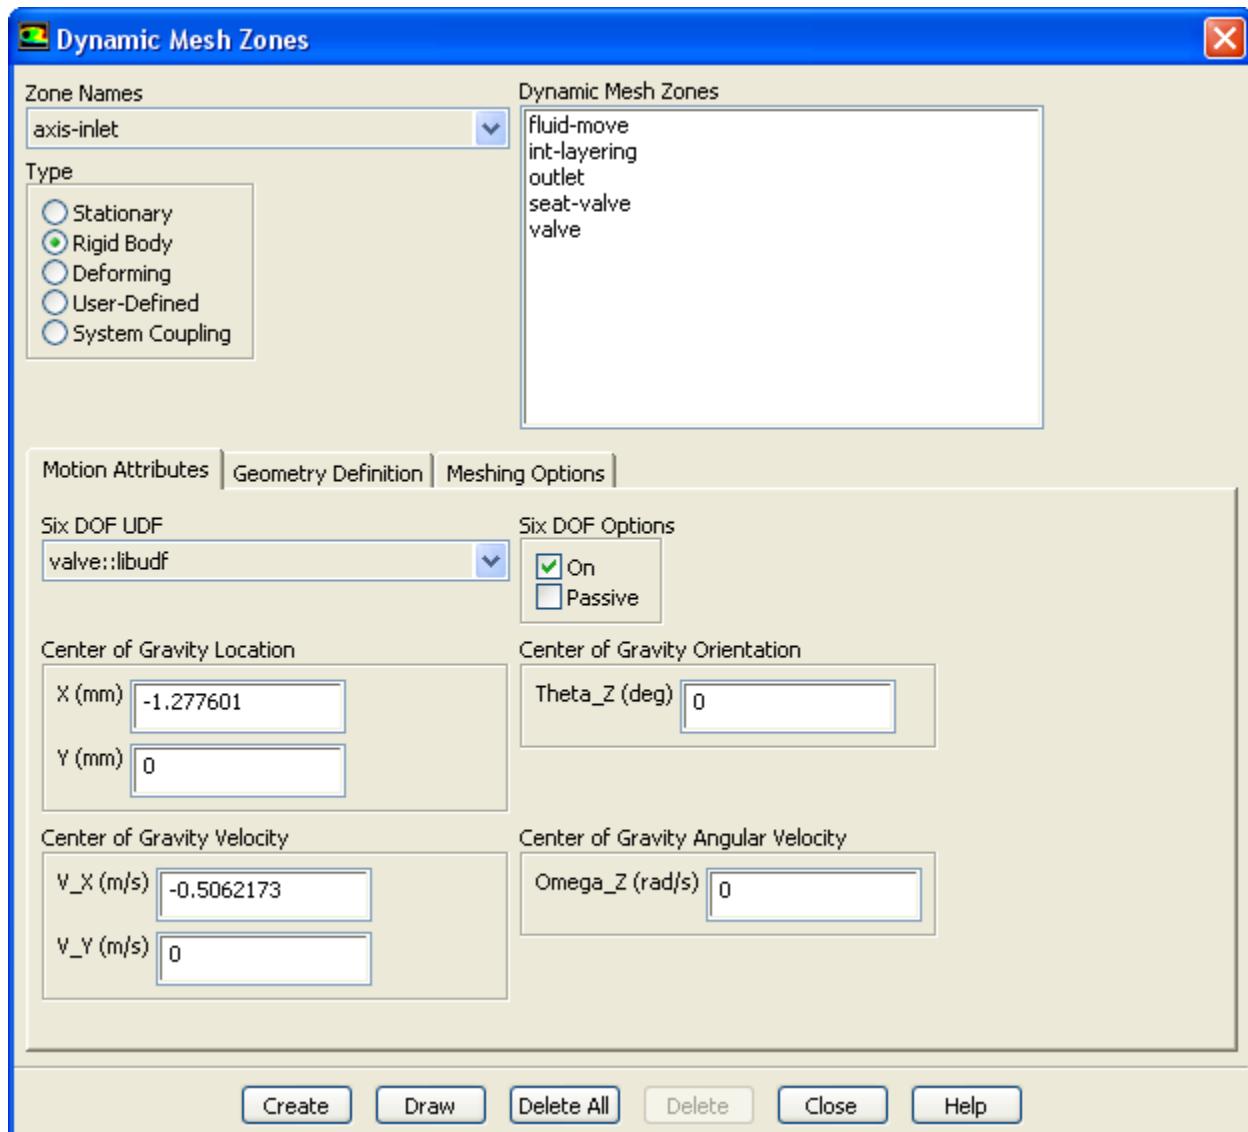

Note that the **Passive** option under **Six DOF Options** is used when you do not want the forces and moments on the zone to be taken into consideration.

6. Specify the initial location of the center of gravity for the rigid body by entering the coordinates of the center of gravity in **Center of Gravity Location**.
7. Specify the orientation of the object with respect to the center of gravity (in the inertia coordinate system) by entering the orientations of the center of gravity in **Center of Gravity Orientation**.

For most cases, this is an initial reference orientation that ANSYS FLUENT later updates, letting you keep track of the object's current orientation. The center of gravity orientation is most useful when using the Six DOF solver, where it is used to compute the transformation matrices ([Six DOF \(6DOF\) Solver Theory](#) in the [Theory Guide](#)).

8. When using the Six DOF solver, specify the velocity of the center of gravity with respect to the inertia coordinate system by entering the velocity of the center of gravity in **Center of Gravity Velocity**. Also, specify the angular velocity of the center of gravity with respect to the inertia coordinate system by entering the angular velocity of the center of gravity in **Center of Gravity Angular Velocity**.

Figure 11.80 The Dynamic Mesh Zones Dialog Box for a Rigid Body Motion Using the Six DOF Solver

- If you are solving an in-cylinder problem, specify the direction of the reference axis of the valves or piston in **Valve/Piston Axis**.

The current valve lift or piston stroke is automatically updated in **Lift/Stroke** when you click **Create** based on the parameters you have specified earlier when you first invoke the in-cylinder option.

- If the rigid body zone is a face zone that is not a boundary of a CutCell dynamic cell zone, specify the **Cell Height** for each **Adjacent Zone** in the **Meshing Options** tab. The **Cell Height** is the ideal cell height (h_{ideal} in [Equation 11–15 \(p. 592\)](#) and [Equation 11–16 \(p. 593\)](#)) that is used by ANSYS FLUENT to determine when the prismatic layer next to the rigid body should be split or merged with the layer next to it. If the adjacent zone is tetrahedral or triangular, the ideal height is used by ANSYS FLUENT to determine if adjacent cells need to be agglomerated for local remeshing. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a `DEFINE_DYNAMIC_ZONE_PROPERTY` UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS FLUENT, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

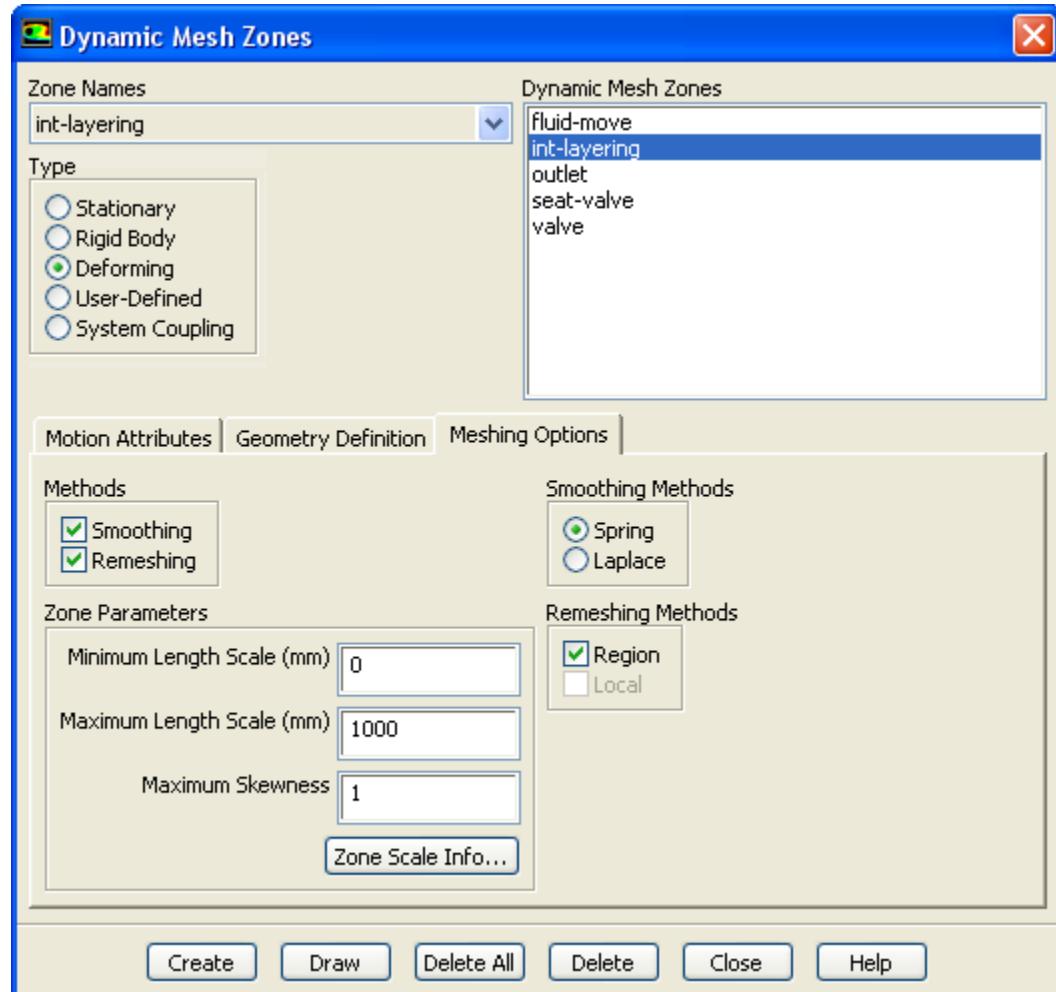

Refer to the [UDF Manual](#) for information about UDFs.

11. If the rigid body zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4. of [Stationary Zones \(p. 646\)](#).
12. If the dynamic zone is a face zone with an adjacent boundary layer mesh, you must enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab if want the boundary layer to move rigidly with the moving face zone. For example, this option is necessary if you are applying face region remeshing with prism layers and you have not decomposed the mesh volume (see [Face Region Remeshing with Prism Layers \(p. 607\)](#)). In such circumstances, the **Deform Adjacent Boundary Layer with Zone** option ensures that the base prism elements shown in [Figure 11.43 \(p. 609\)](#) will move rigidly with the piston.
13. Click **Create**.

11.6.7.4. Deforming Motion

To define a deforming zone in your model, follow the steps below.

Figure 11.81 The Dynamic Mesh Zones Dialog Box for a Deforming Motion

1. Select the deforming zone in the **Zone Names** drop-down list.
2. Select the **Deforming** option under **Type**.
3. Specify the geometry of the deforming zone in the **Geometry Definition** tab. There are four options:
 - If no geometry is available, select **faceted** in the **Definition** drop-down list.
 - If the geometry is a plane, select **plane** in the **Definition** drop-down list. To define the plane, enter the position of a point on the plane in **Point on Plane** and the plane normal in **Plane Normal**.
 - If the geometry is a cylinder, select **cylinder** in the **Definition** drop-down list. To define the cylinder, enter the **Cylinder Radius**, the **Cylinder Origin** and the **Cylinder Axis**.
 - If the geometry is described by a user-defined function, select **user-defined** in the **Definition** drop-down list and the appropriate user-defined functions in the **Geometry UDF** drop-down list. See the [UDF Manual](#) for information on user-defined functions.

For 3D simulations, ANSYS FLUENT allows you to preserve features not only between the different face zones, but also within a face zone. For any geometry definition (**faceted**, **plane**, **cylinder**, or **user-defined**), you can indicate whether you want to include features of a specific angle by selecting **Include Features** under **Feature Detection** and setting the **Feature Angle** in degrees.

For more information, see [Feature Detection \(p. 617\)](#).

When available, the geometry information is used to project nodes on the deforming zone after remeshing the face zone, or if nodes are moved from the spring-based smoothing method.

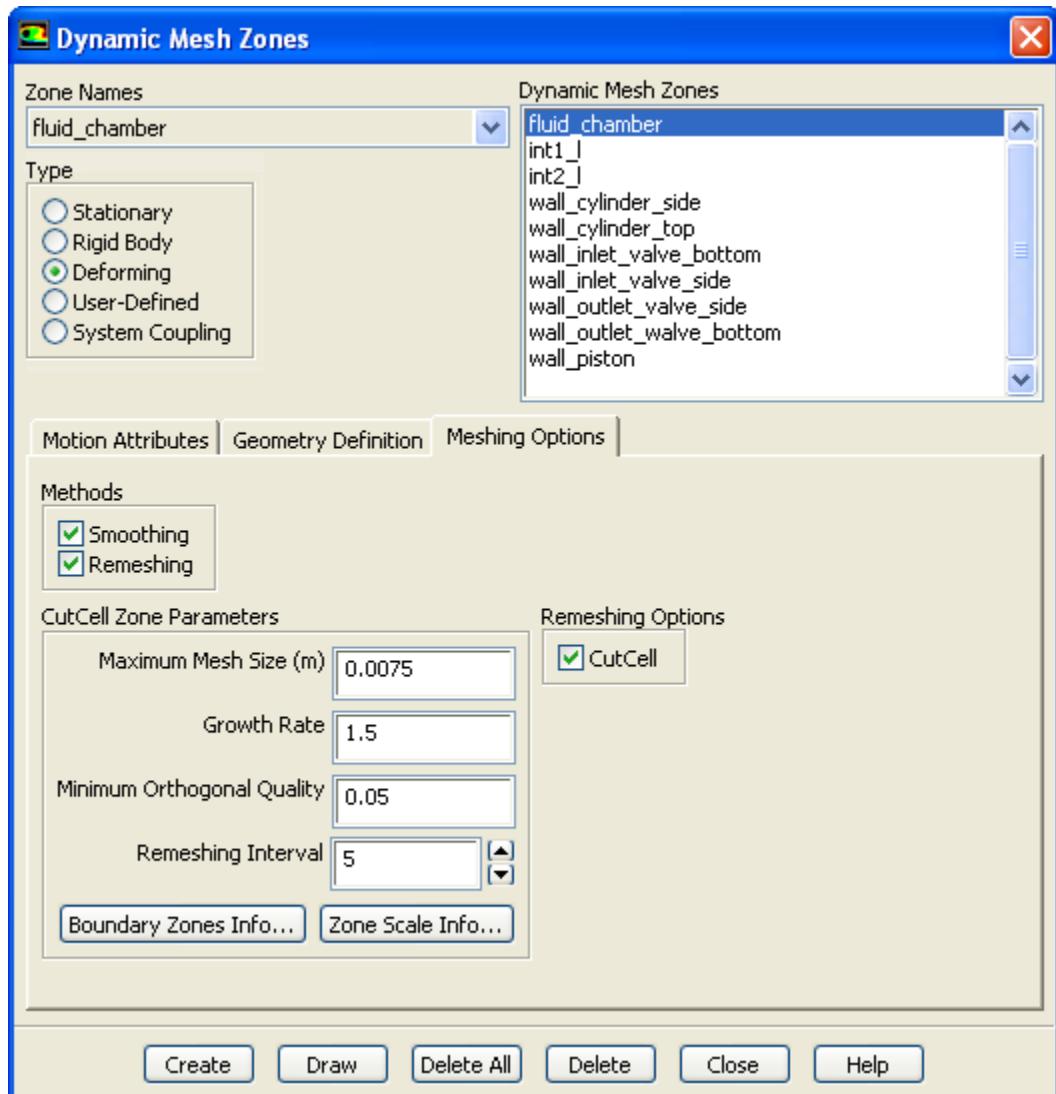

4. For deforming face and cell zones that are not CutCell zones, specify the appropriate remeshing parameters in the **Meshing Options** tab.

You can locally disable or enable **Smoothing** and or **Remeshing** and use any **Smoothing** and or **Remeshing** method.

You can view the vital statistics of your zone by clicking the **Zone Scale Info...** button. This opens the [Zone Scale Info Dialog Box \(p. 2043\)](#), where you can view the minimum and maximum length scale values, as well as the maximum skewness values.

If you selected a cell or face zone, you need to enter **Minimum Length Scale**, **Maximum Length Scale** and **Maximum Skewness** if you want impose a different set of remeshing criteria, other than those you specified globally in the [Dynamic Mesh Task Page \(p. 2024\)](#). This is not required for cell zones since the global settings for the dynamic mesh parameters are used if ANSYS FLUENT determines that the local settings are unreasonable. You should use the information found in the [Zone Scale Info Dialog Box \(p. 2043\)](#) in order to set your values.

5. To specify that a deforming cell zone is remeshed using the CutCell zone method, enable the **CutCell** option in the **Remeshing Options** group box of the **Meshing Options** tab (see [Figure 11.82 \(p. 655\)](#)). Note that this option is only available if you have previously enabled the **CutCell Zone** option in the **Remeshing** tab of the **Mesh Method Settings** dialog box (see [Figure 11.33 \(p. 597\)](#)).

Figure 11.82 The Dynamic Mesh Zones Dialog Box for a Deforming CutCell Cell Zone

After the **CutCell** option has been enabled, you need to enter values for the global CutCell parameters **Maximum Mesh Size** and **Growth Rate**, as well as the controls for the remeshing frequency, **Minimum Orthogonal Quality** and **Remeshing Interval**.

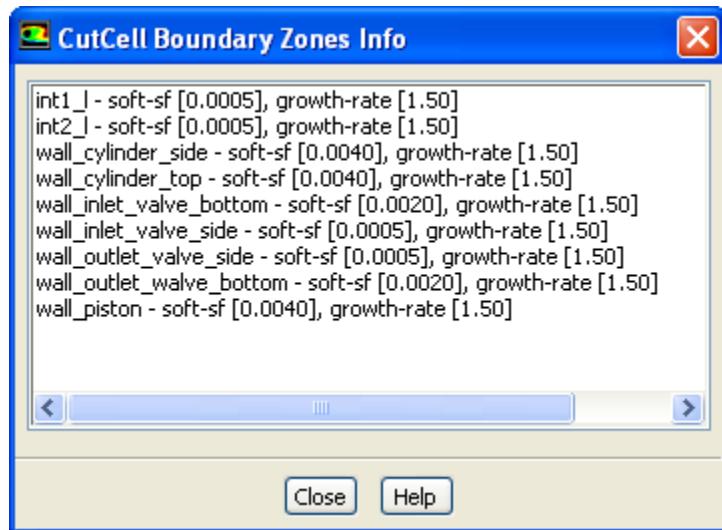

The **Maximum Mesh Size** specified for the CutCell cell zone controls the global maximum size of the Cartesian cells. The global **Growth Rate** is used for all mesh-based size functions applied to CutCell boundary zones that are not defined as dynamic zones. When selecting values for these controls, it may be helpful to view the statistics of your cell zone by clicking on the **Zone Scale Info...** button. This opens the [Zone Scale Info Dialog Box \(p. 2043\)](#), where you can view the minimum and maximum length scale values, as well as the maximum skewness values.

The CutCell remeshing is performed automatically whenever cells exhibit an orthogonal quality (as defined in [Mesh Quality \(p. 145\)](#)) that is less than the specified **Minimum Orthogonal Quality**. The remeshing is also performed periodically after the calculation has undergone the number of time steps you specified for the **Remeshing Interval**.

Click the **Boundary Zones Info...** button to open the **CutCell Boundary Zones Info** dialog box ([Figure 11.83 \(p. 656\)](#)). This dialog box lists all the boundary zones associated with the CutCell cell zone, along with the associated size functions and zonal meshing parameters. It is recommended

that you revisit this dialog box after you have created all of the dynamic zones, in order to review all of the parameters you have set.

Figure 11.83 The CutCell Boundary Zones Info Dialog Box

6. If the deforming zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4. of *Stationary Zones* (p. 646).
7. Click **Create**.

11.6.7.5. User-Defined Motion

For a zone that is deforming and moving, you can define the position of each node on the general deforming/moving zone using a user-defined function (UDF). To define a moving and deforming zone, follow the steps below.

1. Select the moving and deforming zone in the **Zone Names** drop-down list.
2. Select the **User-Defined** option under **Type**.
3. In the **Motion Attributes** tab, select the user-defined function that defines the geometry and motion of the zone from the **Mesh Motion UDF** drop-down list. See the [UDF Manual](#) for information on user-defined functions used to specify user-defined motion.
4. For a face zone that is not a boundary of a CutCell dynamic cell zone, you can specify the **Cell Height** in the **Meshing Options** tab for any **Adjacent Zone** which is involved in local remeshing or dynamic layering. The **Cell Height** specifies the ideal height (h_{ideal} in [Equation 11-15 \(p. 592\)](#) and [Equation 11-16 \(p. 593\)](#)) of the adjacent cells. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a **DEFINE_DYNAMIC_ZONE_PROPERTY** UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS FLUENT, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

Refer to the separate [UDF Manual](#) for information about UDFs.

5. If the face zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4. of *Stationary Zones* (p. 646).
6. If the dynamic zone is a face zone with an adjacent boundary layer mesh, and you want to use the boundary layer smoothing method (as described in *Boundary Layer Smoothing Method* (p. 587)), enable the **Deform Adjacent Boundary Layer with Zone** option in the **Meshing Options** tab.
7. Click **Create**.

11.6.7.5.1. Specifying Boundary Layer Deformation Smoothing

For a boundary layer that deforms according to the adjacent face zone, the zone that is deforming and moving is usually defined using a user-defined function (UDF), as described in *User-Defined Motion* (p. 656). To define a moving and deforming boundary layer, perform the steps that follow.

If the boundary layer borders a face zone that is only moving and is not deforming, you should consider applying rigid body motion to the face zone (see *Rigid Body Motion* (p. 649)) rather than user-defined motion, as rigid body motion usually involves a simpler UDF.

1. Set up the moving and deforming zone.
 - a. Select the moving and deforming zone in the **Zone Names** drop-down list.
 - b. Select the **User-Defined** option under **Type**.
 - c. In the **Motion Attributes** tab, select the user-defined function that defines the geometry and motion of the zone from the **Mesh Motion UDF** drop-down list.
 - d. In the **Meshing Options** tab, enable the **Deform Adjacent Boundary Layer with Zone** option.
 - e. Click **Create**.
2. Set up a deforming dynamic zone for the fluid zone that contains the boundary layer.
 - a. Select the fluid zone that contains the boundary layer from the **Zone Names** drop-down list.
 - b. Select **Deforming** from **Type** list.
 - c. In the **Meshing Options** tab, enable **Smoothing** and **Remeshing** in the **Methods** group box.
 - d. Click **Create**.
3. If the fluid zone set up in the step 2. consists entirely of the boundary layer elements, set up a deforming dynamic zone for the neighboring fluid zone. This step is necessary because the deforming boundary layer will deform the adjacent cells.
 - a. Select the fluid zone that neighbors the boundary layer zone from the **Zone Names** drop-down list.
 - b. Select **Deforming** from **Type** list.
 - c. In the **Meshing Options** tab, enable **Smoothing** and **Remeshing** in the **Methods** group box.
 - d. Click **Create**.

11.6.7.6. System Coupling Motion

For a zone that is involved in a system coupling, the motion is defined by the application that ANSYS FLUENT is coupled with on this zone. For more details about setting up a simulation with system

coupling see the [FLUENT in Workbench User's Guide](#) and the [System Coupling Guide](#). To define a system coupling zone, follow the steps below.

1. Select the moving and deforming zone in the **Zone Names** drop-down list.
2. Select the **System Coupling** option under **Type**.
3. If the system coupling zone is not a boundary of a CutCell dynamic cell zone, you can specify the **Cell Height** in the **Meshing Options** tab for any **Adjacent Zone** which is involved in local remeshing or dynamic layering. The **Cell Height** specifies the ideal height (h_{ideal} in [Equation 11–15 \(p. 592\)](#) and [Equation 11–16 \(p. 593\)](#)) of the adjacent cells. Make a selection in the **Cell Height** drop-down menu to specify this value as either a **constant** or a compiled user-defined function.

If you select the **constant** option, enter a value in the **Cell Height** text-entry box.

If you choose to use a compiled user-defined function to define an ideal cell height that varies as a function of time or crank angle, you must first define a `DEFINE_DYNAMIC_ZONE_PROPERTY` UDF. After you have compiled the UDF source file, built a shared library, and loaded it into ANSYS FLUENT, the name of the UDF library will be available for selection in the **Cell Height** drop-down list.

Refer to the separate [UDF Manual](#) for information about UDFs.

4. If the system coupling zone is a boundary of a CutCell dynamic cell zone (this is automatically detected if the CutCell dynamic cell zone is created first), then enter values for the **Maximum Mesh Size** and **Growth Rate** in the **Meshing Options** tab, as described in step 4. of [Stationary Zones \(p. 646\)](#).
5. Click **Create**.

Note

If the **System Coupling** option is enabled, and ANSYS FLUENT is not involved with a system coupling simulation, then this zone type behaves in the same way as a stationary zone.

11.6.7.7. Solid-Body Kinematics

ANSYS FLUENT uses solid-body kinematics if the motion is prescribed based on the position and orientation of the center of gravity of a moving object. This is applicable to both cell and face zones.

The motion of the solid-body can be specified either as a profile or as a user-defined function (UDF). A profile may be defined by the following profile fields:

- time (time)
- crank angle (angle) (in-cylinder flows only)
- position (x, y, z)
- linear velocity (v_x, v_y, v_z)
- angular velocity ($\omega_x, \omega_y, \omega_z$)
- orientation ($\theta_x, \theta_y, \theta_z$)

For in-cylinder simulations, the velocity profiles for valves can be expressed as a function of crank angle instead of time. In addition, transient boundary condition profiles can also be expressed as a function

of crank angle instead of time. For more information about transient profiles, see [Defining Transient Cell Zone and Boundary Conditions \(p. 393\)](#).

Below are two examples of a profile format:

```
((movement_linear 3 point)
(time
0 1 2 )
(x
2 3 4 )
(v_y
0 -5 0 )
)

((movement_angular 3 point)
(time
0 1 2 )
(omega_x
2 3 4 )
)
```

For in-cylinder flows, crank angles can be included in transient tables as well as transient profiles, in a similar fashion to time. An example of a transient table using (crank) angle is as follows:

```
example 2 3 1
angle temperature
0 300
180 500
360 300
```

An example of a transient profile using (crank) angle is as follows:

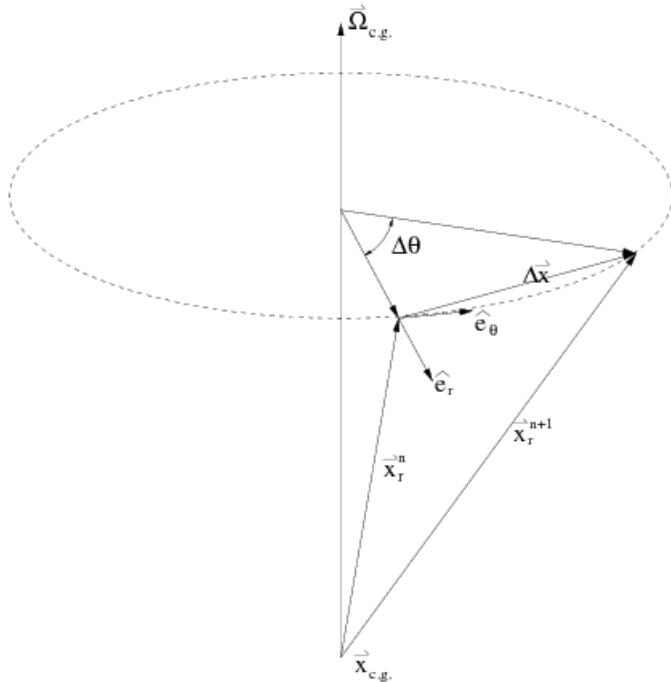

```
((example transient 3 1)
(angle
0.000000e+00 1.800000e+02 3.600000e+02)
(temperature
3.000000e+02 5.000000e+02 3.000000e+02)
)
```

In addition to the motion description, you must also specify the starting location of the center of gravity and orientation of the solid body. In 2D cases (and 3D cases that do not use the six DOF solver), ANSYS FLUENT automatically updates the center of gravity position and orientation at every time step such that

$$\begin{aligned}\bar{x}_{c.g.}^{n+1} &= \bar{x}_{c.g.}^n + \vec{v}_{c.g.} \Delta t \\ \bar{\theta}_{c.g.}^{n+1} &= \bar{\theta}_{c.g.}^n + \vec{\Omega}_{c.g.} \Delta t\end{aligned}\tag{11-32}$$

where $\bar{x}_{c.g.}$ and $\bar{\theta}_{c.g.}$ are the position and orientation of the center of gravity, $\vec{v}_{c.g.}$ and $\vec{\Omega}_{c.g.}$ are the linear and angular velocities of the center of gravity. 3D, six DOF cases use a more complex form of [Equation 11-32 \(p. 659\)](#) when updating θ .

Typically, $\bar{\theta}$ is chosen to be an appropriate set of Euler angles. In this case, the solid-body motion must be specified using a user-defined function (DEFINE_CG_MOTION).

Figure 11.84 Solid Body Rotation Coordinates

The position vectors on the solid body are updated based on rotation about the instantaneous angular velocity vector $\vec{\Omega}_{c.g.}$. For a finite rotation angle $\Delta\theta = |\vec{\Omega}_{c.g.}| \Delta t$, the final position of a vector \vec{x}_r on the solid body with respect to $\vec{x}_{c.g.}$ can be expressed as (See *Figure 11.84* (p. 660))

$$\vec{x}_r^{n+1} = \vec{x}_r^n + \Delta \vec{x} \quad (11-33)$$

where $\Delta \vec{x}$ can be shown to be

$$\Delta \vec{x} = | \vec{x}_r^n - \vec{x}_{c.g.} | [\sin(\Delta\theta) \hat{e}_\theta + (\cos(\Delta\theta) - 1) \hat{e}_r] \quad (11-34)$$

The unit vectors \hat{e}_θ and \hat{e}_r are defined as

$$\hat{e}_\theta = \frac{\vec{\Omega}_{c.g.} \times \vec{x}_r}{|\vec{\Omega}_{c.g.} \times \vec{x}_r|} \quad (11-35)$$

$$\hat{e}_r = \frac{\hat{e}_\theta \times \vec{\Omega}_{c.g.}}{|\hat{e}_\theta \times \vec{\Omega}_{c.g.}|} \quad (11-36)$$

If the solid body is also translating with $\vec{v}_{c.g.}$ the $n + 1$ position vector on the solid body can be expressed as

$$\bar{x}^{n+1} = \bar{x}_{c.g.}^n + \bar{v}_{c.g.} \Delta t + \bar{x}_r^{n+1} \quad (11-37)$$

where \bar{x}_r^{n+1} is given by [Equation 11-33 \(p. 660\)](#).

11.6.8. Previewing the Dynamic Mesh

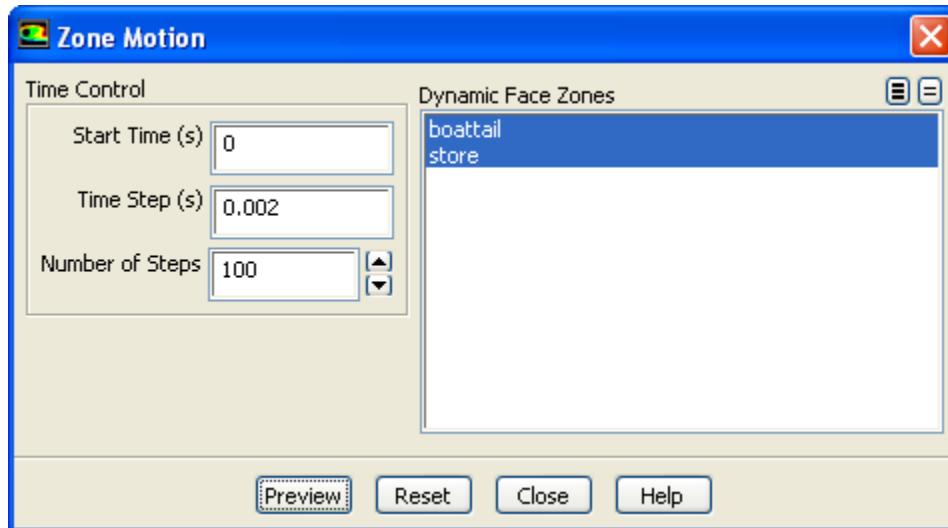

When you have specified the mesh update methods and their associated parameters, and you have defined the motion of dynamic zones, as described in [Specifying the Motion of Dynamic Zones \(p. 645\)](#), you can preview the motion of the mesh or the zone as it changes with time before you start your simulation. The same dynamic zone or mesh motion will be executed when you start your simulation.

11.6.8.1. Previewing Zone Motion

You can preview the motion of zones with **Rigid Body** or **User-Defined** motion using the [Zone Motion Dialog Box \(p. 2043\)](#) ([Figure 11.85 \(p. 661\)](#)).

Dynamic Mesh → Display Zone Motion...

Figure 11.85 The Zone Motion Dialog Box

The zone motion preview only updates the graphical representation (in the graphics window) of the zones that you have selected in the **Dynamic Face Zones** list. Only zones that have been specified with either **User-Defined** or **Rigid Body** motion type are available for zone motion preview. To use the **Zone Motion** preview:

1. In the [Zone Motion Dialog Box \(p. 2043\)](#), select the face zones for which you want to preview the motion from the **Dynamic Face Zones** list. The **Dynamic Face Zones** list displays zones which have either **User-Defined** or **Rigid Body** motion specified. By default, all such zones are selected.
2. Enter the **Start Time**, **Time Step**, and **Number of Steps** under **Time Control**.
3. Click the **Preview** button to preview the zone motion. This positions the mesh according to the specified **Start Time**, and then integrates the position of the selected surfaces in time. The zone positions at the specified **Start Time** can be previewed without any subsequent motion by entering 0 for the **Number of Steps**.

- Click **Reset** to restore the mesh to its initial state.

Previewing the zone motion can also be used as a postprocessor for six DOF simulations (see [Using the Six DOF Solver \(p. 634\)](#)).

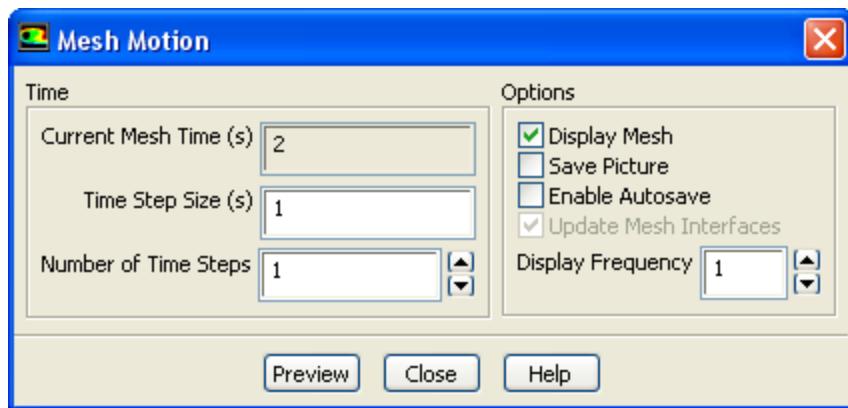

11.6.8.2. Previewing Mesh Motion

The mesh motion preview is different from the zone motion described above in that the mesh connectivity is changed in mesh motion.

To preview the dynamic mesh of a transient case, you can use the [Mesh Motion Dialog Box \(p. 2044\)](#) ([Figure 11.86 \(p. 662\)](#))

Dynamic Mesh → Preview Mesh Motion...

Figure 11.86 The Mesh Motion Dialog Box

The procedure is as follows:

- Save the case file.

File → Write → **Case...**

Important

Note that the mesh motion will actually update the node locations as well as the connectivity of the mesh, so you must be sure to save your case file before doing the dynamic mesh motion. Once you have advanced the mesh by a certain number of time steps, you will not be able to recover the previous status of the mesh, other than by reloading the appropriate ANSYS FLUENT case file.

- Specify the **Number of Time Steps** and the size of each time step (**Time Step Size**). The current time will be displayed in the **Current Mesh Time** field after the dynamic mesh has been advanced the specified number of steps.

Note that if you turned on the in-cylinder option, the **Time Step Size** is automatically calculated from the **Crank Angle Step Size** and the **Crank Shaft Speed** that you have specified in the **In-Cylinder** tab of the [Options Dialog Box \(p. 2030\)](#).

3. To view the dynamic mesh in the graphics window, enable the **Display Mesh** option. In addition, you can control the frequency at which ANSYS FLUENT should display an updated mesh in the **Display Frequency** field. To save a picture file of the mesh each time ANSYS FLUENT updates it during the preview, turn on the **Save Picture** option. This opens the *Save Picture Dialog Box* (p. 2144) (see *Saving Picture Files* (p. 119)).

 4. Turn on **Enable Autosave** to use the automatic saving feature to specify the file name and frequency with which case and data files should be saved during the solution process. This opens the *Autosave Case During Mesh Motion Preview Dialog Box* (p. 2045).
- See *Automatic Saving of Case and Data Files* (p. 68) for details about the use of this feature. This provides a convenient way for you to save results at successive time steps for later postprocessing.
5. Enable the **Update Mesh Interfaces** option to update the interface at every time step.
 6. Click **Preview** to start the preview. ANSYS FLUENT will update the dynamic mesh by moving and deforming the face and cell zones that you have specified as dynamic zones. Click **Apply** to save your settings for mesh motion.

During the preview, information about the dynamic mesh will be displayed in the console window for each time step. Note that for the in-cylinder option, the reported Maximum Cell Skew is calculated only from zones undergoing remeshing. This ensures that you can always ascertain whether the skewness is increasing in the deforming zones. To report the maximum skewness of a cell from *any* zone, you can click the **Report Quality** button in the *General Task Page* (p. 1763).

 **General → Report Quality**

11.6.9. Steady-State Dynamic Mesh Applications

While many dynamic mesh problems are transient, you can use dynamic meshes for steady-state applications as well. Some examples of steady-state applications include: checking the valve application after reaching a steady-state valve position; or after a fluid-structure interface application has reached a steady-state solution.

There are no differences in the meshing aspect between steady-state cases and transient cases. Furthermore, setting up a steady-state simulation is similar to setting up a transient case, described in *Using Dynamic Meshes* (p. 573). However, there are a few differences which you should note:

- A CG_MOTION UDF is needed to specify the motion of the boundary: a transient profile used in transient cases cannot be used in steady-state cases.
- The dti_{me} passed to the CG_MOTION UDF is 1 by default: if a displacement of 1 mm is needed to move the boundary, you can specify the velocity to be 1e-3 m/s.
- Dynamic mesh parameters can be different since an interpolation error is no longer a concern.
- If you have enabled local remeshing for your steady-state application, you can instruct ANSYS FLUENT to perform additional remeshing after the boundary has moved. This additional remeshing is based on skewness criteria, and can further increase the quality of your mesh. See *Dynamic Mesh Update Methods* (p. 575) for further details.

The mesh must be manually updated through journal files or execute commands. To update the mesh, you can use the *Mesh Motion Dialog Box* (p. 2044).

 **Run Calculation → Preview Mesh Motion...**

Alternatively, you can use the following text command:

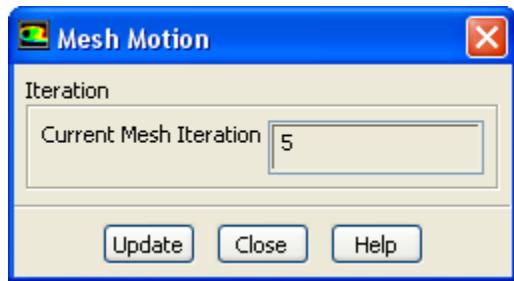

`solve → mesh-motion`

which can also be used as an execute command in the *Execute Commands Dialog Box* (p. 2103):

↳ **Calculation Activities → Create/Edit... (Execute Commands)**

You can display dynamic mesh statistics (such as minimum and maximum volumes and maximum cell and face skewness) by clicking the **Update** button in the *Mesh Motion Dialog Box* (p. 2044) (*Figure 11.87* (p. 664)).

Figure 11.87 The Mesh Motion Dialog Box for Steady-State Dynamic Meshes

Important

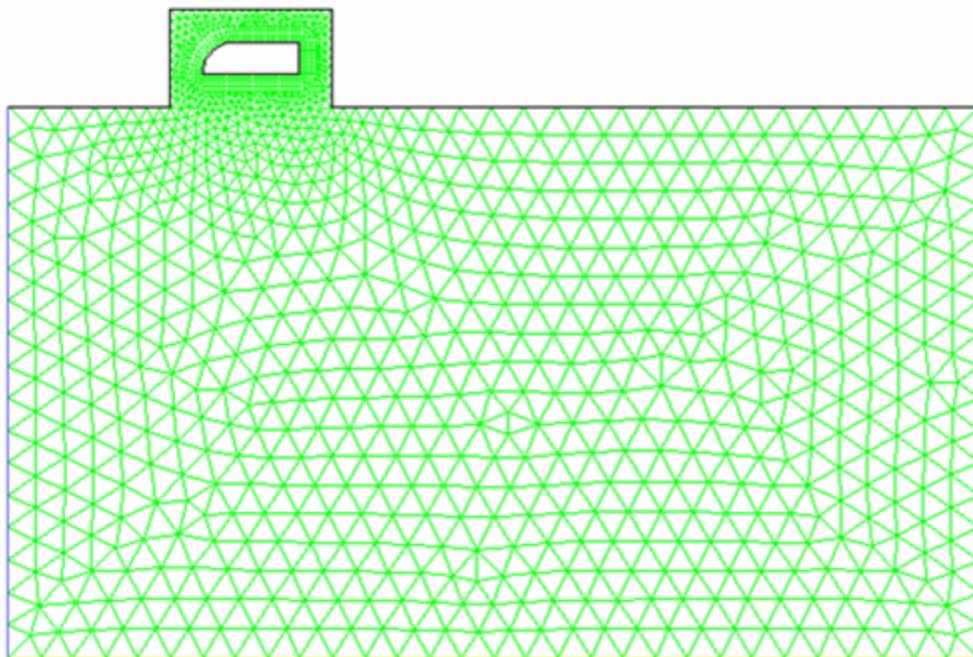

The following options are not available for steady-state applications:

- **In-Cylinder**
- **Six DOF**
- **Implicit Update**

Also, the **Dynamic Mesh Events** dialog box is not available for steady-state applications.

11.6.9.1. An Example of Steady-State Dynamic Mesh Usage

Consider a rescue drop case shown in *Figure 11.88* (p. 665). The object can be moved in any position in the steady-state solver, after which steady-state analyses can be performed at different object positions.

Figure 11.88 Initial Object Position

The dynamic mesh parameters setup is identical for the steady-state and transient cases, which is described in [Setting Dynamic Mesh Modeling Parameters \(p. 574\)](#). When setting up the dynamic zones, the procedures are similar to those described in [Specifying the Motion of Dynamic Zones \(p. 645\)](#), except that the UDF selected from the **Motion UDF/Profile** drop-down list is different. In steady-state cases the **dtime** passed to the UDF is by default 1. So, in this example, the object will move 50 mm each time the following UDF is executed:

```
#include "udf.h"

DEFINE_CG_MOTION(pod,dt,vel,omega,time,dtime)

{
    NV_S(vel,=,0);
    NV_S(omega,=,0);
    vel[1] = -50e-3;
}
```

The resulting mesh is shown in [Figure 11.90 \(p. 666\)](#).

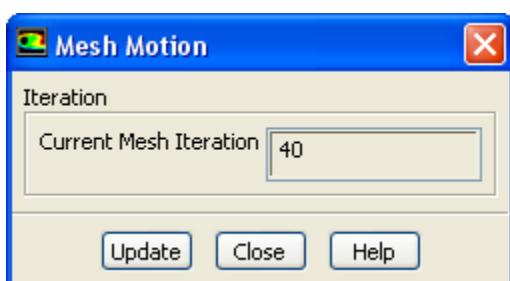

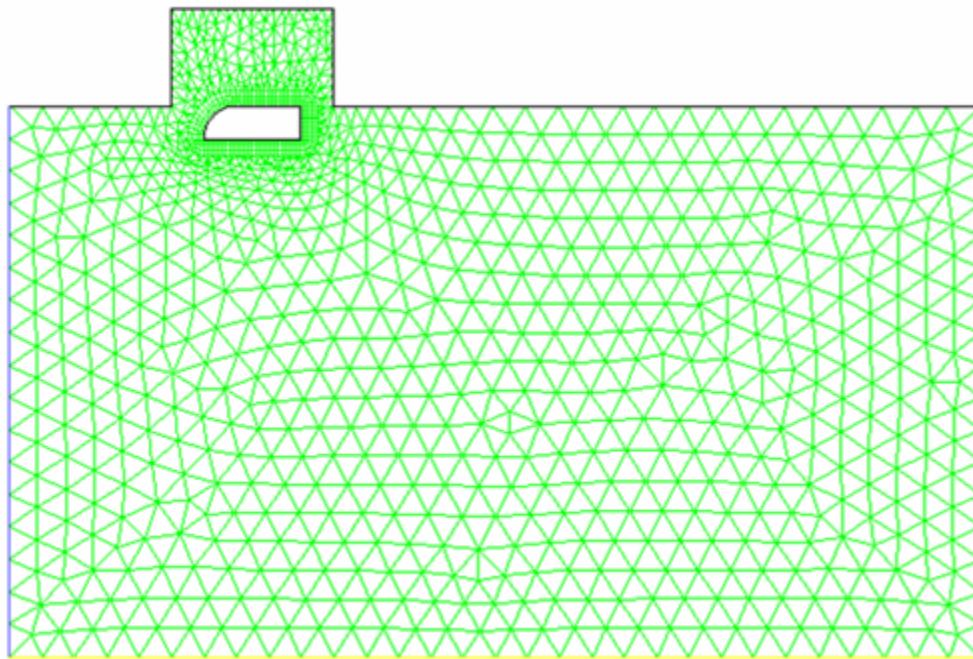

Figure 11.89 The Mesh Motion Dialog Box After 40 Updates

Figure 11.90 Final Object Position After 40 Executions

Chapter 12: Modeling Flows Using the Mesh Morpher/Optimizer

This chapter describes the setup and use of the mesh morpher/optimizer in ANSYS FLUENT.

Details about the mesh morpher/optimizer are presented in the following sections:

- 12.1. Introduction
- 12.2. The Optimization Process
- 12.3. Optimizers
- 12.4. Setting Up the Mesh Morpher/Optimizer

12.1. Introduction

Shape optimization has increasingly become a critical field in the area of CFD. ANSYS FLUENT provides a mesh morphing capability that allows you to solve shape optimization problems [37] ([p. 2369](#)). This capability is suitable for problems that require minimal design changes in the geometry in order to satisfy certain criteria. The target criteria can be specified in the form of an objective function to be minimized through optimization routines. For example, you could optimize the shape of a car for reduced drag. As another example, you could specify a more complex objective function to minimize the drag/lift ratio of an airfoil.

The mesh morpher/optimizer in ANSYS FLUENT has the following advantages:

- The optimization problem can be solved inside ANSYS FLUENT. You can maintain the topology of the initial design, while generating solutions for desired configurations without having to go back and change the geometry and mesh it again.
- The mesh morpher can handle multiple deformation regions.

For additional information, please see the following section:

12.1.1. Limitations

Note the following limitations of the ANSYS FLUENT mesh morpher/optimizer:

- Arbitrarily-shaped deformation regions are not supported.
- If the surface to surface (S2S) radiation model is enabled, the view factors will need to be recomputed at the very least when the optimization is complete. If the objective function is a function of temperature, the view factors will need to be recomputed after each design change.
- The mesh morpher/optimizer should not be used with dynamic or sliding mesh problems.
- If you restart a case file with a mesh that was deformed by the built-in optimizer, you must revise the mesh morpher/optimizer settings for the revised mesh.

12.2. The Optimization Process

All optimization problems require that you identify parameters that can be modified in order to reach the optimized solution. In the case of the mesh morpher/optimizer, it is the geometry that needs to be

parameterized. Geometric parameterization for general shapes used in CFD can be very complicated, due to the large variety of shapes available in engineering applications. In order to minimize such complications in your ANSYS FLUENT simulation, the problem of shape parameterization is reduced to a problem of the parameterization of changes in the geometry. The parameter values can either be manually specified and the results analyzed, or one of the optimizers can be used to automatically adjust the parameter values in search of a minimum of the objective function.

The next essential requirement for mesh morphing is a tool that can smoothly alter the shape, irrespective of the underlying mesh topology. In ANSYS FLUENT, this is accomplished using a free form deformation technique. This technique manipulates designated deformation regions via displacements applied to a set of control points. The mesh region that is to be deformed is overlaid with a "box" (i.e., a rectangle for 2D cases and a rectangular hexahedron for 3D) comprised of a specified number of uniformly-distributed control points in global coordinates. Each parametric change to the geometry is defined by a set of user-specified scaling factors. These scaling factors specify the displacement of each control point for a unit change in the parameter value. The resulting displacements are applied to the mesh as a smooth deformation by using the tensor product of Bernstein polynomials.

The next requirement is to have an optimizer that is robust enough to handle a wide range of problems. By coupling such optimizers with your CFD analysis, you can greatly improve your design with minimal intervention. You can use built-in optimizers to satisfy the condition as specified through an objective function. The mesh morpher/optimizer provides you with access to five optimizers that are not based on gradients. Alternatively, you can manually specify the values of the parameters, and then run the case with the deformed mesh to see if a given condition is satisfied.

12.3. Optimizers

The internal optimizers used as part of the mesh morpher/optimizer capability in ANSYS FLUENT use direct search methods for optimization. Direct search methods are zeroth order, as they only use the objective function values for optimization. The direct search methods do not use the derivatives.

The following is a list of advantages of direct search methods:

- Direct search methods do not require derivatives for optimization.
- Direct search methods are robust for problems with discontinuities and in situations where the derivative computation is not possible or unreliable.

The following is a list of disadvantages of direct search methods:

- Convergence proof is not clearly defined.
- The rate of convergence can be very slow.

General explanations of the five different internal optimizers available in ANSYS FLUENT are provided in the following sections:

[12.3.1. The Compass Optimizer](#)

[12.3.2. The Simplex Optimizer](#)

[12.3.3. The Torczon Optimizer](#)

[12.3.4. The Powell Optimizer](#)

[12.3.5. The Rosenbrock Optimizer](#)

12.3.1. The Compass Optimizer

In the Compass optimizer [110 (p. 2373)], the parameters are adjusted one by one until the objective function is minimized. This optimizer starts with a given value and then evaluates the function value

in all the basic directions. The direction here refers to the positive and negative increments to the initial parameter values. If there is a reduction in the function value, then that point becomes an improved point. If there is no improvement in the function values, then the step length is reduced by half and the search is repeated in all directions. The algorithm terminates when the step size falls below a certain tolerance.

The Compass optimizer initially makes rapid progress towards the solution. While this method might quickly approach the minimum value of an objective function, it may be slow to detect this fact. It may also converge very slowly if the level sets of the objective function are extremely elongated.

12.3.2. The Simplex Optimizer

The Simplex optimizer is also referred to as the Downhill Simplex optimizer [111 (p. 2373)], [113 (p. 2373)] and the Nelder-Mead method [112 (p. 2373)]. It is based on the idea of geometric simplexes; for example, a 2D simplex is a triangle, and a 3D simplex is a tetrahedron.

For optimization purposes, ANSYS FLUENT requires that simplexes are regular polyhedra (i.e., not degenerate polyhedra with collapsed sides). Each vertex of the geometric simplex represents one function evaluation (which in this case is one CFD run), and the number of vertices corresponds to the number of parameters. For the free form deformation method that is used by ANSYS FLUENT to parameterize changes in shapes, the number of active control points will determine the number of vertices of the geometric simplex.

Minimization of the objective function is performed based on a set of the rules about the “quality” of each vertex. The vertex quality is the value of the function evaluated for each position of the control point. A set of geometric operations such as reflection, expansion, contraction, and shrinking are performed in order to find the region in which to look for the minimum of the function. Because optimization here is formulated as a minimization problem, the simplex optimizer algorithm seeks the “worst” vertex, that is, the vertex that has the largest value when the corresponding parameter is evaluated. By performing the reflection around the center of the gravity, the new value of the function is obtained after performing the CFD run. Similarly, the operations of expansion, contraction, and shrinking are used to obtain the minimum of the function.

The Simplex optimizer is known to work well, but it suffers from the large number of function evaluations. It also requires smooth objective functions for convergence.

12.3.3. The Torczon Optimizer

The Torczon optimizer [107 (p. 2372)] is a slightly modified version of the simplex optimizer described previously. Given an initial vertex, this optimizer tries to find a better vertex that has a function value that is strictly less than the function value at the previous best vertex. There are three possible trial steps: the rotation step, the expansion step, and the contraction step. The algorithm always computes the rotation step and then tests to see if a new best vertex has been identified. If it has, then the expansion step is computed. Otherwise, the algorithm computes and automatically accepts the contraction step.

12.3.4. The Powell Optimizer

For the Powell optimizer, the method used is based on the number of dimensions of the problem. For optimization problems of single dimension (i.e., problems with a single parameter), the golden section search algorithm [108 (p. 2372)] is used to find the optimal value for the objective function. In this algorithm, the optimal value is found by reducing the size of the bracketing triplet, until the size of the bracket

(i.e., the distance between the outer points of the triplet) reaches a certain tolerance level. In all the cases, the middle point of the new triplet is determined to be the best value obtained so far.

For multidimensional problems (i.e., problems with multiple parameters), the minimum value and the largest decrease is found using the golden search algorithm for each dimension, in order to find the conjugate directions. A conjugate direction is a direction that when searched will not alter the minimum value attained by the previous movement in another direction; in other words, a direction in which the gradient is perpendicular to the first direction. After finding the N linearly independent, mutually conjugate directions, one pass will find the exact minimum value. For functions that are not quadratic, repeated cycles of N line minimizations will converge to minimum.

12.3.5. The Rosenbrock Optimizer

In the Rosenbrock optimizer [109 (p. 2373)], after the initial direction is found, multiple steps are taken in that direction until the least value is attained. The process starts with an arbitrary length e . If this initial step succeeds (i.e., the new value of the function is less than or equal to the old value), the length e is multiplied by α , where α is more than 1. If the steps fails, the length e is multiplied by β , where β is between -1 and 0. The direction or the parameter which needs to be modified is determined by advancing all the parameters by the step length e and then selecting the best among those which yield a function value that is less than the previous value. After that point is accepted as the best point, the process is repeated. These steps continue to repeat until e becomes so small so that any further change in the value of e does not significantly reduce the value of the function.

12.4. Setting Up the Mesh Morpher/Optimizer

The procedure for setting up and using the mesh morpher/optimizer for shape optimization is as follows:

1. Read the case into ANSYS FLUENT.

File → Read → Case...

2. If you want to use one of the built-in optimizers rather than specifying the deformation manually, you will need to provide an objective function in one of three ways: either as a UDF, a Scheme source file, or a customized function that is based on output parameters (i.e., values from flux, force, surface integral, or volume integral reports). The goal of the optimizer is to deform the mesh in such a way that this objective function is minimized. ANSYS FLUENT will run the solution for a given design stage until convergence is reached, and then check to see if the objective function is satisfied. If the objective function is not satisfied, ANSYS FLUENT will proceed to the next design, and so on, until convergence is achieved from the point of view of the optimizer. You can specify the optimizer convergence criteria in step 8.d.iii.
 - a. If you want to provide the objective function as a user-defined function (UDF), perform the steps that follow. For more information about UDFs, see the separate [UDF Manual](#).
 - i. Write a UDF using the `DEFINE_ON_DEMAND` macro to define the objective function. The function name must be `objective_function`. At the end of the objective function, the `rpvar morpher/objective_function` needs to be set to the `(current - target)` value. It is this value that the optimizer will attempt to minimize.
 - ii. Compile the UDF using the **Compiled UDFs** dialog box. Make sure `libudf` appears as the **Library Name**.

Define → User-Defined → Functions → Compiled...

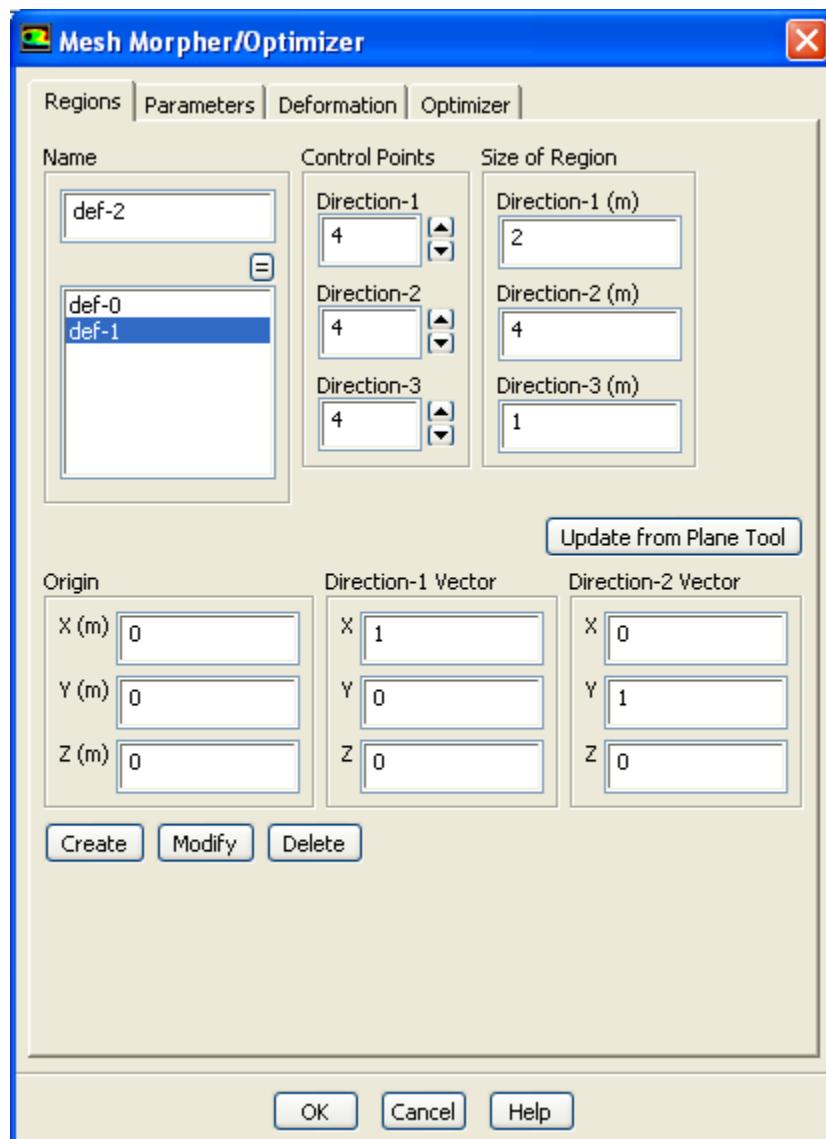

- b. If you want to provide the objective function as a Scheme source file, perform the following steps:

- i. Write a Scheme source file to define the objective function. The procedure name must be `objective-function`. At the end of the objective function, the `rpvar` morpher/objective-function needs to be set to the `(current - target)` value. It is this value that the optimizer will attempt to minimize.
 - ii. Load the Scheme source file (see *Reading Scheme Source Files* (p. 75) for details).
3. Open the **Mesh Morpher/Optimizer** dialog box by clicking the **Define/Mesh Morpher/Optimizer...** menu item.

Define → Mesh Morpher/Optimizer...

The first time you select the **Define/Mesh Morpher/Optimizer...** menu item in a session, a question dialog box will ask you whether you want to enable the mesh morpher/optimizer. Click **Yes** to load the libraries and open the **Mesh Morpher/Optimizer** dialog box (*Figure 12.1* (p. 671)).

Figure 12.1 The Regions Tab of the Mesh Morpher/Optimizer Dialog Box

4. Define the region(s) of the domain where the mesh will be deformed in order to optimize the shape, by performing the following steps in the **Mesh Morpher/Optimizer** dialog box. Each deformation region will be defined as a “box”, that is, a rectangle for 2D cases and a rectangular hexahedron for 3D cases.

Important

It is recommended that you define each deformation region to be bigger than the area of interest, in order to maintain proper continuity between deforming and non-deforming regions.

- a. Click the **Regions** tab to reveal the settings shown in *Figure 12.1* (p. 671).
- b. Enter a name for a deformation region in the text-entry box at the top of the **Name** group box.
- c. Define an origin for the deformation region by entering the Cartesian coordinates of a point in the **X**, **Y**, and (for 3D) **Z** number-entry boxes in the **Origin** group box.
- d. Define the first direction vector of the deformation region relative to the **Origin** coordinates, by entering values in the **X**, **Y**, and (for 3D) **Z** number-entry boxes in the **Direction-1 Vector** group box.

For 2D cases, ANSYS FLUENT will automatically define the second direction vector of the deformation region to be perpendicular to the **Direction-1 Vector**, and will display the components in the uneditable **Direction-2 Vector** group box.

- e. For 3D cases, define the second direction vector of the deformation region relative to the **Origin** coordinates, by entering values in the **X**, **Y**, and **Z** number-entry boxes in the **Direction-2 Vector** group box. If the vector you define is not perpendicular to the **Direction-1 Vector**, ANSYS FLUENT will automatically redefine the second vector to be the projection of the **Direction-2 Vector** you entered onto a plane that is perpendicular to the **Direction-1 Vector**. Based on this definition, the **Direction-2 Vector** you define cannot be colinear with the **Direction-1 Vector**.

The third direction vector of the deformation region will be automatically defined as the cross product of the first and second direction vectors.

- f. You have the option of using the line tool (for 2D cases) or the plane tool (for 3D cases) to define the direction vectors of the deformation region. Set up the line tool or the plane tool (as described in *Using the Line Tool* (p. 1481) and *Using the Plane Tool* (p. 1485), respectively), and then click the **Update from Line Tool** or **Update from Plane Tool** button to update the values in the **Direction-1 Vector** and (for 3D cases) **Direction-2 Vector** group boxes.
- g. Define the overall dimensions of the deformation region by entering length values for **Direction-1**, **Direction-2**, and (for 3D cases) **Direction-3** in the **Size of Region** group box.
- h. Define the number of control points you want along each direction vector of the deformation region by entering values for **Direction-1**, **Direction-2**, and (for 3D cases) **Direction-3** in the **Control Points** group box. The total number of control points for the region will be the product of the numbers you enter. Increasing the number of control points allows you greater control of the deformation, but also increases the computational expense.

Important

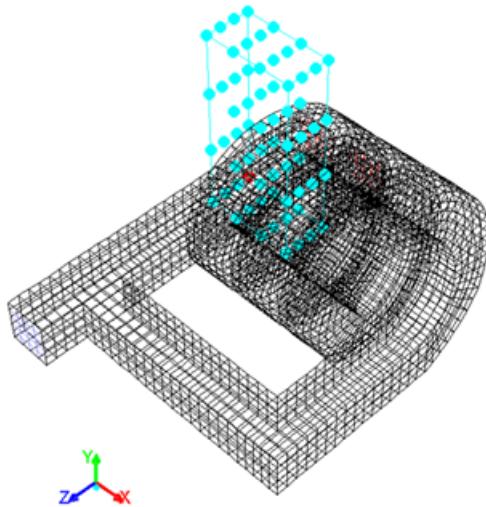

When you define multiple deformation regions, you must ensure that all the deformation regions have the same number of control points in each direction.

- i. Save the settings you have created for the deformation region by clicking the **Create** button. The name of the deformation region will be added (and selected) in the selection list at the bottom of the **Name** group box. A new default name will be automatically entered in the text-entry box

at the top of the **Name** group box, in preparation for any deformation regions you wish to create in the future.

Note that the control points of the deformation region selected in the **Name** selection list will be automatically displayed in the graphics window (see [Figure 12.2 \(p. 673\)](#)). If you would like to have no control points displayed in the graphics window, you can deselect the item by clicking the button located above the right side of the **Name** selection list.

Figure 12.2 Displaying the Control Points of a Deformation Region

- j. If you need to modify the deformation region at any point, select it in the **Name** selection list, revise the appropriate settings, and click the **Modify** button. The updated control points will be displayed in the graphics window.

Important

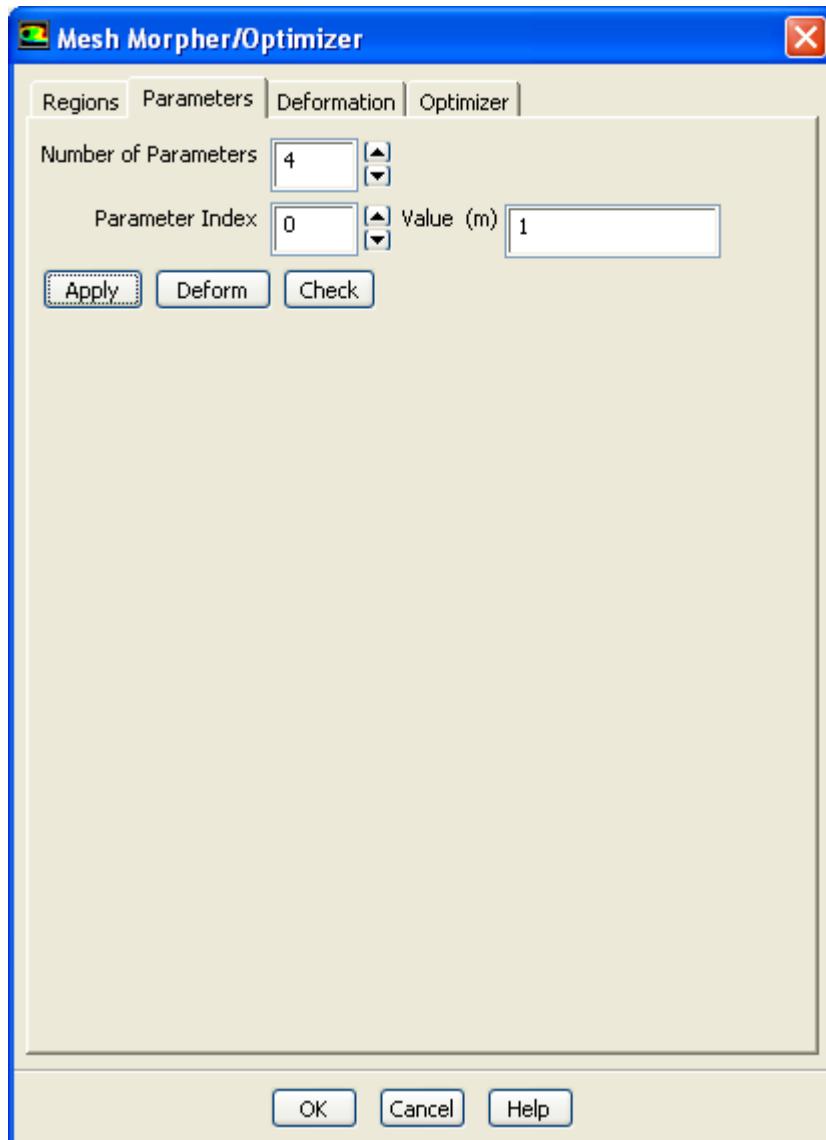

When modifying an existing deformation region, be sure to click **Modify** rather than **Create**. If you click **Create**, you will not modify the deformation region, but will instead create a new one with the modified settings.

- k. If you need to delete the deformation region at any point, select it in the **Name** selection list and click the **Delete** button.
 - l. Create any additional deformation regions as necessary by repeating steps 4.b.–k.
-

Important

Overlapping deformation regions are not supported.

5. Set up the parameters for deformation.
 - a. Click the **Parameters** tab to reveal the settings shown in [Figure 12.3 \(p. 674\)](#).

Figure 12.3 The Parameters Tab of the Mesh Morpher/Optimizer Dialog Box

- b. Enter the **Number of Parameters**. This number may be as low as the maximum number of parameters you will define on a single control point, or as high as the total number of parameters you will set on all of the control points combined.
- c. If you want to manually specify the deformation rather than using the built-in optimizers, perform the following steps to define the parameters:
 - i. Click the **Optimizer** tab to reveal the settings shown in *Figure 12.5* (p. 678).
 - ii. Select **none** from the **Optimizer** drop-down list.
 - iii. Click the **Parameters** tab.
 - iv. Enter the **Parameter Index** for the parameter you wish to define. Note that the first parameter has an index of **0**.
 - v. Enter the **Value** for the parameter specified in **Parameter Index**. The **Value** defines a magnitude of deformation for the parameter, which is then multiplied with each of the directional components you specify in the **Scaling Factors** group box of the **Deformation** tab to produce the overall displacement of a control point.

Note that the **Value** text-entry box is only editable when you have **none** selected from the **Optimizer** drop-down list in the **Optimizer** tab.

- vi. Click the **Apply** button to save the setting for the parameter.
 - vii. At any point you can use the **Deform** and **Check** buttons, to display the deformed mesh in the graphics window and to check the mesh, respectively. These buttons are more fully described in the steps that follow, as they are also available in the **Deformation** tab and are more useful after you have finalized the **Deformation** tab settings.
 - viii. Repeat steps 5.c.iv.–vii. until all of the parameters have been defined.
6. You have the option of defining constraints on the boundary zones, in order to limit the freedom of particular zones that fall within the deformation region(s) during the morphing of the mesh. The following options are available:
- unconstrained
- This option specifies that the boundary zone is completely free to be deformed according to the assigned parameters. By default, all wall zones are unconstrained.
- fixed
- This option specifies that the boundary zone is fixed and will not be deformed. None of the zones are fixed by default.

Important

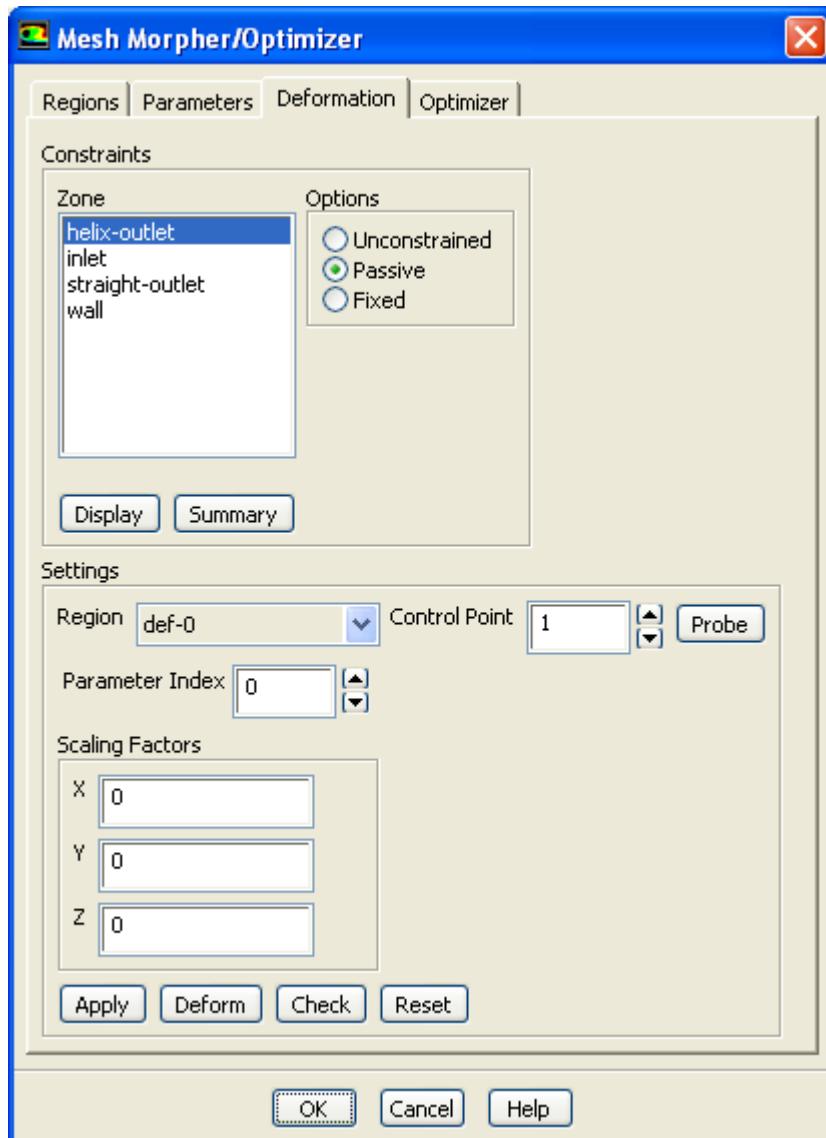

If you specify one or more fixed boundary zones in a deformation region, you must ensure that there is at least one unconstrained boundary zone in the region as well.

- passive

This option specifies that the nodes of the boundary zone are partially constrained to varying degrees, based on their proximity to adjacent boundary zones that are fixed. The nodes in a passive boundary zone behave in a similar manner to the interior mesh nodes, in order to ensure that there is a smooth transition between fixed and unconstrained boundary zones. By default, all boundary zones that are not walls (e.g., inlets, outlets, symmetry, and periodic boundaries) are passive.

To define the constraints on the boundary zones, perform the following steps.

- a. Click the **Deformation** tab to reveal the settings shown in *Figure 12.4* (p. 676).

Figure 12.4 The Deformation Tab of the Mesh Morpher/Optimizer Dialog Box

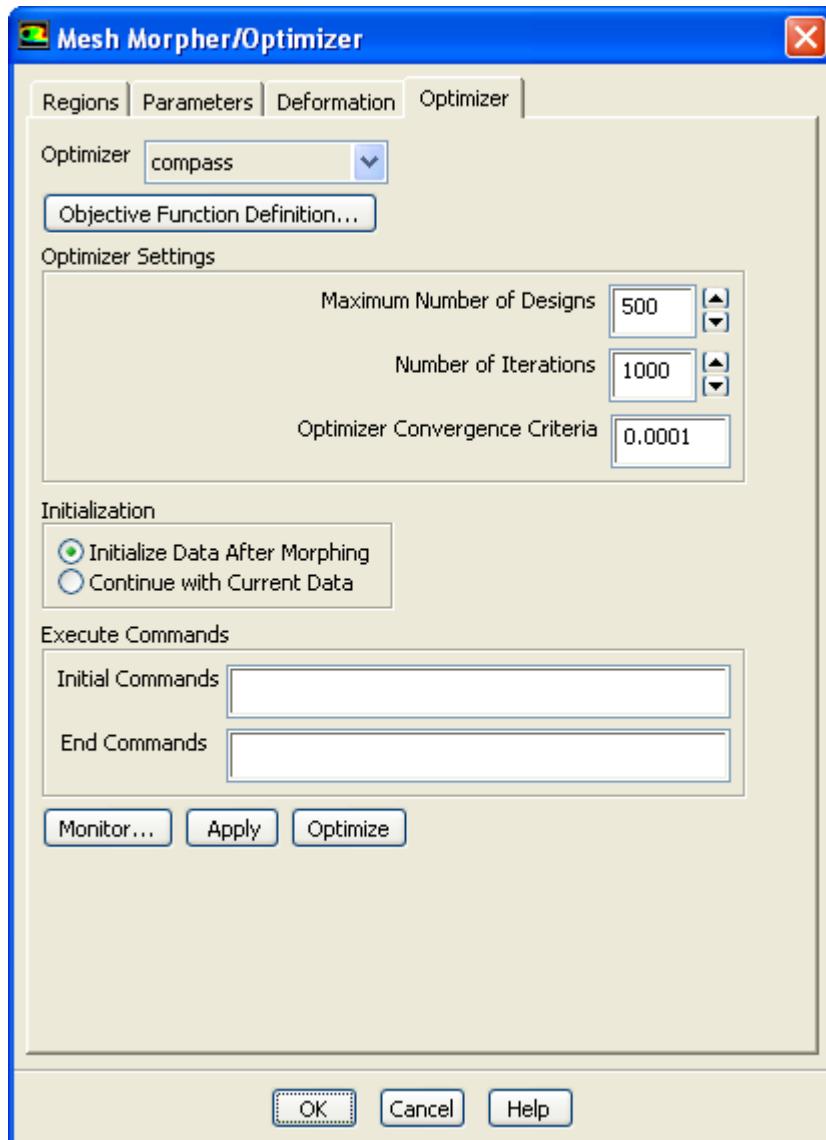

- b. To revise the default constraint on a boundary zone, select the zone name from the **Zones** selection list in the **Constraints** group box, and then select either **Unconstrained**, **Passive**, or **Fixed** from the **Options** list.
 - c. Click **Display** if you want view the boundary zone selected from the **Zones** selection list, in order to verify the zone for which you are defining constraints.
 - d. Click **Summary** if you would like to print a list in the console that summarizes the constraint definitions for all of the boundary zones.
7. Assign the deformation parameters to the control points.
- a. Click the **Regions** tab and select a region from the **Name** selection list, so that it is displayed in the graphics window.
 - b. Click the **Deformation** tab to reveal the settings shown in *Figure 12.4 (p. 676)*.
 - c. Select the same region you selected in step 7.a. (i.e., the displayed region) from the **Region** drop-down list in the **Settings** group box.

- d. Specify a control point in the current **Region** to which you want to assign deformation parameters by entering the index number for **Control Point**. The current **Control Point** will be highlighted in the graphics window; if you want to see the highlighted control point and cannot locate it, you should adjust the view in the graphic display window.
Alternatively, you can specify the control point by clicking the **Probe** button and clicking on a control point in the graphics window with the **mouse-probe** button of the mouse (see *Controlling the Mouse Button Functions* (p. 1548) for details).
- e. Enter the **Parameter Index** of a parameter you want to assign to the current **Control Point**. Note that the first parameter has an index of **0**.
- f. Define the scaling factors that will be applied to the deformation parameters in the **X**, **Y**, and (for 3D) **Z** directions by entering values in the **Scaling Factors** group box. If you use a built-in optimizer, these scaling factors provide the direction of the displacement of the control point and the optimizer determines the overall magnitude of displacement. Alternatively, if you manually specify the deformation, the values you enter in the **Scaling Factors** group box are multiplied with the **Value** specified in the **Parameters** tab to define the displacement of the control point.
- g. Click the **Apply** button to save the settings for the current **Parameter Index** of the current **Control Point**.
- h. If **none** is selected from the **Optimizer** selection list in the **Optimizer** tab, you can click the **Deform** button to display the deformed mesh (that results from the saved parameter settings) in the graphics display. The **Deform** button allows you to manually specify the deformation.
- i. If **none** is selected from the **Optimizer** selection list in the **Optimizer** tab, you can click the **Check** button to print out a mesh check report in the console for the currently displayed mesh. The mesh check report is the same as that produced by the **Check** button in the **General** task page, as described in *Mesh Check Report* (p. 174).

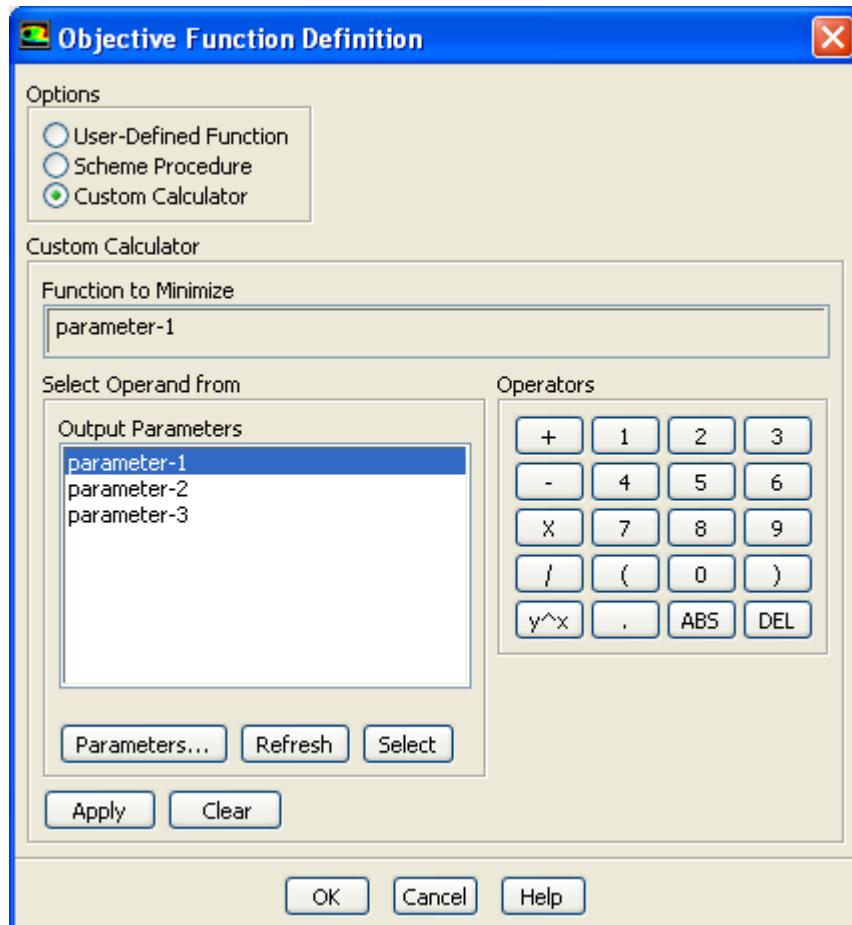

Important

If you save parameter settings but do not click the **Deform** button, the mesh check report will not account for the mesh that is produced from those settings.

- j. Click the **Reset** button if you want to revert to the original mesh without the deformations that result from the **Deform** button.
 - k. Repeat steps 7.e.–j. for each additional parameter you want to define for the current **Control Point** in the current **Region**.
 - l. Repeat steps 7.d.–k. for each additional control point in the current **Region** to which you want to assign deformation parameters.
 - m. Repeat steps 7.a.–l. for each additional region in which you want to apply parameters to control points.
8. If you are using the built-in optimizers, define the optimizer settings.
 - a. Click the **Optimizer** tab to reveal the settings shown in *Figure 12.5* (p. 678).

Figure 12.5 The Optimizer Tab of the Mesh Morpher/Optimizer Dialog Box

- b. Select an optimizer from the **Optimizer** drop-down list. The available optimizers are not based on gradients, and include the following: **compass**, **powell**, **rosenbrock**, **simplex**, and **torczon**. For more information about how these optimizers function, see *Optimizers* (p. 668).
- c. Click the **Objective Function Definition...** button to open the **Objective Function Definition** dialog box (*Figure 12.6* (p. 679)).

Figure 12.6 The Objective Function Definition Dialog Box

- i. Make a selection in the **Options** group box to specify whether the objective function that will be minimized during the optimization process is a **User-Defined Function**, a **Scheme Procedure**, or a customized function of output parameters as defined by the **Custom Calculator**. Your selection should correspond with the actions you took in step 2.
- ii. If you selected **Custom Calculator** in the previous step, define the objective function via the GUI controls in the **Custom Calculator** group box. As you click the buttons in this group box, text and symbols will appear in the **Function to Minimize** text box. You *cannot* edit the contents of this box directly; if you want to delete part or all of the function, use the **DEL** or **Clear** button, respectively.

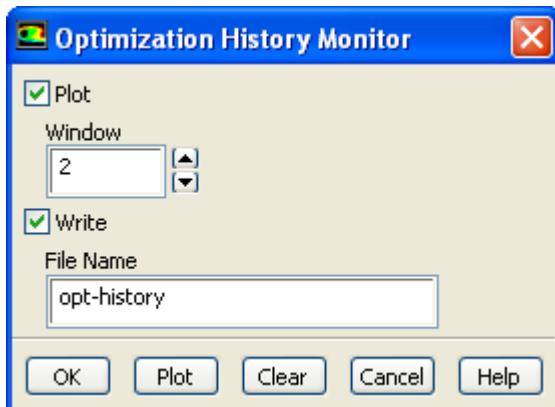

You can include output parameters in the definition of the function by making a selection from the **Output Parameters** list and clicking **Select**. If you want to add a new output parameter to the selection list or check the definition of an existing one, you can click the **Parameters...** button and use the **Parameters** dialog box (as described in [Creating Output Parameters \(p. 1633\)](#)); be sure to click the **Refresh** button when you return to the **Objective Function Definition** dialog box, so that the **Output Parameters** list is updated. You can also use **Operators** to manipulate the output parameters in the function.

You can click the **Apply** button at any point to save your function. When it is fully defined, click the **OK** button to save your settings and close the **Objective Function Definition** dialog box.

- d. Define the settings in the **Optimizer Settings** group box.

- i. Enter a value for **Maximum Number of Designs**, to specify the maximum number of design stages the optimizer will undergo to reach the specified objective function. Note that this number is not the number displayed in the console during the optimization process. Each optimizer undergoes a certain number of design modifications (called “runs”) before it converges to a design for a particular design stage. The **Run** number displayed in the console refers to the actual design modifications (including the inner loop) irrespective of the optimizer, whereas the **Maximum Number of Designs** value is the maximum number of converged designs provided by the optimizer.
- ii. Enter the **Number of Iterations**, to specify the maximum number of iterations ANSYS FLUENT performs for each design change.
- iii. Enter a number for **Optimizer Convergence Criteria**, to specify the convergence criteria for the optimizer.
- e. Specify how the solution variables should be treated after the mesh is deformed by making a selection in the **Initialization** group box. Select **Initialize Data After Morphing** to specify that the solution variables should be initialized to the values specified in the **Solution Initialization** task page after deformation. Select **Continue with Current Data** to specify that the solution variables remain the values obtained in the previous design iteration.
- f. If you want to plot and/or record the optimization history (i.e., how the value of the objective function varies with each design stage), click the **Monitor...** button to open the **Optimization History Monitor** dialog box (*Figure 12.7 (p. 680)*). Then perform the steps that follow.

Figure 12.7 The Optimization History Monitor Dialog Box

- i. Enable the **Plot** option if you want to display a plot of the optimization history in the graphics window indicated in the **Window** number-entry box. Note that if you want to observe the mesh deformations during the optimization process, you must make sure that **Window** is not set to the ID of the graphics window that is displaying the mesh.
- ii. Enable the **Write** option if you want to save the optimization history data in a file, and specify the **File Name**.

Note that you can display a plot of the optimization history data generated during the last calculation, even if the **Plot** or the **Write** options were not enabled during the calculation, as long as you have not discarded the data using the **Clear** button. Simply click the **Plot** button and the plot will be displayed in the active graphics window.

- g. You have the option of specifying commands that will be executed during the optimization runs of the mesh morpher/optimizer, via the text-entry boxes in the **Execute Commands** group box. A command can be a text command or the name of a command macro you have

defined (or will define), as described in [Defining Macros \(p. 1402\)](#). You can also enter a series of text commands and/or macros, as long as they are separated by a semi-colon (;).

During optimization runs, deformation occurs as part of every design iteration. You decide the specific point during the design iteration that the command is executed:

- If you want a command to be executed after the design has been modified, but before ANSYS FLUENT has started to run the calculation for that design stage, enter the command in the **Initial Commands** text-entry box. There are no restrictions on the commands that can be entered: you can enter commands that read saved data, perform FMG initialization, execute an entirely independent on-demand UDF, or even call a Scheme routine.
- If you want a command to be executed after the solution has run and converged for a design stage, enter the command in the **End Commands** text-entry box. There are no restrictions on the commands that can be entered. Examples are commands for postprocessing solution variables, monitoring contours and vectors of different variables, taking snapshots of each design change, etc. at every design stage.

Important

If the command to be executed involves saving a file, see [Saving Files During the Calculation \(p. 1404\)](#) for important general information.

As noted in [Automatic Numbering of Files \(p. 63\)](#), the special character, %i, can be used to create unique file names by including the iteration number. However, by default, the solution will be initialized after each mesh deformation and the iteration count restarted. Therefore, the resulting file name cannot be used to identify which design stage produced it (i.e., the first design stage may converge at 50 iterations, and then the second design stage may converge at 43 iterations). The time that the file was created is a better way to identify where in the series of design stages the file was generated. In addition, some files may be overwritten if two design stages converge in the same number of iterations. Alternatively, if you have selected **Continue with Current Data** under **Initialization** when setting up the optimizer, then the iteration count will not reset and no duplicate filenames will occur.

- h. Click the **Apply** button to save your optimizer settings.
- i. Click the **Optimize** button to initiate the optimization process. Information about each run (i.e., each design modification) that is generated as part of the production of a design stage will be displayed in the console, and the deformed mesh for each run will be updated in the graphics window.
9. Click **OK** to close the **Mesh Morpher/Optimization** dialog box.
10. Run your case file with the deformed mesh.
11. If you want to rerun a case file in which the mesh has been deformed by the **Optimize** button in the **Optimizer** tab, you must revise the settings in the **Mesh Morpher/Optimizer** dialog box so that they are suitable for the revised mesh.

Chapter 13: Modeling Turbulence

This chapter provides details about how to use the turbulence models available in ANSYS FLUENT.

Information about turbulence modeling theory is presented in "[Turbulence](#)" in the [Theory Guide](#). Information about using the turbulence models can be found in the following sections:

- 13.1. Introduction
- 13.2. Choosing a Turbulence Model
- 13.3. Steps in Using a Turbulence Model
- 13.4. Setting Up the Spalart-Allmaras Model
- 13.5. Setting Up the $k-\varepsilon$ Model
- 13.6. Setting Up the $k-\omega$ Model
- 13.7. Setting Up the Transition $k-kl-\omega$ Model
- 13.8. Setting Up the Transition SST Model
- 13.9. Setting Up the Reynolds Stress Model
- 13.10. Setting Up the Scale-Adaptive Simulation (SAS) Model
- 13.11. Setting Up the Detached Eddy Simulation Model
- 13.12. Setting Up the Large Eddy Simulation Model
- 13.13. Setting Up the Embedded Large Eddy Simulation (ELES) Model
- 13.14. Setup Options for all Turbulence Modeling
- 13.15. Defining Turbulence Boundary Conditions
- 13.16. Providing an Initial Guess for k and ε (or k and ω)
- 13.17. Solution Strategies for Turbulent Flow Simulations
- 13.18. Postprocessing for Turbulent Flows

13.1. Introduction

Turbulence is the three-dimensional unsteady random motion observed in fluids at moderate to high Reynolds numbers. As technical flows are typically based on fluids of low viscosity, almost all technical flows are turbulent. Many quantities of technical interest depend on turbulence, such as:

- Mixing of momentum, energy and species
- Heat transfer
- Pressure losses and efficiency
- Forces on aerodynamic bodies
- etc.

While turbulence is, in principle, described by the Navier-Stokes equations, it is not feasible in most situations to resolve the wide range of scales in time and space by Direct Numerical Simulation (DNS) as the CPU requirements would by far exceed the available computing power for any foreseeable future. For this reason, averaging procedures have to be applied to the Navier-Stokes equations to filter out all, or at least, parts of the turbulent spectrum. The most widely applied averaging procedure is Reynolds-averaging (which, for all practical purposes is time-averaging) of the equations, resulting in the Reynolds-Averaged Navier-Stokes (RANS) equations. By this process, all turbulent structures are eliminated from the flow and a smooth variation of the averaged velocity and pressure fields can be obtained. However, the averaging process introduces additional unknown terms into the transport equations (Reynolds

Stresses and Fluxes) which need to be provided by suitable turbulence models (turbulence closure). The quality of the simulation can depend crucially on the selected turbulence model and it is important to make the proper model choice as well as to provide a suitable numerical grid for the selected model. An alternative to RANS are Scale-Resolving Simulation (SRS) models. With SRS methods, at least a portion of the turbulent spectrum is resolved in at least a part of the flow domain. The most well-known such method is Large Eddy Simulation (LES), but many new hybrids (models between RANS and LES) are appearing. As all SRS method require time-resolved simulations with relatively small time steps, it is important to understand that these methods are substantially more computationally expensive than RANS simulations.

ANSYS FLUENT provides the following choices of turbulence models:

- Spalart-Allmaras model
- k - ε models
 - Standard k - ε model
 - Renormalization-group (RNG) k - ε model
 - Realizable k - ε model
- k - ω models
 - Standard k - ω model
 - Shear-stress transport (SST) k - ω model
- $v^2 - f$ model (add-on)
- Transition k - kL - ω model
- Transition SST model
- Reynolds stress models (RSM)
 - Linear pressure-strain RSM model
 - Quadratic pressure-strain RSM model
 - Stress-omega RSM model
- Scale-Adaptive Simulation (SAS) model
- Detached eddy simulation (DES) model, which includes one of the following RANS models.
 - Spalart-Allmaras RANS model
 - Realizable k - ε RANS model
 - SST k - ω RANS model
- Large eddy simulation (LES) model, which includes one of the following sub-scale models.
 - Smagorinsky-Lilly subgrid-scale model
 - WALE subgrid-scale model
 - Dynamic Smagorinsky model
 - Kinetic-energy transport subgrid-scale model

13.2. Choosing a Turbulence Model

It is an unfortunate fact that no single turbulence model is universally accepted as being superior for all classes of problems. The choice of turbulence model will depend on considerations such as the physics of the flow, the established practice for a specific class of problem, the level of accuracy required, the available computational resources, and the amount of time available for the simulation. To make the most appropriate choice of model for your application, you need to understand the capabilities and limitations of the various options.

The purpose of this section is to give an overview of issues related to the turbulence models provided in ANSYS FLUENT. The computational effort and cost in terms of CPU time and memory of the individual models is discussed. While it is impossible to state categorically which model is best for a specific application, general guidelines are presented to help you choose the appropriate turbulence model for the flow you want to model.

For additional information, please see the following sections:

- 13.2.1. Reynolds Averaged Navier-Stokes (RANS) Turbulence Models
- 13.2.2. Scale-Resolving Simulation (SRS) Models
- 13.2.3. Grid Resolution SRS Models
- 13.2.4. Numerics Settings for SRS Models
- 13.2.5. Model Hierarchy

13.2.1. Reynolds Averaged Navier-Stokes (RANS) Turbulence Models

RANS models ([Reynolds \(Ensemble\) Averaging](#) in the [Theory Guide](#)) offer the most economic approach for computing complex turbulent industrial flows. Typical examples of such models are the $k-\epsilon$ or the $k-\omega$ models in their different forms. These models simplify the problem to the solution of two additional transport equations and introduce an Eddy-Viscosity (turbulent viscosity) to compute the Reynolds Stresses. More complex RANS models are available which solve an individual equation for each of the six independent Reynolds Stresses directly (Reynolds Stress Models – RSM) plus a scale equation (ϵ -equation or ω -equation). RANS models are suitable for many engineering applications and typically provide the level of accuracy required. Since none of the models is universal, you have to decide which model is the most suitable for a given applications.

13.2.1.1. Spalart-Allmaras One-Equation Model

The Spalart-Allmaras model is a relatively simple one-equation model that solves a modeled transport equation for the kinematic eddy (turbulent) viscosity. The Spalart-Allmaras model was designed specifically for aeronautics and aerospace applications involving wall-bounded flows and has been shown to give good results for boundary layers subjected to adverse pressure gradients. It is also gaining popularity in turbomachinery applications. Do not use the model as a general purpose model, as it is not well calibrated for free shear flows (large errors for e.g., jet flows).

The Spalart-Allmaras model has been extended within ANSYS FLUENT with a y^+ -insensitive wall treatment (Enhanced Wall Treatment (EWT)). The EWT automatically blends all solution variables from their viscous sublayer formulation to the corresponding logarithmic layer values depending on y^+ . The blending is calibrated to also cover intermediate y^+ values in the buffer layer ($1 < y^+ < 30$)

13.2.1.2. $k-\varepsilon$ Models

Two-equation models are historically the most widely used turbulence models in industrial CFD. They solve two transport equations and model the Reynolds Stresses based using the Eddy Viscosity approach. The standard $k-\varepsilon$ model in ANSYS FLUENT falls within this class of models and has become the workhorse of practical engineering flow calculations in the time since it was proposed by Launder and Spalding [43] (p. 2369). Robustness, economy, and reasonable accuracy for a wide range of turbulent flows explain its popularity in industrial flow and heat transfer simulations.

The draw-back of all $k-\varepsilon$ models is their insensitivity to adverse pressure gradients and boundary layer separation. They typically predict a delayed and reduced separation relative to observations. This can result in overly optimistic design evaluations for flows which separate from smooth surfaces (aerodynamic bodies, diffusers, etc.). The $k-\varepsilon$ model is therefore not widely used in external aerodynamics.

In ANSYS FLUENT, the use of the Realizable $k-\varepsilon$ model is recommended relative to other variants of the $k-\varepsilon$ family. It is recommended to use the $k-\varepsilon$ model in combination with the Enhanced Wall Treatment (EWT). Refer to [Enhanced Wall Treatment \$\varepsilon\$ -Equation \(EWT- \$\varepsilon\$ \)](#) in the [Theory Guide](#) for details. For cases where the flow separates under adverse pressure gradients from smooth surfaces (airfoils, etc.), $k-\varepsilon$ models are generally not recommended.

13.2.1.3. $k-\omega$ Models

The ω -equation offers several advantages relative to the ε -equation. The most prominent one is that the equation can be integrated without additional terms through the viscous sublayer. This makes the formulation of robust y^+ -insensitive Enhanced Wall Treatment (EWT) relatively straightforward. Refer to [Enhanced Wall Treatment \$\omega\$ -Equation \(EWT- \$\omega\$ \)](#) in the [Theory Guide](#) for details. Furthermore, $k-\omega$ models are typically better in predicting adverse pressure gradient boundary layer flows and separation. The downside of the standard ω -equation is a relatively strong sensitivity of the solution depending on the freestream values of k - and ω - outside the shear layer. The use of the standard $k-\omega$ model is, for this reason, not generally recommended in ANSYS FLUENT.

The SST $k-\omega$ model has been designed to avoid the freestream sensitivity of the standard $k-\omega$ model, by combining elements of the ω -equation and the ε -equation. In addition, the SST model has been calibrated to accurately compute flow separation from smooth surfaces. Within the $k-\omega$ model family, it is therefore recommended to use the SST model. The SST model is one of the most widely used models for aerodynamic flows. It is typically somewhat more accurate in predicting the details of the wall boundary layer characteristics than the Spalart-Allmaras model. The SST model (as all ω -equation based models) uses the enhanced wall treatment as default.

For the $k-\omega$ models, so-called low Reynolds number terms (low Re) have been proposed by Wilcox. These are available in ANSYS FLUENT as an option. It is important to point out that these terms are not required for integrating the equations through the viscous sublayer. Their main influence lies in mimicking laminar-turbulent transition processes. However, this functionality is not widely calibrated and for wall-boundary layer transition, the combination of the SST model with the Transition SST model ([Transition SST Model](#) in the [Theory Guide](#)) or the $k-kL$ transition model ([\$k\$ - \$kL\$ - \$\omega\$ Transition Model](#) in the [Theory Guide](#)) is more reliable. The use of the low- Re terms is therefore not encouraged.

13.2.1.4. RSM Models

Reynolds Stress models (RSM) include several effects which are not easily handled by Eddy-Viscosity models. The most important effect is the stabilization of turbulence due to strong rotation and streamline curvature (as observed e.g., in cyclone flows). RSM on the other hand often demand a significant increase in computing time partly due to the additional equations but mostly due to reduced

convergence. This additional effort is not always justified by increased accuracy. Their usage is therefore not generally recommended and should be restricted to flows for which their superiority has been established, especially flow with strong swirl and rotation. If wall boundary layers are important, the combination of RSM and the ω -equation is more accurate than the combination with the ϵ -equation.

13.2.1.5. Laminar-Turbulent Transition Models

Two models for transition prediction are available in ANSYS FLUENT, namely the SST-transition model and the k-kl Transition model. For many test cases, both models produce similar results. Due to its combination with the SST model, the SST-Transition model is favored. It is important to point out that only laminar-turbulent transition of wall boundary layers can be simulated with any of these two models.

Proper mesh refinement and specification of inlet turbulence levels is crucial for accurate transition prediction. In general, there is some additional effort required during the mesh generation phase because a low-Re mesh with sufficient streamwise resolution is needed to accurately resolve the transition region. Furthermore, in regions where laminar separation occurs, additional mesh refinement is necessary in order to properly capture the rapid transition due to the separation bubble. Finally, the decay of turbulence from the inlet to the leading edge of the device should always be estimated before running a solution as this can have a large effect on the predicted transition location. Physically correct values for the turbulence intensity (T_u) should be achieved near the location of transition.

13.2.1.6. Model Enhancements

There are many model enhancements available for turbulence models. While such enhancements can improve simulations in some cases, they can also have detrimental effects. The general recommendation is therefore to use them with caution.

As noted above, the use of low-Re terms in combination with the ω -equation is not generally recommended.

Another model enhancement which should be used with care is the compressibility correction of Sarkar ([73] (p. 2371)). It can improve the prediction of free shear layers at high Mach numbers, but has also shown a pronounced negative impact on wall boundary layers. It is therefore not generally recommended. For historic reasons it is set to default for the compressible solver. It is advised to turn it off by hand unless the application is mainly to free shear flows.

Buoyancy has a pronounced effect on turbulence (Effects of Buoyancy on Turbulence in the Theory Guide). The use of the source term in the k-equation is therefore recommended for buoyancy affected flows. The source term in the ϵ -equation and ω -equation is much less established and the term should be activated with care.

13.2.1.7. Wall Treatment RANS Models

It is recommended to use the Enhanced Wall Treatment for all models for which it is available (Spalart-Allmaras, ϵ -equation and ω -equation). It provides the most consistent wall shear stress and wall heat transfer predictions with the least sensitivity to y^+ values. (see an Overview of the Spalart-Allmaras model, Enhanced Wall Treatment ϵ -Equation (EWT- ϵ), and Enhanced Wall Treatment ω -Equation (EWT- ω) in the Theory Guide for more information)

In case Wall Functions are used, it is necessary to avoid grids with fine near wall spacing. It is recommended to use $y^+ > 30$ in the entire domain. The application of Wall Functions is, however, not generally recommended as they do not allow a systematic refinement of the near wall grid. Wall Functions

are especially damaging for flows at low to medium Reynolds numbers ($Re \sim 10^4 - 10^6$), as the assumption of an extended logarithmic layer is not valid in these cases. In case that Wall Functions are desired, the option of Scalable Wall Functions ([Scalable Wall Functions](#) in the [Theory Guide](#)) avoids the grid restrictions and can be run on fine meshes.

13.2.1.8. Grid Resolution RANS Models

Grid generation has a strong impact on model accuracy. There are many considerations which have to be followed when generating high quality CFD grids. From a turbulence modelling standpoint, the most important one is that the relevant shear layers should be covered by at least ~ 10 cells normal to the layer. Below this resolution, the model will not be able to provide its calibrated performance. Especially for free shear flows, whose location is not known during grid generation, this is a requirement which is hard to achieve. Nevertheless, you should be aware that for lower resolution, the model performance can degrade.

For wall bounded flows, a structured mesh in wall-normal direction is highly recommended. The structured portion of the mesh should cover the entire boundary layer and extend beyond the boundary layer thickness to avoid restricting the growth of the boundary layer. Advanced turbulence models for wall boundary layers like the Spalart-Allmaras model and the SST model will only provide improved results to other models if a minimum of 10 or more structured (hex or prism) cells are located inside the boundary layer. In addition, one should ensure that the prism layer covers the wall boundary layer entirely. Note that these are not specific requirements of these models, but are general requirements for wall boundary layer simulations.

Both, ε -based and ω -based models offer Enhanced Wall Treatment options (see [Enhanced Wall Treatment \$\varepsilon\$ -Equation \(EWT- \$\varepsilon\$ \)](#) and [Enhanced Wall Treatment \$\omega\$ -Equation \(EWT- \$\omega\$ \)](#) in the [Theory Guide](#) for more information), which make the models relatively insensitive to the y^+ -value of the wall cell. Generally speaking, it is more important to ensure that the boundary layer is covered with sufficient cells, then to achieve a certain y^+ criterion. However, for simulations with high accuracy demands on the wall boundary layer (especially for heat transfer predictions) near wall meshes with $y^+ \sim 1$ are recommended. When wall functions are used, it is essential to avoid meshes with y^+ values lower than ~ 30 as the wall shear stress and the wall heat transfer can and will seriously deteriorate under such conditions. For this reason, the usage of Enhanced Wall Treatments (to be selected for ε -equation and default for ω -equation based models) is recommended.

For transition models (see [k- kL- \$\omega\$ Transition Model](#) and [Transition SST Model](#) in the [Theory Guide](#)), more stringent grid resolution requirements apply than for standard RANS models, as transition modelling requires the resolution of the thin laminar boundary layer upstream of the transition location. For this reason, a low-Re mesh ($y^+ < 1$) with sufficient streamwise resolution is needed to accurately resolve the transition region. Furthermore, in regions where laminar separation occurs, additional mesh refinement is necessary, in order to properly capture the rapid transition due to the separation bubble. Finally, the decay of turbulence from the inlet to the leading edge of the device should always be estimated before running a solution as this can have a large effect on the predicted transition location.

13.2.2. Scale-Resolving Simulation (SRS) Models

The alternative to RANS models are models which resolve at least a portion of the turbulence for at least a portion of the flow domain. Such models are generally termed 'Scale-Resolving'.

13.2.2.1. Large Eddy Simulation (LES)

The most widely known such modelling concept is Large Eddy Simulation (LES). It is based on the approach of resolving large turbulent structures in space and time down to the grid limit everywhere in the flow. However, while widely used in the academic community, LES had very limited impact on industrial simulations. The reason lies in the excessively high resolution requirements for wall boundary layers. Near the wall, the largest scales in the turbulent spectrum are nevertheless geometrically very small and require a very fine grid and a small time step. In addition, unlike RANS, the grid cannot only be refined in the wall normal direction, but also needs to resolve turbulence in the wall parallel plane. This can only be achieved for flows at very low Reynolds number and on very small geometric scales (the extent of the LES domain cannot be much larger than 10-100 times the boundary layer thickness parallel to the wall). For this reason the use of LES is only recommended for flows where wall boundary layers are not relevant and need not be resolved or for flows where the boundary layers are laminar due to the low Reynolds number. In such cases, the most balanced LES model is the WALE model (see [Wall-Adapting Local Eddy-Viscosity \(WALE\) Model](#) in the [Theory Guide](#)). It offers a good compromise between model complexity and generality. It also allows computing laminar shear (boundary) layers without any model impact.

An extension to LES is Wall-Modeled LES (WMLES). It allows the LES computation of wall bounded flows at higher Reynolds number without the large increase in grid resolution required for conventional LES at high Reynolds numbers. For WMLES, the grid resolution is largely independent of the Reynolds number with respect to the grid cells required per boundary layer volume (see [Algebraic Wall-Modeled LES Model \(WMLES\)](#) in the [Theory Guide](#)).

13.2.2.2. Hybrid RANS-LES Models

In order to avoid the high resolution requirements of LES, numerous hybrid models have been developed in recent years. These are models which combine certain elements of RANS and LES approaches in a way which allows the simulation of high Reynolds number flows. With hybrid models, the attached wall boundary layers are typically covered by the RANS part of the model, while large detached regions are handled in 'LES' mode, meaning with a partial resolution of the turbulent spectrum in space and time. Hybrid models rely on a strong enough flow instability to generate turbulent structures in the separated zone. This is typically the case for flows behind bluff bodies, where URANS models predict single-mode periodic vortex shedding. Hybrid models allow these vortices to generate smaller eddies down to the available grid limit. [Figure 13.1 \(p. 690\)](#) shows a typical scenario: While the application of a standard RANS model in unsteady mode results in a single frequency vortex shedding (left), the application of hybrid models allows a break-up of the large structures into smaller scales. This is beneficial for predicting the correct mixing behind the body or to extract spectral information (e.g., for acoustic simulations). At the same time, the wall boundary layers are covered by the RANS part of the hybrid model avoiding the excessive resolution requirements of LES.

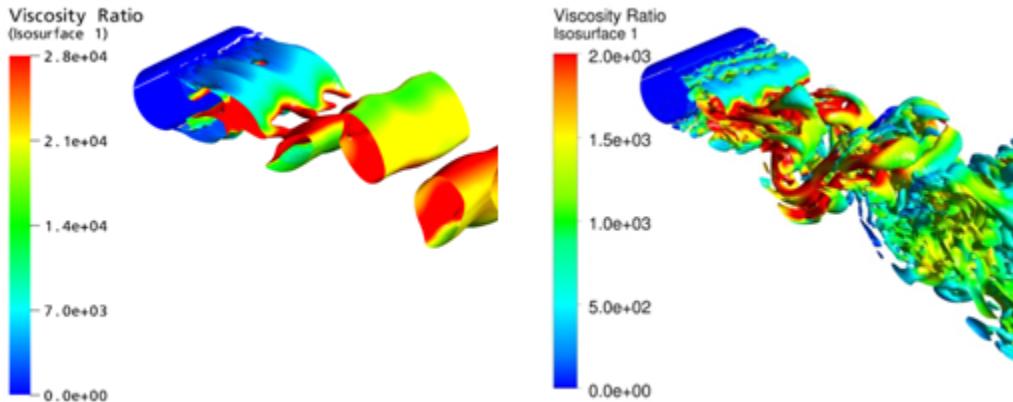

Figure 13.1 Illustration of SST-URANS vs. SST-SAS Models

Figure 13.1 (p. 690) shows a circular cylinder in a cross flow at $Re = 3.6 \times 10^6$. The left hand side illustrates the SST-URANS model, while the right-hand side illustrates the SST-SAS model. The iso-surface of $Q = S^2 - Q^2$ is colored according to the eddy viscosity ratio μ_t / μ (note that the scale in the right-hand side figure is smaller by a factor of 14).

13.2.2.2.1. Scale-Adaptive Simulation (SAS)

The SAS modelling approach (see [Scale-Adaptive Simulation \(SAS\) Model](#) in the [Theory Guide](#)) as proposed by Menter et al ([53] (p. 2370)[54] (p. 2370)) is based on the introduction of the von Karman length scale, L_{vK} , into the turbulence equations (in case of the SST model it enters into the ω -equation). L_{vK} is defined as the ratio of the first divided by the second derivative of the velocity vector (times the von Karman constant $\kappa=0.41$):

$$L_{vK} = \kappa \left| \frac{U'}{U''} \right| ; \quad U'' = \sqrt{\frac{\partial^2 U_i}{\partial x_k^2} \frac{\partial^2 U_i}{\partial x_j^2}} ;$$

$$U' = S = \sqrt{2 \cdot S_{ij} S_{ij}} ; \quad S_{ij} = \frac{1}{2} \left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_j}{\partial x_i} \right) \quad (13-1)$$

The inclusion of this term allows the model to adjust its length scale to already resolved scales in the flow and thereby provide a low enough eddy viscosity to allow the model to operate in 'LES' mode.

The SAS approach has the advantage that the RANS part of the model is unaffected by the grid spacing and will therefore not allow a deterioration of model accuracy as seen in DES in regions of refined grid but insufficient flow instability. However, in cases where the flow instability is not strong enough, the SAS will remain in RANS mode and will not produce unsteady structures. While this is often a sign that the RANS model is still reasonably capable of handling the flow, it is a limitation if unsteady information is required (e.g., in acoustics). In such cases, the internal interface option of the ELES implementation can be applied to convert modeled turbulence into resolved turbulence (see [Internal Interface Without LES Zone](#) in the [Theory Guide](#)).

13.2.2.3. Detached Eddy Simulation (DES)

The DES model (see [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#)) achieves the switch between RANS and LES by a comparison of the turbulent length scale L_t with the grid spacing (maximum of cell edge). The model selects the minimum of both and thereby switches between RANS and LES mode by replacing ε in the k-equation by:

$$\varepsilon = \frac{k^{3/2}}{L_t} \rightarrow \varepsilon = \frac{k^{3/2}}{\min(L_t, c_{DES} \Delta_{\max})} \quad (13-2)$$

Once the model selects the grid spacing as the minimum, the model is operating in 'LES' mode.

The grid spacing enters explicitly into the DES model. This can affect the RANS solution in regions, where the grid is between RANS and LES resolution (so-called 'gray zones' in DES) and/or where the flow instability is not strong enough to generate LES structures. Another issue to consider with DES is the problem of 'grid-induced-separation' (GIS). It occurs if the grid for an attached wall boundary layer flow is refined to a point where the DES limiter becomes active and affects the RANS solution. However, in such situations, the flow instability is not strong enough to balance the reduced RANS content by resolved turbulence. This will typically result in an artificial flow separation at the location of grid refinement. It typically happens if $\Delta_{\max} < \delta$ (δ being the boundary layer thickness). Remedies for this situation have been proposed by Menter et al. who recommended using the F1 and F2 blending functions of the SST-DES model to shield the boundary layers from the DES limiter. Later, alternative blending functions for the same purpose have been proposed by Spalart et al. ([74] (p. 2371)) – resulting in the terminology Delayed DES (DDES). The DDES model as originally proposed for the Spalart-Allmaras model provided limited protection against GIS for two-equation models such as SST and k- ε . Therefore, the DDES function has been re-calibrated for the SST and k- ε models and is now the recommended choice and the default setting when using these models.

A further refinement is provided by the Improved DDES (IDDES) formulation of Strelets et al. ([79] (p. 2371)), which extends the LES zone of the model to the outer part of wall boundary layers. This allows the simulation of wall boundary layers in Wall Modeled LES (WMLES) mode. In this model, the IDDES model is applied like a LES model, typically with the specification of unsteady inlet conditions. The grid resolution requirements for WMLES are much less stringent than for LES.

All of the above shielding function variants are available in ANSYS FLUENT. For the Spalart-Allmaras model, the original DDES shielding function is used. For the k- ε and the SST models, the DDES function has been re-calibrated for better boundary layer protection. The re-calibrated DDES function is the default selection and is recommended over the use of the F1-SST or F2-SST functions for the SST model. Despite the potential difficulties in the application of hybrid methods, they have the potential to greatly expand the usage of Scale-Resolving Simulation models for engineering applications, as they avoid the excessive resolution required by LES for wall boundary layers. IDDES in WMLES mode is an advanced option and should only be used if you are familiar with the original literature and the grid requirements for this model.

13.2.2.4. Zonal Modeling and Embedded LES (ELES)

As pointed out in the previous sections, hybrid models rely on flow instabilities to generate turbulent structures in large separated regions without the explicit introduction of unsteadiness through the boundary conditions. However, there are situations, where such instabilities are not present or are not reliable to serve this purpose. In such cases, it is desirable to apply RANS and the LES models in pre-defined zones and provide clearly defined interfaces between them. At these interfaces, the modeled

turbulent kinetic energy from the upstream RANS model is converted explicitly to resolved scales at an internal boundary to the LES zone. The LES zone can then be limited to the region of interest where unsteady results are required. ELES is available in ANSYS FLUENT and allows the combination of most RANS model with classical LES models. It is important to emphasize that in this mode, a full LES resolution is required within the LES zone. In the LES zone, using the WALE model is recommended (see [Wall-Adapting Local Eddy-Viscosity \(WALE\) Model](#) in the [Theory Guide](#)).

13.2.3. Grid Resolution SRS Models

Grid Resolution SRS models are discussed in the following sections:

13.2.3.1. Wall Boundary Layers

13.2.3.2. Free Shear Flows

13.2.3.1. Wall Boundary Layers

For a wall-resolved LES, it is typically recommended to use a mesh with a grid spacing scaling with $\Delta x^+ \approx 40$, $\Delta y^+ \approx 20$, $\Delta z^+ \approx 20$ where x is the streamwise, y the wall normal and z the spanwise direction (e.g., channel flow). However, in complex applications, the distinction between streamwise and spanwise direction is not feasible and then $\Delta x^+ \approx 20$, $\Delta y^+ \approx 20$, $\Delta z^+ \approx 20$ would be required. This scaling demonstrates the strong Reynolds number dependency of the LES approach for wall bounded flows.

For the IDDES model in WMLES mode, the above requirements can be relaxed. The grid spacing no longer scale with the wall friction, but with the boundary layer thickness δ . It is recommended to use $\Delta x \approx \Delta z \approx (0.05 - 0.1) \cdot \delta$. The wall normal resolution should be like for a finely resolved RANS simulation, meaning a near wall resolution of $\Delta y^+ \approx 1$ and around 30 nodes inside the boundary layer.

The other hybrid models, SAS and DDES, require near wall resolution as in the underlying RANS models, as the boundary layers are covered in RANS mode. For the DDES (and the IDDES model run in DDES mode) model, Grid Induced Separation (GIS) may occur when not using the SST-F2 shielding function for $\Delta x_{\max} < \delta$. For the SST-F2 function the value is more $\Delta x_{\max} < 0.1 \cdot \delta$. This does however to a certain extent depend on the pressure gradient. Note however, that the SST-F2 function can reduce the effectiveness of the DDES model to switch into scale-resolving mode.

13.2.3.2. Free Shear Flows

For free shear flows, it is difficult to provide general recommendations, as there are many different flow scenarios. The current recommendation is therefore based on the most common (and most frequent) free shear flow – a turbulent mixing layer. It will not necessarily apply to other free shear flows like jets and you are advised to perform tests as to the optimal resolution of your specific flow.

For free shear flows and SRS models, one should aim for uniform isotropic cells (all edges have similar length). The shear layer should be covered by ~10-20 cells. As the layer thickness is often hard to estimate, one can also look at the ratio

$$R_l = \frac{L_t}{\Delta_{\max}}; \quad L_t = \frac{k^{3/2}}{\varepsilon} = \frac{k^{1/2}}{0.09\omega} \quad (13-3)$$

Where Δ_{\max} is the maximum cell edge length. It is available in ANSYS CFD-Post for all turbulence models. This estimate should be based on the RANS solution and not on the SAS/DES solution for the given flow! The above requirement for the mixing layer translates into:

$$R_l > 5 - 10 \quad (13-4)$$

In these estimates, 10 cells across the layer (or $R_l = 5$) is truly a lower limit. The higher values of 20 cells and $R_l = 10$ are much safer.

13.2.4. Numerics Settings for SRS Models

For Scale-Resolving Simulations (SRS), specific discretization and solver settings are required to achieve optimal accuracy with minimal numerical effort. The recommendations given below should be considered as a starting point for your specific flow application and are not generic, but problem dependent. The recommendations are based on incompressible, single phase flow without chemical reactions or other complex additional physics. In case your simulation features additional complex physical effects, it requires adjusting the recommended solver settings accordingly. In most cases, this will mean that a higher effort needs to be invested into the coupling of the equations (e.g. lower time step, reduced under-relaxation, higher iteration count, smaller residuals), in order to avoid a de-coupling of different physical phenomena.

For SRS models, it is generally recommended to use the pressure-based solver, as it offers optimized schemes for resolving turbulence relative to the density based solver.

For Scale-Resolving Simulations, optimal numerics settings are essential for achieving accurate results in an acceptable time frame. The reason is that at the SRS models operate at the resolution limit of the provided grid where the smallest scales are of the order of the grid spacing and the time resolution. Numerics settings therefore have to be chosen to provide an optimal balance between accuracy and robustness.

It is generally recommended to initialize the solution from a (reasonably) converged RANS simulation.

13.2.4.1. Time Discretization

For Scale-Resolving Simulations, the resolution of the turbulent structures in time is essential for the success of the simulation. This is, to the largest extent, defined by the selected time step. As the SRS model is operating at the grid limit, you should select a time step that ensures a Courant-Friedrichs-Levy (CFL) number of

$$CFL = \frac{U \Delta t}{\Delta x} < 1 \quad (13-5)$$

The CFL number is computed by the solver and can be checked based on an initial RANS simulation, for example. It is important to emphasize that this is not a numerical limit and that the solver will be able to sustain much larger CFL numbers. In complex applications, there will always be limited regions of fine cells or large velocities and you should not restrict the CFL number based on such zones. The recommendation of $CFL = 1$ should be applied in the main SRS region in combination with a uniform

isotropic grid. It is recommended to vary the time step for each type of application and explore its optimal value. This can substantially save on computing costs.

The time derivative should be computed by the Second Order Implicit option. (See [User Inputs for Time-Dependent Problems](#) (p. 1366) for guidelines on setting solution parameters for transient calculations in general.)

13.2.4.2. Spatial Discretization

For SRS models, it is important to minimize the numerical dissipation of the scheme in order to avoid damping of the smallest scales by numerical dissipation. For spatial discretization, the choice is between the Central Difference (CD) scheme (see [Central-Differencing Scheme](#) in the [Theory Guide](#)) and the Bounded Central Difference scheme (BCD) (see [Bounded Central Differencing Scheme](#) in the [Theory Guide](#)). The Central Difference scheme is the least dissipative and provides the highest resolution accuracy for the smallest scales. Especially for aero-acoustics simulations, where the spectral content at higher frequencies can be important, this is a desirable feature. However, Central Difference schemes are prone to solution oscillations (checker boarding) in the velocity field. When using the Central Difference scheme, it is therefore important to provide a high quality mesh (no mesh jumps, isotropic cells and high resolution in critical zones) and to avoid large time steps (the CFL number should be smaller than 1 in the main SRS region). It is recommended to visually monitor the solution regularly in order to avoid wasting computational resources. In case oscillations appear, the choice is to: improve the mesh; reduce the time step; or to switch to the slightly more dissipative, but also more robust Bounded Central Difference scheme. In many complex applications, the Bounded Central Difference Scheme is the numerics option of choice. It typically provides sufficiently low dissipation to allow the turbulent structures to evolve, but, at the same time, is robust enough to handle non-optimal grids as they are typically encountered in industrial simulations. In addition, the Bounded Central Difference scheme is also suitable for hybrid methods like SAS and DES, and will provide stable solutions in RANS regions, with highly stretched grids and with a CFL number larger than 1. For ELES, the numerical scheme in the LES zone can be selected independently from the settings in the RANS zone. The RANS region can then be computed with standard higher order upwind schemes and the LES zone can be covered by either the Central Difference scheme or the Bounded Central Difference scheme.

For gradient discretization, it is recommended to select the Least Squares Cell Based option, or the Green-Gauss Node Based option, to ensure a second order interpolation on non-orthogonal grids.

For pressure interpolation, it is recommended to use the second order scheme, or the body-force-weighted scheme. Due to its higher dissipation, the PRESTO! scheme (see [Pressure Interpolation Schemes](#) in the [Theory Guide](#)) can result in a delayed formation or damping of turbulent structures. It is therefore not recommended for SRS.

13.2.4.3. Iterative Scheme

The selection of the iterative scheme will mostly affect the computational costs as the cost per iteration between these methods is rather different. However, recommendations are not straightforward, as the higher cost per iteration of a scheme can be offset by faster convergence within the time step.

The fastest scheme is the Non-Iterative Time Advancement (NITA) scheme (see [Non-Iterative Time-Advancement Scheme](#) in the [Theory Guide](#) as well as [Setting Solution Controls for the Non-Iterative Solver](#) (p. 1326)). This scheme typically works well for limited LES zones and high quality meshes. It is also important to ensure a low time step of a CFL number below 1. For the NITA scheme, all explicit under-relaxation factors are, by default, set equal to one. With NITA, it has slight advantages to use the fractional step method if there is no involvement of more complex physics, when otherwise the PISO scheme can be more beneficial.

In case the application is too complex for the NITA scheme to provide a solution, the iterative SIMPLEC ([SIMPLE vs. SIMPLEC \(p. 1322\)](#)) or PISO ([PISO \(p. 1322\)](#)) schemes are the next possible option. They should be preferred relative to the SIMPLE scheme, as they show faster convergence per time step and can be run with more aggressive under-relaxation (higher values equal to 1 or close to 1). If such settings prevent convergence within the time step, then check if your time step is small enough for maintaining CFL numbers below 1 in the SRS region – if not, then try reducing Δt . If this is not possible, or does not lead to satisfactory convergence, then reduce the under-relaxation factors to values between the default settings and 1. For skewed meshes or meshes with problematic quality, the reduction of explicit relaxation factor for pressure correction down to 0.7 from 1 can be very helpful.

13.2.4.3.1. Convergence Control

The convergence criterion within each time step will strongly affect solution costs, as a low criterion will result in an increased number of iterations. It is not possible to provide general recommendations, as the required residual depends on the application. The most relevant residual in the SRS models is the continuity residual. It should be converged by approximately 2 orders of magnitude per time step for a CFL number ~ 1 . This should be achievable with around 5-10 maximum iterations per time step for flows involving no other physical models. Be sure to check the impact of convergence on your solution to ensure that the residual is reduced to a level consistent with your problem.

For simulations with small CFL values, the **Extrapolate variables** option (available in the [Run Calculation Task Page \(p. 2107\)](#)) can be very beneficial. This can substantially reduce the number of iterations within the time step up to 40% when the convergence control is based on the convergence criteria.

In case your simulation requires the combination of additional physical models, such as combustion or multiphase, a reduction of the under-relaxation factors might be required. In this case, the number of maximum iterations per time step can be increased to achieve the desired residual reduction.

For hybrid RANS/LES simulations, such as the SAS and DES models, there can be situations where the RANS portion of the flow limits convergence (e.g., due to poor grid quality). In such cases, the application of the coupled solver should be considered. For the coupled pressure-based solver, each iteration is typically more expensive than for the SIMPLEC algorithm, but this is at least partly off-set by faster convergence. The recommendations concerning residuals are similar to the SIMPLEC method, but the maximal number of iterations can be reduced to values as low as 2-5 for highly unstable flows, and 5-10 for more sensible flows and acoustics simulations.

13.2.5. Model Hierarchy

As discussed, turbulence modelling is a balance between accuracy and cost. The recommendation is to use RANS models as much as possible and as long as they provide the accuracy required for the simulation. RANS models will remain the work-horse of turbulence modelling for many years to come. Within the RANS family, eddy-viscosity models are typically sufficient for most engineering flow simulations. The application of RSM is only recommended for flows which are known to systematically benefit from their usage and justify the increase in computing power.

In cases where steady RANS or URANS models cannot provide the accuracy or unsteady information required, it is recommended to switch to the SAS approach. It is relatively forgiving in terms of the grid resolution and will not deteriorate the results in case of insufficient resolution in the unsteady zone. The SAS model will only provide scale-resolution if a strong flow instability is present. Visual inspection (using iso-surfaces of the Q-criterion) will quickly allow a judgment if the model provides sufficient unsteadiness and resolution relative to the grid spacing. In such cases, the internal interface option of the ELES implementation can be applied to convert modeled turbulence into resolved turbulence (see [Internal Interface Without LES Zone](#) in the [Theory Guide](#)).

DDES (DES is not recommended) models can allow the formation of unsteadiness even for cases where SAS remains stable. DDES does require a more carefully crafted grid in the LES zone due to the DES grid influence on the RANS solution. For the SST-DES model, use the default DDES blending function for shielding.

ELES is recommended in cases where limited zones with high accuracy requirements are embedded inside a larger RANS zone. At the interface between the RANS and the LES zone, unsteady turbulence is generated either by the Spectral Synthesizer or the Vortex Method. For wall bounded flows, this method requires a very fine near wall resolution in the LES zone.

Pure LES should only be applied to free shear flows (e.g., combustion chambers without wall influence, etc.) or to very limited domains using meshes with fine LES near wall resolution. It is important to be aware of the strong increase of grid resolution requirements with Reynolds number for wall bounded flows. For wall boundary layers at higher Reynolds numbers, the IDDES model can be run in WMLES mode – meaning with specified unsteady inlet conditions.

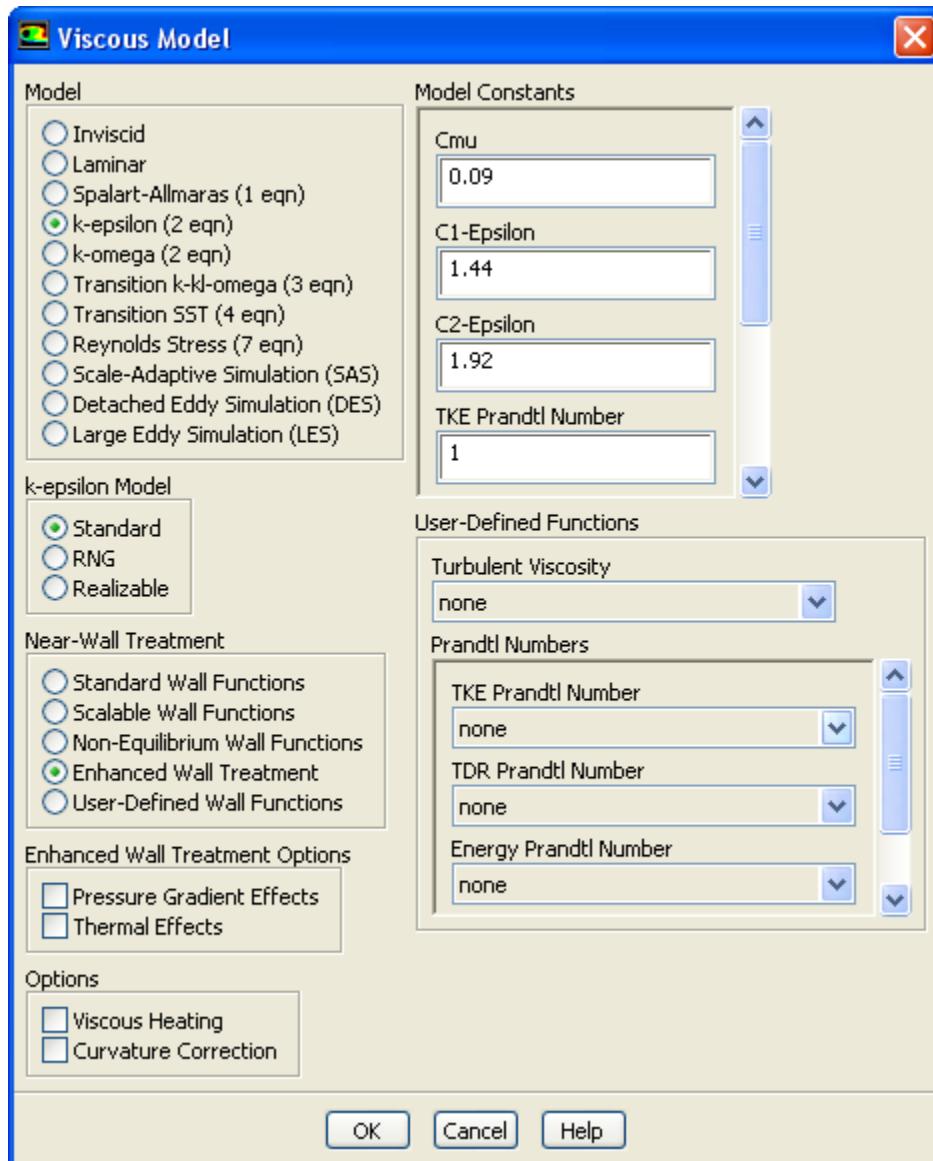

13.3. Steps in Using a Turbulence Model

When your ANSYS FLUENT model includes turbulence you need to activate the relevant model and options, and supply turbulent boundary conditions. These inputs are described in this section.

The procedure for setting up a turbulent flow problem is described below. (Note that this procedure includes only those steps necessary for the turbulence model itself; you will need to set up other models, boundary conditions, etc. as usual.)

1. To activate one of the turbulence models, select either **Spalart-Allmaras**, **k-epsilon**, **k-omega**, **Transition k-kl-omega**, **Transition SST**, **Reynolds Stress**, **Scale-Adaptive Simulation**, **Detached Eddy Simulation**, or **Large Eddy Simulation (LES)** under **Model** in the *Viscous Model Dialog Box* (p. 1778) (*Figure 13.2* (p. 697)).

Figure 13.2 The Viscous Model Dialog Box

If you choose the **k-epsilon** model, select either **Standard**, **RNG**, or **Realizable** under the **k-epsilon Model**. If you choose the **k-omega** model, select **Standard** or **SST** under **k-omega Model**.

Important

The **Detached Eddy Simulation** and the **Large Eddy Simulation (LES)** models are available only for 3D cases.

2. If the flow involves walls, and you are using one of the $k-\varepsilon$ models or the RSM, choose one of the following options for the **Near-Wall Treatment** in the **Viscous Model** dialog box:
 - **Standard Wall Functions**
 - **Scalable Wall Functions**
 - **Non-Equilibrium Wall Functions**

- Enhanced Wall Treatment
- User-Defined Wall Functions

For more information about these near-wall options, see [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#). By default, the standard wall function is enabled.

For more information about the automatically defined near-wall treatment for the Spalart-Allmaras model, see [Wall Boundary Conditions](#) in the [Theory Guide](#).

For more information about the automatically defined near-wall treatment for the k - ω model, see [Wall Boundary Conditions](#) in the [Theory Guide](#).

For more information about the automatically defined near-wall treatment for the LES model, see [Inlet Boundary Conditions for the LES Model](#) in the [Theory Guide](#).

3. Enable the appropriate turbulence modeling options in the **Viscous Model** dialog box. See [Setup Options for all Turbulence Modeling](#) (p. 716)
4. Specify the boundary conditions for the solution variables.

Boundary Conditions

See [Defining Turbulence Boundary Conditions](#) (p. 721) for details.

5. Specify the initial guess for the solution variables.

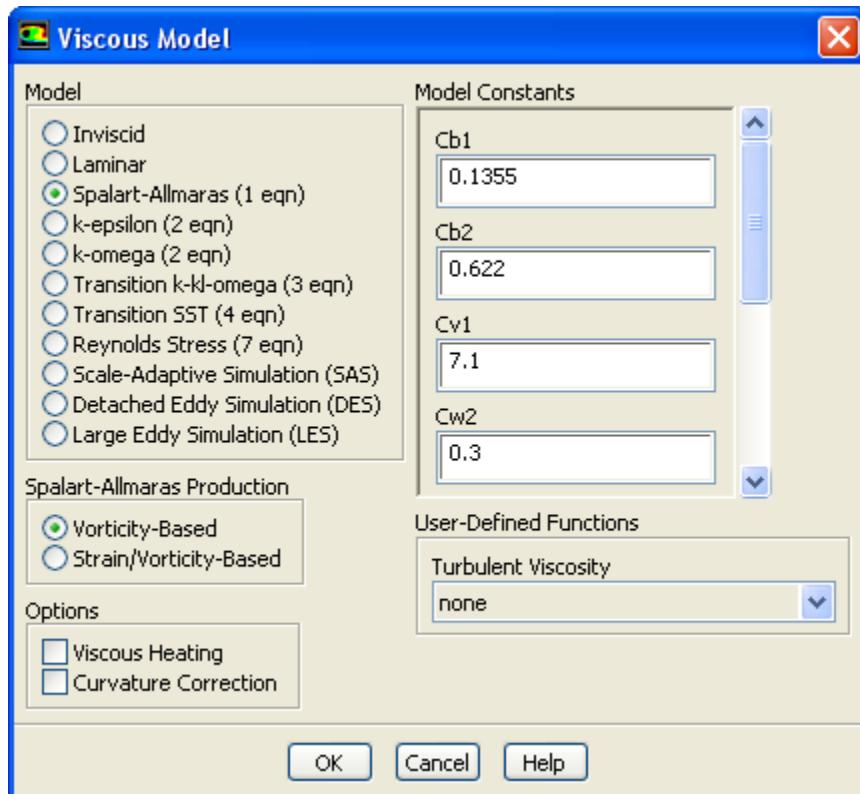

Solution Initialization

See [Providing an Initial Guess for \$k\$ and \$\varepsilon\$ \(or \$k\$ and \$\omega\$ \)](#) (p. 725) for details. Note that Reynolds stresses are automatically initialized using k , and therefore need not be initialized explicitly.

13.4. Setting Up the Spalart-Allmaras Model

If you choose the Spalart-Allmaras model, the following options are available:

- vorticity-based production ([Vorticity- and Strain/Vorticity-Based Production](#) (p. 717))
- strain/vorticity-based production ([Vorticity- and Strain/Vorticity-Based Production](#) (p. 717))
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects](#) (p. 717))
- curvature correction ([Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models](#) (p. 717))

Figure 13.3 The Viscous Model Dialog Box Displaying the Spalart-Allmaras Production

13.5. Setting Up the $k-\varepsilon$ Model

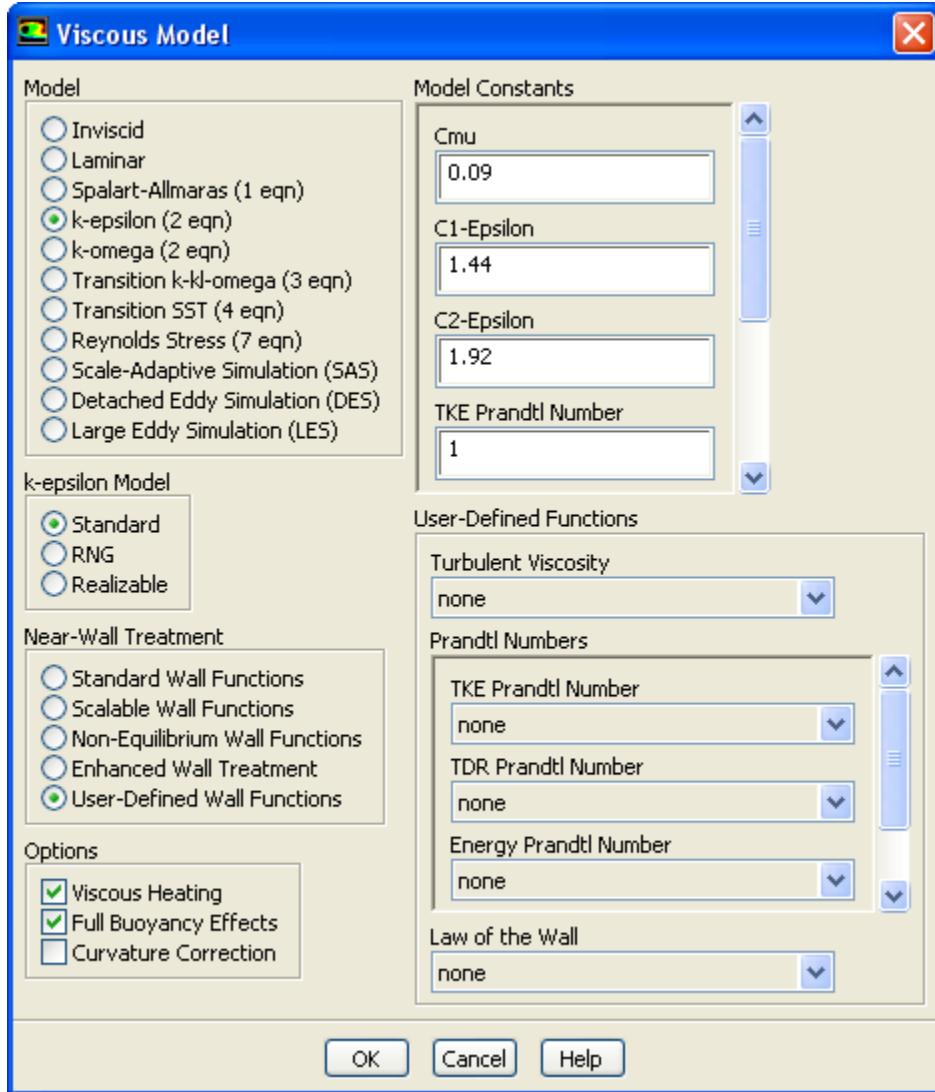

For additional information, please see the following sections:

- 13.5.1. Setting Up the Standard or Realizable $k-\varepsilon$ Model
- 13.5.2. Setting Up the RNG $k-\varepsilon$ Model

13.5.1. Setting Up the Standard or Realizable $k-\varepsilon$ Model

If you choose the standard $k-\varepsilon$ model or the realizable $k-\varepsilon$ model, the following options are available:

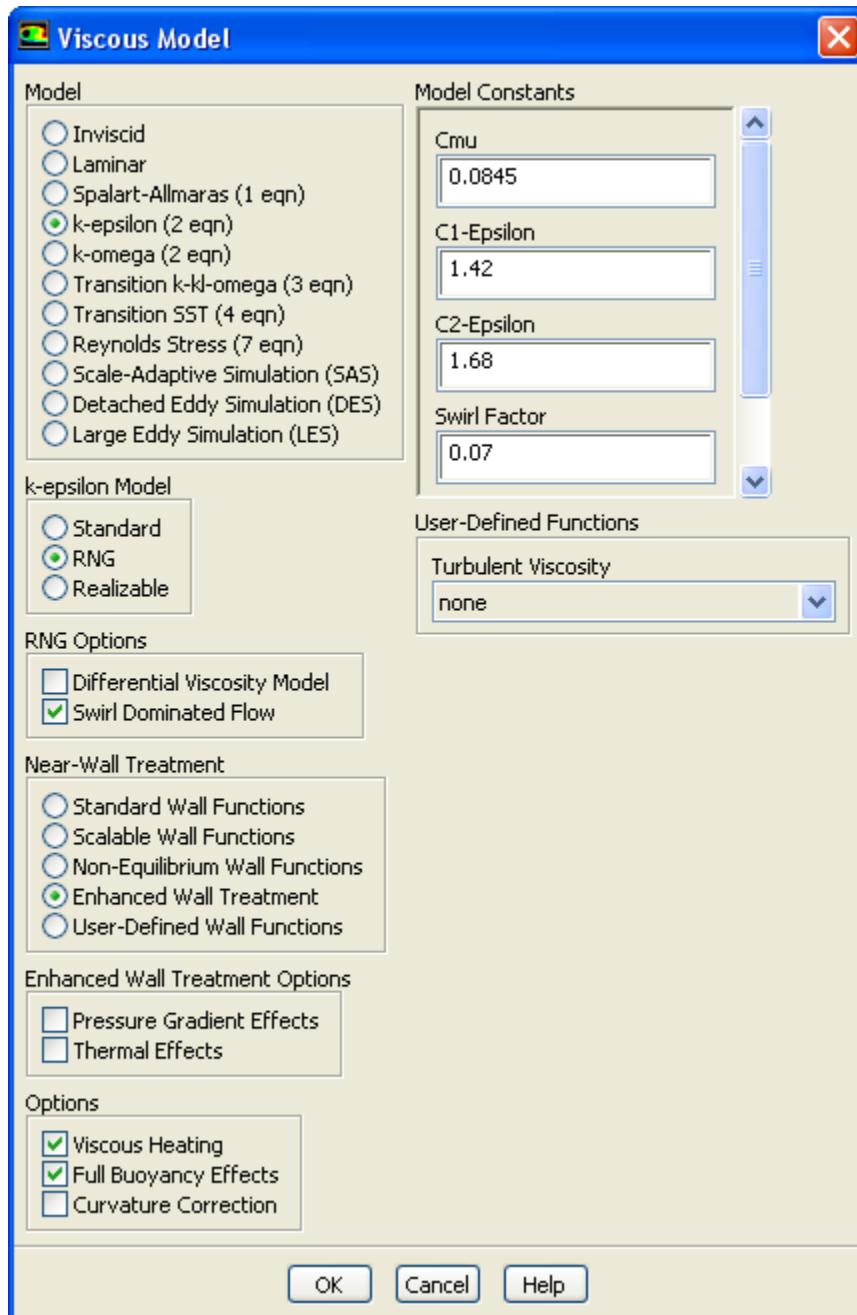

- viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 717))
- inclusion of buoyancy effects on ε (see *Effects of Buoyancy on Turbulence in the $k-\varepsilon$ Models* in the *Theory Guide*)
- inclusion of curvature correction (*Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models* (p. 717))

Figure 13.4 The Viscous Model Dialog Box Displaying the Standard k- ε Model

13.5.2. Setting Up the RNG k- ε Model

If you choose the RNG k - ε model, the following options are available:

- differential viscosity model (*Differential Viscosity Modification* (p. 718))
- swirl modification (*Swirl Modification* (p. 718))
- viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 717))
- inclusion of buoyancy effects on ε (see *Effects of Buoyancy on Turbulence in the k- ε Models* in the *Theory Guide*)
- inclusion of curvature correction (*Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models* (p. 717))

Figure 13.5 The Viscous Model Dialog Box Displaying the RNG $k-\varepsilon$ Model

For all $k-\varepsilon$ models, one the following near-wall treatments must be selected (see [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the Theory Guide):

- standard wall functions
- scalable wall functions
- non-equilibrium wall functions
- enhanced wall treatment
- user-defined wall functions

If you choose the enhanced wall treatment, the following options are available:

- pressure gradient effects (*Including Pressure Gradient Effects* (p. 719))
- thermal effects (*Including Thermal Effects* (p. 719))

If you choose the user-defined wall functions near-wall treatment, hook your UDF under **Law of the Wall**, as shown in *Figure 13.4* (p. 700).

13.6. Setting Up the k - ω Model

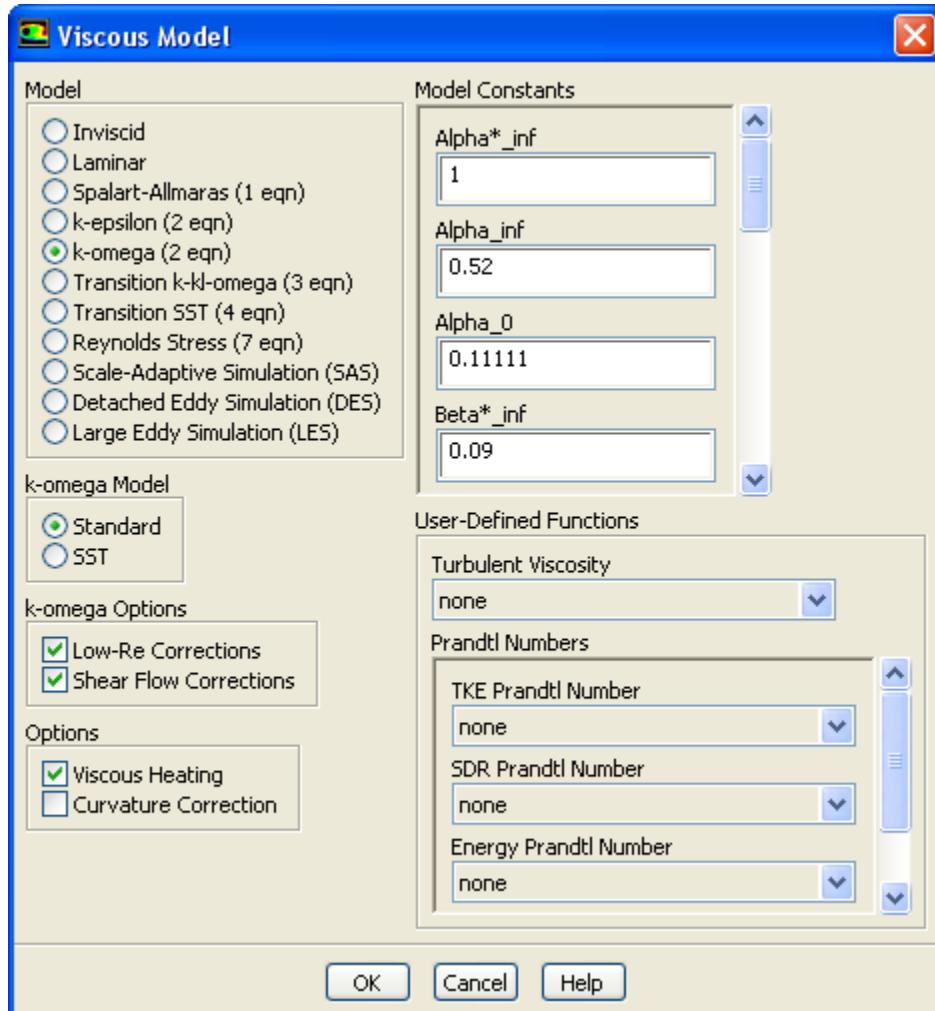

For additional information, please see the following sections:

- 13.6.1. Setting Up the Standard k - ω Model
- 13.6.2. Setting Up the Shear-Stress Transport k - ω Model

13.6.1. Setting Up the Standard k - ω Model

If you choose the standard k - ω model, the following options are available:

- low-Re corrections (*Low-Re Corrections* (p. 718))
- shear flow corrections (*Shear Flow Corrections* (p. 718))
- turbulence damping (available with the VOF and Mixture models and the Eulerian multiphase model when using the immiscible fluid model) (*Turbulence Damping* (p. 719))
- viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 717))
- inclusion of curvature correction (*Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models* (p. 717))

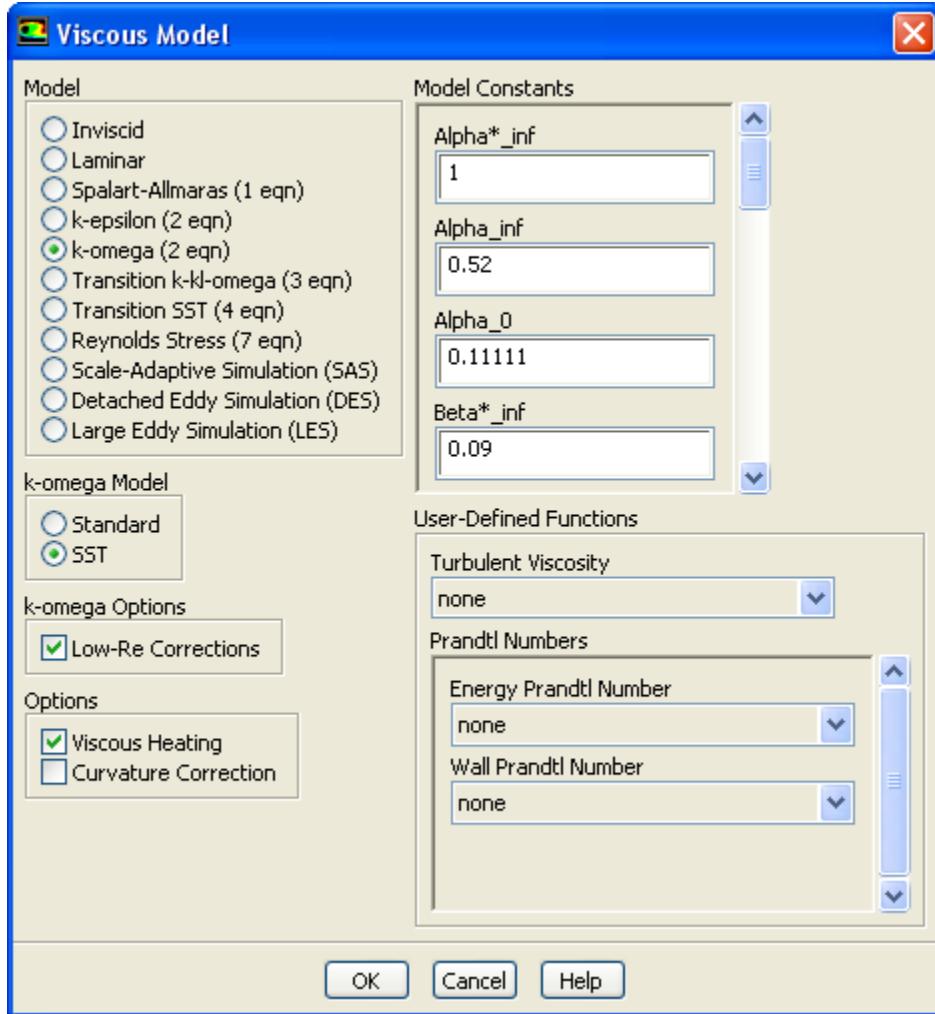

Figure 13.6 The Viscous Model Dialog Box Displaying the Standard k - ω Model

The k - ω models use enhanced wall functions as the near-wall treatment (see [Enhanced Wall Treatment for Momentum and Energy Equations](#) in the [Theory Guide](#)).

13.6.2. Setting Up the Shear-Stress Transport k - ω Model

If you choose the shear-stress transport k - ω model, the following options are available:

- low-Re corrections ([Low-Re Corrections \(p. 718\)](#))
- turbulence damping (available with the VOF and Mixture models and the Eulerian multiphase model when using the immiscible fluid model) ([Turbulence Damping \(p. 719\)](#))
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects \(p. 717\)](#))
- inclusion of curvature correction ([Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models \(p. 717\)](#))

Figure 13.7 The Viscous Model Dialog Box Displaying the SST k- ω Model

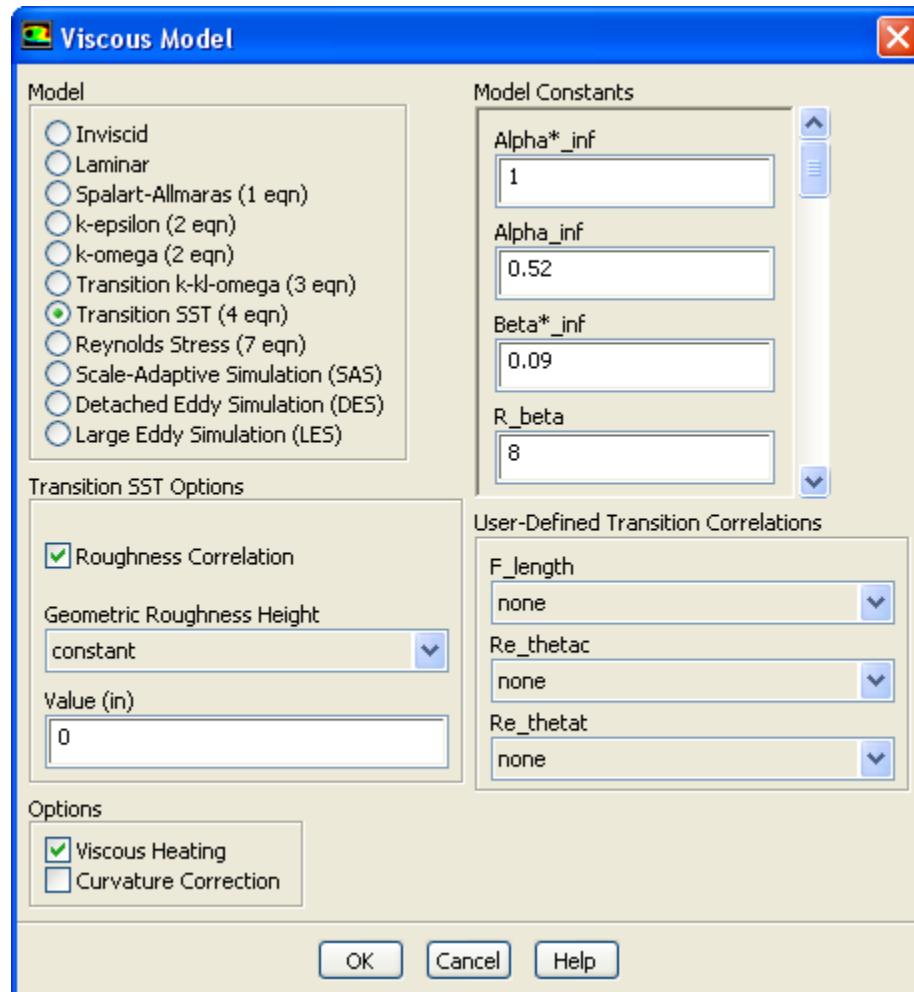

13.7. Setting Up the Transition k- kL - ω Model

If you choose the Transition k - kL - ω model, it is not necessary to modify any of the model constants.

13.8. Setting Up the Transition SST Model

If you choose the Transition SST model, the following options are available:

- roughness correlation ([Transition SST and Rough Walls](#) in the Theory Guide)
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects \(p. 717\)](#))
- inclusion of curvature correction ([Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models \(p. 717\)](#))

Figure 13.8 The Viscous Model Dialog Box for the Transition SST Model

You can customize your transition correlations, which are used in conjunction with the Transition SST model. The user-defined functions that you can hook are:

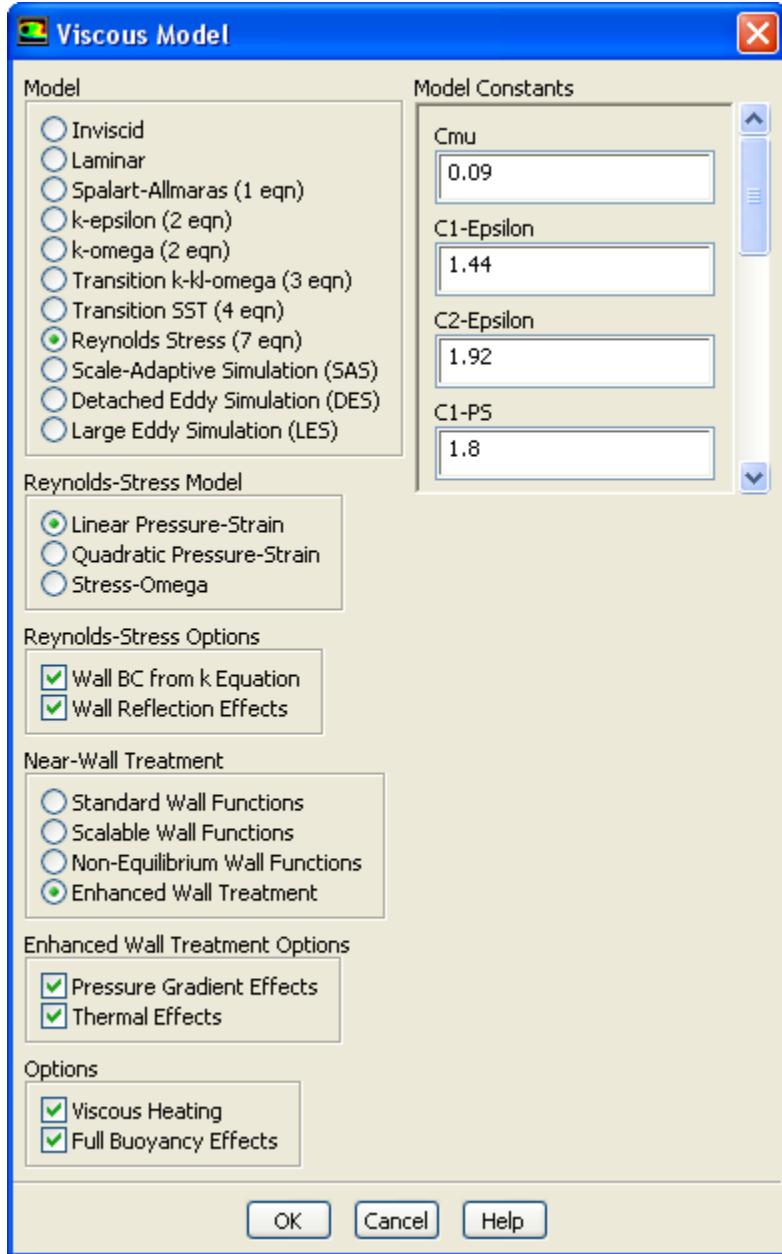

- transition length function (**F_length**).
- critical momentum thickness Reynolds number (**Re_thetac**).
- transition onset momentum thickness Reynolds number (**Re_thetat**).

For detailed information about the transition correlation UDFs, see [DEFINE_TRANS UDFs](#) in the [UDF Manual](#).

13.9. Setting Up the Reynolds Stress Model

If you choose the RSM, the following submodels are available:

- linear pressure-strain model (see [Linear Pressure-Strain Model](#) in the [Theory Guide](#))
- quadratic pressure-strain model ([Quadratic Pressure-Strain Model](#) (p. 720))
- Stress-Omega ([Stress-Omega Pressure-Strain](#) (p. 720))

Figure 13.9 The Viscous Model Dialog Box Displaying the Reynolds Stress Model Options

The following Reynolds-stress options are available:

- wall boundary conditions for the Reynolds stresses from the k equation ([Solving the \$k\$ Equation to Obtain Wall Boundary Conditions \(p. 719\)](#)) for the linear and quadratic pressure-strain models
- wall reflection effects on Reynolds stresses ([Including the Wall Reflection Term \(p. 719\)](#)) for the linear pressure-strain model

Other options that are available based on your case setup include:

- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects \(p. 717\)](#))
- inclusion of buoyancy effects on ε (see [Effects of Buoyancy on Turbulence in the \$k\$ - \$\varepsilon\$ Models in the Theory Guide](#))

For the Reynolds stress model, the following near-wall treatments are available (see [Near-Wall Treatments for Wall-Bounded Turbulent Flows](#) in the [Theory Guide](#)):

- standard wall functions
- scalable wall functions
- non-equilibrium wall functions
- enhanced wall treatment

If wall boundary conditions for the Reynolds stresses from the k equation and/or wall reflection effects on Reynolds stresses are/is selected, then all the above near-wall treatments are available for selection.

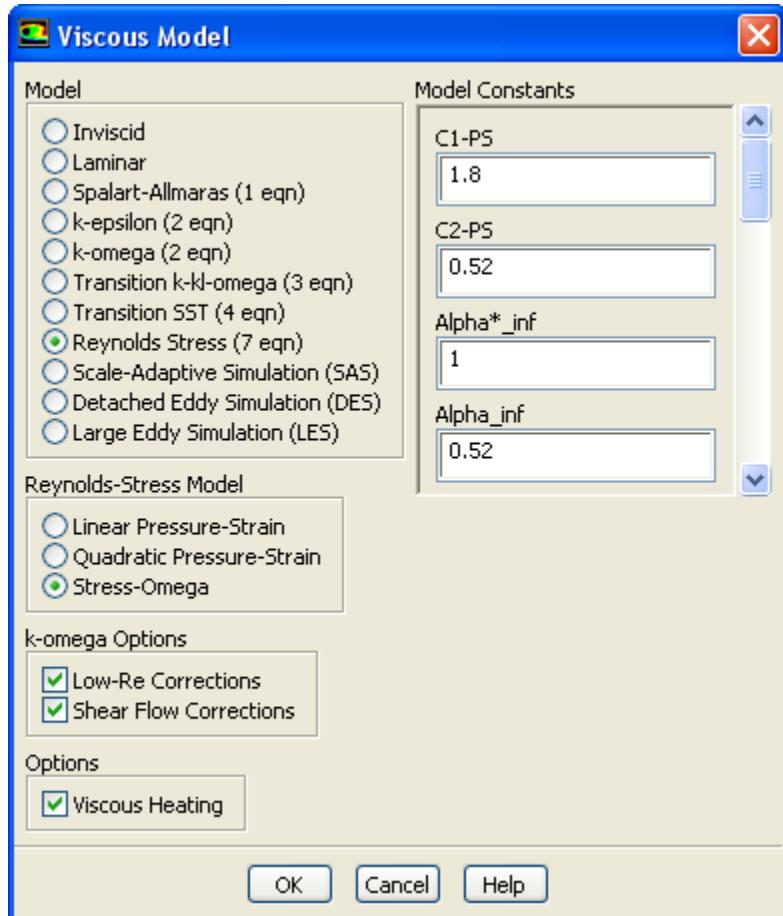

If you choose the enhanced wall treatment, the following options are available:

- pressure gradient effects ([Including Pressure Gradient Effects \(p. 719\)](#))
- thermal effects ([Including Thermal Effects \(p. 719\)](#))

If the quadratic pressure-strain model is selected, then you can set either the standard wall functions or the non-equilibrium wall functions.

If **Stress-Omega** is selected, you cannot select any near-wall treatments and should use an LRN mesh. You do have the option of selecting any or all of the following $k - \omega$ options:

- low-Re corrections ([Low-Re Corrections \(p. 718\)](#))
- shear flow corrections ([Shear Flow Corrections \(p. 718\)](#))

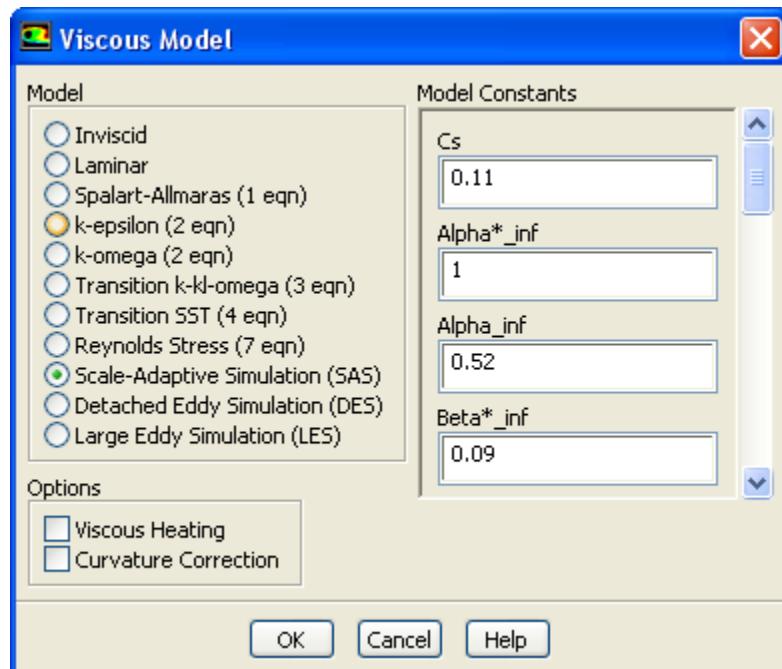

Figure 13.10 The Viscous Model Dialog Box Displaying the Stress-Omega Model Options

13.10. Setting Up the Scale-Adaptive Simulation (SAS) Model

The SAS turbulence model is an approach for the simulation of unsteady turbulent flows. You can enable the SAS turbulence model by selecting **Scale-Adaptive Simulation (SAS)** from the **Model** list in the **Viscous Model** dialog box.

Models → Viscous → Edit...

Figure 13.11 The Viscous Model Dialog Box Displaying the Scale-Adaptive Simulation (SAS) Model

For SAS and DES simulation setups, the **Bounded Central Differencing** scheme (available in the **Solution Methods** task page) is recommended for momentum discretization, and is the default setting.

13.11. Setting Up the Detached Eddy Simulation Model

The following submodels are available when selecting the DES model:

- Spalart-Allmaras
- Realizable k - ε
- SST k - ω

For additional information, please see the following sections:

[13.11.1. Setting Up the Spalart-Allmaras DES Model](#)

[13.11.2. Setting Up the Realizable \$k\$ - \$\varepsilon\$ DES Model](#)

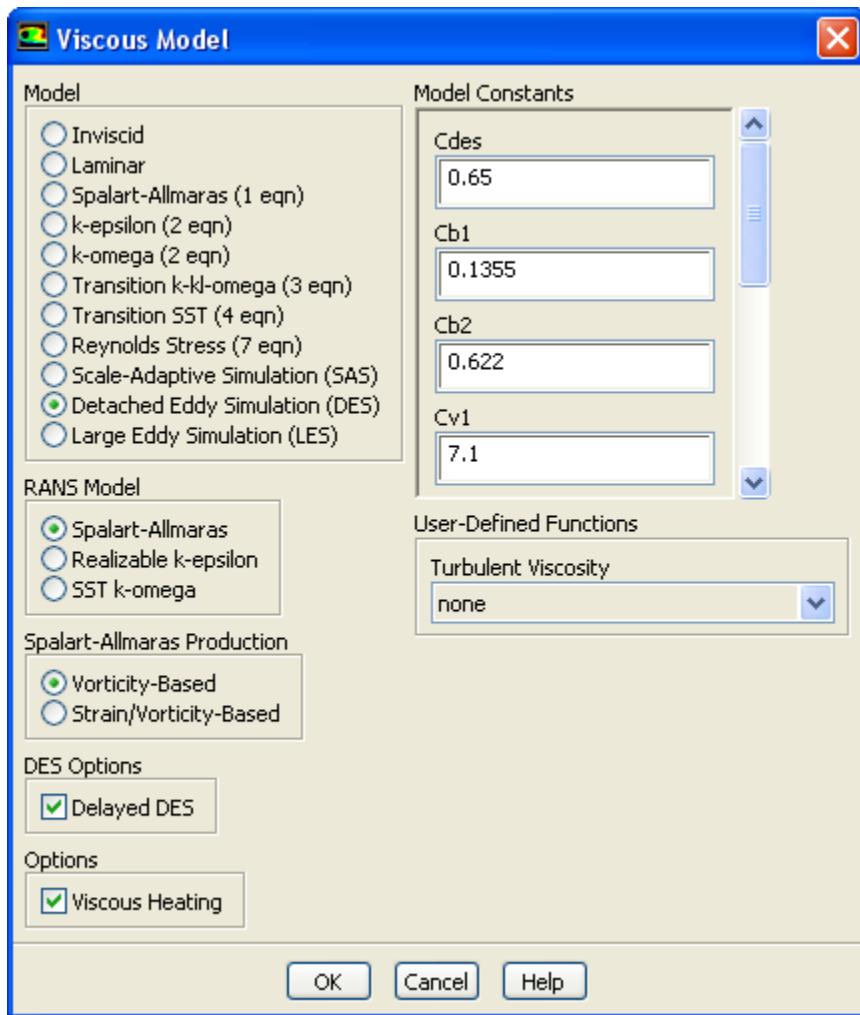

[13.11.3. Setting Up the SST \$k\$ - \$\omega\$ DES Model](#)

13.11.1. Setting Up the Spalart-Allmaras DES Model

ANSYS FLUENT uses Equation 4–226 (in the [Theory Guide](#)) to compute the value of the length scale \tilde{d} for the Spalart-Allmaras model. By default, the empirical constant C_{des} is set to 0.65. You can change its value in the **Cdes** field under **Model Constants**. The following options are available for this model:

- vorticity-based production ([Vorticity- and Strain/Vorticity-Based Production \(p. 717\)](#))
- strain/vorticity-based production ([Vorticity- and Strain/Vorticity-Based Production \(p. 717\)](#))
- delayed DES ([Delayed Detached Eddy Simulation \(DDES\) \(p. 718\)](#))
- viscous heating (always activated for the density-based solvers) ([Including the Viscous Heating Effects \(p. 717\)](#))

Figure 13.12 The Viscous Model Dialog Box Displaying the Spalart-Allmaras Detached Eddy Simulation Model Options

Additionally, you can perform the following DES-specific function by using the `/define/models/viscous/detached-eddy-simulation?` text command:

- Modify only the length scales that appear in the destruction term in ν_t equation (the default is to modify all length scales within the ν_t equation)

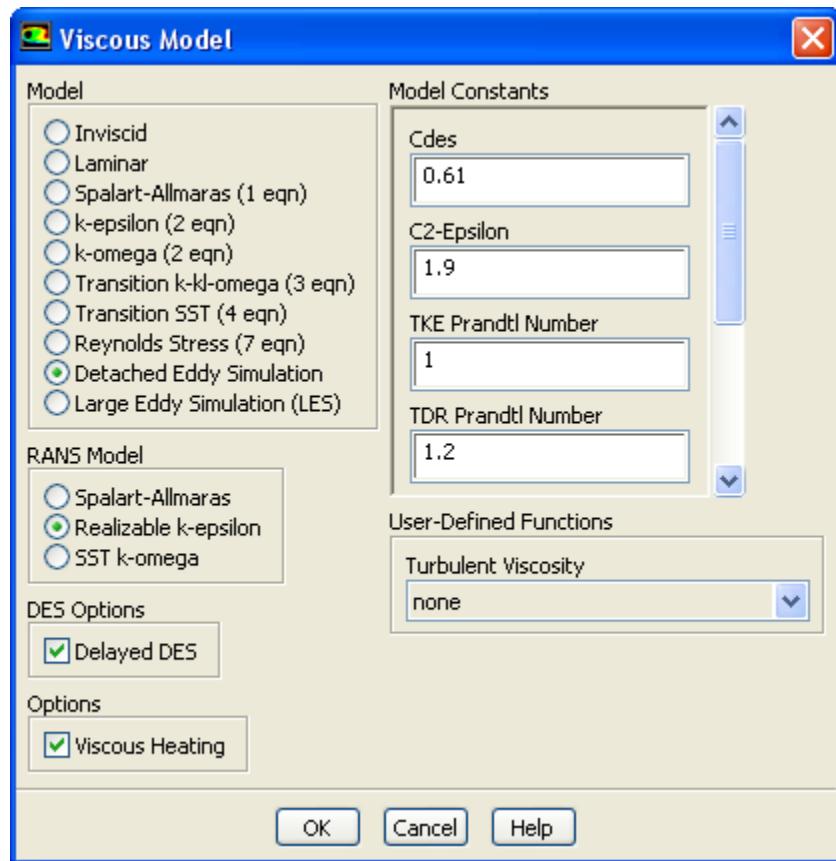

13.11.2. Setting Up the Realizable k - ε DES Model

For the Realizable k - ε submodel, the model-specific options are

- delayed DES (*Delayed Detached Eddy Simulation (DDES)* (p. 718))
- viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 717))

The model constant C_{des} is set to 0.61 for the Realizable k - ε model (see Realizable k - ε Based DES Model in the Theory Guide).

Figure 13.13 The Viscous Model Dialog Box Displaying the Realizable k- ϵ Detached Eddy Simulation Model Options

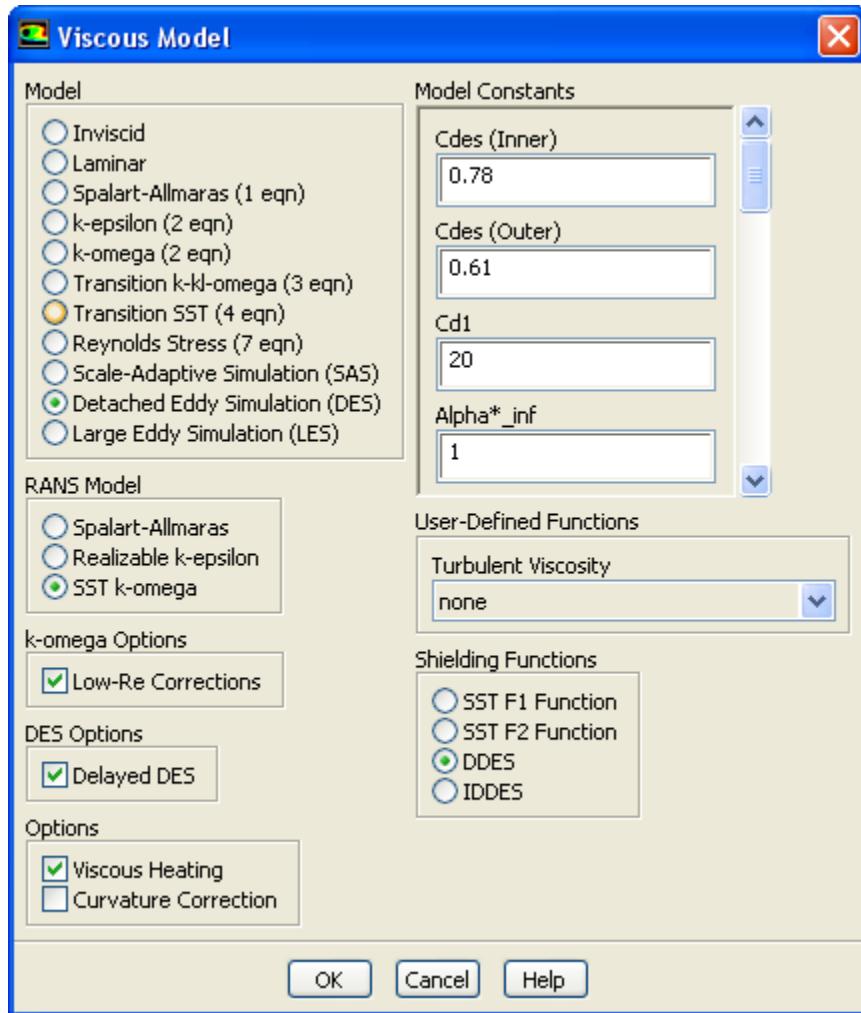

13.11.3. Setting Up the SST k - ω DES Model

For the SST k - ω sub-model, the model-specific options that you can select are

- delayed DES (*Delayed Detached Eddy Simulation (DDES)* (p. 718))
- viscous heating (always activated for the density-based solvers) (*Including the Viscous Heating Effects* (p. 717))
- inclusion of curvature correction (*Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models* (p. 717))
- low-Re corrections k - ω option (*Low-Re Corrections* (p. 718))
- Shielding functions, F1, F2, DDES (Delayed DES) and IDDES (Improved Delayed DES) (*Shielding Functions for the SST Detached Eddy Simulation Model* (p. 721))

The model constant C_{des} is set to 0.61 for the SST k - ω RANS model (see *SST k- ω Based DES Model* in the *Theory Guide*).

Figure 13.14 The Viscous Model Dialog Box Displaying the SST k- ω Detached Eddy Simulation Model Options

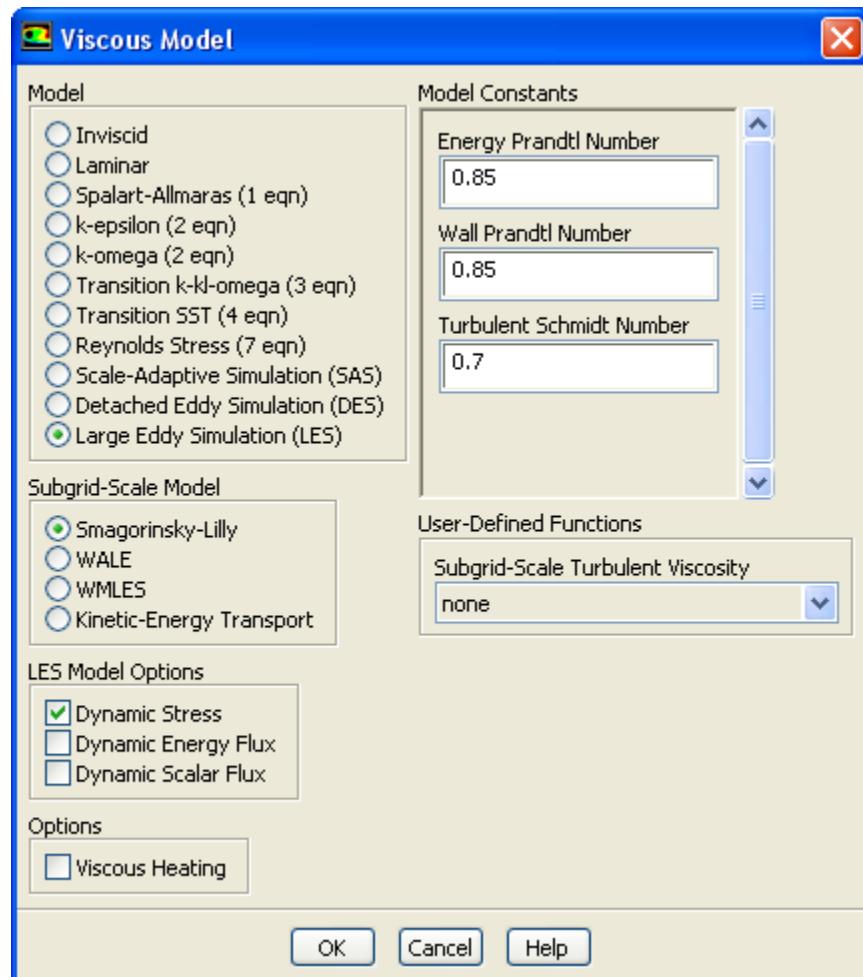

13.12. Setting Up the Large Eddy Simulation Model

If you choose the LES model, the following subgrid-scale submodels are available (*Subgrid-Scale Model* (p. 720)):

- Smagorinsky-Lilly
- WALE
- WMLES
- Kinetic-Energy Transport

Figure 13.15 The Viscous Model Dialog Box Displaying the Large Eddy Simulation Model Options

The LES options that are available for the Smagorinsky-Lilly are

- Dynamic Stress
- Dynamic Energy Flux (available only when the Dynamic Stress Model is enabled)
- Dynamic Scalar Flux

The LES options that are available when the Kinetic-Energy Transport submodel is selected are **Dynamic Energy Flux** and **Dynamic Scalar Flux**.

It is also possible to modify the **Model Constants**, but this is not necessary for most applications. For more information about the constants, see [Spalart-Allmaras Model through Large Eddy Simulation \(LES\) Model](#) (in the [Theory Guide](#)). Note that **C1-PS** and **C2-PS** are the constants C_1 and C_2 in the linear pressure-strain approximation of [Equation 4-186](#) and [Equation 4-187](#) (in the [Theory Guide](#)), and **C1'-PS** and **C2'-PS** are the constants C'_1 and C'_2 in [Equation 4-188](#) (in the [Theory Guide](#)). **C1-SSG-PS**, **C1'-SSG-PS**, **C2-SSG-PS**, **C3-SSG-PS**, **C3'-SSG-PS**, **C4-SSG-PS**, and **C5-SSG-PS** are the constants C_1 , C_1^* , C_2 , C_3 , C_3^* , C_4 , and C_5 in the quadratic pressure-strain approximation of [Equation 4-197](#) (in the [Theory Guide](#)).

13.13. Setting Up the Embedded Large Eddy Simulation (ELES) Model

As described in [Embedded Large Eddy Simulation \(ELES\)](#) in the [Theory Guide](#), the Embedded Large Eddy Simulation model is used when modeling a smaller embedded LES zone within a larger RANS computational domain. Recall that the interface between the upstream RANS zone and the LES zone needs to be defined (by assigning the interface to a velocity fluctuation algorithm). In addition, the interface between the LES zone and the downstream RANS zone needs to be considered.

This section describes how to set up the Embedded Large Eddy Simulation model.

1. In the **Viscous Model** dialog box, enable any RANS model (k - ε , k - ω , etc.), or you can select DES or SAS. The only RANS model not compatible with ELES is the Spalart-Allmaras model, as a one-equation model cannot provide the required turbulent length scale to the interface method.

If a RANS model is selected, the model is applied globally to the computational domain, however, values are frozen within the ELES region. The frozen state of the ELES zone is used to determine the flow conditions (for k - ε , k - ω , etc.) at the downstream LES-RANS zone interface. Note that this approach requires a fairly well converged global RANS solution to start with.

If DES or SAS is used, these models are not frozen, but run in the background in the ELES region, obtaining proper flow conditions (for k - ε , k - ω , etc.) at the downstream LES-RANS zone interface.

2. For the specified fluid cell zone, enable **LES Zone** in the **Fluid** dialog box ([Figure 13.16 \(p. 715\)](#)). This enables the **Embedded LES** tab in the **Fluid** dialog box.

Note

When DES or SAS is used for the global model, this and the next step can, but need not, be skipped. (Keep in mind the general limitations of DES in free, wall-independent flows.) If you choose to skip these steps, then proceed with step 4.

3. In the **Embedded LES** tab, you can then specify the **Embedded Subgrid Scale Model**, and the **Momentum Spatial Discretization**.

For the **Embedded Subgrid Scale Model**, the following subgrid-scale submodels are available ([Subgrid-Scale Model \(p. 720\)](#)):

- Smagorinsky-Lilly
- WALE
- Dynamic Smagorinsky-Lilly
- WMLES

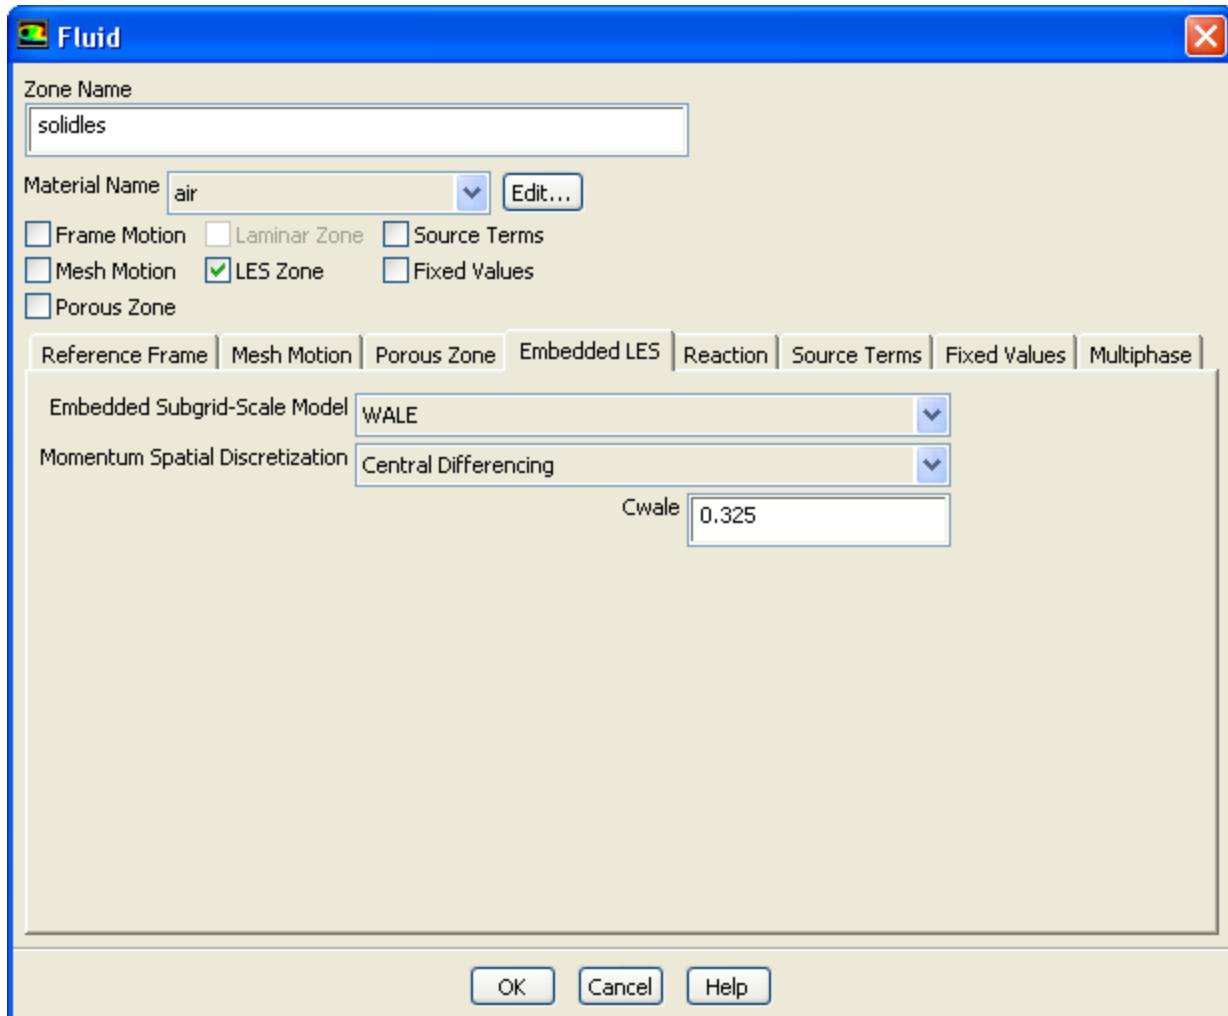

When the Smagorinsky-Lilly model is selected, you can specify a value for C_s (see [Dynamic Smagorinsky-Lilly Model](#) in the [Theory Guide](#) for details). Likewise, when the WALE model is selected, you can specify a value for C_{wale} (or C_w , see [Wall-Adapting Local Eddy-Viscosity \(WALE\) Model](#) in the [Theory Guide](#) for details).

For the **Momentum Spatial Discretization**, the following options are available:

- Bounded Central Differencing

- Central Differencing

Figure 13.16 Specifying an ELES Zone in the Fluid Dialog Box

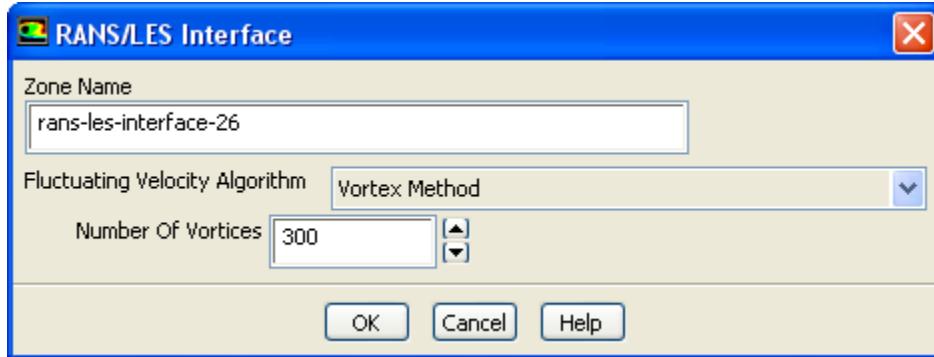

4. Select an appropriate interior interface and designate it as the RANS-LES interface, by selecting the boundary zone under **Zones** in the **Boundary Conditions** task page, and assign to **rans-les-interface** for the boundary **Type**. Click **Edit...** to display the **RANS/LES Interface** dialog box (*Figure 13.17 (p. 716)*), where you can assign a **Zone Name**, as well as the **Fluctuating Velocity Algorithm**, and the **Number of Vortices**. The options for the **Fluctuating Velocity Algorithm** are:

- No Perturbations
- Spectral Synthesizer
- Vortex Method

For more information about these options, please refer to [Inlet Boundary Conditions for the LES Model](#) in the [Theory Guide](#).

Note that the **Number of Vortices** is the amount of vortices that the selected method distributes randomly over the face zone and uses to generate turbulent fluctuations. The value should be large enough to make sure there are no spots on the face zone that are unaffected by any vortex. Large numbers may slightly increase the CPU effort, but will not impair the results.

Figure 13.17 Specifying a RANS/LES Interface

If the RANS/LES interface is a non-conformal mesh interface, you can find the name of the interior zone that you want to change into a **rans-les-interface** zone in the [Mesh Interfaces Task Page \(p. 2021\)](#).

Important

It is recommended that the RANS-LES interface be situated in a region where there is no backflow.

13.14. Setup Options for all Turbulence Modeling

For more information about the various options available for the turbulence models, see [Spalart-Allmaras Model](#) through [Large Eddy Simulation \(LES\) Model](#) (in the Theory Guide). Instructions for activating these options are provided here.

For additional information, please see the following sections:

- [13.14.1. Including the Viscous Heating Effects](#)
- [13.14.2. Including Turbulence Generation Due to Buoyancy](#)
- [13.14.3. Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models](#)
- [13.14.4. Vorticity- and Strain/Vorticity-Based Production](#)
- [13.14.5. Delayed Detached Eddy Simulation \(DDES\)](#)
- [13.14.6. Differential Viscosity Modification](#)
- [13.14.7. Swirl Modification](#)
- [13.14.8. Low-Re Corrections](#)
- [13.14.9. Shear Flow Corrections](#)
- [13.14.10. Turbulence Damping](#)
- [13.14.11. Including Pressure Gradient Effects](#)
- [13.14.12. Including Thermal Effects](#)
- [13.14.13. Including the Wall Reflection Term](#)
- [13.14.14. Solving the k Equation to Obtain Wall Boundary Conditions](#)
- [13.14.15. Quadratic Pressure-Strain Model](#)
- [13.14.16. Stress-Omega Pressure-Strain](#)
- [13.14.17. Subgrid-Scale Model](#)
- [13.14.18. Customizing the Turbulent Viscosity](#)
- [13.14.19. Customizing the Turbulent Prandtl and Schmidt Numbers](#)
- [13.14.20. Modeling Turbulence with Non-Newtonian Fluids](#)
- [13.14.21. Shielding Functions for the SST Detached Eddy Simulation Model](#)

13.14.1. Including the Viscous Heating Effects

For information about including viscous heating effects in your model, see [Inclusion of the Viscous Dissipation Terms](#) in the [Theory Guide](#) and [Solving Heat Transfer Problems](#) (p. 737).

13.14.2. Including Turbulence Generation Due to Buoyancy

If you specify a non-zero gravity force (in the [Operating Conditions Dialog Box](#) (p. 1952)), and you are modeling a non-isothermal flow, the generation of turbulent kinetic energy due to buoyancy (G_b in [Equation 4–33](#)) is, by default, always included in the k equation. However, ANSYS FLUENT does not, by default, include the buoyancy effects on ε .

To include the buoyancy effects on ε , you must turn on the **Full Buoyancy Effects** option under **Options** in the [Viscous Model Dialog Box](#) (p. 1778).

This option is available for all three k - ε models and for the RSM.

13.14.3. Including the Curvature Correction for the Spalart-Allmaras and Two-Equation Turbulence Models

Eddy-viscosity models display an insensitivity to streamline curvature and system rotation, which play a significant role in many turbulent flows of practical interest, as described in [Curvature Correction for the Spalart-Allmaras and Two-Equation Models](#) in the [Theory Guide](#). A modification to the turbulence production term is available to sensitize the following standard eddy-viscosity models to the effects of streamline curvature and system rotation:

- Spalart-Allmaras one-equation model
- Standard, RNG, and Realizable (k - ε)-models
- Standard (k - ω), SST and Transition SST
- Scale-Adaptive Simulation (SAS) and Detached Eddy Simulation with SST (DES-SST).

Please note that both the RNG- and Realizable (k - ε) turbulence models already have their own terms to include rotational or swirl effects (see [RNG Swirl Modification](#) and [Modeling the Turbulent Viscosity](#) in the [Theory Guide](#) for more information). The curvature correction option should therefore be used with caution for these two models and is offered mainly for completeness for RNG and Realizable (k - ε).

Enable the **Curvature Correction** option under **Options** in the [Viscous Model Dialog Box](#) (p. 1778).

13.14.4. Vorticity- and Strain/Vorticity-Based Production

For the Spalart-Allmaras model, you can choose either **Vorticity-Based Production** or **Strain/Vorticity-Based Production** under **Spalart-Allmaras Production** in the [Viscous Model Dialog Box](#) (p. 1778). If you choose **Vorticity-Based Production**, ANSYS FLUENT will compute the value of the deformation tensor S using [Equation 4–22](#) (in the [Theory Guide](#)); if you choose **Strain/Vorticity-Based Production**, it uses [Equation 4–24](#) (in the [Theory Guide](#)).

(These options will not appear unless you have activated the Spalart-Allmaras model.)

13.14.5. Delayed Detached Eddy Simulation (DDES)

The **Delayed DES** option is recommended when using the DES model. This option preserves the RANS model throughout the boundary layer. For more information, see [Detached Eddy Simulation \(DES\)](#) in the [Theory Guide](#).

13.14.6. Differential Viscosity Modification

The RNG turbulence model in ANSYS FLUENT has an option of using a differential formula for the effective viscosity μ_{eff} ([Equation 4–38](#) in the [Theory Guide](#)) to account for the low-Reynolds-number effects. To enable this option, the **Differential Viscosity Model** option under **RNG Options** in the [Viscous Model Dialog Box](#) (p. 1778) needs to be enabled.

Important

This option appears when you have activated the RNG k - ε model.

13.14.7. Swirl Modification

After you have chosen the RNG model, the swirl modification takes effect, by default, for all three-dimensional flows and axisymmetric flows with swirl. The default swirl constant (α_s in [Equation 4–40](#) in the [Theory Guide](#)) is set to 0.07, which works well for weakly to moderately swirling flows. However, for strongly swirling flows, you may need to use a larger swirl constant.

To change the value of the swirl constant, you must first enable the **Swirl Dominated Flow** option under **RNG Options** in the [Viscous Model Dialog Box](#) (p. 1778).

Important

This option will not appear unless you have activated the RNG k - ε model.

13.14.8. Low-Re Corrections

If either of the k - ω models are used, you may enable a low-Reynolds-number correction to the turbulent viscosity by enabling the **Low-Re Corrections** option under **k-omega Options** in the **Viscous Model** dialog box. By default, this option is not enabled, and the damping coefficient (α^* in [Equation 4–68](#) in the [Theory Guide](#)) is equal to 1.

13.14.9. Shear Flow Corrections

In the standard k - ω model, you also have the option of including corrections to improve the accuracy in predicting free shear flows. The **Shear Flow Corrections** option under the **k-omega Options** is enabled by default in the **Viscous Model** dialog box, as these corrections are included in the standard k - ω model [102] (p. 2372). When this option is enabled, ANSYS FLUENT will calculate f_β^* using [Equation 4–78](#) (in the [Theory Guide](#)) and f_β using [Equation 4–85](#) (in the [Theory Guide](#)). If this option is disabled, f_β^* and f_β will be set equal to 1.

13.14.10. Turbulence Damping

In the standard or SST $k-\omega$ model, you have the option of including turbulence damping, which is required for the accurate modeling of the interfacial area. The **Turbulence Damping** option under **k-omega Options** is available for the VOF and Mixture models and also available with the Eulerian multiphase model when using the immiscible fluid model. When this option is enabled, you can set the **Damping Factor**, which by default is set to 10. For a theoretical discussion about turbulence damping, please refer to [Turbulence Damping](#).

13.14.11. Including Pressure Gradient Effects

If the enhanced wall treatment is used, you may include the effects of pressure gradients by enabling the **Pressure Gradient Effects** option under the **Enhanced Wall Treatment Options**. When this option is enabled, ANSYS FLUENT will include the coefficient α in [Equation 4-310](#) (in the [Theory Guide](#)).

13.14.12. Including Thermal Effects

If the enhanced wall treatment is used, you may include thermal effects by enabling the **Thermal Effects** option under **Enhanced Wall Treatment Options**. When this option is enabled, ANSYS FLUENT will include the coefficient β in [Equation 4-310](#) (in the [Theory Guide](#)). γ will also be included in [Equation 4-310](#) when the **Thermal Effects** option is enabled if the ideal gas law is selected for the fluid density in the **Create/Edit Materials** dialog box.

13.14.13. Including the Wall Reflection Term

If the RSM is used with the default model for pressure strain, ANSYS FLUENT will, by default, include the wall-reflection effects in the pressure-strain term. That is, ANSYS FLUENT will calculate $\phi_{ij,w}$ using [Equation 4-188](#) (in the [Theory Guide](#)) and include it in [Equation 4-185](#) (in the [Theory Guide](#)). Note that wall-reflection effects are not included if you have selected the quadratic pressure-strain model.

Important

The empirical constants and the function f used in the calculation of $\phi_{ij,w}$ are calibrated for simple canonical flows such as channel flows and flat-plate boundary layers involving a single wall. If the flow involves multiple walls and the wall has significant curvature (e.g., an axisymmetric pipe or curvilinear duct), the inclusion of the wall-reflection term in [Equation 4-188](#) (in the [Theory Guide](#)) may not improve the accuracy of the RSM predictions. In such cases, you can disable the wall-reflection effects by turning off the **Wall Reflection Effects** under **Reynolds-Stress Options** in the [Viscous Model Dialog Box](#) (p. 1778).

13.14.14. Solving the k Equation to Obtain Wall Boundary Conditions

In the RSM, ANSYS FLUENT, by default, uses the explicit setting of boundary conditions for the Reynolds stresses near the walls, with the values computed with [Equation 4-215](#) (in the [Theory Guide](#)). The turbulent kinetic energy, k , is calculated by solving the k equation obtained by summing [Equation 4-182](#) (in the [Theory Guide](#)) for normal stresses. To disable this option and use the wall boundary conditions given in [Equation 4-216](#) (in the [Theory Guide](#)), turn off the **Wall BC from k Equation** under the **Reynolds-Stress Options** in the **Viscous Model** dialog box.

Important

This option will not appear unless you have activated the **Reynolds Stress** model.

13.14.15. Quadratic Pressure-Strain Model

To use the quadratic pressure-strain model described in **Quadratic Pressure-Strain Model** (in the [Theory Guide](#)), enable the **Quadratic Pressure-Strain Model** option under **Reynolds-Stress Options** in the [Viscous Model Dialog Box \(p. 1778\)](#). (This option will not appear unless you have activated the RSM.) The following options are not available when the **Quadratic Pressure-Strain Model** is enabled:

- **Wall Reflection Effects** under **Reynolds-Stress Options**
- **Enhanced Wall Treatment** under **Near-Wall Treatment**

13.14.16. Stress-Omega Pressure-Strain

To use the Low-Reynold-Number Stress-Omega option described in [Low-Re Stress-Omega Model](#), turn on the **Stress-Omega** option under **Reynolds-Stress Model** in the [Viscous Model Dialog Box \(p. 1778\)](#). (This option will not appear unless you have activated the RSM.) The following options are not available when the **Stress-Omega** option is enabled:

- **Wall BC from k Equation** under **Reynolds-Stress Options**
- **Wall Reflection Effects** under **Reynolds-Stress Options**
- **Standard Wall Functions** under **Near-Wall Treatment**
- **Scalable Wall Functions** under **Near-Wall Treatment**
- **Non-Equilibrium Wall Functions** under **Near-Wall Treatment**
- **Enhanced Wall Treatment** under **Near-Wall Treatment**

Instead, the following options have to be set:

- **Low-Re Corrections** under **k-omega Options**
- **Shear Flow Corrections** under **k-omega Options**

13.14.17. Subgrid-Scale Model

If you have selected the **Large Eddy Simulation** model, you will be able to choose one of the subgrid-scale models described in [Subgrid-Scale Models](#) (in the [Theory Guide](#)). You can choose from the **Smagorinsky-Lilly**, **WALE**, or **Kinetic-Energy Transport** subgrid-scale models. Note that **Dynamic Stress** is an option available with the **Smagorinsky-Lilly** model, while the **Kinetic-Energy Transport** model is always run as a dynamic model.

Important

These options will not appear unless you have activated the LES model.

13.14.18. Customizing the Turbulent Viscosity

If you are using the Spalart-Allmaras, k - ε , k - ω , DES, or LES models, a UDF can be used to customize the turbulent viscosity. This option will enable you to modify μ_t in the case of the Spalart-Allmaras, k - ε , and k - ω models, and incorporate completely new subgrid models in the case of the LES model. More information about UDFs can be found in the [UDF Manual](#).

In the [Viscous Model Dialog Box](#) (p. 1778), under **User-Defined Functions**, select the appropriate user-defined function in the **Turbulent Viscosity** drop-down list. For the LES model, select the appropriate UDF in the **Subgrid-Scale Turbulent Viscosity** drop-down list.

13.14.19. Customizing the Turbulent Prandtl and Schmidt Numbers

If you are using the standard or realizable k - ε model or the standard k - ω model, a UDF can be used to customize the turbulent Prandtl and Schmidt numbers. This option will allow you to calculate σ_k and either σ_ε or σ_ω (depending on the choice of either k - ε or k - ω model) by using a UDF. You will also be able to calculate the value of the energy turbulent Prandtl number (Pr_t in [Equation 4-57](#) in the [Theory Guide](#)) and the turbulent Prandtl number at the wall (Pr_t in [Equation 4-283](#) in the [Theory Guide](#)) in this way. More information about UDFs can be found in the [UDF Manual](#).

In the [Viscous Model Dialog Box](#) (p. 1778), under **User-Defined Functions**, select the appropriate UDF from the drop-down lists under **Prandtl and Schmidt Numbers**. Options include: **TKE Prandtl Number**, **TDR Prandtl Number** (k - ε models only), **SDR Prandtl Number** (k - ω model only), **Energy Prandtl Number**, **Wall Prandtl Number**, and **Turbulent Schmidt Number**.

13.14.20. Modeling Turbulence with Non-Newtonian Fluids

If the turbulent flow involves non-Newtonian fluids, you can use the `define/models/ viscous/turbulence-expert/turb-non-newtonian?` text command to enable the selection of non-Newtonian options for the material viscosity. See [Viscosity for Non-Newtonian Fluids](#) (p. 431) for details about these options.

13.14.21. Shielding Functions for the SST Detached Eddy Simulation Model

The SST shielding (or blending) functions, F1 and F2 (which is more conservative than F1), are defined in [Equation 4-102](#) and [Equation 4-104](#) in the [Theory Guide](#), respectively. In addition, the SST shielding functions DDES (Delayed DES) and IDDES (Improved Delayed DES), are described in [SST k- \$\omega\$ Based DES Model](#) and [Improved Delayed Detached Eddy Simulation \(IDDES\)](#) in the [Theory Guide](#). DDES is recommended and is used as the default.

13.15. Defining Turbulence Boundary Conditions

For additional information, please see the following sections:

- [13.15.1. The Spalart-Allmaras Model](#)
- [13.15.2. \$k\$ - \$\varepsilon\$ Models and \$k\$ - \$\omega\$ Models](#)
- [13.15.3. Reynolds Stress Model](#)
- [13.15.4. Large Eddy Simulation Model](#)

13.15.1. The Spalart-Allmaras Model

When you are modeling turbulent flows in ANSYS FLUENT using the Spalart-Allmaras model, you must provide the boundary conditions for \tilde{v} in addition to other mean solution variables. The boundary conditions for \tilde{v} at the walls are internally taken care of by ANSYS FLUENT, which obviates the need for your inputs. The boundary condition input for \tilde{v} , which you must enter in ANSYS FLUENT, is the one at inlet boundaries (velocity inlet, pressure inlet, etc.). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

You may want to include the effects of the wall roughness on selected wall boundaries. In such cases, you can specify the roughness parameters (roughness height and roughness constant) in the dialog boxes of the corresponding wall boundaries (see [Setting the Roughness Parameters \(p. 322\)](#)).

13.15.2. k - ε Models and k - ω Models

When you are modeling turbulent flows in ANSYS FLUENT using one of the k - ε models or one of the k - ω models, you must provide the boundary conditions for k and ε (or k and ω) in addition to other mean solution variables. The boundary conditions for k and ε (or k and ω) at the walls are internally taken care of by ANSYS FLUENT, which obviates the need for your inputs. The boundary condition inputs for k and ε (or k and ω), which you must enter in ANSYS FLUENT, are the ones at inlet boundaries (velocity inlet, pressure inlet, etc.). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

See [Determining Turbulence Parameters \(p. 262\)](#) for details about specifying the boundary conditions for k and ε (or k and ω) at the inlets.

You may want to include the effects of the wall roughness on selected wall boundaries. In such cases, you can specify the roughness parameters (roughness height and roughness constant) in the dialog boxes for the corresponding wall boundaries (see [Setting the Roughness Parameters \(p. 322\)](#)).

Note

If you have selected the **Enhanced Wall Treatment** option as the **Near-Wall Treatment**, then the **Wall Roughness** parameters will not be accessible.

Additionally, you can control whether or not to set the turbulent viscosity to zero within a laminar zone. If the fluid zone in question is laminar, the text command `define/boundary-conditions/fluid` will contain an option called `Set Turbulent Viscosity to zero within laminar zone?`. By setting this option to `yes`, ANSYS FLUENT will set both the production term in the turbulence transport equation and μ_t to zero. In contrast, when the **Laminar Zone** option is enabled in a **Fluid** cell zone condition dialog box, only the production term is set to zero. See [Specifying a Laminar Zone \(p. 223\)](#) for details about laminar zones.

Important

Note that the laminar zone feature is also available for the Spalart-Allmaras and RSM models.

13.15.3. Reynolds Stress Model

The specification of turbulent boundary conditions for the RSM is the same as for the other turbulence models for all boundaries except at boundaries where flow enters the domain. Additional input methods are available for these boundaries and are described here.

When you choose to use the RSM, the default inlet boundary condition inputs required are identical to those required when the k - ε model is active. You can input the turbulence quantities using any of the turbulence specification methods described in [Determining Turbulence Parameters \(p. 262\)](#). ANSYS FLUENT then uses the specified turbulence quantities to derive the Reynolds stresses at the inlet from the assumption of isotropy of turbulence:

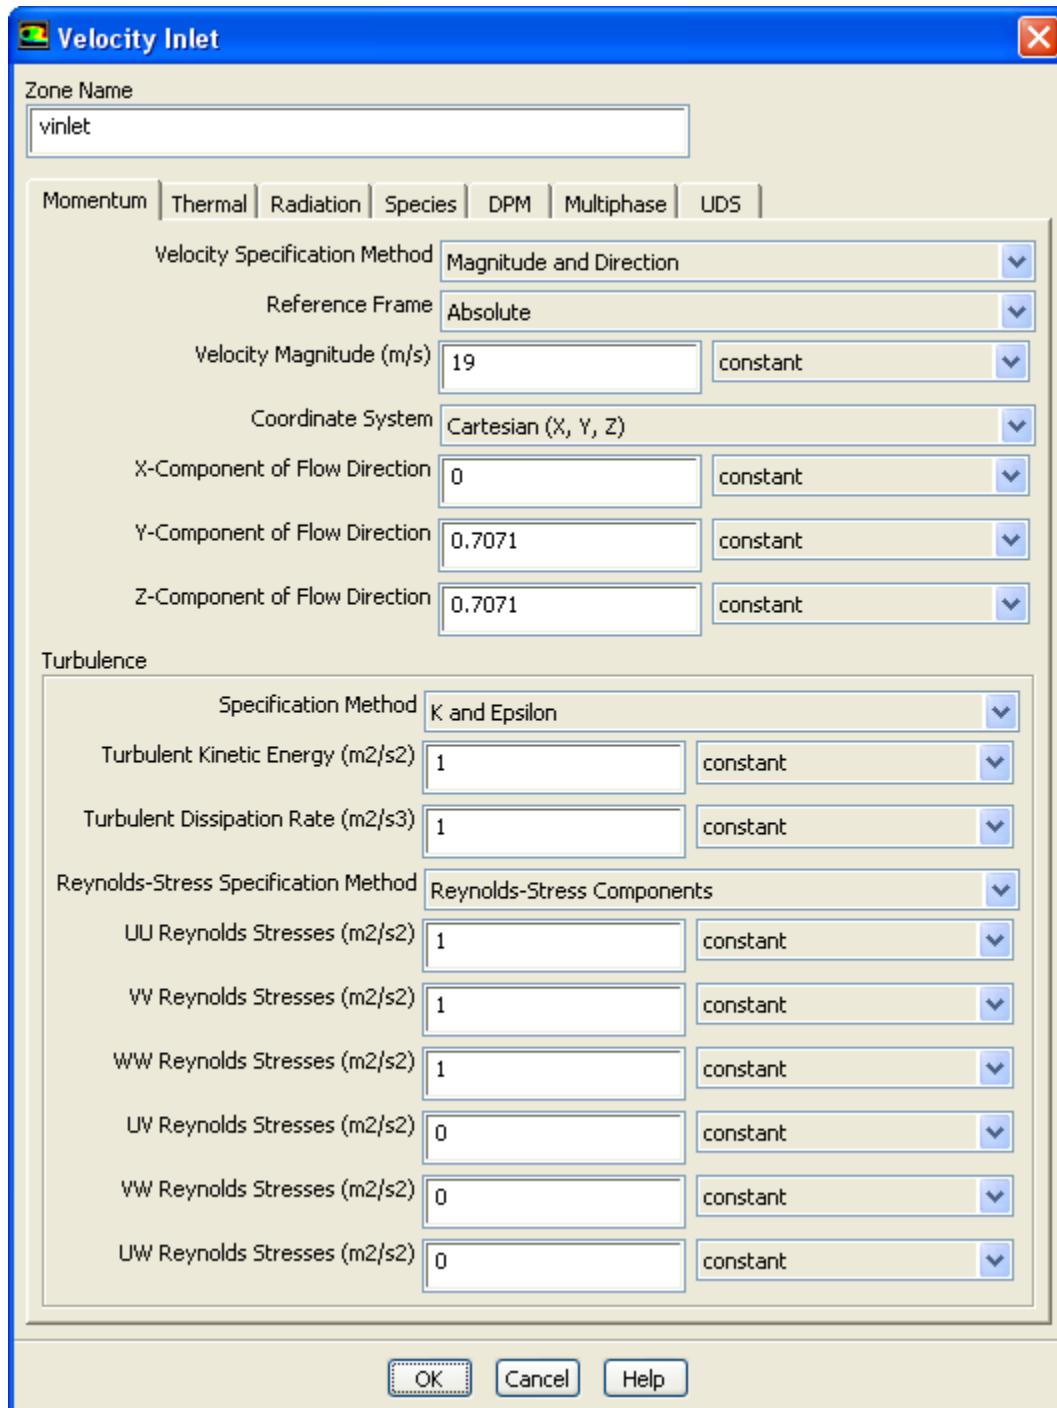

$$\overline{u_i'^2} = \frac{2}{3}k \quad (i = 1, 2, 3) \quad (13-6)$$

$$\overline{u_i' u_j'} = 0.0 \quad (13-7)$$

where $\overline{u_i'^2}$ is the normal Reynolds stress component in each direction. The boundary condition for ε is determined in the same manner as for the k - ε turbulence models (see [Determining Turbulence Parameters \(p. 262\)](#)). To use this method, you will select **K or Turbulence Intensity** as the **Reynolds-Stress Specification Method** in the appropriate boundary condition dialog box.

Alternately, you can directly specify the Reynolds stresses by selecting the **Reynolds-Stress Components** as the **Reynolds-Stress Specification Method** in the boundary condition dialog box. When this option is selected, you should input the Reynolds stresses directly.

You can set the Reynolds stresses by using constant values, profile functions of coordinates (see [Profiles \(p. 382\)](#)), or user-defined functions (in the [UDF Manual](#)).

Figure 13.18 Specifying Inlet Boundary Conditions for the Reynolds Stresses

13.15.4. Large Eddy Simulation Model

It is possible to specify the magnitude of random fluctuations of the velocity components at an inlet only if the velocity inlet boundary condition is selected. In this case, you must specify a **Turbulence Intensity** that determines the magnitude of the random perturbations on individual mean velocity components as described in [Inlet Boundary Conditions for the LES Model](#) (in the [Theory Guide](#)). For all boundary types other than velocity inlets, the boundary conditions for LES remain the same as for laminar flows.

13.16. Providing an Initial Guess for k and ε (or k and ω)

For flows using one of the k - ε models, one of the k - ω models, or the RSM, the converged solutions or (for unsteady calculations) the solutions after a sufficiently long time has elapsed should be independent of the initial values for k and ε (or k and ω). For better convergence, however, it is beneficial to use a reasonable initial guess for k and ε (or k and ω).

In general, it is recommended that you start from a fully-developed state of turbulence. When you use the enhanced wall treatment for the k - ε models or the RSM, it is critically important to specify fully-developed turbulence fields. Guidelines are provided below.

- If you were able to specify reasonable boundary conditions at the inlet, it may be a good idea to compute the initial values for k and ε (or k and ω) in the whole domain from these boundary values. (See [Initializing the Solution \(p. 1348\)](#) for details.)
- For more complex flows (e.g., flows with multiple inlets with different conditions) it may be better to specify the initial values in terms of turbulence intensity. 5–10% is enough to represent fully-developed turbulence. The values of k can then be computed from the turbulence intensity and the characteristic mean velocity magnitude of your problem ($k = 1.5 \left(Iu_{avg} \right)^2$).

You should specify an initial guess for ε so that the resulting eddy viscosity ($C_\mu \frac{k^2}{\varepsilon}$) is sufficiently large in comparison to the molecular viscosity. In fully-developed turbulence, the turbulent viscosity is roughly two orders of magnitude larger than the molecular viscosity. From this, you can compute ε .

$$\varepsilon = C_\mu \frac{k^2}{\mu_T} = C_\mu \frac{k^2}{\frac{\mu_T}{\mu} \mu} \quad (13-8)$$

where $\frac{\mu_T}{\mu}$ is the turbulent viscosity ratio which can be prescribed at the inlet and then used for the domain initialization.

Note that, for the RSM, Reynolds stresses are initialized automatically using [Equation 13–6 \(p. 723\)](#) and [Equation 13–7 \(p. 723\)](#).

13.17. Solution Strategies for Turbulent Flow Simulations

Compared to laminar flows, simulations of turbulent flows are more challenging in many ways. For the Reynolds-averaged approach, additional equations are solved for the turbulence quantities. Since the equations for mean quantities and the turbulent quantities (μ_t , k , ε , ω , or the Reynolds stresses) are strongly coupled in a highly non-linear fashion, it takes more computational effort to obtain a converged turbulent solution than to obtain a converged laminar solution. The LES model, while embodying a simpler, algebraic model for the subgrid-scale viscosity, requires a transient solution on a very fine mesh.

The fidelity of the results for turbulent flows is largely determined by the turbulence model being used. Here are some guidelines that can enhance the quality of your turbulent flow simulations.

For additional information, please see the following sections:

- 13.17.1. Mesh Generation
- 13.17.2. Accuracy
- 13.17.3. Convergence
- 13.17.4. RSM-Specific Solution Strategies
- 13.17.5. LES-Specific Solution Strategies

13.17.1. Mesh Generation

The following are suggestions to follow when generating the mesh for use in your turbulent flow simulation:

- First imagine the flow under consideration, then identify the main flow features expected in the flow using your physical intuition or any data for a similar flow situation. Generate a mesh that can resolve the major features that you expect.
- If the flow is wall-bounded, and the wall is expected to affect the flow significantly, then take additional care when generating the mesh. You should avoid using a mesh that is too fine (for the wall-function approach) or too coarse (for the enhanced wall treatment approach). See *Grid Resolution RANS Models* (p. 688) and *Wall Boundary Layers* (p. 692) for details.

13.17.2. Accuracy

The suggestions below are provided to help you obtain better accuracy in your results:

- Use the turbulence model that is better suited for the salient features you expect to see in the flow (see *Choosing a Turbulence Model* (p. 685)).
- Because the mean quantities have larger gradients in turbulent flows than in laminar flows, it is recommended that you use high-order schemes for the convection terms. This is especially true if you employ a triangular or tetrahedral mesh. Note that excessive numerical diffusion adversely affects the solution accuracy, even with the most elaborate turbulence model.
- In some flow situations involving inlet boundaries, the flow downstream of the inlet is dictated by the boundary conditions at the inlet. In such cases, you should exercise care to make sure that reasonably realistic boundary values are specified.

13.17.3. Convergence

The suggestions below are provided to help you enhance convergence for turbulent flow calculations:

- Starting with excessively crude initial guesses for mean and turbulence quantities may cause the solution to diverge. A safe approach is to start your calculation using conservative (small) under-relaxation parameters and (for the density-based solvers) a conservative Courant number, and increase them gradually as the iterations proceed and the solution begins to settle down.
- It is also helpful for faster convergence to start with reasonable initial guesses for the k and ε (or k and ω) fields. Particularly when the enhanced wall treatment is used, it is important to start with a sufficiently developed turbulence field, as recommended in *Providing an Initial Guess for k and ε (or k and ω)* (p. 725), to avoid the need for an excessive number of iterations to develop the turbulence field.
- When you are using the RNG k - ε model, an approach that might help you achieve better convergence is to obtain a solution with the standard k - ε model before switching to the RNG model. Due to the additional non-linearities in the RNG model, lower under-relaxation factors and (for the density-based solvers) a lower Courant number might also be necessary.

Note that when you use the enhanced wall treatment, you may sometimes find during the calculation that the residual for ε is reported to be zero. This happens when your flow is such that Re_y is less than 200 in the entire flow domain, and ε is obtained from the algebraic formula ([Equation 4–304 in the Theory Guide](#)) instead of from its transport equation.

13.17.4. RSM-Specific Solution Strategies

Using the RSM creates a high degree of coupling between the momentum equations and the turbulent stresses in the flow, and thus the calculation can be more prone to stability and convergence difficulties than with the k - ε models. When you use the RSM, therefore, you may need to adopt special solution strategies in order to obtain a converged solution. The following strategies are generally recommended:

- Begin the calculations using the standard k - ε model. Turn on the RSM and use the k - ε solution data as a starting point for the RSM calculation.
- Use low under-relaxation factors (0.2 to 0.3) and (for the density-based solvers) a low Courant number for highly swirling flows or highly complex flows. In these cases, you may need to reduce the under-relaxation factors both for the velocities and for all of the stresses.

Instructions for setting these solution parameters are provided below. If you are applying the RSM to prediction of a highly swirling flow, you will want to consider the solution strategies discussed in [Swirling and Rotating Flows \(p. 519\)](#) as well.

13.17.4.1. Under-Relaxation of the Reynolds Stresses

ANSYS FLUENT applies under-relaxation to the Reynolds stresses. You can set under-relaxation factors using the [Solution Controls Task Page \(p. 2052\)](#).

Solution Controls

The default settings of 0.5 are recommended for most cases. You may be able to increase these settings and speed up the convergence when the RSM solution begins to converge.

In some situations, when poor convergence is observed one might facilitate the convergence rates by modifying some of the under-relaxation values whilst leaving the others unchanged. This might be a more successful approach than the simple scaling of all under-relaxation values.

13.17.4.2. Disabling Calculation Updates of the Reynolds Stresses

In some instances, you may wish to let the current Reynolds stress field remain fixed, skipping the solution of the Reynolds transport equations while solving the other transport equations. You can activate/deactivate all Reynolds stress equations in the **Equations** dialog box, accessed from the [Solution Controls Task Page \(p. 2052\)](#).

Solution Controls → Equations...

13.17.4.3. Residual Reporting for the RSM

When you use the RSM for turbulence, ANSYS FLUENT reports the equation residuals for the individual Reynolds stress transport equations. You can apply the usual convergence criteria to the Reynolds stress residuals: normalized residuals in the range of 10^{-3} usually indicate a practically-converged solution.

However, you may need to apply tighter convergence criteria (below 10^{-4}) to ensure full convergence.

13.17.5. LES-Specific Solution Strategies

Large eddy simulation involves running a transient solution from some initial condition, on an appropriately fine mesh, using an appropriate time step size. The solution must be run long enough to become independent of the initial condition and to enable the statistics of the flow field to be determined.

The following are suggestions to follow when running a large eddy simulation:

1. Start by running a steady state flow simulation using a Reynolds-averaged turbulence model such as standard k - ε , k - ω , or even RSM. Run until the flow field is reasonably converged and then use the `solve/initialize/init-instantaneous-vel` text command to generate the instantaneous velocity field out of the steady-state RANS results. This command must be executed before LES is enabled. This option is available for all RANS-based models and it will create a much more realistic initial field for the LES run. Additionally, it will help in reducing the time needed for the LES simulation to reach a statistically stable mode. This step is optional.
2. When you enable LES, ANSYS FLUENT will automatically turn on the unsteady solver option and choose the second-order implicit formulation. You will need to set the appropriate time step size and all the needed solution parameters. (See [User Inputs for Time-Dependent Problems \(p. 1366\)](#) for guidelines on setting solution parameters for transient calculations in general.) The bounded central differencing spatial discretization scheme will be automatically enabled for momentum equations. Both the bounded central-differencing and pure central-differencing schemes are available for all equations when running LES simulations.
3. Run LES until the flow becomes statistically steady. The best way to see if the flow is fully developed and statistically steady is to monitor forces and solution variables (e.g., velocity components or pressure) at selected locations in the flow.
4. Zero out the initial statistics using the `solve/initialize/init-flow-statistics` text command. Before you restart the solution, enable **Data Sampling for Time Statistics** in the [Run Calculation Task Page \(p. 2107\)](#), as described in [User Inputs for Time-Dependent Problems \(p. 1366\)](#). With this option enabled, ANSYS FLUENT will gather data for time statistics while performing a large eddy simulation. You can set the **Sampling Interval** such that **Data Sampling for Time Statistics** can be performed at the specified frequency. When **Data Sampling for Time Statistics** is enabled, the statistics collected at each sampling interval can be postprocessed and you can then view both the mean and the root-mean-square (RMS) values in ANSYS FLUENT. The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.
5. Continue until you get statistically stable data. The duration of the simulation can be determined beforehand by estimating the mean flow residence time in the solution domain (L/U , where L is the characteristic length of the solution domain and U is a characteristic mean flow velocity). **The simulation should be run for at least a few mean flow residence times.**

Instructions for setting the solution parameters for LES are provided below.

13.17.5.1. Temporal Discretization

ANSYS FLUENT provides both first-order and second-order temporal discretizations. **For LES, the second-order discretization is recommended.**

Solution Methods

13.17.5.2. Spatial Discretization

Overly diffusive schemes such as the first-order upwind or power law scheme should be avoided, because they may unduly damp out the energy of the resolved eddies. The central-differencing based schemes are recommended for all equations when you use the LES model. ANSYS FLUENT provides two central-differencing based schemes: *pure* central-differencing and *bounded* central-differencing. The bounded scheme is the default option when you select LES or DES.

Solution Methods

13.18. Postprocessing for Turbulent Flows

ANSYS FLUENT provides postprocessing options for displaying, plotting, and reporting various turbulence quantities, which include the main solution variables and other auxiliary quantities.

Turbulence quantities that can be reported for the Spalart-Allmaras model are as follows:

- **Modified Turbulent Viscosity**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Yplus**

Turbulence quantities that can be reported for the k - ε models are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Wall Ystar**
- **Turbulent Reynolds Number (Re_y)** (only when the enhanced wall treatment is used for the near-wall treatment)

Turbulence quantities that can be reported for the k - ω models are as follows:

- **Turbulent Kinetic Energy (k)**

- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**

Turbulence quantities that can be reported for the transition $k-l-\omega$ model are as follows:

- **Turbulent Kinetic Energy (k)**
- **Laminar Kinetic Energy**
- **Total Fluctuation Energy**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Production of laminar k**
- **Turbulent Viscosity**
- **Turbulent Viscosity (large-scale)**
- **Turbulent Viscosity (small-scale)**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**

Turbulence quantities that can be reported for the transition SST model are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Intermittency**

- **Intermittency Effective**
- **Momentum Thickness Re**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**

Turbulence quantities that can be reported for the RSM are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **UU Reynolds Stress**
- **VV Reynolds Stress**
- **WW Reynolds Stress**
- **UV Reynolds Stress**
- **VW Reynolds Stress**
- **UW Reynolds Stress**
- **Turbulent Dissipation Rate (Epsilon)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**

Turbulence quantities that can be reported for the SAS model are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Specific Dissipation Rate (Omega)**
- **Production of k**

- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Yplus**
- **Wall Ystar**
- **Normalized Q criterion**

Turbulence quantities that can be reported for the DES model are as follows:

- **Modified Turbulent Viscosity**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Yplus**
- **Relative Length Scale (DES)**
- **Normalized Q criterion**

Turbulence quantities that can be reported for the LES model are as follows:

- **Turbulence Kinetic Energy**
- **Turbulence Intensity**
- **Subgrid Kinetic Energy**
- **Production of k**
- **Subgrid Turbulent Viscosity**
- **Subgrid Effective Viscosity**
- **Subgrid Turbulent Viscosity Ratio**
- **Subgrid Filter Length**
- **Subgrid Test-Filter Length**
- **Subgrid Dissipation Rate**
- **Subgrid Dynamic Viscosity Const**
- **Subgrid Dynamic Prandtl Number**
- **Subgrid Dynamic Sc of Species**
- **Subtest Kinetic Energy**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**

- **Wall Yplus**
- **Normalized Q criterion**

Additional turbulence quantities can be reported for the Embedded LES (ELES) model.

Note

Within the Embedded LES zone, the modeled eddy viscosity is determined by an algebraic sub-grid scale eddy viscosity model. The global turbulence model is either frozen or, if it is either SAS or DES with an underlying two-equation RANS model, runs in a "passive mode", i.e. without affecting the momentum equations.

Hence, most turbulence postprocessing in the Embedded LES zone refers to the frozen or "passive" global turbulence model. Special care is necessary with the modeled eddy viscosity, because there are two to consider: one from the frozen / passive global turbulence model; and one from the "local" algebraic sub-grid scale model that is running within the Embedded LES zone and actually affects the momentum equations.

- Some postprocessing quantities refer to a "passive" global turbulence model or are zero if the global model cannot run in "passive" mode and therefore is frozen in the Embedded LES zone.
 - **Turbulent Viscosity**
 - **Turbulent Viscosity Ratio**
- In the Embedded LES zone, the sub-grid scale eddy viscosity from the local algebraic model, which actually affects the momentum equations, is displayed as:
 - **LES Subgrid Turbulent Viscosity**
- The following quantities are specific to the Dynamic LES sub-grid scale eddy viscosity models. They are available in Embedded LES zones if the Dynamic Smagorinsky model is used in any Embedded LES zone; they are also available for global LES with the Dynamic Smagorinsky or the Dynamic TKE Transport sub-grid scale model:
 - **Subgrid Test-Filter Length**
 - **Subgrid Dynamic Viscosity Const**
 - **Subtest Kinetic Energy**

All of these variables can be found in the **Turbulence...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See [Field Function Definitions \(p. 1653\)](#) for their definitions.

For additional information, please see the following sections:

- [13.18.1. Custom Field Functions for Turbulence](#)
- [13.18.2. Postprocessing Turbulent Flow Statistics](#)
- [13.18.3. Troubleshooting](#)

13.18.1. Custom Field Functions for Turbulence

In addition to the quantities listed in [Postprocessing for Turbulent Flows \(p. 729\)](#), above, you can define your own turbulence quantities using the [Custom Field Function Calculator Dialog Box \(p. 2264\)](#).

Define → Custom Field Functions...

The following functions may be useful:

- the ratio of production of k to its dissipation ($G_k/\rho\varepsilon$)
- the ratio of the mean flow to turbulent time scale, η ($\equiv Sk/\varepsilon$)
- the Reynolds stresses derived from the Boussinesq formula (e.g., $-\bar{u}\bar{v} = \nu_t \frac{\partial u}{\partial y}$)

13.18.2. Postprocessing Turbulent Flow Statistics

As described in [Large Eddy Simulation \(LES\) Model](#) (in the [Theory Guide](#)), LES involves the solution of a transient flow field, but it is the mean flow quantities that are of interest from an engineering standpoint.

For all other turbulent flow, if **Data Sampling for Time Statistics** is enabled in the [Run Calculation Task Page \(p. 2107\)](#), ANSYS FLUENT gathers data for time statistics while performing the simulation. The statistics that ANSYS FLUENT collects at each sampling interval (which consists of the mean and the root-mean-square (RMS) values) can be postprocessed by selecting **Unsteady Statistics...** in any of the postprocessing dialog boxes. You can view several variables that include, but are not limited to, shear stresses (**Resolved UV/UW/VW Reynolds Stress**), flow heat fluxes (**Resolved UT/VT/WT Heat Flux**), and species statistics (**RMS Mass Fraction** of species and **Mean Mass Fraction** of species). If you select **Unsteady Wall Statistics...** in any of the postprocessing dialog boxes, you can view wall statistics such as **Mean Pressure Coefficient**, **Mean Wall Shear Stress**, **Mean X-Wall Shear Stress**, **Mean Y-Wall Shear Stress**, **Mean Z-Wall Shear Stress**, **Mean Skin Friction Coefficient**, **Mean Surface Heat Flux**, **Mean Surface Heat Transfer Coef.**, **Mean Surface Nusselt Number**, **Mean Surface Stanton Number**. Note that these quantities are only the statistical evaluation of sampled solution data, and do not contain any kind of modeled turbulent fluctuations. See [Postprocessing for Time-Dependent Problems \(p. 1378\)](#) for details.

The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean and RMS values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

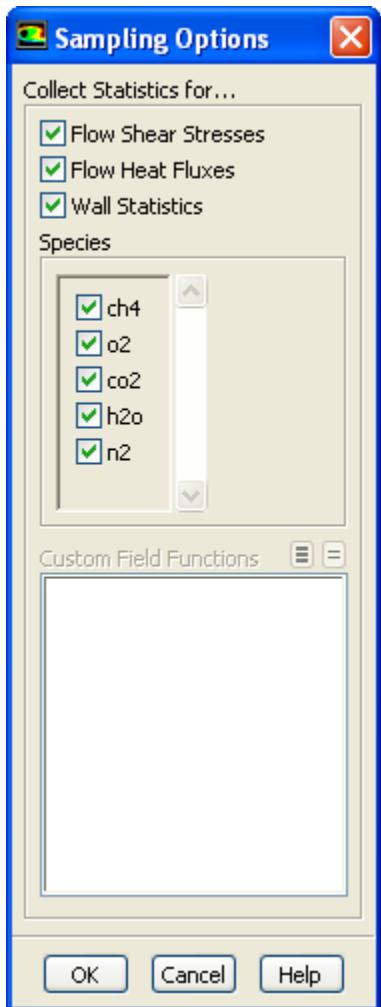

Important

Note that *mean* statistics are collected only in interior cells and not on wall surfaces. Therefore, when node or cell values of mean quantities are plotted on the wall surface, you are actually plotting values in nearby cells attached to the wall.

There may be cases when you want to control what set of variables are available for postprocessing. To enable or disable certain variables, go to

 **Run Calculation** → **Sampling Options...**

The **Sampling Options** dialog box will open, where you can enable or disable the statistics shown in [Figure 13.19 \(p. 735\)](#).

Figure 13.19 Sampling Options Dialog Box

Important

When including or excluding statistics on variables, it is recommended that you re-initialize the flow statistics.

13.18.3. Troubleshooting

You can use the postprocessing options not only for the purpose of interpreting your results but also for investigating any anomalies that may appear in the solution. For instance, you may want to plot contours of the k field to check if there are any regions where k is erroneously large or small. You should see a high k region in the region where the production of k is large. You may want to display the turbulent viscosity ratio field in order to see whether or not the turbulence takes full effect. Usually the turbulent viscosity is at least two orders of magnitude larger than molecular viscosity for fully-developed turbulent flows modeled using the RANS approach (i.e., not using LES). You may also want to see whether you are using an adequate near-wall mesh for the enhanced wall treatment. To ensure this, you can display filled contours of Re_y (turbulent Reynolds number) overlaid on the mesh.

Chapter 14: Modeling Heat Transfer

This chapter provides details about the heat transfer models available in ANSYS FLUENT. Information is presented in the following sections:

- [14.1. Introduction](#)
- [14.2. Modeling Conductive and Convective Heat Transfer](#)
- [14.3. Modeling Radiation](#)
- [14.4. Modeling Periodic Heat Transfer](#)

14.1. Introduction

The flow of thermal energy from matter occupying one region in space to matter occupying a different region in space is known as heat transfer. Heat transfer can occur by three main mechanisms: conduction, convection, and radiation. Physical models involving conduction and/or convection only are the simplest (*Modeling Conductive and Convective Heat Transfer* (p. 737)), while buoyancy-driven flow or natural convection (*Natural Convection and Buoyancy-Driven Flows* (p. 743)), and flow involving radiation (*Modeling Radiation* (p. 751)) are more complex. Depending on your problem, ANSYS FLUENT will solve a variation of the energy equation that takes into account the heat transfer methods you have specified. ANSYS FLUENT is also able to predict heat transfer in periodically repeating geometries (*Modeling Periodic Heat Transfer* (p. 813)), thus greatly reducing the required computational effort in certain cases.

14.2. Modeling Conductive and Convective Heat Transfer

ANSYS FLUENT allows you to include heat transfer within the fluid and/or solid regions in your model. Problems ranging from thermal mixing within a fluid to conduction in composite solids can thus be handled by ANSYS FLUENT.

When your ANSYS FLUENT model includes heat transfer you will need to activate the relevant physical models, supply thermal boundary conditions, and input material properties (which may vary with temperature) that govern heat transfer. For information about heat transfer theory, see *Heat Transfer Theory* in the *Theory Guide*. Information about heat transfer theory and how to set up and use heat transfer in your ANSYS FLUENT model is presented in the following subsections:

- [14.2.1. Solving Heat Transfer Problems](#)
- [14.2.2. Solution Strategies for Heat Transfer Modeling](#)
- [14.2.3. Postprocessing Heat Transfer Quantities](#)
- [14.2.4. Natural Convection and Buoyancy-Driven Flows](#)
- [14.2.5. Shell Conduction Considerations](#)

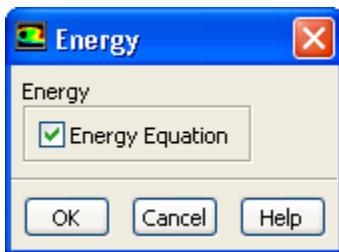

14.2.1. Solving Heat Transfer Problems

The procedure for setting up a heat transfer problem is described below. Note that this procedure includes only those steps necessary for the heat transfer model itself; you will need to set up other models, boundary conditions, etc. as usual.

1. To activate the calculation of heat transfer, enable the **Energy Equation** option in the **Energy** dialog box (*Figure 14.1* (p. 738)).

◆ Models → Energy → Edit...

Figure 14.1 The Energy Dialog Box

2. (Optional, pressure-based solver only.) If you are modeling viscous flow and you want to include the viscous heating terms in the energy equation, enable the **Viscous Heating** option in the **Viscous Model** dialog box.

◆ Models → Viscous → Edit...

As noted in [Inclusion of the Viscous Dissipation Terms](#) in the Theory Guide, the viscous heating terms in the energy equation are (by default) ignored by ANSYS FLUENT when the pressure-based solver is used. They are always included for the density-based solver. Viscous dissipation should be enabled when the shear stress in the fluid is large (e.g., in lubrication problems) and/or in high-velocity, compressible flows. See [Equation 5–9](#) in the [Theory Guide](#).

3. Define thermal boundary conditions at flow inlets, flow outlets, and walls.

◆ Boundary Conditions

At flow inlets and exits you will set the temperature; at walls you may use any of the following thermal conditions:

- specified heat flux
- specified temperature
- convective heat transfer
- external radiation
- combined external radiation and external convective heat transfer

[Thermal Boundary Conditions at Walls \(p. 322\)](#) provides details on the model inputs that govern these thermal boundary conditions. The default thermal boundary condition at inlets is a specified temperature of 300 K; at walls the default condition is zero heat flux (adiabatic). See [Cell Zone and Boundary Conditions \(p. 211\)](#) for details about boundary condition inputs.

Important

If your heat transfer application involves two separated fluid regions, see the information provided below.

4. Define material properties for heat transfer.

◆ Materials

Heat capacity and thermal conductivity must be defined, and you can specify many properties as functions of temperature as described in [Physical Properties](#) (p. 403).

14.2.1.1. Limiting the Predicted Temperature Range

For stability reasons, ANSYS FLUENT includes a limit on the predicted temperature range. The purpose of the temperature ceiling and floor is to improve the stability of calculations in which the temperature should physically lie within known limits. Sometimes intermediate solutions of the equations give rise to temperatures beyond these limits for which property definitions, etc. are not well defined.

The temperature limits keep the temperatures within the expected range for your problem. If the ANSYS FLUENT calculation predicts a temperature above the maximum limit, the stored temperature values are “pegged” at this maximum value. The default for the temperature ceiling is 5000 K. If the ANSYS FLUENT calculation predicts a temperature below the minimum limit, the stored temperature values are “pegged” at this minimum value. The default for the temperature minimum is 1 K.

If you expect the temperature in your domain to exceed 5000 K, use the **Solution Limits** dialog box to increase the **Maximum Temperature**.

 **Solution Controls** → **Limits...**

14.2.1.2. Modeling Heat Transfer in Two Separated Fluid Regions

If your heat transfer application involves two fluid regions separated by a solid zone or a wall, as illustrated in [Figure 14.2](#) (p. 739), you will need to define the problem with some care. Specifically:

- You should not use outflow boundary conditions in either fluid.
- You can establish separate fluid properties by selecting a different fluid material for each zone. For species calculations, however, you can only select a single mixture material for the entire domain.

Figure 14.2 Typical Counterflow Heat Exchanger Involving Heat Transfer Between Two Separated Fluid Streams

14.2.2. Solution Strategies for Heat Transfer Modeling

Although many simple heat transfer problems can be successfully solved using the default solution parameters assumed by ANSYS FLUENT, you may accelerate the convergence of your problem and/or improve the stability of the solution process using some of the guidelines provided in this section.

14.2.2.1. Under-Relaxation of the Energy Equation

When you use the pressure-based solver, ANSYS FLUENT under-relaxes the energy equation using the under-relaxation parameter defined by you in the **Solution Controls** task page, as described in [Setting Under-Relaxation Factors](#) (p. 1323).

 **Solution Controls**

If you are using the non-adiabatic non-premixed combustion model, you will set the energy under-relaxation factor as usual but you will also set an under-relaxation factor for temperature, as described below.

ANSYS FLUENT uses a default under-relaxation factor of 1.0 for the energy equation, regardless of the form in which it is solved (temperature or enthalpy). In problems where the energy field impacts the fluid flow (via temperature-dependent properties or buoyancy) you should use a lower value for the under-relaxation factor, in the range of 0.8–1.0. In problems where the flow field is decoupled from the temperature field (no temperature-dependent properties or buoyancy forces), you can usually retain the default value of 1.0.

14.2.2.2. Under-Relaxation of Temperature When the Enthalpy Equation is Solved

When the enthalpy form of the energy equation is solved (i.e., when you are using the non-adiabatic non-premixed combustion model), ANSYS FLUENT also under-relaxes the temperature, updating the temperature by only a fraction of the change that would result from the change in the (under-relaxed) enthalpy values. This second level of under-relaxation can be used to good advantage when you would like to let the enthalpy field change rapidly, but the temperature response (and its effect on fluid properties) to lag. ANSYS FLUENT uses a default setting of 1.0 for the under-relaxation on temperature and you can modify this setting using the **Solution Controls** task page.

14.2.2.3. Disabling the Species Diffusion Term

If you are solving for species transport using the pressure-based solver and you encounter convergence difficulties, you may want to consider disabling the **Diffusion Energy Source** option in the **Species Model** dialog box.

  **Models** → **Species** → **Edit...**

When this option is disabled, ANSYS FLUENT will neglect the effects of species diffusion on the energy equation.

Note that species diffusion effects are always included when the density-based solver is used.

14.2.2.4. Step-by-Step Solutions

Often the most efficient strategy for predicting heat transfer is to compute an isothermal flow first and then add the calculation of the energy equation. The procedure differs slightly, depending on whether or not the flow and heat transfer are coupled.

14.2.2.4.1. Decoupled Flow and Heat Transfer Calculations

If your flow and heat transfer are decoupled (no temperature-dependent properties or buoyancy forces), you can first solve the isothermal flow (energy equation turned off) to yield a converged flow-field solution and then solve the energy transport equation alone.

Important

Since the density-based solver always solves the flow and energy equations together, the procedure for solving for energy alone applies to the pressure-based solver, only.

You can temporarily disable the flow equations or the energy equation by disabling the **Energy** option in the **Equations** dialog box

 **Solution Controls** → **Equations...**

or

 **Models** →  **Energy** → **Edit...**

14.2.2.4.2. Coupled Flow and Heat Transfer Calculations

If the flow and heat transfer are coupled (i.e., your model includes temperature-dependent properties or buoyancy forces), you can first solve the flow equations before enabling energy. Once you have a converged flow-field solution, you can enable energy and solve the flow and energy equations simultaneously to complete the heat transfer simulation.

14.2.3. Postprocessing Heat Transfer Quantities

For information about postprocessing heat transfer quantities, see the following sections:

- 14.2.3.1. Available Variables for Postprocessing
- 14.2.3.2. Definition of Enthalpy and Energy in Reports and Displays
- 14.2.3.3. Reporting Heat Transfer Through Boundaries
- 14.2.3.4. Reporting Heat Transfer Through a Surface
- 14.2.3.5. Reporting Averaged Heat Transfer Coefficients
- 14.2.3.6. Exporting Heat Flux Data

14.2.3.1. Available Variables for Postprocessing

ANSYS FLUENT provides reporting options for simulations involving heat transfer. You can generate graphical plots or reports of the following variables/functions:

- **Static Temperature**
- **Total Temperature**
- **Enthalpy**
- **Relative Total Temperature**
- **Renthalpy**
- **Wall Temperature (Outer Surface)**
- **Wall Temperature (Inner Surface)**
- **Total Enthalpy**
- **Total Enthalpy Deviation**
- **Entropy**
- **Total Energy**
- **Internal Energy**
- **Total Surface Heat Flux**
- **Surface Heat Transfer Coef.**
- **Surface Nusselt Number**

- **Surface Stanton Number**

The first 12 variables listed above are contained in the **Temperature...** category of the variable selection drop-down list that appears in postprocessing dialog boxes, and the remaining variables are in the **Wall Fluxes...** category. See [Field Function Definitions \(p. 1653\)](#) for their definitions.

14.2.3.2. Definition of Enthalpy and Energy in Reports and Displays

The definitions of the reported values of enthalpy and energy will be different depending on whether the flow is compressible or incompressible.

14.2.3.3. Reporting Heat Transfer Through Boundaries

You can use the **Flux Reports** dialog box to compute the heat transfer through each boundary of the domain, or to sum the heat transfer through all boundaries to check the heat balance.

Reports → **Fluxes** → **Set Up...**

It is recommended that you perform a heat balance check to ensure that your solution is truly converged.

14.2.3.4. Reporting Heat Transfer Through a Surface

You can use the **Surface Integrals** dialog box to compute the heat transfer through any boundary or any surface created using the methods described in [Creating Surfaces for Displaying and Reporting Data \(p. 1473\)](#).

Reports → **Surface Integrals** → **Set Up...**

To report the mass flow rate of enthalpy

$$Q = \int H \rho \vec{v} \cdot d\vec{A} \quad (14-1)$$

choose **Flow Rate** for the **Report Type** in the **Surface Integrals** dialog box, select **Enthalpy** (in the **Temperature...** category) as the **Field Variable**, and select the surface(s) on which to integrate.

14.2.3.5. Reporting Averaged Heat Transfer Coefficients

The **Surface Integrals** dialog box can also be used to generate a report of averaged heat transfer

coefficient h on a surface ($\frac{1}{A} \int h dA$).

Reports → **Surface Integrals** → **Set Up...**

In the **Surface Integrals** dialog box, choose **Area-Weighted Average** for **Report Type**, select **Surface Heat Transfer Coef.** (in the **Wall Fluxes...** category) as the **Field Variable**, and select the surface.

14.2.3.6. Exporting Heat Flux Data

It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. To save a heat flux file, you will use the `custom-heat-flux` text command.

```
file → export → custom-heat-flux
```

Heat transfer data will be exported in the following free format for each face zone that you select for export:

```
zone-name nfacs
x_f y_f z_f A Q T_w T_c HTC
.
.
```

Each block of data starts with the name of the face zone (`zone-name`) and the number of faces in the zone (`nfacs`). Next there is a line for each face (i.e., `nfacs` lines), each containing the components of the face centroid (`x_f`, `y_f`, and, in 3D, `z_f`), the face area (`A`), the heat transfer rate (`Q`), the face temperature (`T_w`), the adjacent cell temperature (`T_c`), and the heat transfer coefficient (`HTC`). If the heat transfer coefficient is calculated based on wall function ([Equation 34–54 \(p. 1707\)](#)), then Q is the convective heat transfer rate. Otherwise, Q will be the total heat transfer rate, including radiation heat transfer.

14.2.4. Natural Convection and Buoyancy-Driven Flows

When heat is added to a fluid and the fluid density varies with temperature, a flow can be induced due to the force of gravity acting on the density variations. Such buoyancy-driven flows are termed natural-convection (or mixed-convection) flows and can be modeled by ANSYS FLUENT.

For more information about the theory behind natural convection and buoyancy-driven flows, see [Natural Convection and Buoyancy-Driven Flows Theory](#) in the [Theory Guide](#).

14.2.4.1. Modeling Natural Convection in a Closed Domain

When you model natural convection inside a closed domain, the solution will depend on the mass inside the domain. Since this mass will not be known unless the density is known, you must model the flow in one of the following ways:

- Perform a transient calculation. In this approach, the initial density will be computed from the initial pressure and temperature, so the initial mass is known. As the solution progresses over time, this mass will be properly conserved. If the temperature differences in your domain are large, you must follow this approach.
- Perform a steady-state calculation using the Boussinesq model (described in [The Boussinesq Model \(p. 744\)](#)). In this approach, you will specify a constant density, so the mass is properly specified. This approach is valid only if the temperature differences in the domain are small. If not, you use the transient approach.

Important

For a closed domain, you can use the *incompressible* ideal gas law only with a *fixed* operating pressure. It *cannot* be used with a floating operating pressure. You can use the *compressible* ideal gas law with either *floating* or *fixed* operating pressure.

See [Floating Operating Pressure \(p. 529\)](#) for more information about the floating operating pressure option.

14.2.4.2. The Boussinesq Model

For many natural-convection flows, you can get faster convergence with the Boussinesq model than you can get by setting up the problem with fluid density as a function of temperature. This model treats density as a constant value in all solved equations, except for the buoyancy term in the momentum equation:

$$(\rho - \rho_0)g \approx -\rho_0\beta(T - T_0)g \quad (14-2)$$

where ρ_0 is the (constant) density of the flow, T_0 is the operating temperature, and β is the thermal expansion coefficient. [Equation 14-2 \(p. 744\)](#) is obtained by using the Boussinesq approximation $\rho = \rho_0(1 - \beta\Delta T)$ to eliminate ρ from the buoyancy term. This approximation is accurate as long as changes in actual density are small; specifically, the Boussinesq approximation is valid when $\beta(T - T_0) \ll 1$.

14.2.4.3. Limitations of the Boussinesq Model

The Boussinesq model should not be used if the temperature differences in the domain are large. In addition, it cannot be used with species calculations, combustion, or reacting flows.

14.2.4.4. Steps in Solving Buoyancy-Driven Flow Problems

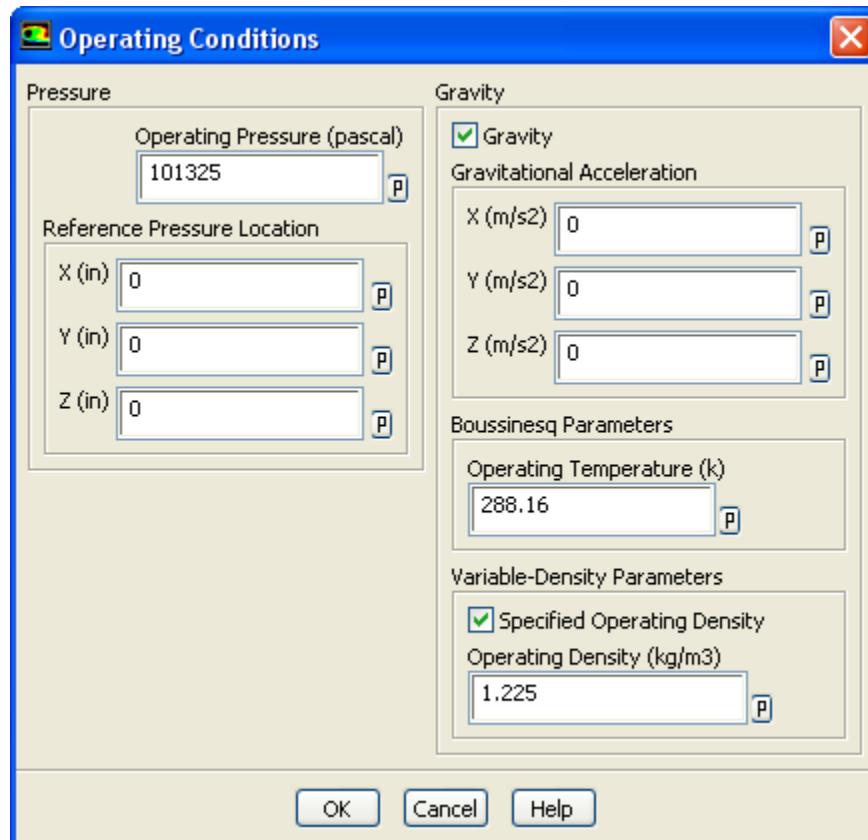

The procedure for including buoyancy forces in the simulation of mixed or natural convection flows is described below.

1. Activate the calculation of heat transfer, by enabling the **Energy** option in the **Energy** dialog box.

Models → **Energy** → **Edit...**

2. Define the operating conditions in the **Operating Conditions** dialog box ([Figure 14.3 \(p. 745\)](#)).

Cell Zone Conditions → **Operating Conditions...**

Figure 14.3 The Operating Conditions Dialog Box

- Enable the **Gravity** option under **Gravity**.
- Enter the appropriate values in the **X**, **Y**, and (for 3D) **Z** fields for **Gravitational Acceleration** for each Cartesian coordinate direction. (Note that the default gravitational acceleration in ANSYS FLUENT is zero.)
- If you are using the incompressible ideal gas law, check that the **Operating Pressure** is set to an appropriate (non-zero) value.
- Depending on whether or not you use the Boussinesq approximation, specify the appropriate parameters described below:
 - If you are not using the Boussinesq model, the inputs are as follows:
 - If necessary, enable the **Specified Operating Density** option in the **Operating Conditions** dialog box, and enter a value for the **Operating Density**. See below for details.
 - Define the fluid density as a function of temperature as described in *Defining Properties Using Temperature-Dependent Functions* (p. 417) and *Density* (p. 421).

Materials

- If you are using the Boussinesq model (described in *The Boussinesq Model* (p. 744)) the inputs are as follows:
 - Enter the **Operating Temperature** (T_0 in *Equation 14–2* (p. 744)) in the **Operating Conditions** dialog box.

- ii. Select **boussinesq** in the drop-down list for **Density** in the **Create/Edit Materials** dialog box as described in *Defining Properties Using Temperature-Dependent Functions (p. 417)* and *Density (p. 421)*, and enter a constant value.
- iii. Also in the **Create/Edit Materials** dialog box, enter an appropriate value for the **Thermal Expansion Coefficient** (β in *Equation 14–2 (p. 744)*) for the fluid material.

Note that if your model involves multiple fluid materials you can choose whether or not to use the Boussinesq model for each material. As a result, you may have some materials using the Boussinesq model and others not. In such cases, you will need to set all the parameters described above in this step.

3. Define the boundary conditions.

Boundary Conditions

The boundary pressures that you input at pressure inlet and outlet boundaries are the redefined pressures as given by *Equation 14–3 (p. 746)*. In general you should enter equal pressures, p' , at the inlet and exit boundaries of your ANSYS FLUENT model if there are no externally-imposed pressure gradients.

4. Set the parameters that control the solution.

Solution Methods

- a. Select **Body Force Weighted** or **Second Order** in the drop-down list for **Pressure** under **Spatial Discretization** in the **Solution Methods** task page.
- b. If you are using the pressure-based solver, selecting **PRESTO!** as the **Spatial Discretization** method for **Pressure** is the recommended approach.
- c. Add cells near the walls to resolve boundary layers, if necessary.

See also *Solving Heat Transfer Problems (p. 737)* for information on setting up heat transfer calculations.

14.2.4.5. Operating Density

When the Boussinesq approximation is not used, the operating density ρ_0 appears in the body-force term in the momentum equations as $(\rho - \rho_0)g$. This form of the body-force term follows from the redefinition of pressure in ANSYS FLUENT as

$$p'_s = p_s - \rho_0 g x \quad (14-3)$$

The hydrostatic pressure in a fluid at rest is then

$$p'_s = 0 \quad (14-4)$$

14.2.4.5.1. Setting the Operating Density

By default, ANSYS FLUENT will compute the operating density by averaging over all cells. In some cases, you may obtain better results if you explicitly specify the operating density instead of having the solver compute it for you. For example, if you are solving a natural-convection problem with a pressure

boundary, it is important to understand that the pressure you are specifying is p'_s in [Equation 14–3](#) (p. 746). Although you will know the actual pressure p_s , you will need to know the operating density ρ_0 in order to determine p'_s from p_s . Therefore, you should explicitly specify the operating density rather than use the computed average. The specified value should, however, be representative of the average value.

In some cases the specification of an operating density will improve convergence behavior, rather than the actual results. For such cases use the approximate bulk density value as the operating density and be sure that the value you choose is appropriate for the characteristic temperature in the domain.

Note that if you are using the Boussinesq approximation for all fluid materials, the operating density ρ_0 does not appear in the body-force term of the momentum equation. Consequently, you need not specify it.

14.2.4.6. Solution Strategies for Buoyancy-Driven Flows

For high-Rayleigh-number flows you may want to consider the solution guidelines below. In addition, the guidelines presented in [Solution Strategies for Heat Transfer Modeling](#) (p. 739) for solving other heat transfer problems can also be applied to buoyancy-driven flows. No steady-state solution exists for some laminar, high-Rayleigh-number flows.

14.2.4.6.1. Guidelines for Solving High-Rayleigh-Number Flows

When you are solving a high-Rayleigh-number flow ($Ra > 10^8$), you should follow one of the procedures outlined below for best results.

The first procedure uses a steady-state approach:

1. Start the solution with a lower value of Rayleigh number (e.g., 10^7) and run it to convergence using the first-order scheme.
2. To change the effective Rayleigh number, change the value of gravitational acceleration (e.g., from 9.8 to 0.098 to reduce the Rayleigh number by two orders of magnitude).
3. Use the resulting data file as an initial guess for the higher Rayleigh number and start the higher-Rayleigh-number solution using the first-order scheme.
4. After you obtain a solution with the first-order scheme you may continue the calculation with a higher-order scheme.

The second procedure uses a time-dependent approach to obtain a steady-state solution [\[31\]](#) (p. 2368):

1. Start the solution from a steady-state solution obtained for the same or a lower Rayleigh number.
2. Estimate the time constant as [\[10\]](#) (p. 2367)

$$\tau = \frac{L}{U} \sim \frac{L^2}{\alpha} (PrRa)^{-1/2} = \frac{L}{\sqrt{g\beta \Delta TL}} \quad (14-5)$$

where L and U are the length and velocity scales, respectively. Use a time step Δt such that

$$\Delta t \approx \frac{\tau}{4} \quad (14-6)$$

Using a larger time step Δt may lead to divergence.

3. After oscillations with a typical frequency of $f\tau = 0.05\text{--}0.09$ have decayed, the solution reaches steady state. Note that τ is the time constant estimated in [Equation 14-5 \(p. 747\)](#) and f is the oscillation frequency in Hz. In general this solution process may take as many as 5000 time steps to reach steady state.

14.2.4.7. Postprocessing Buoyancy-Driven Flows

The postprocessing reports of interest for buoyancy-driven flows are the same as for other heat transfer calculations. See [Postprocessing Heat Transfer Quantities \(p. 741\)](#) for details.

14.2.5. Shell Conduction Considerations

For more information about shell conduction considerations, see the following sections:

- [14.2.5.1. Introduction](#)
- [14.2.5.2. Physical Treatment](#)
- [14.2.5.3. Limitations of Shell Conduction Walls](#)
- [14.2.5.4. Managing Shell Conduction Walls](#)
- [14.2.5.5. Initialization](#)
- [14.2.5.6. Postprocessing](#)

14.2.5.1. Introduction

By default, ANSYS FLUENT treats walls as zero thickness presenting no thermal resistance to heat transfer across them. If a thickness is specified for walls then the appropriate thermal resistance across the wall thickness is imposed, although conduction is considered in the wall in the normal direction only. There are applications, however, where conduction in the planar direction of the wall is also important. For these applications, you have two options: you can either mesh the thickness or you can use the shell conduction approach. Shell conduction can be used to model thin sheets without the need to mesh the wall thickness in a preprocessor. When the shell conduction approach is utilized, you have the ability to easily switch on and off conjugate heat transfer on any wall. When you specify a thickness for the wall, a material property, and enable **Shell Conduction** in the **Wall** dialog box (as described in [Shell Conduction in Thin-Walls \(p. 327\)](#)) or in the **Shell Conduction Walls** dialog box ([Managing Shell Conduction Walls \(p. 749\)](#)), then during the solution process ANSYS FLUENT automatically grows a layer of prism cells or hex cells for the wall, depending on the type of face mesh that is utilized.

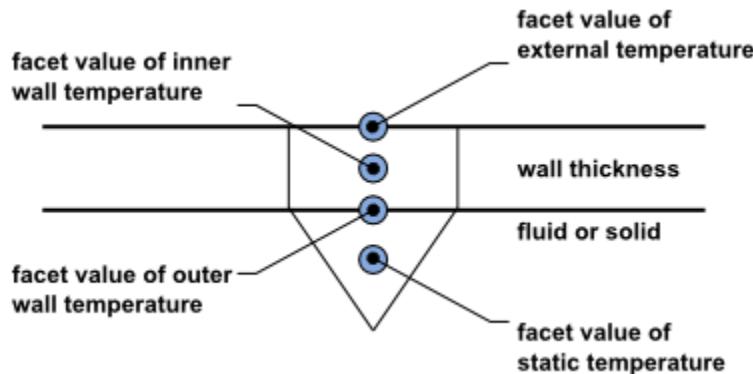

Shell conduction can be used to account for thermal mass in transient thermal analysis problems such as soaking. It can also be used for multiple junctions and allows heat conduction through the junctions. Shell conduction can be applied on boundary walls as well as internal walls.

14.2.5.2. Physical Treatment

In the case of shell conduction that is applied on a boundary wall, the original wall is treated as a coupled wall, where the surface that is adjacent to the fluid cells is referred to as the “outer” surface, and the temperature of the surface that is away from the adjacent fluid cells is referred to as the “external temperature (shell)”. The surface that is in the middle of the cells grown for the wall is referred to as the “inner” surface. See [Figure 14.4 \(p. 749\)](#). Note that the definition for the inner surface of a shell

conduction model differs from the definition used for thin walls without shell conduction (compare *Figure 14.4* (p. 749) with *Figure 7.35* (p. 325)).

Figure 14.4 A Case for Shell Conduction

The boundary condition that you specify on the original wall is applied to the inner surface. Note however, that internal emissivity is applied at the outer surface. The shell boundaries (the sides of the shell zone) need boundary conditions as well. If the wall with shell conduction is connected to another wall that has no shell conduction, the shell side will take its boundary condition. The sides will be adiabatic if they are connected to face zones having a boundary condition type other than **wall**. If the attached wall has shell conduction, the common sides at the junction will be coupled.

14.2.5.3. Limitations of Shell Conduction Walls

The following is a list of limitations for the shell conduction model:

- Shells cannot be created on non-conformal interfaces.
- Shell conduction cannot be used on moving wall zones.
- Shell conduction cannot be used with FMG initialization.
- Shell conduction is not available for 2D.
- Shell conduction is available only when the pressure-based solver is used.
- Shell conducting walls cannot be split or merged. If you need to split or merge a shell conducting wall, you will need to turn off the **Shell Conduction** option for the wall (in the **Wall** dialog box, perform the split or merge operation, and then enable **Shell Conduction** for the new wall zones).
- The shell conduction model cannot be used on a wall zone that has been adapted. If you want to perform adaption elsewhere in the computational domain, be sure to use the mask register described in *Manipulating Adaption Registers* (p. 1459). This will ensure that adaption is not performed on the shell conducting wall.
- Fluxes at the ends of a shell conducting wall are not included in heat balance reports. These fluxes are accounted for correctly in the ANSYS FLUENT solution, but are not listed in the flux report.

14.2.5.4. Managing Shell Conduction Walls

The **Shell Conduction Walls** dialog box is a convenient application, which allows you to manage, define, and display shell conduction zones all in one location. You can

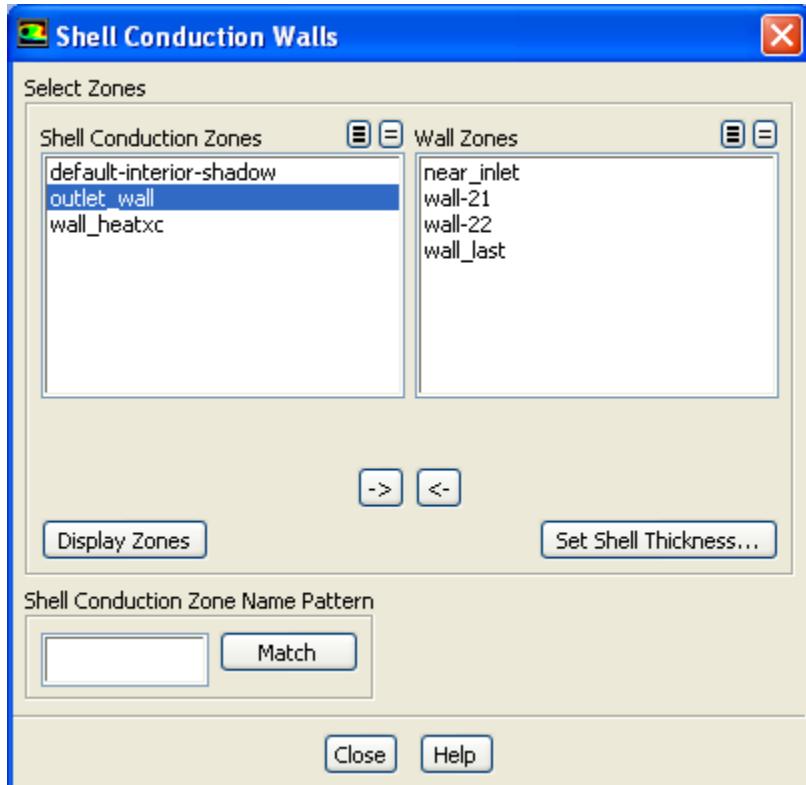

- Display any wall zone.
- Enable or disable shell conduction for a wall.

- Set the thickness for shell conduction walls.

Note that you can still enable shell conduction and set the thickness of a wall in the **Wall** boundary conditions dialog box, as described in [Shell Conduction in Thin-Walls \(p. 327\)](#). However, the **Shell Conduction Walls** dialog box provides you with an alternative to do such activities from a single dialog box for all the walls, instead of visiting the individual **Wall** boundary condition dialog boxes.

Define → Shell Conduction Walls...

Figure 14.5 The Shell Conduction Walls Dialog Box

To manage shell conduction using the **Shell Conduction Walls** dialog box, do the following:

1. Use the $->$ and $<-$ arrows to enable or disable shell conduction. Zones with shell conduction enabled are listed under **Shell Conduction Zones** and those without shell conduction are listed under **Wall Zones**. In essence, the $->$ button disables shell conduction and the $<-$ button enables shell conduction.
2. Click the **Display Zones** button to display the selected wall(s) in the graphics window. Note that you can select walls with or without shell conduction. The zones will be displayed with different colors depending on the option selected in **Mesh Colors** dialog box accessible from the **Mesh Display** dialog box.
3. Click the **Set Shell Thickness...** button to open the **Set Shell Thickness** dialog box ([Figure 14.6 \(p. 751\)](#)), where you can set the thicknesses of the selected **Shell Conduction Zones**.

Figure 14.6 The Set Shell Thickness Dialog Box

- a. If you want to apply the same thickness to all the selected shell conduction zones, enter the value in the **Thickness** field and click the **Apply** button.
 - b. If you want to apply different thicknesses to the selected shell conduction zones, enter the values against each zone listed in the **Shell Conduction Zones** group box and click the **OK** button.
4. You can use the **Shell Conduction Zone Name Pattern** to select only shell conduction zones with names that match the specified pattern.

14.2.5.5. Initialization

Shell zones can be patched using the **Patch** dialog box.

◆ **Solution Initialization → Patch...**

14.2.5.6. Postprocessing

Shell zones can be postprocessed. The **Temperature...** category provides various options: the shell cell temperature is stored as **Wall Temperature (Inner Surface)**; the temperature of the surface adjacent to the fluid cells is stored as **Wall Temperature (Outer Surface)**; and the temperature of the surface that is away from the fluid cells is stored as **External Temperature (Shell)**. If a more detailed analysis of the solid zone and surfaces is required, then you should consider using a layer of solid zones in your model.

14.3. Modeling Radiation

Information about radiation modeling is presented in the following sections:

- 14.3.1. Using the Radiation Models
- 14.3.2. Setting Up the P-1 Model with Non-Gray Radiation
- 14.3.3. Setting Up the DTRM
- 14.3.4. Setting Up the S2S Model
- 14.3.5. Setting Up the DO Model
- 14.3.6. Defining Material Properties for Radiation
- 14.3.7. Defining Boundary Conditions for Radiation
- 14.3.8. Solution Strategies for Radiation Modeling
- 14.3.9. Postprocessing Radiation Quantities
- 14.3.10. Solar Load Model

For theoretical information about the radiation models in ANSYS FLUENT, refer to **Modeling Radiation** in the [Theory Guide](#).

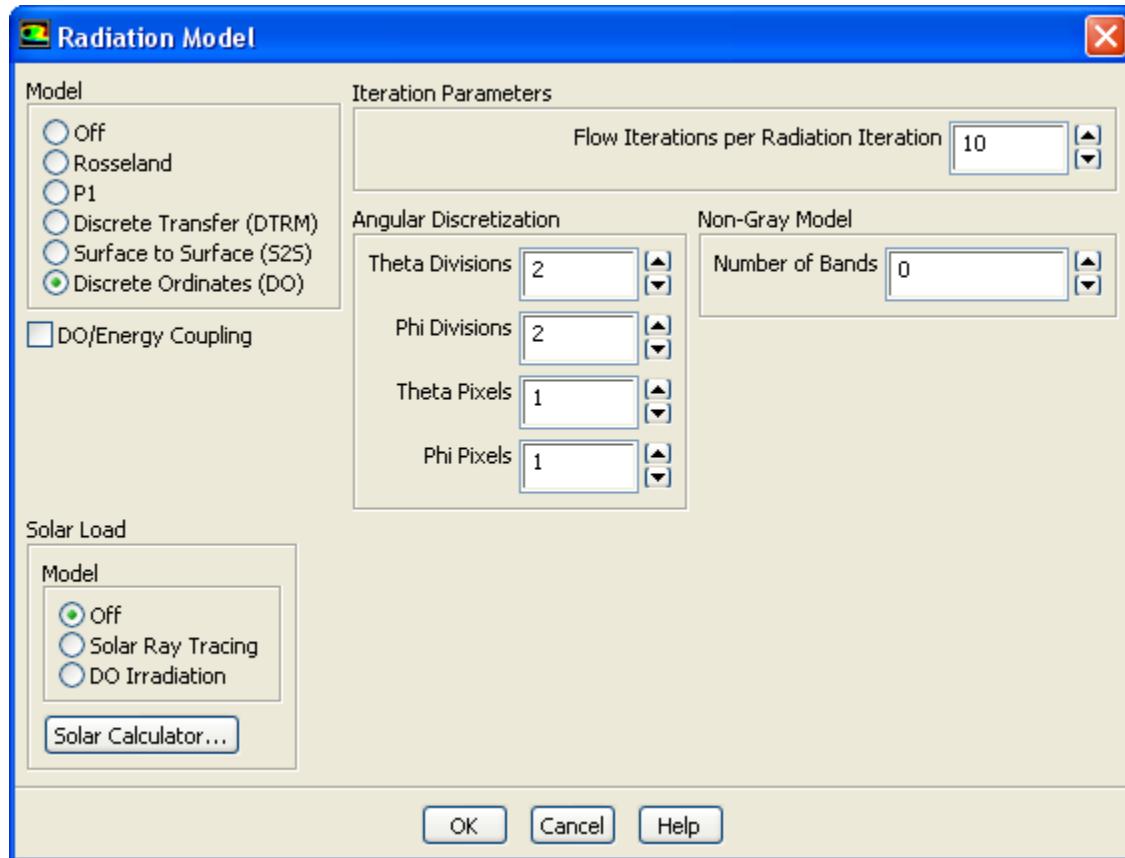

14.3.1. Using the Radiation Models

The procedure for setting up and solving a radiation problem is outlined below, and described in detail in referenced sections. Steps that are relevant only for a particular radiation model are noted as such. The steps that are pertinent to radiation modeling, are shown here. For information about inputs related to other models that you are using in conjunction with radiation, see the appropriate sections for those models.

1. Activate radiative heat transfer by selecting a radiation model (**Rosseland**, **P1**, **Discrete Transfer (DTRM)**, **Surface to Surface (S2S)**, or **Discrete Ordinates**) under **Model** in the **Radiation Model** dialog box (*Figure 14.7 (p. 752)*).

Models → Radiation → Edit...

Figure 14.7 The Radiation Model Dialog Box (DO Model)

Important

The **Rosseland** model can be used only with the pressure-based solver.

Note that when the P-1, the DTRM, the S2S, or the DO model is activated, the **Radiation Model** dialog box expands to show additional parameters. These parameters will not appear if you select the Rosseland model. If you are running a 3d case, you will have the added option of using the

solar load model. The solar load options will be displayed in the dialog box, below the radiation model settings.

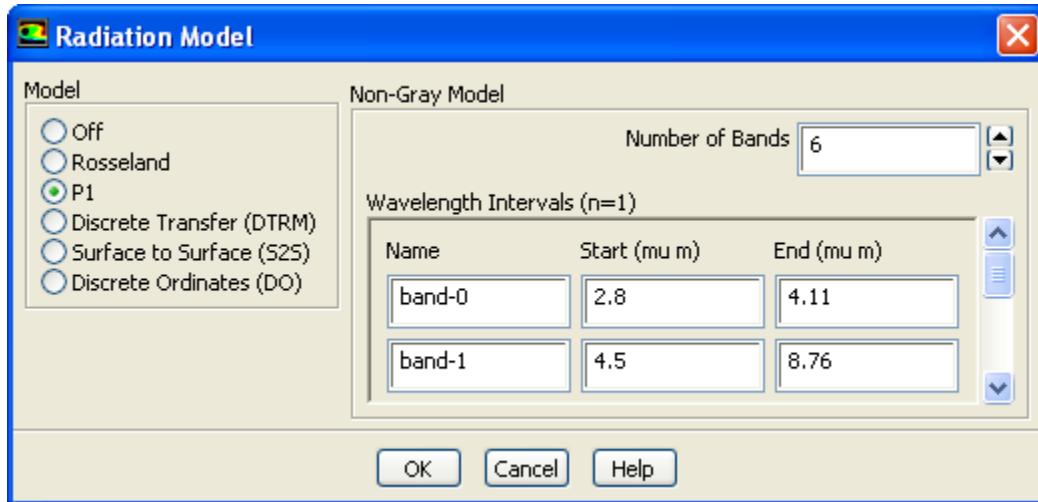

When the radiation model is active, the radiation fluxes will be included in the solution of the energy equation at each iteration. If you set up a problem with the radiation model turned on, and you then decide to turn it off completely, you must select the **Off** button in the **Radiation Model** dialog box.

Note that when you enable a radiation model, ANSYS FLUENT will automatically enable the energy equation so that step is not needed.

2. Set the appropriate radiation parameters.
 - a. If you are modeling non-gray radiation using the P-1 model, define the non-gray radiation parameters as described in *Setting Up the P-1 Model with Non-Gray Radiation* (p. 753).
 - b. If you are using the DTRM, define the ray tracing as described in *Setting Up the DTRM* (p. 754).
 - c. If you are using the S2S model, define the surface clusters and view factors settings and compute or read the view factors as described in *Setting Up the S2S Model* (p. 757).
 - d. If you are using the DO model, choose **DO/Energy Coupling** if desired, define the angular discretization as described in *Setting Up the DO Model* (p. 768) and, if relevant, define the non-gray radiation parameters as described in *Defining Non-Gray Radiation for the DO Model* (p. 769).
3. Define the material properties as described in *Defining Material Properties for Radiation* (p. 772).
4. Define the boundary conditions as described in *Defining Boundary Conditions for Radiation* (p. 772). If your model contains a semi-transparent medium, see the information below on setting up semi-transparent media.
5. Set the parameters that control the solution (DTRM, DO, S2S, and P-1 only) as described in *Solution Strategies for Radiation Modeling* (p. 781).
6. Run the solution as described in *Running the Calculation* (p. 784).
7. Postprocess the results as described in *Postprocessing Radiation Quantities* (p. 785).

14.3.2. Setting Up the P-1 Model with Non-Gray Radiation

If you want to model non-gray radiation using the P-1 model, you can specify the **Number of Bands** under **Non-Gray Model** in the expanded **Radiation Model** dialog box (*Figure 14.8* (p. 754)). By default, the **Number of Bands** is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases directly with the number of bands, you should try to minimize the number of bands used. When a non-zero **Number of Bands** is specified, the **Radiation Model** dialog box will expand once again to show the **Wavelength Intervals**. For each wavelength band, you can specify a **Name**, as well as the **Start** and **End** wavelength of the band in μm . Note that the wavelength bands are specified for vacuum ($n = 1$). For more information about non-gray radiation calculations, see *Defining Non-Gray Radiation for the DO Model* (p. 769).

Figure 14.8 The Radiation Model Dialog Box (Non-Gray P-1 Model)

ANSYS FLUENT allows you to use a user-defined function (UDF) to modify the emissivity weighting factor $F(0 \rightarrow n\lambda_2 T) - F(0 \rightarrow n\lambda_1 T)$ (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of the radiative transfer equation for the non-gray model, as shown in [Equation 5–25](#) in the [Theory Guide](#). For more information, see the [UDF Manual](#).

14.3.3. Setting Up the DTRM

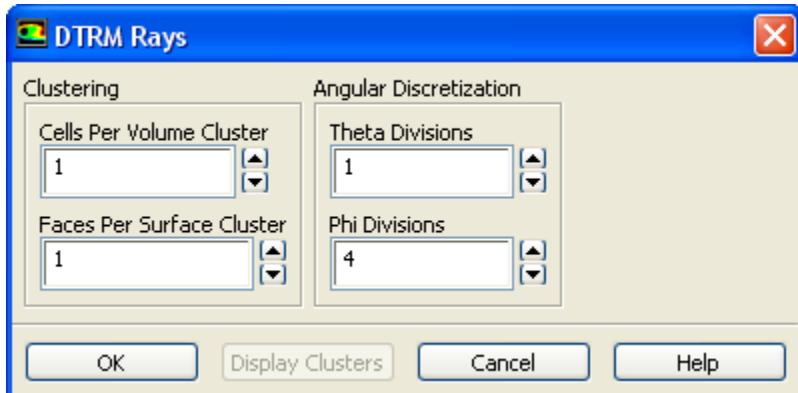

For information about setting up the DTRM, see the following sections:

- [14.3.3.1. Defining the Rays](#)
- [14.3.3.2. Controlling the Clusters](#)
- [14.3.3.3. Controlling the Rays](#)
- [14.3.3.4. Writing and Reading the DTRM Ray File](#)
- [14.3.3.5. Displaying the Clusters](#)

14.3.3.1. Defining the Rays

When you select the **Discrete Transfer** model and click **OK** in the **Radiation Model** dialog box, the **DTRM Rays** dialog box ([Figure 14.9 \(p. 755\)](#)) will open automatically. If you need to modify the current settings later in the problem setup or solution procedure, you can open this dialog box manually using the **Define/DTRM Rays...** menu item.

Figure 14.9 The DTRM Rays Dialog Box

In this dialog box you will set parameters for and create the rays and clusters discussed in [The DTRM Equations](#) in the [Theory Guide](#).

The procedure is as follows:

1. To control the number of radiating surfaces and absorbing cells, set the **Cells Per Volume Cluster** and **Faces Per Surface Cluster**. (See the explanation below.)
2. To control the number of rays being traced, set the number of **Theta Divisions** and **Phi Divisions**. (Guidelines are provided below.)
3. When you click **OK** in the **DTRM Rays** dialog box, [The Select File Dialog Box \(p. 33\)](#) will open prompting you for the name of the "ray file". After you have specified the file name and chosen whether to write a binary ray file, ANSYS FLUENT will write the ray file and then read it afterward. During the write process the status of the DTRM ray tracing will be reported in the ANSYS FLUENT console. For example:

```
Completed 25% tracing of DTRM rays
Completed 50% tracing of DTRM rays
Completed 75% tracing of DTRM rays
Completed 100 % tracing of DTRM rays
```

See following sections for details on **DTRM Rays** dialog box inputs.

Important

If you cancel the **DTRM Rays** dialog box without writing and reading the ray file, the DTRM will be disabled.

14.3.3.2. Controlling the Clusters

Your inputs for **Cells Per Volume Cluster** and **Faces Per Surface Cluster** will control the number of radiating surfaces and absorbing cells. By default, each is set to 1, so the number of surface clusters (radiating surfaces) will be the number of boundary faces, and the number of volume clusters (absorbing cells) will be the number of cells in the domain. For small 2D problems, these are acceptable numbers, but for larger problems you will want to reduce the number of surface and/or volume clusters in order to reduce the ray-tracing expense. See [Clustering](#) in the [Theory Guide](#) for details about clustering.

14.3.3.3. Controlling the Rays

Your inputs for **Theta Divisions** and **Phi Divisions** will control the number of rays being traced from each surface cluster (radiating surface).

Theta Divisions defines the number of discrete divisions in the angle θ used to define the solid angle about a point P on a surface. The solid angle is defined as θ varies from 0 to 90 degrees (in the [Theory Guide](#)), and the default setting of 1 for the number of discrete settings implies that there will be one ray traced from the surface.

Phi Divisions defines the number of discrete divisions in the angle ϕ used to define the solid angle about a point P on a surface. The solid angle is defined as ϕ varies from 0 to 360 degrees ([Figure 5.2: "Angles \$\theta\$ and \$\phi\$ Defining the Hemispherical Solid Angle About a Point P" in the Theory Guide](#)). The default setting of 4 implies that each ray traced from the surface will be located at a 90° angle, and in combination with the default setting for **Theta Divisions**, above, implies that 4 rays will be traced from each surface control volume. In many cases, it is recommended that you at least double the number of divisions in θ and ϕ .

14.3.3.4. Writing and Reading the DTRM Ray File

After you have activated the DTRM and defined all of the parameters controlling the ray tracing, you must create a ray file which will be read back in and used during the radiation calculation. The ray file contains a description of the ray traces (path lengths, cells traversed by each ray, etc.). This information is stored in the ray file, instead of being recomputed, in order to speed up the calculation process.

By default, a binary ray file will be written. You can also create text (formatted) ray files by turning off the **Write Binary Files** option in [The Select File Dialog Box \(p. 33\)](#).

Important

Do not write or read a compressed ray file, because ANSYS FLUENT will not be able to access the ray tracing information properly from a compressed ray file.

The ray filename must be specified to ANSYS FLUENT only once. Thereafter, the filename is stored in your case file and the ray file will be automatically read into ANSYS FLUENT whenever the case file is read. ANSYS FLUENT will remind you that it is reading the ray file after it finishes reading the rest of the case file by reporting its progress in the console.

Note that the ray filename stored in your case file may not contain the full name of the directory in which the ray file exists. The full directory name will be stored in the case file only if you initially read the ray file through the GUI (or if you typed in the directory name along with the filename when using the text interface). In the event that the full directory name is absent, the automatic reading of the ray file may fail (since ANSYS FLUENT does not know in which directory to look for the file), and you will need to manually specify the ray file, using the **File/Read/DTRM Rays...** menu item. The safest approaches are to use the GUI when you first read the ray file or to supply the full directory name when using the text interface.

Important

You should recreate the ray file whenever you do anything that changes the mesh, such as:

- change the type of a boundary zone
- adapt or reorder the mesh
- scale the mesh

You can open the **DTRM Rays** dialog box directly with the **Define/DTRM Rays...** menu item.

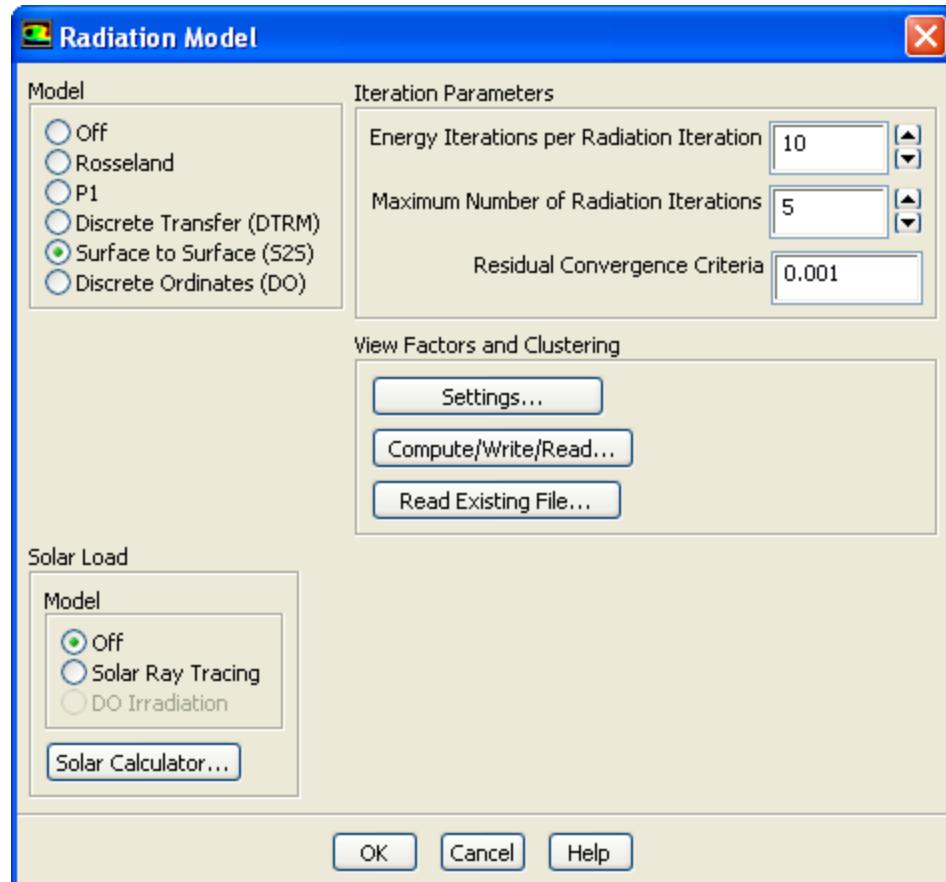

14.3.3.5. Displaying the Clusters

Once a ray file has been created or read in manually, you can click the **Display Clusters** button in the **DTRM Rays** dialog box to graphically display the clusters in the domain. See *Displaying Rays and Clusters for the DTRM* (p. 787) for additional information about displaying rays and clusters.

14.3.4. Setting Up the S2S Model

When you select the **Surface to Surface (S2S)** model, the **Radiation Model** dialog box will expand to show additional parameters (see *Figure 14.10* (p. 757)). In these additional group boxes, you will set the solution parameters (see *S2S Solution Parameters* (p. 783) for further details), access the view factors and clustering settings, and compute the view factors for your problem or read previously computed view factors into ANSYS FLUENT.

Figure 14.10 The Radiation Model Dialog Box (S2S Model)

The S2S radiation model is very expensive in terms of computation effort and memory requirements when there are a large number of radiating surfaces. You can reduce the number of radiating surfaces by grouping faces together to form surface clusters. The surface cluster information (coordinates and connectivity of the nodes, surface cluster IDs) is used by ANSYS FLUENT in the radiosity calculations and to compute the view factors.

Important

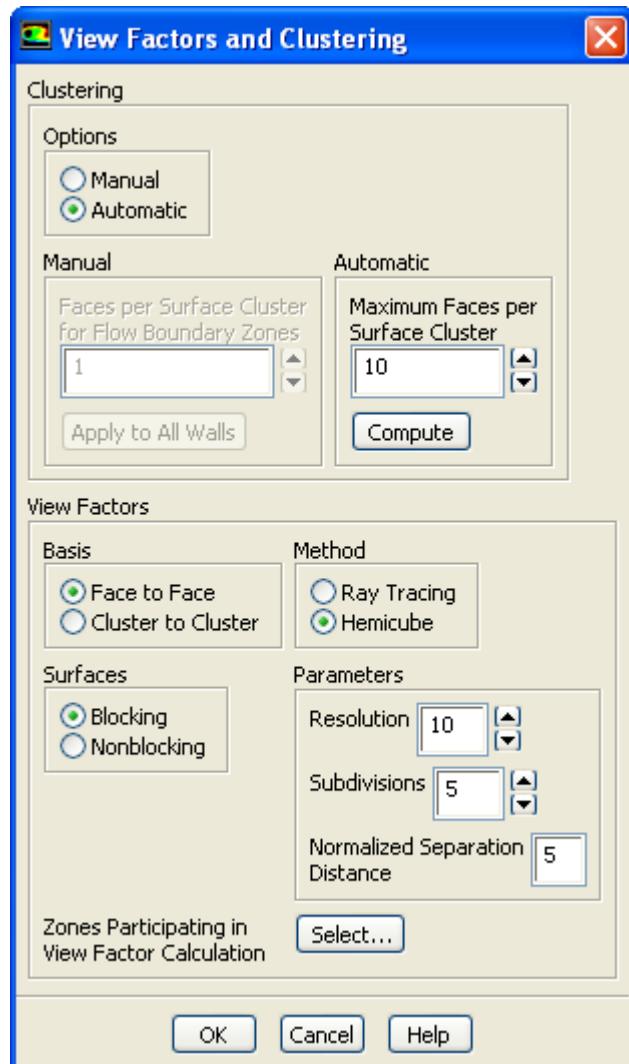

- You should recreate the surface cluster information whenever you do anything that changes the mesh, such as:
 - change the type of a boundary zone
 - reorder the mesh
 - scale the mesh

Note that you do *not* need to recalculate view factors after shell conduction at any wall has been enabled or disabled. See [Thermal Boundary Conditions at Walls \(p. 322\)](#) for more information about shell conduction.

- ANSYS FLUENT will warn you to recreate the cluster/view factor file if a boundary zone has been changed from a wall to an internal wall (or vice versa), or if a boundary zone has been merged, separated, or fused.

14.3.4.1. View Factors and Clustering Settings

You can use the **View Factors and Clustering** dialog box ([Figure 14.11 \(p. 759\)](#)) to define how the surface clusters are formed and how the view factors are calculated for the S2S model. To open this dialog box, click **Settings...** in the **View Factors and Clustering** group box in the [Radiation Model Dialog Box \(p. 1790\)](#) ([Figure 14.10 \(p. 757\)](#)) or use the **File/Write/Surface Clusters...** menu item.

Figure 14.11 The View Factors and Clustering Dialog Box

14.3.4.1.1. Forming Surface Clusters

You can set the number of faces per surface cluster (FPSC) for each flow boundary (i.e., exhaust fan, inlet vent, intake fan, outlet vent, mass-flow inlet, pressure far-field, pressure inlet, pressure outlet, outflow, and velocity inlet boundary) and wall that is adjacent to a fluid zone; in this way, you can control the number of radiating surfaces and (if you select **Cluster to Cluster** for **Basis**) view factor surfaces. By default, the FPSC value is set to 1 everywhere, so the number of surface clusters (radiating/view factor surfaces) will be equal to the number of boundary faces. For small 2D problems, this is an acceptable number. For larger problems, you may want to reduce the number of surface clusters to reduce both the size of the view factor file and the memory requirement. Such a reduction in the number of clusters, however, comes at the cost of some accuracy. See [Clustering](#) in the [Theory Guide](#) for details about clustering.

Important

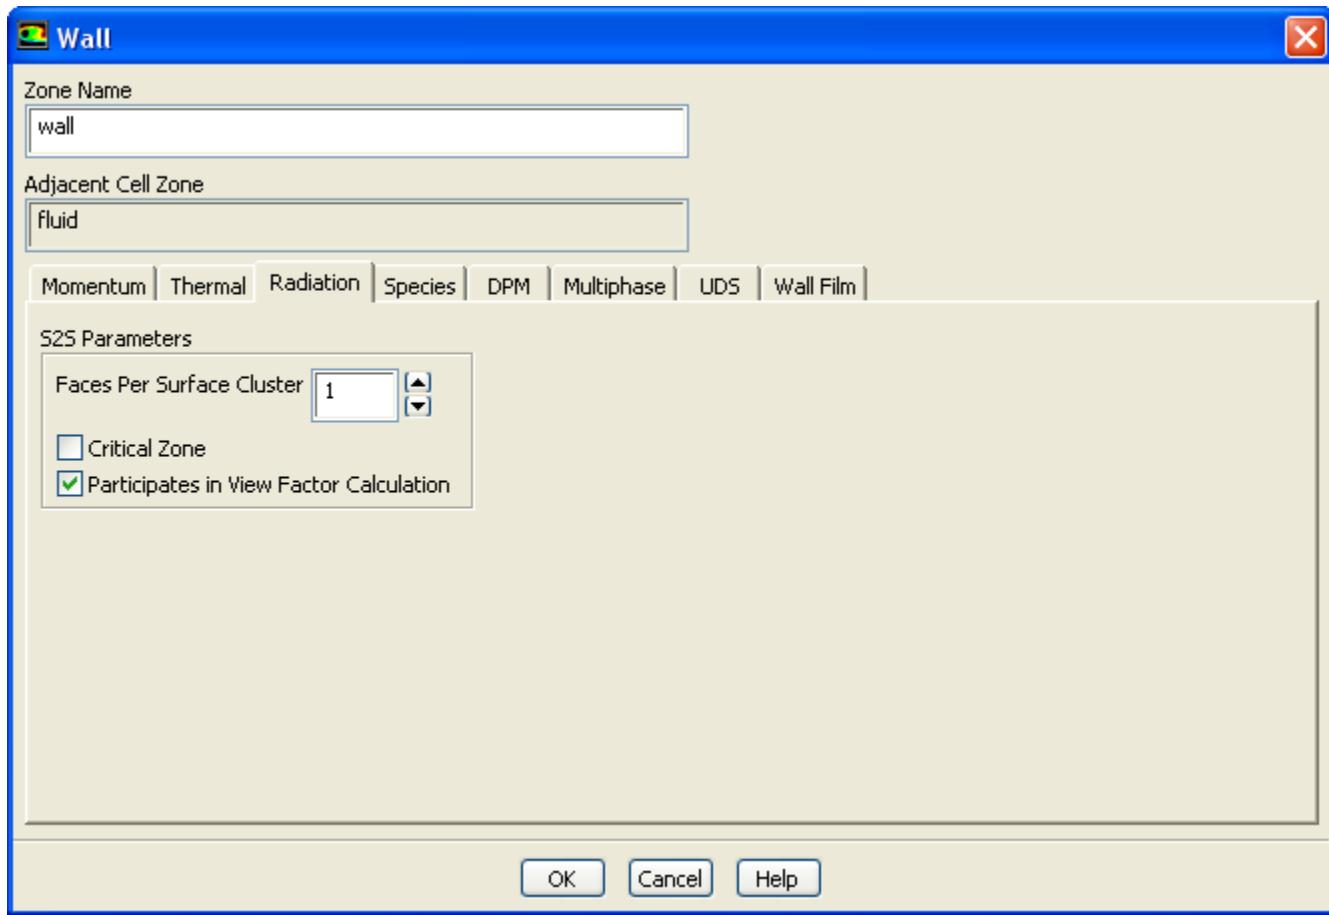

If you plan to use the cluster to cluster basis for the view factor calculation, be sure that the FPSC values are appropriate for both the radiosity calculation and the view factors.

The **Clustering** group box in the **View Factors and Clustering** dialog box (*Figure 14.11 (p. 759)*) provides two methods for revising the default FPSC values:

- manual
- automatic

If you select **Manual** in the **Options** group box, you can specify an FPSC value for all flow boundaries in the **Faces per Surface Cluster for Flow Boundary Zones** number-entry box in the **Manual** group box. If you then click **Apply to All Walls**, you will apply this value to all wall zones that are adjacent to fluid zones as well. For a wall that requires a different FPSC value (i.e., you may want a lower value for walls in critical areas, and higher values in non-critical areas), you will need to open the boundary condition dialog box (*Figure 14.12 (p. 760)*) for that particular wall and modify the **Faces Per Surface Cluster** in the **S2S Parameters** group box of the **Radiation** tab. Note that the **Radiation** tab also allows you to specify whether the wall participates in the view factor calculation, as described in *Specifying Boundary Zone Participation* (p. 763).

Figure 14.12 The Wall Dialog Box

Important

The **Faces Per Surface Cluster** number-entry box will not be visible in the GUI on wall boundary zones that are attached to a solid.

Using the manual method to specify the FPSC values for walls can become very cumbersome if the model involves a large number of radiating faces, which is typically the case in underhood models. In

such circumstances, it is recommended that you use the automatic clustering method instead. In this method, different FPSC values are assigned to the walls automatically, based on the distance of the walls from and the FPSC values of the walls that are defined as critical. The steps you will need to take are as follows:

1. Select **Automatic** from the **Options** list in the **View Factors and Clustering** dialog box.
2. For each wall that you deem critical, perform the following actions in the **Wall** dialog box ([Figure 14.12 \(p. 760\)](#)):
 - a. Click the **Radiation** tab.
 - b. Enter an appropriate value for **Faces Per Surface Cluster** in the **S2S Parameters** group box.
 - c. Enable the **Critical Zone** option.
 - d. Click **OK** to close the **Wall** dialog box.
3. Enter the **Maximum Faces per Surface Cluster** value in the **View Factors and Clustering** dialog box and click the **Compute** button. ANSYS FLUENT will automatically calculate and update the **Faces Per Surface Cluster** values for all **Wall** dialog boxes adjacent to fluid zones that do not have **Critical Zone** enabled, without computing the clusters.
4. You can check the automatically assigned FPSC values by opening the boundary condition dialog box of any non-critical wall of interest and examining the value for **Faces Per Surface Cluster** in the **S2S Parameters** group box of **Radiation** tab. You can manually modify the value for **Faces Per Surface Cluster** as necessary.

14.3.4.1.1. Setting the Split Angle for Clusters

Whether you set the FPSC value manually or automatically, you have the option of modifying the cutoff or “split” angle between adjacent face normals for the purpose of controlling surface clustering. The split angle sets the limit for which adjacent faces are clustered. A smaller split angle allows for a better representation of the view factor. By default, no surface cluster will contain any face that has a face normal greater than 20° . To modify the value of this parameter, you can use the `split-angle` text command:

```
define → models → radiation → s2s-parameters → split-angle
```

or

```
file → write-surface-clusters → split-angle
```

14.3.4.1.2. Setting Up the View Factor Calculation

You can control many aspects of how the view factors are calculated for your S2S model: how surfaces are defined; the computational method and related parameters; whether surface blocking will be accounted for; and which boundary zones will participate in the calculation. All of these controls are available in the **View Factors** group box in the **View Factors and Clustering** dialog box ([Figure 14.11 \(p. 759\)](#)), and are described in the sections that follow.

14.3.4.1.2.1. Selecting the Basis for Computing View Factors

ANSYS FLUENT allows two ways to define the surfaces used for the view factor calculation, as described in [Clustering and View Factors](#) in the [Theory Guide](#). If you want the surfaces to be the boundary faces of the mesh, select **Face to Face** for **Basis** in the **View Factor** group box of the **View Factors and Clustering** dialog box. This is the default selection.

Alternatively, you can select **Cluster to Cluster** for **Basis**, in order to reduce the computational expense and storage requirements. In this case, the surfaces used to calculate the view factors are the clusters defined by the settings in the **Cluster** group box of the **View Factors and Clustering** dialog box. The reduction in computational time will be proportional to the number of surface clusters used in the view factor calculation. The trade-offs of using the cluster to cluster basis for the calculation are that the accuracy may decrease, and the following limitations apply:

- The mesh must be 3D.
- Only the hemicube method can be used, as described in [Selecting the Method for Computing View Factors \(p. 762\)](#).
- You cannot subdivide the faces as part of the hemicube method parameters, which can cause the view factors to be overestimated.
- Polyhedral meshes are restricted to 1 face per surface cluster.

14.3.4.1.2.2. Selecting the Method for Computing View Factors

ANSYS FLUENT provides two methods for computing view factors: the ray tracing method (which is selected by default) and the hemicube method. The following limitations apply:

- The hemicube method is available only for 3D and axisymmetric cases.
- The ray tracing method should not be used when any of the zones are defined as periodic, as this type of zone is not currently supported.
- The ray tracing method is only available when **Face to Face** is selected for **Basis**.

The hemicube method uses a differential area-to-area method and calculates the view factors on a row-by-row basis. The view factors calculated from the differential areas are summed to provide the view factor for the whole surface. This method originated from the use of the radiosity approach in the field of computer graphics [16] (p. 2367).

To use the hemicube method to compute the view factors, select **Hemicube** from the **Method** list in the **View Factors and Clustering** dialog box. It is recommended that you use the hemicube method for large, complex models with few obstructing surfaces between the radiating surfaces.

The hemicube method is based upon three assumptions about the geometry of the surfaces: aliasing, visibility, and proximity. To validate these assumptions, you can specify three different hemicube parameters, which can help you obtain better accuracy in calculating view factors. In most cases, however, the default settings will be sufficient.

- **Aliasing**—The true projection of each visible face onto the hemicube can be accurately accounted for by using a finite-resolution hemicube. As described previously, the faces are projected onto a hemicube. Because of the finite resolution of the hemicube, the projected areas and resulting view factors may be overestimated or underestimated. Aliasing effects can be reduced by increasing the value of the **Resolution** of the hemicube in the **Parameters** group box.
- **Visibility**—The visibility between any two faces does not change. In some cases, face i has a complete view of face k from its centroid, but some other face j occludes much of face k from face i . In such a case, the hemicube method will overestimate the view factor between face i and face k calculated from the centroid of face i . This error can be reduced by subdividing face i into smaller subsurfaces. You can specify the number of subsurfaces by entering a value for **Subdivisions** in the **Parameters** group box. Note that you cannot subdivide the faces when **Cluster to Cluster** is selected for **Basis**.
- **Proximity**—The distance between faces is great compared to the effective diameter of the faces. The proximity assumption is violated whenever faces are close together in comparison to their effective

diameter or are adjacent to one another. In such cases, the distances between the centroid of one face and all points on the other face vary greatly. Since the view factor dependence on distance is non-linear, the result is a poor estimate of the view factor.

In the **Parameters** group box, you can set a limit for the **Normalized Separation Distance**, which is the ratio of the minimum face separation to the effective diameter of the face. If the computed normalized separation distance is less than the specified value, the face will then be divided into a number of subfaces until the normalized distances of the subfaces are greater than the specified value. Alternatively, you can specify the number of subfaces to create for such faces by entering a value for **Subdivisions**.

While the hemicube method projects radiating surfaces onto a hemicube, the ray tracing method instead traces rays through the centers of every hemicube face to determine which surfaces are visible through that face. Also, the ray tracing method is OpenMP parallelized and will therefore use all available processors when performing the ray tracing calculations (for further details, visit <http://www.openmp.org>). As a result, the calculation time is reduced for large, complex geometries that have obstructions between the radiating surfaces (such as automotive underhood simulations). Note that the ray tracing method does not subdivide the faces (as can be done when using the hemicube method by setting the **Subdivisions** or **Normalized Separation Distance** parameters), and so the view factors may be less accurate than those calculated using the hemicube method for surfaces that have a normalized separation distance less than 5.

To use the ray tracing method to compute the view factors, select **Ray Tracing** from the **Method** list in the **View Factors and Clustering** dialog box. You can adjust the value of the **Resolution** in the **Parameters** group box in order to reduce the impact of aliasing effects, as described previously.

14.3.4.1.2.3. Accounting for Blocking Surfaces

View factor calculations depend on the geometric orientations of surface pairs with respect to each other. Two situations may be encountered when examining surface pairs:

- If there is no obstruction between the surface pairs under consideration, then they are referred to as “nonblocking” surfaces.
- If there is another surface blocking the views between the surfaces under consideration, then they are referred to as “blocking” surfaces. Blocking will change the view factors between the surface pairs and require additional checks to compute the correct value of the view factors.

For cases with blocking surfaces, select **Blocking** from the **Surfaces** list in the **View Factors and Clustering** dialog box. For cases with nonblocking surfaces, you can choose either **Blocking** or **Nonblocking** without affecting the accuracy. However, it is better to choose **Nonblocking** for such cases, as it takes less time to compute.

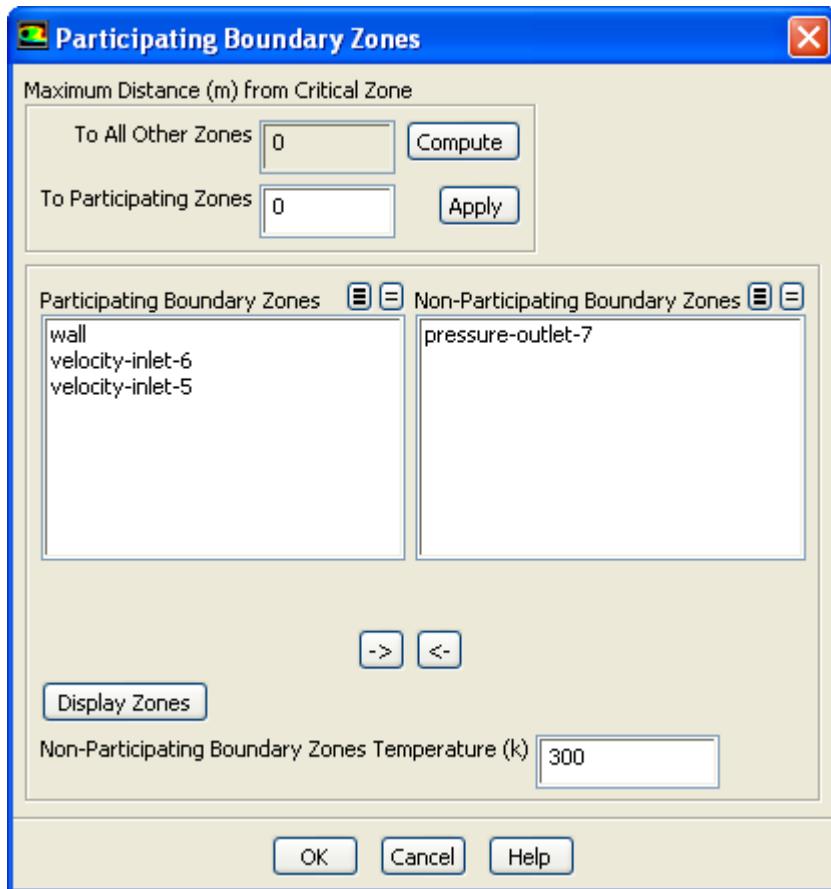

14.3.4.1.2.4. Specifying Boundary Zone Participation

You can choose to exclude walls and inlet and exit boundaries from participating in the view factor calculation. If you are unsure whether it is necessary to calculate view factors for a particular boundary zone ahead of time, it is recommended that you allow it to participate; you can always reverse this decision as part of a future calculation run.

There are two ways in which you can enable/disable the participation of walls and inlet and exit boundaries in the view factor calculation. One of those ways is to use the **Participates in View Factor Calculation** option in the **Radiation** tab of the boundary condition dialog box. The other method is to use the **Participating Boundary Zones** dialog box (*Figure 14.13 (p. 764)*), which is accessed by clicking the **Select...** button next to the **Zones Participating in View Factor Calculation** label in the **View**

Factors and Clustering dialog box. For cases that are comprised of a very large number of zones, such as underhood applications, the latter method is recommended.

Figure 14.13 The Participating Boundary Zones Dialog Box

The **Participating Boundary Zones** dialog box allows you to easily specify those zones that are participating or non-participating without having to visit the boundary conditions dialog box of each zone. For cases that have a small number of boundary zones, you can simply select the zones that you do not want to participate in the view factor calculation from the **Participating Boundary Zones** list and click the arrow button that points to the left, so that the zones are moved to the **Non-Participating Boundary Zones** list; if you make an error, you can always reverse this process (i.e., select a zone in the **Non-Participating Boundary Zones** list and click the arrow button that points to the right). This can be cumbersome for cases that have a large number of boundary zones, and so the following procedure is recommended instead:

1. Make sure that your clustering options (see *Forming Surface Clusters* (p. 759)) are appropriate for your view factor settings:
 - a. Select **Automatic** from the **Options** list in the **Clustering** group box of the **View Factors and Clustering** dialog box, as this enables some GUI items in the **Participating Boundary Zones** dialog box.

Important

Note that if you do not want to use the **Automatic** option for the clustering, you can revert to the **Manual** option after you are done using the **Participating Boundary Zones** dialog box.

- b. Verify that the walls you specified as critical (by enabling the **Critical Zone** option in the **Radiation** tab of the boundary condition dialog box) also correspond to those that are critical for the view factor calculation. You must have specified at least one critical zone for the steps that follow.
2. Click the **Compute** button in the **Maximum Distance from Critical Zone** dialog box, to update the value displayed for **To All Other Zones**. This value represents the maximum distance between the centroids of a critical zone and a non-critical zone in the mesh; it is for information purposes only, and cannot be edited in this dialog box.
3. Based on the value displayed for **To All Other Zones**, enter a threshold value for **To Participating Zones**. The value you enter will specify the maximum distance allowed between the centroids of a critical zone and a zone that participates in the view factor calculation. Then click the **Apply** button to move all zones beyond this distance into the **Non-Participating Boundary Zones** list.
4. Review the zones displayed in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists. If necessary, select zones in these lists and use the arrow buttons to move them to the appropriate list, as described previously.

If at any point you want to visually identify zones displayed in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists, select the zones and click the **Display Zones** button. Only the selected zones will be displayed in the graphics window.

If any zones are displayed in the **Non-Participating Boundary Zones** list, ensure to enter an appropriate temperature for **Non-Participating Boundary Zones Temperature**. In most cases the appropriate value is the ambient temperature, which by default is assumed to be 300 K.

After you have specified which zones do not participate in view factor calculation and set their temperature, click **OK** to store the settings and close the **Participating Boundary Zones** dialog box. You can then proceed to computing the view factors, as described in the section that follows.

14.3.4.2. Computing View Factors

ANSYS FLUENT can compute the view factors for your problem in the current session and save them to a file for use in the current session and future sessions. Alternatively, you can save the surface cluster information and view factor parameters to a file, calculate the view factors outside ANSYS FLUENT, and then read the view factors into ANSYS FLUENT. These methods for computing view factors are described in the following sections.

Important

For large meshes or complex models, it is recommended that you calculate the view factors outside ANSYS FLUENT and then read them into ANSYS FLUENT before starting your simulation.

14.3.4.2.1. Computing View Factors Inside ANSYS FLUENT

To compute view factors in your current ANSYS FLUENT session, you must first set the parameters for the view factor calculation in the **View Factors and Clustering** dialog box (see [View Factors and Clustering](#)).

tering Settings (p. 758) for details) and click **OK** to save them. When you have set the view factor and surface cluster parameters, click the **Compute/Write/Read...** button in the **View Factors and Clustering** group box of the **Radiation Model** dialog box. A **Select File** dialog box will open, prompting you for the name of the file in which ANSYS FLUENT should save the surface cluster information and the view factors. After you have specified the file name, ANSYS FLUENT will write the surface cluster information to the file. ANSYS FLUENT will use the surface cluster information to compute the view factors, save the view factors to the same file, and then automatically read the view factors. The ANSYS FLUENT console will report the status of the view factor calculation. For example:

```
Completed 25% calculation of viewfactors  
Completed 50% calculation of viewfactors  
Completed 75% calculation of viewfactors  
Completed 100 % calculation of viewfactors
```

Important

- The view factor file format for this version of ANSYS FLUENT is known as the compressed row format (CRF) which is a more efficient way of writing view factors than in prior versions of ANSYS FLUENT. In the CRF format, only non-zero view factors with their associated cluster IDs are stored to the file. This reduces the size of the .s2s file, and reduces the time it takes to read the file into ANSYS FLUENT. While the CRF file format is the default, you can still use the older file format if necessary. Contact your support engineer for more information.
- View factors using ray tracing is computed with the MPI/OpenMP hybrid model for parallel runs. By default, all the available cores within a machine are used as OpenMP threads. You can overwrite this option by setting the desired number of cores or processors to be used as OpenMP threads using the (%set-openmp-threads N) scheme command, where N is the number of cores or processors to be used as OpenMP threads. You can query the OpenMP threads being set using the (%get-openmp-threads) scheme command.

Note

For cases which use the S2S model and contain non-conformal interfaces, intersection of the interface zones will occur during the initialization process, which will cause relabeling of faces throughout the domain. If the view factors are computed before initialization, a mismatch with the case may occur after initialization. Therefore, for such cases, perform the following steps:

- Read the case.
- Disable the S2S model if it is already enabled.
- Initialize the case.
- Save the case and data and read it back. This step is needed since you could unintentionally read the case before initialization and try to read the view factor file, which was generated after the intersections were taken.
- Enable the S2S model.
- Compute the view factors and proceed as usual.

14.3.4.2.2. Computing View Factors Outside ANSYS FLUENT

To compute view factors outside ANSYS FLUENT, you must save the surface cluster information and view factor parameters to a file.

File → Write → Surface Clusters...

ANSYS FLUENT will open the **View Factors and Clustering** dialog box, where you will set the view factor and surface cluster parameters (see [View Factors and Clustering Settings \(p. 758\)](#) for details). When you click **OK** in the **View Factors and Clustering** dialog box, a **Select File** dialog box will open, prompting you for the name of the file in which ANSYS FLUENT should save the surface cluster information and view factor parameters to the file. If the specified **Filename** ends in **.gz** or **.Z**, appropriate file compression will be performed.

To calculate the view factors outside ANSYS FLUENT, enter one of the following commands:

- For the serial solver:

```
utility viewfac inputfile
```

where *inputfile* is the filename, or the correct path to the filename, for the surface cluster information and view factor parameters file that you saved from ANSYS FLUENT. You can then read the view factors into ANSYS FLUENT, as described below.

- For the parallel solver:

- Viewfac utility module:

```
utility viewfac -tnprocs [-pinterconnect] [-mpi=mpi type] -cnf= hosts_file inputfile
```

where *inputfile* is the filename for which you will need to provide the full path.

- Raytracing utility module:

```
utility raytracing -tnprocs [-pinterconnect] [-mpi=mpi type] -cnf= hosts_file [-ompthreads=N] inputfile
```

where *inputfile* is the filename for which you will need to provide the full path.

On Windows:

-tnprocs specifies the number of processes to use. When the **-cnf** option is present, the **hosts** file argument is used to determine which computers to use for the parallel job. For example, if there are 8 computers listed in the hosts file and you want to run a job with 4 processes, set **nprocs** to 4 (i.e. **-t 4**) and ANSYS FLUENT will use the first 4 machines listed in the hosts file. Note that this does not apply to the Compute Cluster Server (CCS).

-pinterconnect (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See [Table 35.1: Supported Interconnects for the Windows Platform \(p. 1726\)](#), [Table 35.2: Available MPIs for Windows Platforms \(p. 1727\)](#), and [Table 35.3: Supported MPIs for Windows Architectures \(Per Interconnect\) \(p. 1727\)](#) for more information.

-mpi=mpi type (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect (HP MPI) will be used (the use of the default MPI is recommended). The available MPIs for Windows are shown in [Table 35.2: Available MPIs for Windows Platforms \(p. 1727\)](#).

- cnf=hosts file specifies the hosts file, which contains a list of the computers on which you want to run the parallel job. You will need to supply the full pathname to the file, or you can use an explicit host list such as -cnf=host1,host2,...,hostn
- ompthreads=N (optional) where N is the desired number of OpenMP threads to be used per machine.

On Linux:

-tnprocs specifies the number of processes to used. When the -cnf option is present, the hosts file argument is used to determine which computers to use for the parallel job. For example, if there are 10 computers listed in the hosts file and you want to run a job with 5 processes, set nprocs to 5 (i.e. -t5) and ANSYS FLUENT will use the first 5 machines listed in the hosts file.

-pinterconnect (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See *Table 35.4: Supported Interconnects for Linux Platforms (Per Platform)* (p. 1731), *Table 35.5: Available MPIs for Linux Platforms* (p. 1731), and *Table 35.6: Supported MPIs for Linux Architectures (Per Interconnect)* (p. 1731) for more information.

-mpi=mpi type (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect will be used (the use of the default MPI is recommended). The available MPIs for Linux are shown in *Table 35.5: Available MPIs for Linux Platforms* (p. 1731).

-cnf=hosts file specifies the hosts file, which contains a list of the computers on which you want to run the parallel job, you will need to supply the full pathname to the file.

-ompthreads=N (optional) where N is the desired number of OpenMP threads to be used per machine.

14.3.4.3. Reading View Factors into ANSYS FLUENT

If the view factors for your problem have already been computed (either inside or outside ANSYS FLUENT) and saved to a file, you can read them into ANSYS FLUENT. To read in the view factors, click **Read Existing File...** button in the **View Factors and Clustering** group box of the **Radiation Model** dialog box. A **Select File** dialog box will open where you can specify the name of the file containing the view factors. You can also manually specify the view factors file, using the **File/Read/View Factors...** menu item.

Important

While the previous .s2s view factor file format can still be read seamlessly into ANSYS FLUENT, there is now a more efficient compressed row format (CRF) that can be read into ANSYS FLUENT (see the section on Computing View Factors Inside ANSYS FLUENT). You can take advantage of the reduced size of the CRF file and thus the reduced time it takes to read the file into ANSYS FLUENT, by converting the existing old file format to the new format (without having to recompute the view factors) using the following command at the command prompt in your working directory:

```
utility viewfac -c1 -o new.s2s.gz old.s2s.gz
```

where new.s2s.gz is the CRF format to which you want the old file format (old.s2s.gz) converted.

14.3.5. Setting Up the DO Model

For information about setting up the DO model, see the following sections:

- 14.3.5.1. Angular Discretization
- 14.3.5.2. Defining Non-Gray Radiation for the DO Model
- 14.3.5.3. Enabling DO/Energy Coupling

14.3.5.1. Angular Discretization

When you select the **Discrete Ordinates** model, the **Radiation Model** dialog box will expand to show inputs for **Angular Discretization** (see [Figure 14.7 \(p. 752\)](#)). In this section, you will set parameters for the angular discretization and pixelation described in [Angular Discretization and Pixelation](#) in the [Theory Guide](#).

Theta Divisions (N_θ) and **Phi Divisions** (N_ϕ) will define the number of control angles used to discretize each octant of the angular space (see [Figure 5.3: "Angular Coordinate System"](#) in the [Theory Guide](#)). Note that higher levels of discretization are recommended for problems where specular exchange of radiation is important to increase the likelihood of the correct beam direction being captured. For a 2D model, ANSYS FLUENT will solve only 4 octants (due to symmetry); thus, a total of $4N_\theta N_\phi$ directions \vec{s} will be solved. For a 3D model, 8 octants are solved, resulting in $8N_\theta N_\phi$ directions \vec{s} . By default, the number of **Theta Divisions** and the number of **Phi Divisions** are both set to 2. For most practical problems, these settings are acceptable, however, a setting of 2 is considered to be a coarse estimate. Increasing the discretization of **Theta Divisions** and **Phi Divisions** to a minimum of 3, or up to 5, will achieve more reliable results. A finer angular discretization can be specified to better resolve the influence of small geometric features or strong spatial variations in temperature, but larger numbers of **Theta Divisions** and **Phi Divisions** will add to the cost of the computation.

Theta Pixels and **Phi Pixels** are used to control the pixelation that accounts for any control volume overhang (see [Figure 5.7: "Pixelation of Control Angle"](#) in the [Theory Guide](#) and the figures and discussion preceding it). For problems involving gray-diffuse radiation, the default pixelation of 1×1 is usually sufficient. For problems involving symmetry, periodic, specular, or semi-transparent boundaries, a pixelation of 3×3 is recommended and will achieve acceptable results. The computational effort, as a result of increasing the pixelation, is less than the computational effort caused by increasing the divisions. You should be aware, however, that increasing the pixelation adds to the cost of computation.

Important

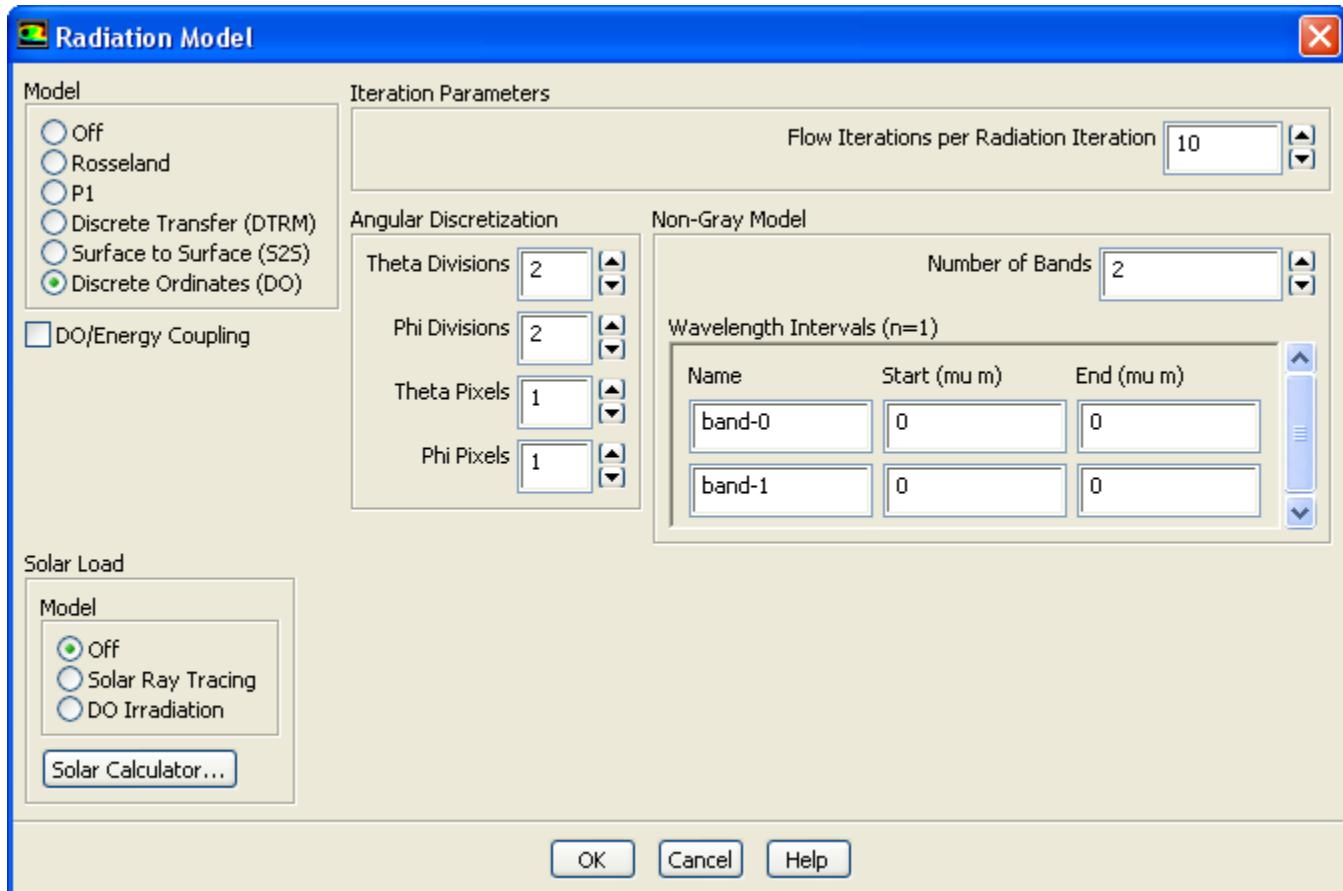

Note that pixelations are applied to boundary faces by default.

14.3.5.2. Defining Non-Gray Radiation for the DO Model

If you want to model non-gray radiation using the DO model, you can specify the **Number of Bands** (N) under **Non-Gray Model** in the expanded **Radiation Model** dialog box ([Figure 14.14 \(p. 770\)](#)). For a 2D model, ANSYS FLUENT will solve $4N_\theta N_\phi N$ directions. For a 3D model, $8N_\theta N_\phi N$ directions will be solved. By default, the **Number of Bands** is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases directly with the number of bands, you should try to minimize the number of bands used. In many cases, the absorption coefficient or the wall emissivity is effectively constant for the wavelengths of importance in the temperature range of the problem. For such cases, the gray DO model can be used with little loss of accuracy. For other cases, non-gray behavior is important, but relatively few bands are necessary. For typical glasses, for example, two or three bands will frequently suffice.

When a non-zero **Number of Bands** is specified, the **Radiation Model** dialog box will expand once again to show the **Wavelength Intervals** (Figure 14.14 (p. 770)). You can specify a **Name** for each wavelength band, as well as the **Start** and **End** wavelength of the band in μm . Note that the wavelength bands are specified for vacuum ($n = 1$). ANSYS FLUENT will automatically account for the refractive index in setting band limits for media with n different from unity.

Figure 14.14 The Radiation Model Dialog Box (Non-Gray DO Model)

The frequency of radiation remains constant as radiation travels across a semi-transparent interface. The wavelength, however, changes such that $n\lambda$ is constant. Thus, when radiation passes from a medium with refractive index n_1 to one with refractive index n_2 , the following relationship holds:

$$n_1\lambda_1 = n_2\lambda_2 \quad (14-7)$$

Here λ_1 and λ_2 are the wavelengths associated with the two media. It is conventional to specify the wavelength rather than frequency. ANSYS FLUENT requires you to specify wavelength bands for an equivalent medium with $n = 1$.

For example, consider a typical glass with a step jump in the absorption coefficient at a cut-off wavelength of λ_c . The absorption coefficient is a_1 for $\lambda \leq \lambda_c \mu\text{m}$ and a_2 for $\lambda > \lambda_c \mu\text{m}$. The refractive index of the glass is n_g . Since $n\lambda$ is constant across a semi-transparent interface, the equivalent cut-off wavelength for a medium with $n = 1$ is $n_g\lambda_c$ using Equation 14-7 (p. 770). You should choose two bands in this case, with the limits 0 to $n_g\lambda_c$ and $n_g\lambda_c$ to 100. Here, the upper wavelength limit has been chosen to be a large

number, 100, in order to ensure that the entire spectrum is covered by the bands. When multiple materials exist, you should convert all the cut-off wavelengths to equivalent cut-off wavelengths for an $n = 1$ medium, and choose the band boundaries accordingly.

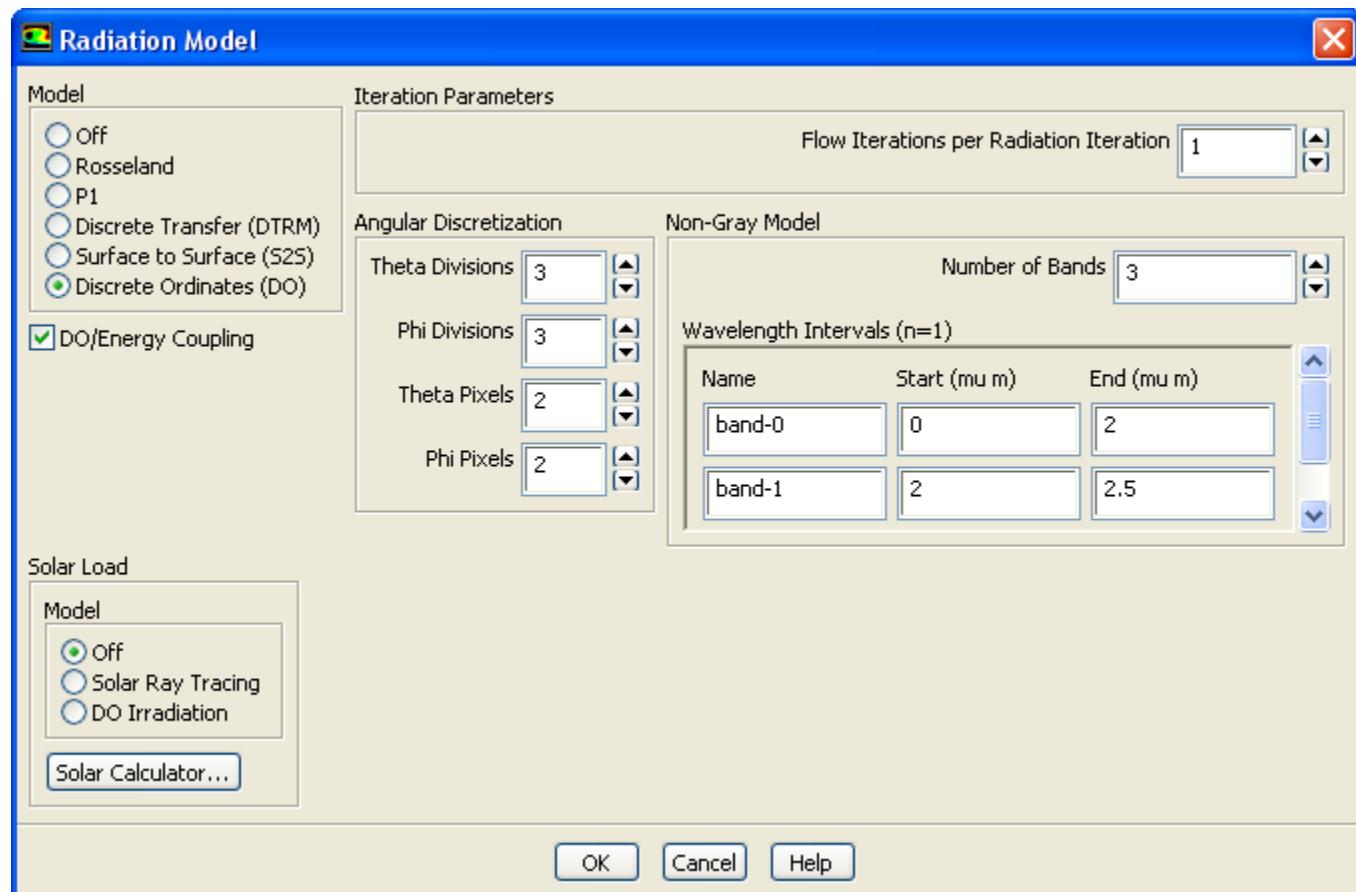

The bands can have different widths and need not be contiguous. You can ensure that the entire spectrum is covered by your bands by choosing $\lambda_{min} = 0$ and $n\lambda_{max}T_{min} \geq 50,000$. Here λ_{min} and λ_{max} are the minimum and maximum wavelength bounds of your wavelength bands, and T_{min} is the minimum expected temperature in the domain.

ANSYS FLUENT allows you to use a user-defined function (UDF) to modify the emissivity weighting factor $F(0 \rightarrow n\lambda_2 T) - F(0 \rightarrow n\lambda_1 T)$ (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of the radiative transfer equation for the non-gray model, as shown in [Equation 5–61](#) in the [Theory Guide](#). For more information, see [DEFINE_EMISSIVITY_WEIGHTING_FACTOR](#) in the [UDF Manual](#).

14.3.5.3. Enabling DO/Energy Coupling

For applications involving optical thicknesses greater than 10, you can enable the **DO/Energy Coupling** option in the **Radiation Model** ([Figure 14.15 \(p. 771\)](#)) in order to couple the energy and intensity equations at each cell, solving them simultaneously. This approach accelerates the convergence of the finite volume scheme for radiative heat transfer and can be used with the gray or non-gray radiation model.

Figure 14.15 The Radiation Model Dialog Box with DO/Energy Coupling Enabled

Important

This option should not be used when the shell conduction model is enabled.

14.3.6. Defining Material Properties for Radiation

When you are using the P-1, DO, or Rosseland radiation model in ANSYS FLUENT, you should be sure to define both the absorption and scattering coefficients of the fluid in the **Create/Edit Materials** dialog box. Note that you can either enter a constant value for these parameters, or you can specify them using a user-defined function (UDF). For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

 **Materials**

If you are modeling semi-transparent media using the DO model, you should also define the refractive index for the semi-transparent fluid or solid material. When using the Rosseland model, you can specify the refractive index only for the fluid material. When using the P-1 model, you should define the refractive index for the fluid material only. For the DTRM, you need to define only the absorption coefficient.

If your model includes gas phase species such as combustion products, absorption and/or scattering in the gas may be significant. The scattering coefficient should be increased from the default of zero if the fluid contains dispersed particles or droplets which contribute to scattering. Alternatively, you can specify the scattering coefficient as a user-defined function (UDF). For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

ANSYS FLUENT allows you to input a composition-dependent absorption coefficient for CO₂ and H₂O mixtures, using the WSGGM. The method for computing a variable absorption coefficient is described in [Radiation in Combusting Flows](#) in the [Theory Guide](#). *Radiation Properties* (p. 454) provides a detailed description of the procedures used for input of radiation properties.

14.3.6.1. Absorption Coefficient for a Non-Gray Model

If you are using the non-gray P-1 model or non-gray DO model, you can specify a different constant absorption coefficient for each of the bands used by the gray-band model, as described in [Radiation Properties](#) (p. 454). You cannot, however, compute a composition-dependent absorption coefficient in each band. If you use the WSGGM to compute a variable absorption coefficient, the value will be the same for all bands. Alternatively, you can specify a user-defined function (UDF) for the absorption coefficient. For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

14.3.6.2. Refractive Index for a Non-Gray Model

If you are using the non-gray P-1 model or non-gray DO model, you can specify a different constant refractive index for each of the bands used by the gray-band model, as described in [Radiation Properties](#) (p. 454). You cannot, however, compute a composition-dependent refractive index in each band.

14.3.7. Defining Boundary Conditions for Radiation

When you set up a problem that includes radiation, you will set additional boundary conditions at inlets, exits, and walls. These inputs are described below.

 **Boundary Conditions**

14.3.7.1. Inlet and Exit Boundary Conditions

14.3.7.1.1. Emissivity

When radiation is active, you can define the emissivity at each inlet and exit boundary when you are defining boundary conditions in the associated inlet or exit boundary dialog box (**Pressure Inlet** dialog box, **Velocity Inlet** dialog box, **Pressure Outlet** dialog box, etc.). Enter the appropriate value for **Internal Emissivity**. The default value for all boundary types is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

For the non-gray P-1 model and the non-gray DO model, the specified constant emissivity will be used for all wavelength bands.

Important

The **Internal Emissivity** boundary condition is not available with the Rosseland model.

14.3.7.1.2. Black Body Temperature

ANSYS FLUENT includes an option that allows you to take into account the influence of the temperature of the gas and the walls beyond the inlet/exit boundaries, and specify different temperatures for radiation and convection at inlets and exits. This is useful when the temperature outside the inlet or exit differs considerably from the temperature in the enclosure. For example, if the temperature of the walls beyond the inlet is 2000 K and the temperature at the inlet is 1000 K, you can specify the outside wall temperature to be used for computing radiative heat flux, while the actual temperature at the inlet is used for calculating convective heat transfer. To do this, you would specify a radiation temperature of 2000 K as the black body temperature.

Although this option allows you to account for both cooler and hotter outside walls, you must use caution in the case of cooler walls, since the radiation from the immediate vicinity of the hotter inlet or outlet almost always dominates over the radiation from cooler outside walls. If, for example, the temperature of the outside walls is 250 K and the inlet temperature is 1500 K, it might be misleading to use 250 K for the radiation boundary temperature. This temperature might be expected to be somewhere between 250 K and 1500 K; in most cases it will be close to 1500 K. Its value depends on the geometry of the outside walls and the optical thickness of the gas in the vicinity of the inlet.

In the flow inlet or exit dialog box (**Pressure Inlet** dialog box, **Velocity Inlet** dialog box, etc.), select **Specified External Temperature** in the **External Black Body Temperature Method** drop-down list, and then enter the value of the radiation boundary temperature as the **Black Body Temperature**.

Important

- If you want to use the same temperature for radiation and convection, retain the default selection of **Boundary Temperature** as the **External Black Body Temperature Method**.
- The **Black Body Temperature** boundary condition is not available with the Rosseland model.

14.3.7.2. Wall Boundary Conditions for the DTRM, and the P-1, S2S, and Rosseland Models

The DTRM and the S2S, Rosseland, and gray P-1 (i.e., **Number of Bands** is set to zero) models assume all walls to be gray and diffuse. The only radiation boundary condition required in the **Wall** dialog box is the emissivity. For the Rosseland model, the internal emissivity is 1. For the DTRM and the S2S and gray P-1 models, you can enter the appropriate value for **Internal Emissivity** in the **Thermal** tab of the **Wall** dialog box. The default value is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

For the non-gray P-1 model, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see [Creating a New Parameter \(p. 218\)](#)). See [Defining Boundary Conditions for Radiation \(p. 772\)](#) for details.

14.3.7.2.1. Boundary Conditions for the S2S Model

When the S2S model is used, you can specify that some of the walls and inlet and exit boundaries are not participating in the view factor calculation. This capability allows you to save time computing the view factors and also reduce the memory required to store the view factor file during the ANSYS FLUENT calculation. See [Specifying Boundary Zone Participation \(p. 763\)](#) for details.

Important

- Whenever you revise which the boundary zones participate in the calculation, you will need to recompute the view factors.
- The **Flux Reports** dialog box will not show the exact balance of the **Radiation Heat Transfer Rate** because the radiative heat transfer to those boundaries that do not participate in the view factor calculation is not included.

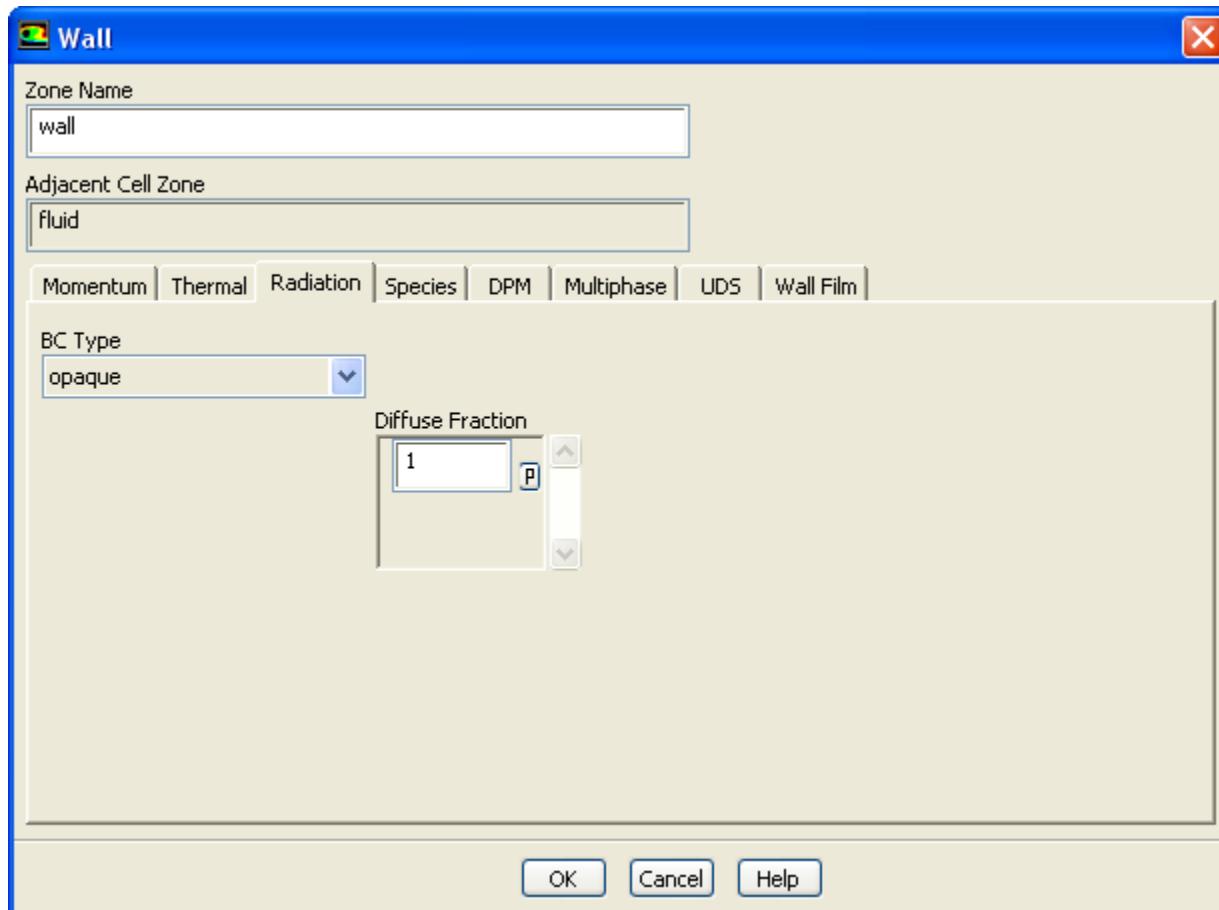

14.3.7.3. Wall Boundary Conditions for the DO Model

When the DO model is used, you can model opaque walls, as discussed in [Boundary and Cell Zone Condition Treatment at Opaque Walls](#) in the [Theory Guide](#), as well as semi-transparent walls ([Cell Zone](#) and [Boundary Condition Treatment at Semi-Transparent Walls](#) in the [Theory Guide](#)).

You can use a diffuse wall to model wall boundaries in many industrial applications since, for the most part, surface roughness makes the reflection of incident radiation diffuse. For highly polished surfaces, such as reflectors or mirrors, the specular boundary condition is appropriate. The semi-transparent boundary condition can be appropriate, for example, when modeling for glass panes in air.

14.3.7.3.1. Opaque Walls

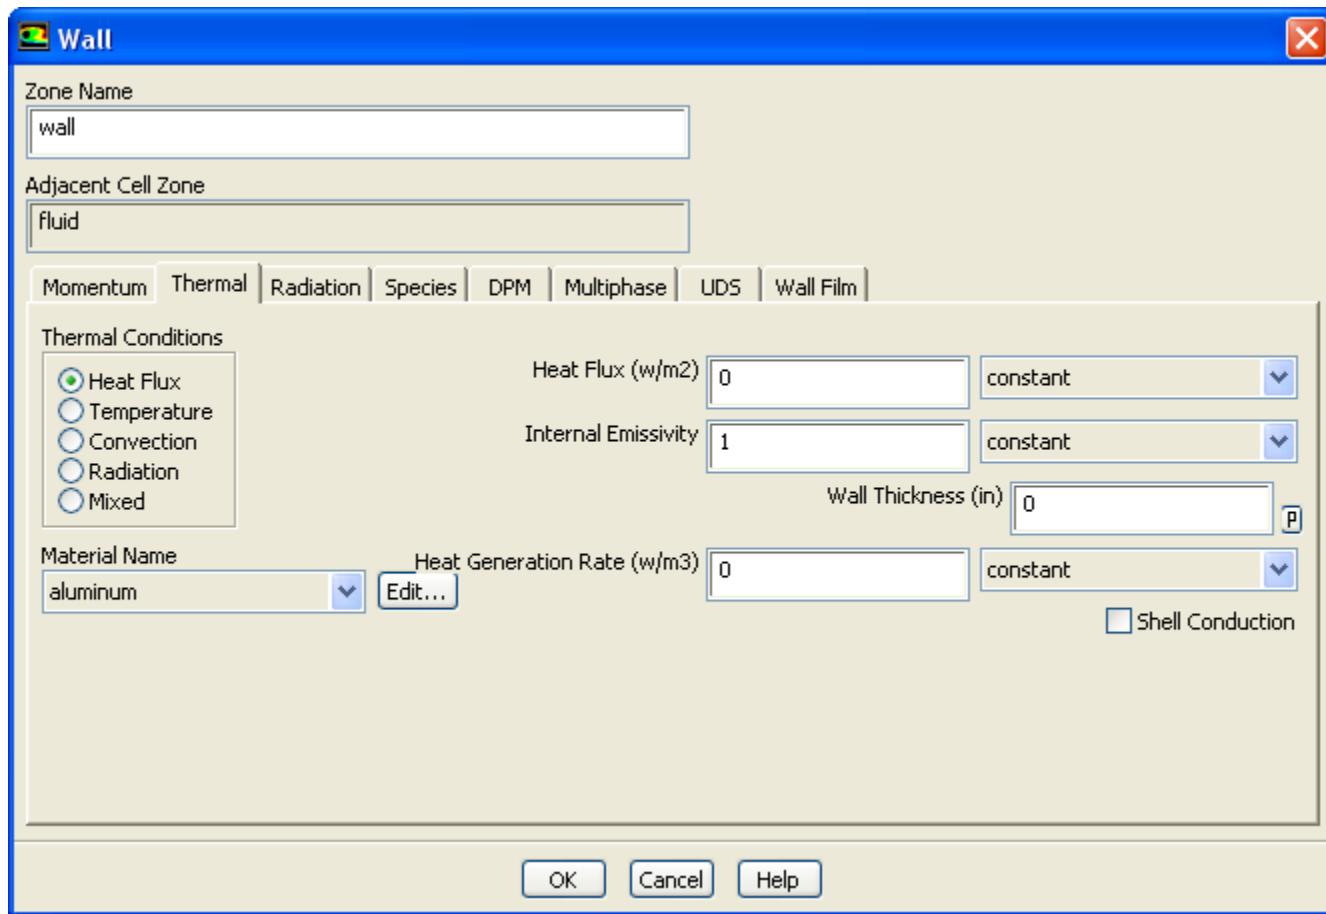

In the **Radiation** tab of the **Wall** dialog box ([Figure 14.16 \(p. 775\)](#)), select **opaque** in the **BC Type** drop-down list to specify an opaque wall. Opaque walls are treated as gray if gray radiation is being computed, or non-gray if the non-gray DO model is being used. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band.

Figure 14.16 The Wall Dialog Box Showing Radiation Conditions for an Opaque Wall

After you have selected **opaque** as the **BC Type**, you can specify the fraction of reflected radiation flux that is to be treated as diffuse. By default, the **Diffuse Fraction** is set to 1, indicating that all of the radiation is diffuse. A diffuse fraction equal to 0 indicates purely specular reflected radiation. A diffuse fraction between 0 and 1 will result in partially diffuse and partially specular reflected energy. See [Boundary and Cell Zone Condition Treatment at Opaque Walls](#) in the Theory Guide for more details.

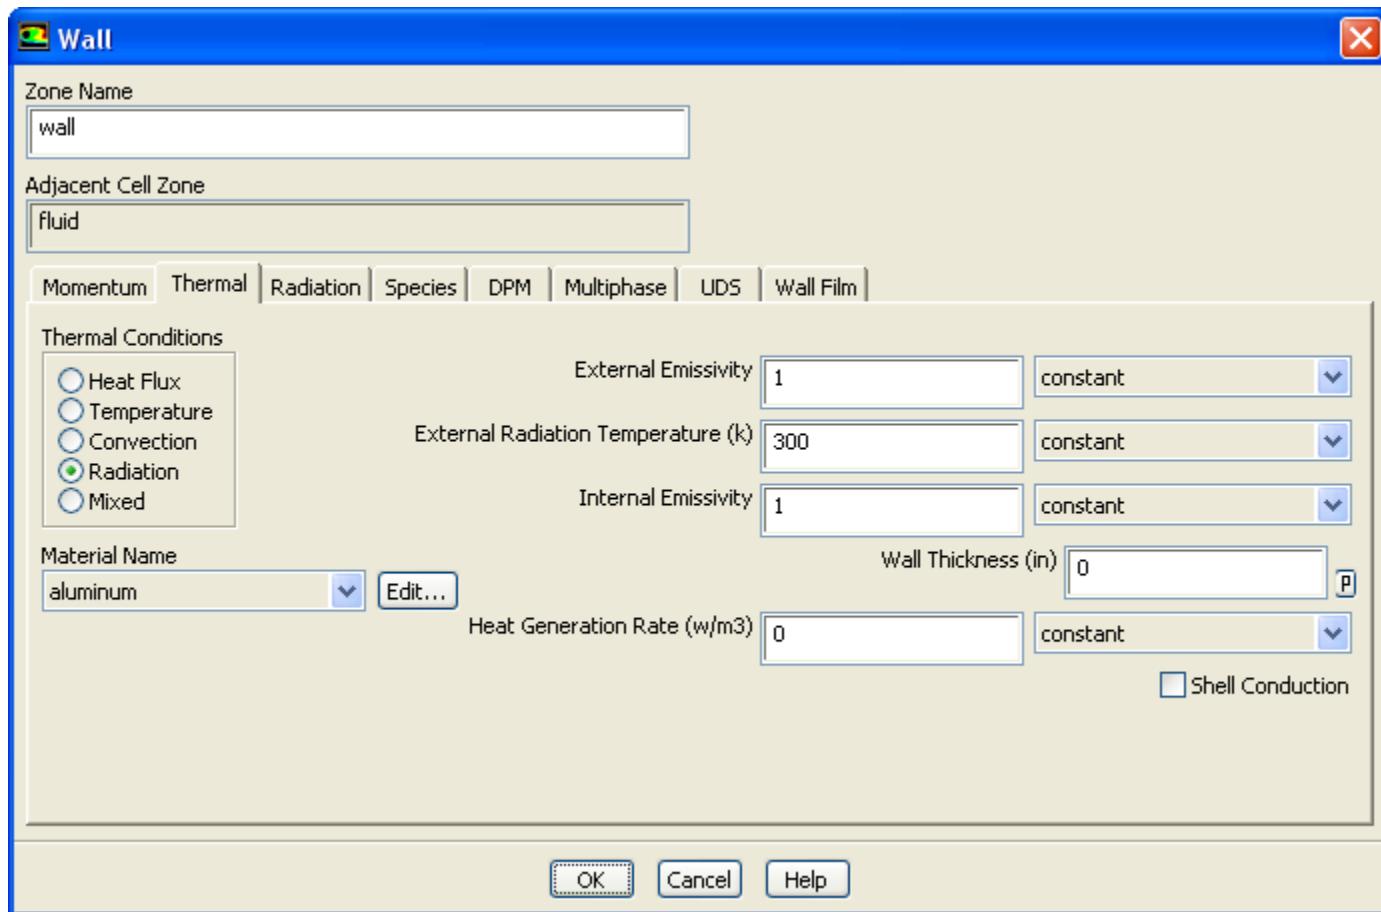

You will also be required to specify the internal emissivity in the **Thermal** tab of the **Wall** dialog box ([Figure 14.17 \(p. 776\)](#)). For gray-radiation DO models, enter the appropriate value for **Internal Emissivity**. (The default value is 1.) The value that you specify will be applied to the diffuse component only. For non-gray DO models, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box. (The default value in each band is 1.) Alternatively, you can specify the internal emissivity using a boundary condition parameter (see [Creating a New Parameter \(p. 218\)](#)).

Figure 14.17 The Wall Dialog Box Showing Internal Emissivity Thermal Conditions for an Opaque Wall

You can also specify the external emissivity and external radiation temperature for a semi-transparent wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box ([Figure 14.18 \(p. 777\)](#)). Alternatively, you can specify a UDF for these parameters.

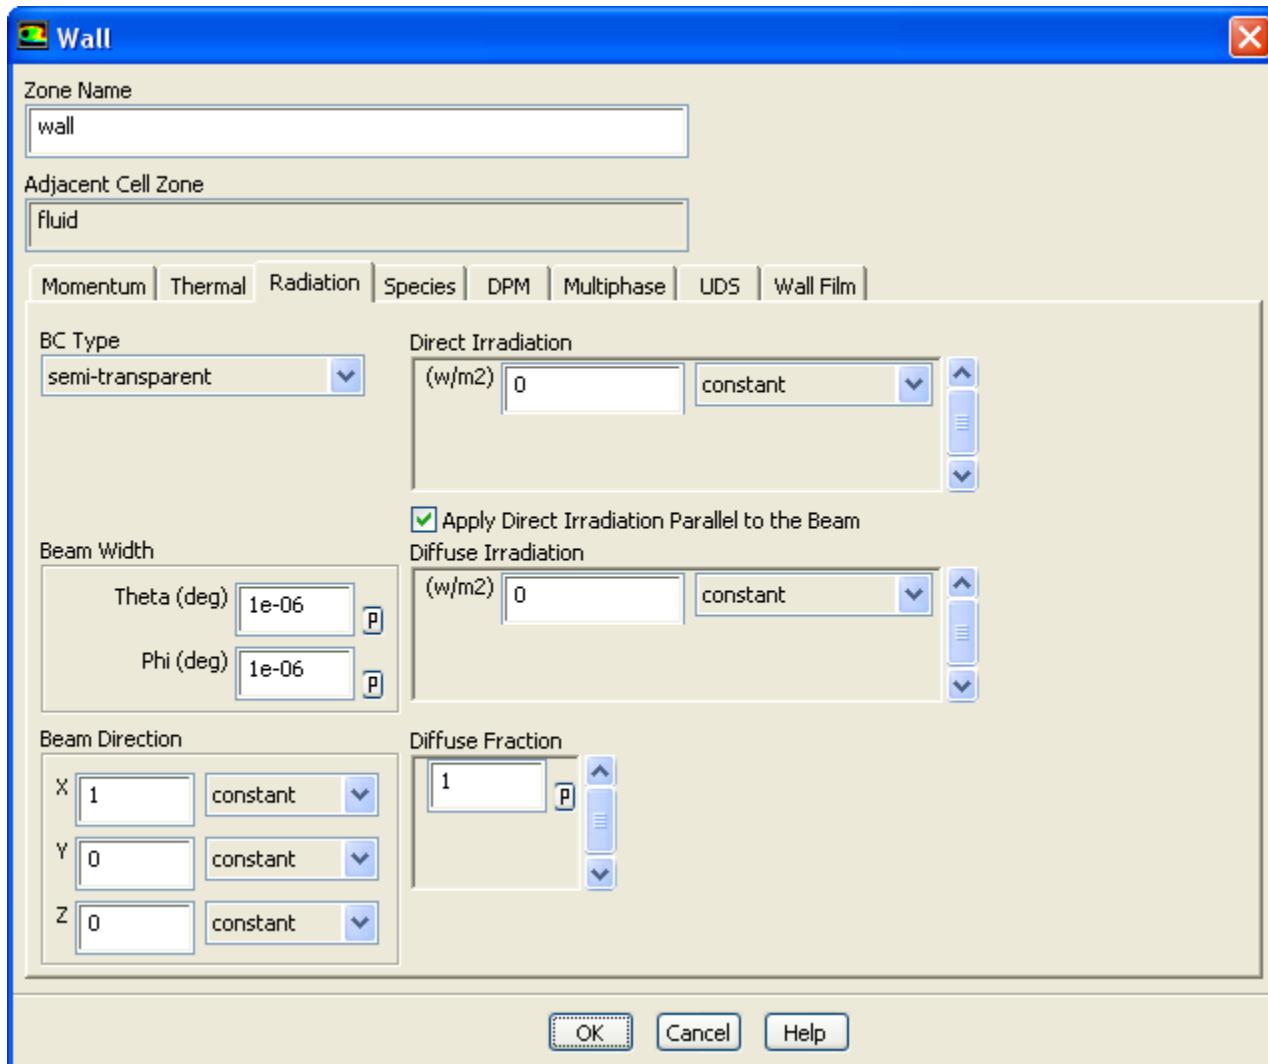

Figure 14.18 The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions

For more information on boundary condition treatment at opaque walls, see [Boundary and Cell Zone Condition Treatment at Opaque Walls](#) in the Theory Guide.

14.3.7.3.2. Semi-Transparent Walls

To define radiation for an exterior semi-transparent wall, click the **Radiation** tab in the **Wall** dialog box and then select **semi-transparent** in the **BC Type** drop-down list ([Figure 14.19 \(p. 778\)](#)). The dialog box will expand to display the semi-transparent wall inputs needed to define an external irradiation flux ([Figure 14.19 \(p. 778\)](#)).

Figure 14.19 The Wall Dialog Box for a Semi-Transparent Wall Boundary

Then perform the following steps:

1. Specify the value of the irradiation flux (in W/m^2) under **Direct** or **Diffuse Irradiation**. If the non-gray DO model is being used, a constant **Direct** or **Diffuse Irradiation** can be specified for each band.

Important

Note that the external diffuse irradiation specified when using **Radiation** or **Mixed** thermal conditions (selected in the **Thermal** tab), or **Diffuse Irradiation** (in the **Radiation** tab) is always distributed hemispherically after transmission through semi-transparent walls (i.e. independent of whether the external semi-transparent boundary wall is defined as a diffusely or specularly reflecting type).

2. **Apply Direct Irradiation Parallel to the Beam** is the default means of specifying the scale of irradiation flux. When enabled, ANSYS FLUENT assumes that the value of **Direct Irradiation** that you specify is the irradiation flux parallel to the **Beam Direction**. When deselected, ANSYS FLUENT instead assumes that the value specified is the flux parallel to the face normals and will calculate the resulting beam

parallel flux for every face. See [Figure 5.12: "DO Irradiation on External Semi-Transparent Wall" in Semi-Transparent Exterior Walls](#) in the Theory Guide for details.

3. Define the **Beam Width** by specifying the beam **Theta** and **Phi** extents. Beam width is specified as the solid angle over which the irradiation is distributed. The default value for beam width is $1e^{-6}$ which is suitable for collimated beam radiation. A beam width less than this is likely to result in zero irradiation flux.
4. Specify the **(X,Y,Z)** vector that defines the **Beam Direction**. The beam direction is defined as the vector of the centroid of the solid angle (beam width). You can specify the **Beam Direction** as a constant, a profile or a UDF. This is especially useful in applications where the shape of the radiative source is circular or cylindrical (or non-linear). For information about boundary profiles, see [Reading and Writing Profile Files \(p. 72\)](#).

Note that the actual direction of the beam of radiation that enters the domain will be further influenced by the solid angles available from the number of divisions set up; the effective direction will be the direction vector of the solid angle that the incoming beam falls into. Finally, any non-zero diffuse fraction will act to spread out (hemispherically, proportional to the diffuse fraction) the irradiation that enters the domain.

For a UDF example that specifies the beam direction, see [Example 5 - Beam Direction Profile at Semi-Transparent Walls](#) in the [UDF Manual](#).

5. Specify the fraction of the irradiation that is to be treated as diffuse as a real number between 0 and 1. By default, the **Diffuse Fraction** is set to 1, indicating that all of the irradiation is diffuse. A diffuse fraction of 0 treats the radiation as purely specular. If you specify a value between 0 and 1, the radiation is treated as partially diffuse and partially specular. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band. See [Diffuse Semi-Transparent Walls](#) in the Theory Guide for details.

Important

- Note that the refractive index of the external medium is assumed to be 1.
- If **Heat Flux** conditions are specified in the **Thermal** tab of the **Wall** dialog box, the specified heat flux is considered to be only the conduction and convection portion of the boundary flux. The given irradiation specifies the incoming exterior radiative flux; the radiative flux transmitted from the domain interior to the outside is computed as a part of the calculation by ANSYS FLUENT. Internal emissivity is ignored for semi-transparent surfaces.
- Note that when a boundary wall is made semi-transparent ANSYS FLUENT calculates the amount of radiation leaving as well as entering the domain. If you do not provide a source of irradiation or a radiating thermal condition (e.g. **Mixed** or **Radiation**) then you are effectively radiating to a temperature of 0 K and it is highly likely you may observe temperatures in your model that are lower than expected. Ensure that the external (incoming) radiant conditions give good account of the surroundings.

You can also specify the external emissivity and external radiation temperature for a semi-transparent wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box ([Figure 14.18 \(p. 777\)](#)). Alternatively, you can specify a user-defined function (UDF) for these parameters. For more information, see [DEFINE_PROPERTY UDFs](#) in the [UDF Manual](#).

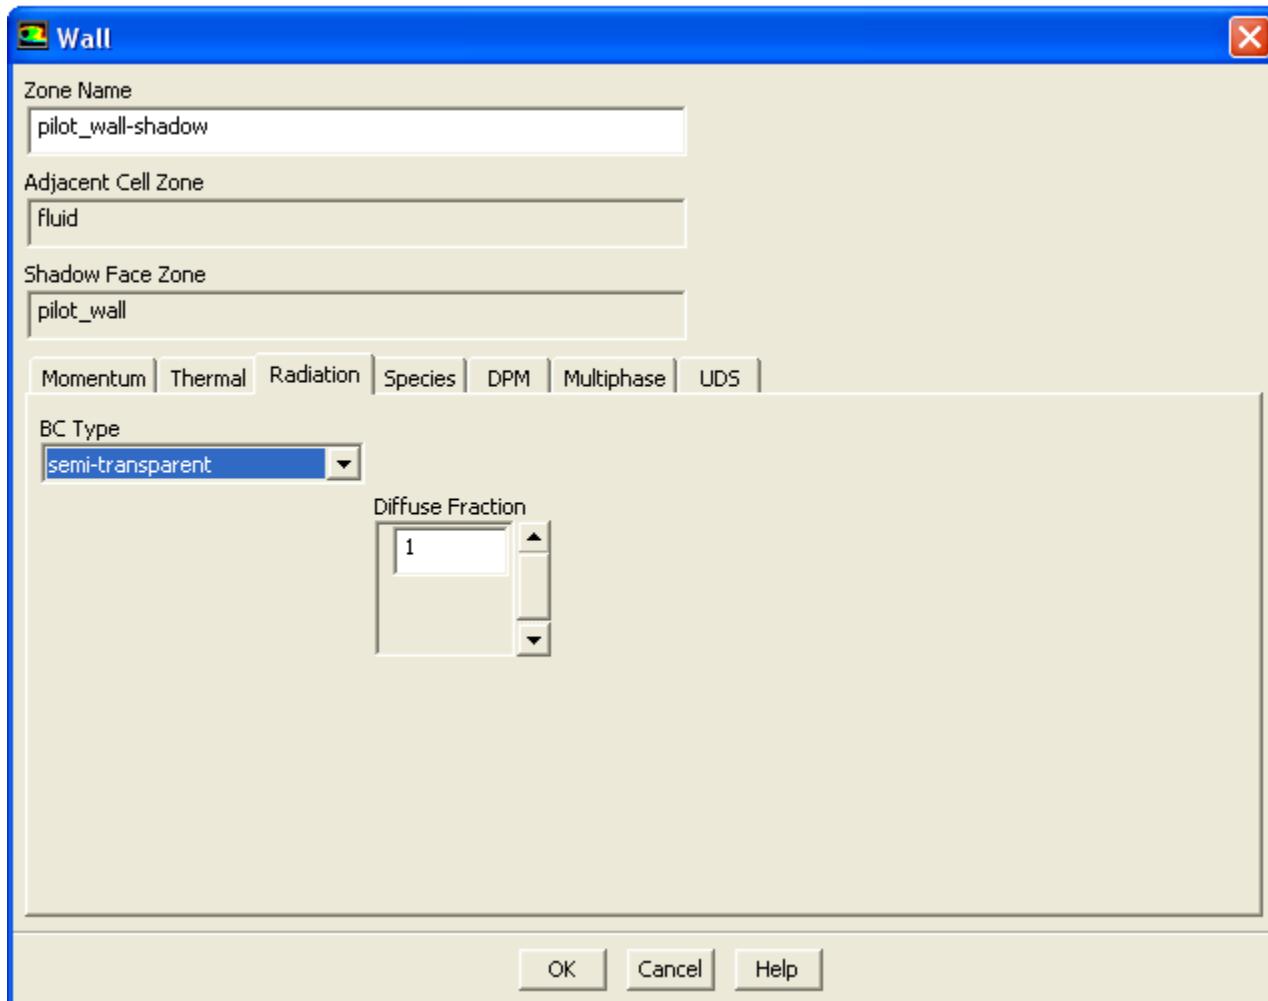

For a detailed description of boundary condition treatment at semi-transparent walls, see [Cell Zone and Boundary Condition Treatment at Semi-Transparent Walls](#) in the Theory Guide.

To define radiation for an interior (two-sided) semi-transparent wall, in the **Wall** dialog box click the **Radiation** tab and then select **semi-transparent** in the **BC Type** drop-down list ([Figure 14.20 \(p. 780\)](#)). Then specify the **Diffuse Fraction** as described for the previous case.

Important

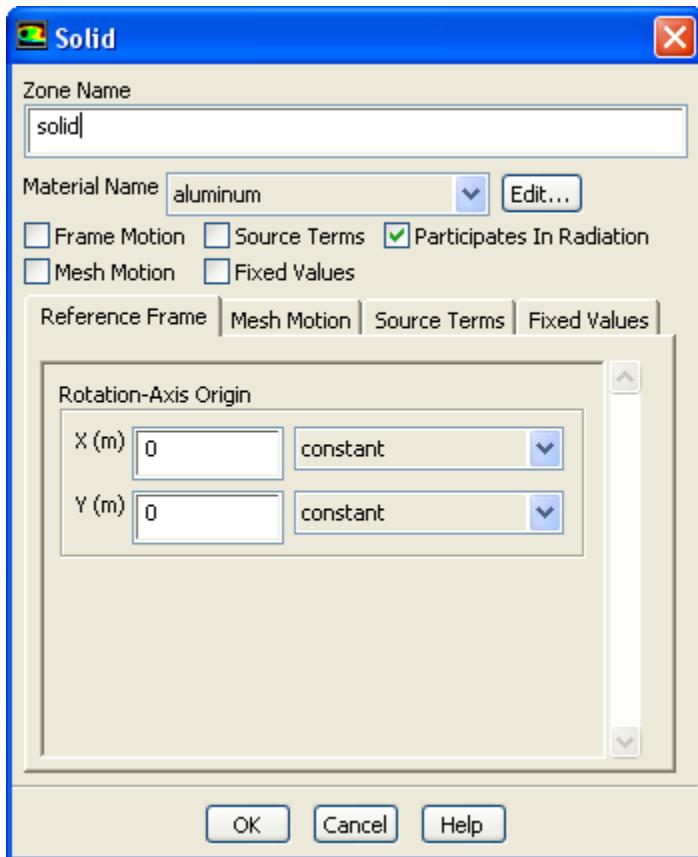

Note that for semi-transparent walls, the internal emissivity defined under thermal conditions is ignored. Emissivity and absorptivity on a semi-transparent surface can only be effected volumetrically in the wall thickness as a consequence of the wall material absorption coefficient. See notes near the end of [Discrete Ordinates \(DO\) Radiation Model Theory](#) in the [Theory Guide](#) discussing limitations around working with the wall thickness.

Figure 14.20 The Wall Dialog Box for an Interior Semi-Transparent Wall

14.3.7.4. Solid Cell Zones Conditions for the DO Model

With the DO model, you can specify whether or not you want to solve for radiation in each cell zone in the domain. By default, the DO equations are solved in all fluid zones, but not in any solid zones. If you want to model semi-transparent media, for example, you can enable radiation in the solid zone(s). To do so, enable the **Participates In Radiation** option in the **Solid** dialog box ([Figure 14.21 \(p. 781\)](#)).

Figure 14.21 The Solid Dialog Box

Important

In general, you should *not* disable the **Participates In Radiation** option for any fluid zones.

See [Solid Semi-Transparent Media](#) in the Theory Guide for more information on solid semi-transparent media.

14.3.7.5. Thermal Boundary Conditions

In general, any well-posed combination of thermal boundary conditions can be used when any of the radiation models is active. The radiation model will be well-posed in combination with fixed temperature walls, conducting walls, and/or walls with set external heat transfer boundary conditions ([Thermal Boundary Conditions at Walls \(p. 322\)](#)). You can also use any of the radiation models with heat flux boundary conditions defined at walls, in which case the heat flux you define will be treated as the sum of the convective and radiative heat fluxes. The exception to this is the case of semi-transparent walls for the DO model. Here, ANSYS FLUENT allows you to specify the convective and radiative portions of the heat flux separately.

14.3.8. Solution Strategies for Radiation Modeling

For the P-1, DTRM, S2S, and the DO radiation models, there are several parameters that control the radiation calculation. You can use the default solution parameters for most problems, or you can modify these parameters to control the convergence and accuracy of the solution. Iteration parameters that are unique for a particular radiation model are specified in the **Radiation Model** dialog box (e.g., **Energy**

Iterations per Radiation Iteration). **Spatial Discretization** ([Discretization](#) in the [Theory Guide](#)) and **Under-Relaxation** ([Under-Relaxation of Variables](#) in the [Theory Guide](#)) are specified in the **Solution Methods** and **Solution Controls** task pages, respectively. The **Convergence Criterion** ([Modifying Convergence Criteria](#) (p. 1387)) is set in the **Residual Monitors** dialog box.

There are no solution parameters to be set for the Rosseland model, since it impacts the solution only through the energy equation.

Important

If radiation is the only model being solved in ANSYS FLUENT, and all other equations are switched off, then the **Energy Iterations per Radiation Iteration** solution parameter that is available for certain radiation models is automatically reset to 1.

14.3.8.1. P-1 Model Solution Parameters

For the P-1 radiation model, you can control the convergence criterion and under-relaxation factor. You should also pay attention to the optical thickness, as described below.

The default convergence criterion for the P-1 model is 10^{-6} , the same as that for the energy equation, since the two are closely linked. See [Monitoring Residuals](#) (p. 1379) for details about convergence criteria. You can set the **Convergence Criterion** for p1 in the **Residual Monitors** dialog box.

 **Monitors** →  **Residuals** → **Edit...**

The under-relaxation factor for the P-1 model is set with those for other variables, as described in [Setting Under-Relaxation Factors](#) (p. 1323). Note that since the equation for the radiation temperature (Equation 5–21 in the [Theory Guide](#)) is a relatively stable scalar transport equation, in most cases you can safely use large values of under-relaxation (0.9–1.0).

For optimal convergence with the P-1 model, the optical thickness $(\alpha + \sigma_s)L$ must be between 0.01 and 10 (preferably not larger than 5). Smaller optical thicknesses are typical for very small enclosures (characteristic size of the order of 1 cm), but for such problems you can safely increase the absorption coefficient to a value for which $(\alpha + \sigma_s)L = 0.01$. Increasing the absorption coefficient will not change the physics of the problem because the difference in the level of transparency of a medium with optical thickness = 0.01 and one with optical thickness <0.01 is indistinguishable within the accuracy level of the computation.

14.3.8.2. DTRM Solution Parameters

When the DTRM is active, ANSYS FLUENT updates the radiation field during the calculation and computes the resulting energy sources and heat fluxes via the ray-tracing technique described in [Ray Tracing](#) in the [Theory Guide](#). ANSYS FLUENT provides several solution parameters appear in the expanded portion of the **Radiation Model** dialog box ([Figure 14.22](#) (p. 783)).

Figure 14.22 The Radiation Model Dialog Box (DTRM)

You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the **Maximum Number of Radiation Iterations**. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The **Residual Convergence Criteria** parameter (0.001 by default) determines when the radiation intensity update is converged. It is defined as the maximum normalized change in the surface intensity from one DTRM radiation iteration to the next (see [Equation 14–8 \(p. 785\)](#)).

You can also control the frequency with which the radiation field is updated as the continuous phase solution proceeds. The **Energy Iterations per Radiation Iteration** parameter is set to 10 by default. This means that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence.

14.3.8.3. S2S Solution Parameters

For the S2S model, as for the DTRM, you can control the frequency with which the radiosity is updated as the continuous-phase solution proceeds. See the previous description of **Energy Iterations per Radiation Iteration**.

If you are using the pressure-based solver and you first solve the flow equations with the energy equation turned off, you should reduce the **Energy Iterations per Radiation Iteration** from 10 to 1

or 2. This will ensure the convergence of the radiosity. If the default value of 10 is kept in this case, it is possible that the flow and energy residuals may converge and the solution will terminate before the radiosity is converged. See [Residual Reporting for the S2S Model \(p. 785\)](#) for more information about residuals for the S2S model.

You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the **Maximum Number of Radiation Iterations**. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The **Residual Convergence Criteria** (0.001 by default) determines when the radiosity update is converged. It is defined as the maximum normalized change in the radiosity from one S2S radiation iteration to the next (see [Equation 14–9 \(p. 785\)](#)).

14.3.8.4. DO Solution Parameters

For the discrete ordinates model, as for the DTRM, you can control the frequency with which the surface intensity is updated as the continuous phase solution proceeds. See the description of **Energy Iterations per Radiation Iteration** for the DTRM, as mentioned in the previous sections.

For most problems, the default under-relaxation of 1.0 for the DO equations is adequate. For problems with large optical thicknesses ($aL > 10$), you may experience slow convergence or solution oscillation. For such cases, under-relaxing the energy and DO equations is useful. Under-relaxation factors between 0.9 and 1.0 are recommended for both equations.

14.3.8.5. Running the Calculation

Once the radiation problem has been set up, you can proceed as usual with the calculation. Note that while the P-1 and DO models will solve additional transport equations and report residuals, the DTRM and the Rosseland and S2S models will not (since they impact the solution only through the energy equation). Residuals for the DTRM and S2S model radiation iterations are reported by ANSYS FLUENT every time such an iteration is performed, as described below.

14.3.8.5.1. Residual Reporting for the P-1 Model

The residual for radiation as calculated by the P-1 model is updated after each iteration and reported with the residuals for all other variables. ANSYS FLUENT reports the normalized P-1 radiation residual as defined in [Monitoring Residuals \(p. 1379\)](#) for the other transport equations.

14.3.8.5.2. Residual Reporting for the DO Model

After each DO iteration, the DO model reports a composite normalized residual for all the DO transport equations. The definition of the residuals is similar to that for the other transport equations (see [Monitoring Residuals \(p. 1379\)](#)).

14.3.8.5.3. Residual Reporting for the DTRM

ANSYS FLUENT does not include a DTRM residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time a DTRM iteration is performed, ANSYS FLUENT will print out the normalized radiation error for each DTRM radiation iteration. The normalized radiation error is defined as

$$E = \frac{\sum_{\text{all radiating surfaces}} (I_{\text{new}} - I_{\text{old}})}{N (\sigma T^4 / \pi)} \quad (14-8)$$

where the error E is the maximum change in the intensity (I) at the current radiation iteration, normalized by the maximum surface emissive power, and N is the total number of radiating surfaces. Note that the default radiation convergence criterion, as noted in *DTRM Solution Parameters* (p. 782), defines the radiation calculation to be converged when E decreases to 10^{-3} or less.

14.3.8.5.4. Residual Reporting for the S2S Model

ANSYS FLUENT does not include an S2S residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time an S2S iteration is performed, ANSYS FLUENT will print out the normalized radiation error for each S2S radiation iteration. The normalized radiation error is defined as

$$E = \frac{\sum_{\text{all radiating surface clusters}} (J_{\text{new}} - J_{\text{old}})}{N \sigma T^4} \quad (14-9)$$

where the error E is the maximum change in the radiosity (J) at the current radiation iteration, normalized by the maximum surface emissive power, and N is the total number of radiating surface clusters. Note that the default radiation convergence criterion, as noted in *DTRM Solution Parameters* (p. 782), defines the radiation calculation to be converged when E decreases to 10^{-3} or less.

14.3.8.5.5. Disabling the Update of the Radiation Fluxes

Sometimes, you may wish to set up your ANSYS FLUENT model with the radiation model active and then disable the radiation calculation during the initial calculation phase. For the P-1 and DO models, you can turn off the radiation calculation temporarily by deselecting **P1** or **Discrete Ordinates** in the **Equations** list, which is accessed via the **Solution Controls** task page. For the DTRM and the S2S model, there is no item in the **Equations**. You can instead set a very large number for **Energy Iterations per Radiation Iteration** in the **Iteration Parameters** group box of the **Radiation Model** dialog box.

If you turn off the radiation calculation, ANSYS FLUENT will skip the update of the radiation field during subsequent iterations, but will leave in place the influence of the current radiation field on energy sources due to absorption, wall heat fluxes, etc. Turning the radiation calculation off in this way can thus be used to initiate your modeling work with the radiation model inactive and/or to focus the computational effort on the other equations if the radiation model is relatively well converged.

14.3.9. Postprocessing Radiation Quantities

Information regarding postprocessing radiation quantities can be found in the following sections:

- [14.3.9.1. Available Variables for Postprocessing](#)
- [14.3.9.2. Reporting Radiative Heat Transfer Through Boundaries](#)
- [14.3.9.3. Overall Heat Balances When Using the DTRM](#)
- [14.3.9.4. Displaying Rays and Clusters for the DTRM](#)
- [14.3.9.5. Reporting Radiation in the S2S Model](#)

14.3.9.1. Available Variables for Postprocessing

ANSYS FLUENT provides radiation quantities that you can use in postprocessing when your model includes the solution of radiative heat transfer. You can generate graphical plots or alphanumeric reports of the following variables/functions:

In the **Radiation...** category:

- **Incident Radiation** (P-1 and DO models)
- **Incident Radiation (Band n)** (non-gray P-1 and non-gray DO models)
- **Absorption Coefficient** (DTRM, P-1, DO, and Rosseland models)
- **Scattering Coefficient** (P-1, DO, and Rosseland models)
- **Refractive Index** (P-1, DO, and Rosseland models)
- **Radiation Temperature** (P-1 and DO models)
- **Surface Cluster ID** (S2S model)

In the **Wall Fluxes...** category:

- **Radiation Heat Flux** (all radiation models)
- **Surface Incident Radiation** (S2S, DTRM, and DO models)
- **Absorbed Radiation Flux** (DO model, semi-transparent wall)
- **Reflected Radiation Flux** (DO model, semi-transparent wall)
- **Transmitted Radiation Flux** (DO model, semi-transparent wall)
- **Beam Irradiation Flux** (DO model, semi-transparent wall)

See [Field Function Definitions \(p. 1653\)](#) for definitions of these postprocessing variables. Note that in addition, incident radiation, transmitted, reflected and absorbed radiation flux are also available on a per-band basis for the non-gray DO model.

Important

- The sign convention on the radiative heat flux is such that the heat flux from the wall surface is a positive quantity.
- It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. See [Exporting Heat Flux Data \(p. 743\)](#) for details.
- Take care not to confuse **Incident Radiation** and **Surface Incident Radiation**. **Incident Radiation** is a volumetric quantity giving the total radiant load passing through the cell (in all directions), whereas **Surface Incident Radiation** is the total radiant load hitting the surface (which will subsequently be absorbed, transmitted and reflected). There is no direct means to report how much radiation has been absorbed/emitted/scattered in cells.

14.3.9.2. Reporting Radiative Heat Transfer Through Boundaries

You can use the **Flux Reports** dialog box to compute the radiative heat transfer through each boundary of the domain, or to sum the radiative heat transfer through all boundaries.

  Reports → Fluxes → Set Up...

See *Fluxes Through Boundaries* (p. 1635) for details about generating flux reports.

14.3.9.3. Overall Heat Balances When Using the DTRM

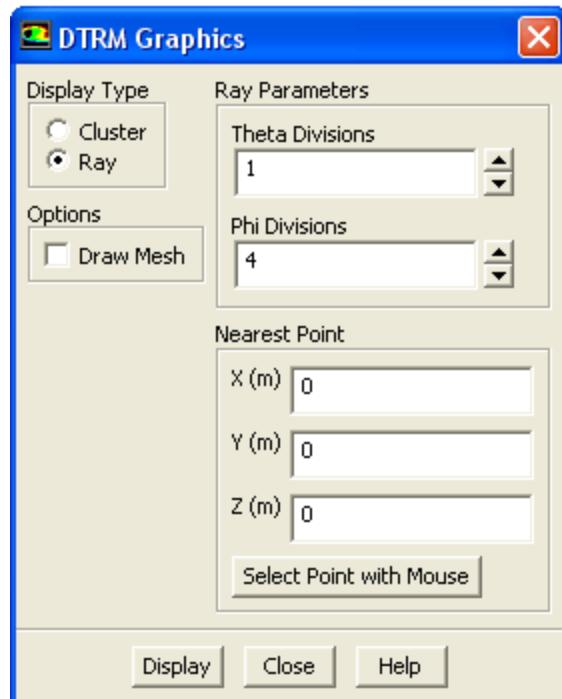

The DTRM yields a global heat balance and a balance of radiant heat fluxes only in the limit of a sufficient number of rays. In any given calculation, therefore, if the number of rays is insufficient you may find that the radiant fluxes do not obey a strict balance. Such imbalances are the inevitable consequence of the discrete ray tracing procedure and can be minimized by selecting a larger number of rays from each wall boundary.

14.3.9.4. Displaying Rays and Clusters for the DTRM

When you use the DTRM, ANSYS FLUENT allows you to display surface or volume clusters, as well as the rays that emanate from a particular surface cluster. You can use the **DTRM Graphics** dialog box (*Figure 14.23* (p. 787)) for all of these displays.

Display → DTRM Graphics...

Figure 14.23 The DTRM Graphics Dialog Box

14.3.9.4.1. Displaying Clusters

To view clusters, select **Cluster** under **Display Type** and then select either **Surface** or **Volume** under **Cluster Type**.

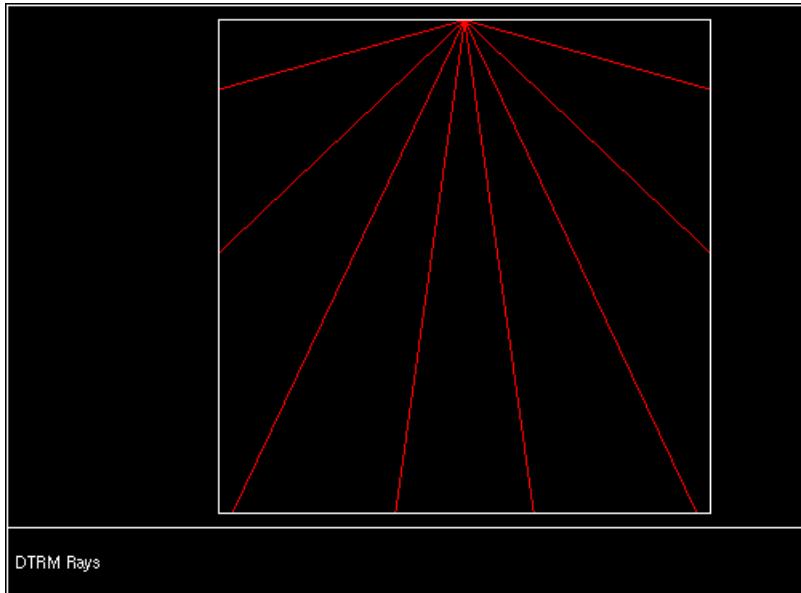

To display all of the surface or volume clusters, select the **Display All Clusters** option under **Cluster Selection** and click the **Display** button.

To display only the cluster (surface or volume) nearest to a specified point, deselect the **Display All Clusters** option and specify the coordinates under **Nearest Point**. You may also use the mouse to choose the nearest point. Click on the **Select Point With Mouse** button and then right-click on a point in the graphics window.

14.3.9.4.2. Displaying Rays

To display the rays emanating from the surface cluster nearest to the specified point, select **Ray** under **Display Type**. Set the appropriate values for **Theta** and **Phi Divisions** under **Ray Parameters** (see [Setting Up the DTRM \(p. 754\)](#) for details), and then click the **Display** button. [Figure 14.24 \(p. 788\)](#) shows a ray plot for a simple 2D geometry.

Figure 14.24 Ray Display

14.3.9.4.3. Including the Mesh in the Display

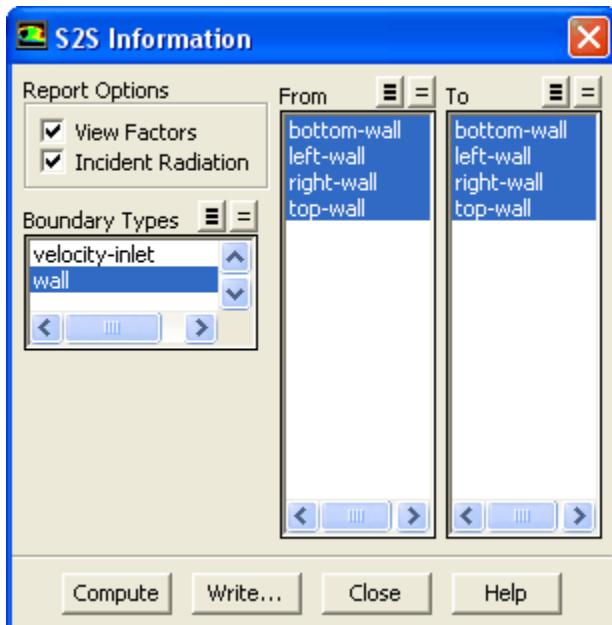

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your ray or cluster display as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with displaying the rays. This is accomplished by enabling the **Draw Mesh** option in the **DTRM Graphics** dialog box. The **Mesh Display** dialog box will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the **DTRM Graphics** dialog box, the mesh display, as defined in the **Mesh Display** dialog box, will be included in the ray or cluster display.

14.3.9.5. Reporting Radiation in the S2S Model

When you use the S2S model, ANSYS FLUENT allows you to view the values of the view factor and radiation emitted from one zone to any other zone. You can use the **S2S Information** dialog box ([Figure 14.25 \(p. 789\)](#)) to generate a report of these values in the console or as a separate file.

Report → S2S Information...

Figure 14.25 The S2S Information Dialog Box

The steps for generating the report are as follows:

1. Specify the values in which you are interested by selecting **View Factors** and/or **Incident Radiation**.
2. Choose the zones for which you would like data by selecting them in the lists under **From** and **To** (at least one zone must be selected under each list). To select all of the zones of a particular type, click that category in the list under **Boundary Types**.
3. Specify how you would like to present the data. To report the values in the console, click the **Compute** button. To write the data as an S2S Info File (.sif format), click the **Write...** button and enter a file name in *The Select File Dialog Box* (p. 33).

The following is an example of how the data is presented:

```
S2S Information
From wall1 to:
      Viewfactor      Incident Radiation
wall1     0.0000          0.0000
wall2     0.2929        171387.7813
wall3     0.2929        155305.7969
wall4     0.4142        29055.9023

From wall2 to:
      Viewfactor      Incident Radiation
wall1     0.2929        306451.9688
wall2     0.0000          0.0000
wall3     0.4142        214195.0938
wall4     0.2929        19153.2715
```

Note that the header listed above (S2S Information) is not displayed in the console.

14.3.10. Solar Load Model

ANSYS FLUENT provides a solar load model that can be used to calculate radiation effects from the sun's rays that enter a computational domain. Two options are available for the model: solar ray tracing and DO irradiation. The ray tracing approach is a highly efficient and practical means of applying solar loads as heat sources in the energy equations. In cases where you want to use the discrete ordinates

(DO) model to calculate radiation effects within the domain, an option is available to supply outside beam direction and intensity parameters directly to the DO model. The solar load model includes a solar calculator utility that can be used to construct the sun's location in the sky for a given time-of-day, date, and position. Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

14.3.10.1. Introduction

Typical applications that are well-suited for solar load simulations include the following:

- automotive climate control (ACC) applications
- human comfort modeling applications in buildings

The effects of solar loading are needed in many ACC applications, where the temperature, humidity, and velocity fields around passengers (and drivers) are desired. ACC systems are tested for their capacity to cool down passenger compartments after they have been "soaked" in intense solar radiation. ANSYS FLUENT's solar load model will enable you to simulate solar loading effects and predict the time it will take to reasonably cool down the cabin of a car that has been exposed to solar radiation, as well as predict the time interval needed to lower the temperature in specified points and areas within the domain.

In the analysis of buildings, solar loading provides a significant burden on the cooling requirement in warm climates, particularly where architects want to use the aesthetics of glazed facades. Even in cooler climates, solar loading can provide a burden during warmer seasons where modern buildings are well insulated against thermal loss during winter months. As well as providing an engineer with a practical tool for determining the solar heating effect inside a building, ANSYS FLUENT's solar load model will allow the solar transmission through all glazed surfaces to be determined over the course of a day, allowing important decisions to be made before undertaking any flow studies. ANSYS FLUENT's solar load model also allows you to simulate porous blinds, which can transmit a portion of the solar radiation while also allowing fluid flow.

14.3.10.2. Solar Ray Tracing

The solar load model's ray tracing algorithm can be used to predict the direct illumination energy source that results from incident solar radiation. It takes a beam that is modeled using the sun position vector and illumination parameters, applies it to any or all wall, porous jump, and inlet/outlet boundary zones that you specify, performs a face-by-face shading analysis to determine well-defined shadows on all boundary faces and interior walls, and computes the heat flux on the boundary faces that results from the incident radiation.

Important

The solar ray tracing model includes only boundary zones that are adjacent to fluid zones in the ray tracing calculation. In other words, boundary zones that are attached to solid zones are ignored.

The resulting heat flux that is computed by the solar ray tracing algorithm is coupled to the ANSYS FLUENT calculation via a source term in the energy equation. The heat sources are added directly to computational cells bordering each face and are assigned to adjacent cells in the following order: shell conduction cells, solid cells, and fluid cells. Heat sources are assigned to one of these types of adjacent cells, only. You can choose to override this order and include adjacent fluid cells in the solar load calculation by issuing a command in the text user interface (see [Text Interface-Only Commands \(p. 809\)](#) for

details). Note that the sun position vector and solar intensity can be entered either directly by you or computed from the solar calculator. Direct and diffuse irradiation parameters can also be specified using a user-defined function (UDF) and hooked to ANSYS FLUENT in the **Radiation Model** dialog box.

The solar ray tracing option allows you to include the effects of direct solar illumination as well as diffuse solar radiation in your ANSYS FLUENT model. A two-band spectral model is used for direct solar illumination and accounts for separate material properties in the visible and infrared bands. A single-band hemispherical-averaged spectral model is used for diffuse radiation. Opaque materials are characterized in terms of two-band absorptivities. A semi-transparent material requires specification of absorptivity and transmissivity. Values that you specify for transmissivity and absorptivity are defined for normal incident rays. ANSYS FLUENT recomputes/interpolates these values for the given angle of incidence.

The solar ray tracing algorithm also accounts for internal scattered and diffusive loading. The reflected component of direct solar irradiation is tracked. A fraction of this radiative heat flux, called internally scattered energy is applied to all the surfaces participating in the solar load calculation, weighted by area. The internally scattered energy depends on the scattering fraction which is specified in the TUI, and whose default value is 1. Depending on the reflectivity of the primary surface, the scattering fraction can be responsible for the inclusion (or exclusion) of a large amount of radiation within the rest of the domain.

Also included as internally scattered energy is the contribution of the transmitted component of diffuse solar irradiation (which enters a domain through semi-transparent walls depending upon the hemispherical transmissivity). The total value of internally scattered energy is reported to the ANSYS FLUENT console. The ambient flux is obtained by dividing the internally scattered energy by the total surface area of the faces participating in the solar load calculation.

Note that **Solar Ray Tracing** is *not* a participating radiation model. It does not deal with emission from surfaces, and the reflecting component of the primary incident load is distributed uniformly across all surfaces rather than being local to the surfaces reflected to. If surface emission is an important factor in your case then you can consider implementing a radiation model (e.g., P-1) in conjunction with **Solar Ray Tracing**.

14.3.10.2.1. Shading Algorithm

The shading calculation that is used for solar ray tracing is a straightforward application of vector geometry. A ray is traced from the centroid of a test face in the direction of the sun. Every other face is checked to determine if the ray intersects the candidate face and if the candidate face is in front of the test face. If both conditions are met, then an opaque face completely shades the test face. A semi-transparent face attenuates the incident energy.

A Barycentric coordinate formulation is used to construct triangle-ray intersections. A quadrilateral ray intersection method is used to handle the case when model surfaces contain quadrilaterals. A quad-tree preprocessing step is applied to reduce the ray tracing algorithm complexity that can lead to long runtime for 10^4 faces and greater. The quad-tree refinement factor can be modified in the text interface. The default value of this parameter is 7 which is sufficient to cover the entire spectrum of mesh sizes between one cell and five million cells. If the mesh is greater than five million cells, an increase in this parameter would reduce the CPU time needed to compute the solar loads.

14.3.10.2.2. Glazing Materials

Incident solar radiation can be applied to glass and plastic glazing materials of various types at wall boundaries, and the effects of coated glazings modeled using the solar ray tracing algorithm. To model solar optical properties, you will need to specify the transmissivity and reflectivity of the material in the

Wall boundary conditions dialog box. You can obtain these values from the glass (or plastic) manufacturer or use data from another source (e.g., ASHRAE Handbook).

Glazing optical properties are dependent on incident angle, and the variation is significant for an incident angle greater than 40 degrees. As the incident angle increases from zero, transmissivity decreases, reflectivity increases, and absorptivity increases initially due to lengthened optical path, and then decreases as more incident radiation is reflected. The shape of the property curve varies with glass type and thickness. This difference is more pronounced for coated glass or for a multiple-pane glazing system. It cannot be assumed that all glazing systems have a universal angular dependence.

For coated glazings, the spectral transmissivity and reflectivity at any incident angle are approximated in the solar load model from the normal angle of incidence [24] (p. 2368).

Transmissivity is given by

$$T(\theta, \lambda) = T(0, \lambda) Tref(\theta) \quad (14-10)$$

where

$$Tref(\theta) = a_0 + a_1 \cos(\theta) + a_2 \cos(\theta^2) + a_3 \cos(\theta^3) + a_4 \cos(\theta^4) \quad (14-11)$$

Reflectivity is given by

$$R(\theta, \lambda) = R(0, \lambda) [1 - Rref(\theta)] + Rref(\theta) \quad (14-12)$$

where

$$Rref(\theta) = b_0 + b_1 \cos(\theta) + b_2 \cos(\theta^2) + b_3 \cos(\theta^3) + b_4 \cos(\theta^4) - Tref(\theta) \quad (14-13)$$

The constants used in [Equation 14-10 \(p. 792\)](#) and [Equation 14-12 \(p. 792\)](#) are for coated glazings and are taken from Finlayson and Arasteh. [24] (p. 2368). The normal transmissivity and reflectivity, $T(0, \lambda)$ and $R(0, \lambda)$ are specified in the **Wall** boundary conditions dialog box.

14.3.10.2.3. Inputs

The following inputs are required for the solar ray tracing algorithm:

- sun direction vector
- direct solar irradiation
- diffuse solar irradiation
- spectral fraction
- direct and IR absorptivity (opaque wall)
- direct and IR absorptivity and transmissivity (semi-transparent wall and porous jump)
- diffuse hemispherical absorptivity and transmissivity (semi-transparent wall)
- solar transmissivity factor
- quad tree refinement factor

- scattering fraction
- ground reflectivity

The sun direction vector is the direction vector looking to the sun, from which the direct irradiation will be incident. You can enter the vector components (**X**, **Y**, **Z**) and the direct and diffuse solar irradiation fluxes in the **Radiation Model** dialog box, or you can have these parameters derived from the solar calculator. These irradiation fluxes can also be specified using a user-defined function ([User-Defined Functions \(UDFs\) for Solar Load \(p. 797\)](#)). The spectral fraction is the final input in the **Radiation Model** dialog box. This defines the split of visible and infra-red (shortwave and longwave respectively) radiation, specifically the fraction of the direct irradiation flux that is in the visible band. These quantities can also be defined through the text interface.

The scattering fraction defines the amount of non-absorbed radiation that will be distributed (uniformly) across all participating surfaces. This is required as the solar load model does not track the rays beyond the first opaque surface. Therefore, a highly glazed space where incident radiation is likely to be reflected back out will have a low value. Conversely, a predominantly opaque (wall-bounded) space where reflected radiation is likely to be incident upon (and ultimately absorbed by) other opaque surfaces will have a high value. This parameter is defined through the text interface only, taking a default value of 1.0:

```
define → models → radiation → solar-parameters → scattering-fraction
```

The ground reflectivity is used by the solar calculator to compute the background diffuse radiation intensity component contributed to by radiation reflected off the ground. This should be based on typical figures for the surface reflectivity of the outside ground surfaces. By default this is set to 0.2, but can be adjusted through the text-interface:

```
define → models → radiation → solar-parameters → ground-reflectivity
```

The quad-tree-refinement parameter determines the level of detail used by the shading algorithm. By default this is set to 7 which will generally work well, but can lie between 0 and 10. This is defined only through the text interface:

```
define → models → radiation → solar-parameters → quad-tree-refinement
```

Further details on the text interface-only entries is provided later in this section (see [Text Interface-Only Commands](#)).

The absorptivity and transmissivity parameters related to a wall or porous jump are entered in the **Wall** (under the **Radiation** tab) or **Porous Jump** boundary condition dialog box, respectively, for the particular boundary zones you wish to participate in solar ray tracing. On flow boundaries you have a solar transmissivity factor to allow you to attenuate the incoming solar flux, e.g. set to 1 for a fully open inlet or set to 0 for a light obscuring louvered inlet.

14.3.10.3. DO Irradiation

The solar load model's discrete ordinates (DO) irradiation option provides you with an easy means of applying a solar load directly to the DO model. Unlike the ray tracing solar load option, the DO irradiation method does not compute heat fluxes and apply them as heat sources to the energy equation. Instead, the irradiation flux is applied directly to semi-transparent walls (which you specify) as a boundary condition, and the radiative heat transfer is derived from the solution of the DO radiative transfer equation.

The following inputs are required for DO irradiation at semi-transparent walls:

- direct irradiation

- diffuse irradiation
- beam direction
- beam width
- diffuse fraction

In the **Wall** boundary condition dialog box for each semi-transparent wall you want to participate in DO irradiation, you can specify that the beam direction, direct irradiation, and diffuse irradiation be derived from the solar parameters (e.g., solar calculator) which you set (or compute) in the **Radiation Model** dialog box. This is done by checking the **Use Beam Direction from Solar Load Model Settings** and **Use Direct and Diffuse Irradiation from Solar Load Model Settings** boxes. When selected, ANSYS FLUENT sets the beam width (the angle subtended by the sun) to the default value of 0.53 degrees for DO irradiation.

Important

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (e.g., radiation coming from the sun), while the sun direction vector in the solar load model points to the sun. Incident radiation and the sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.

14.3.10.4. Solar Calculator

ANSYS FLUENT provides a solar calculator that can be used to compute solar beam direction and irradiation for a given time, date, and position. These values can be used as inputs to the solar ray tracing algorithm or as semi-transparent wall boundary conditions for discrete ordinates (DO) irradiation.

14.3.10.4.1. Inputs/Outputs

Inputs needed for the solar calculator are:

- global position (latitude, longitude, time zone)
- starting date and time
- mesh orientation
- solar irradiation method
- sunshine factor

Global position consists of latitude, longitude, and time zone (relative to GMT). The time of day for a transient simulation is the starting time plus the flow-time. For mesh orientation, you will need to specify the North and East direction vector in the CFD mesh. The default solar irradiation method is Fair Weather Conditions. Alternatively, you can choose the Theoretical Maximum method. The sunshine factor is simply a linear reduction factor for the computed incident load that allows for cloud cover to be accounted for, if appropriate.

You can specify these inputs in the **Solar Calculator** dialog box that is accessible from the **Radiation Model** dialog box (*Figure 14.29 (p. 801)*). Alternatively, you can enter the parameters using text interface commands (*Additional Text Interface Commands (p. 811)*).

The following values are computed by the solar calculator and are displayed in the console whenever the solar calculator is used:

- sun direction vector
- sunshine fraction
- direct normal solar irradiation at earth's surface
- diffuse solar irradiation - vertical and horizontal surface
- ground reflected (diffuse) solar irradiation - vertical surface

Direct normal solar irradiation is computed using the ASHRAE Fair Weather Conditions method, when this option is selected in the solar calculator. Note: Equation 20 and Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals. The theoretical maximum values for direct normal solar irradiation and diffuse solar irradiation are computed using NREL's Theoretical Maximum method, when this option is selected. In practice, these values are unlikely to be experienced due to atmospheric conditions.

ANSYS FLUENT computes the diffuse solar irradiation components (vertical and horizontal) internally for each face in the domain. When the Theoretical Maximum method is chosen, these diffuse irradiation values provide estimates for the maximum vertical and horizontal surface effects.

14.3.10.4.2. Theory

ANSYS FLUENT provides two options for computing the solar load: Fair Weather Conditions method and Theoretical Maximum method. Although these methods are similar, there is a key difference. The Fair Weather Conditions method imposes greater attenuation on the solar load which is representative of atmospheric conditions that are fair –but not completely clear.

The equation for normal direct irradiation applying the Fair Weather Conditions Method is taken from the ASHRAE Handbook:

$$Edn = \frac{A}{e^{\frac{B}{\sin(\beta)}}} \quad (14-14)$$

where A and B are apparent solar irradiation at air mass $m = 0$ and atmospheric extinction coefficient, respectively. These values are based on the earth's surface on a clear day. β is the solar altitude (in degrees) above the horizontal.

The equation for direct normal irradiation that is used for the Theoretical Maximum Method is taken from NREL's Solar Position and Intensity Code (Solpos):

$$Edn = S_{etrn} S_{unprime} \quad (14-15)$$

where S_{etrn} is the top of the atmosphere direct normal solar irradiance and $S_{unprime}$ is the correction factor used to account for reduction in solar load through the atmosphere.

The calculation for the diffuse load in the solar model is based on the approach suggested in the 2001 ASHRAE Fundamental Handbook (Chapter 20, Fenestration). The equation for diffuse solar irradiation on a vertical surface is given by:

$$Ed = CYEdn \quad (14-16)$$

where C is a constant whose values are given in Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals, Y is the ratio of sky diffuse radiation on a vertical surface to that on a horizontal surface (calculated as a function of incident angle), and Edn is the direct normal irradiation at the earth's surface on a clear day.

The equation for diffuse solar irradiation for surfaces other than vertical surfaces is given by:

$$Ed = CEdn \frac{(1 + \cos \varepsilon)}{2} \quad (14-17)$$

where ε is the tilt angle of the surface (in degrees) from the horizontal plane.

The equation for ground reflected solar irradiation on a surface is given by:

$$Er = Edn (C + \sin \beta) \rho_g \frac{(1 - \cos \varepsilon)}{2} \quad (14-18)$$

where ρ_g is the ground reflectivity. The total diffuse irradiation on a given surface will be the sum of Ed and Er when the input for diffuse solar radiation is taken from the solar calculator. Otherwise, if the constant option is selected in the **Radiation** dialog box, then the total diffuse irradiation will be the same as specified in the dialog box.

14.3.10.4.3. Computation of Load Distribution

In calculating the solar load that will be incident on each surface, it is necessary to distinguish between the calculation of diffuse and direct solar loads. A direct load will be tracked from participating transmissive boundary surfaces and non-participating boundary surfaces, the former provides some opportunity to attenuate the incoming flux by absorption and reflection, while the non-participating surfaces allow the flux to enter without any drop in intensity. The direct load is then tracked through the model space until it is incident on an opaque surface, or it exists through a transmissive or non-participating boundary zone. During its passage, its intensity will be attenuated as it passes through participating semi-transparent internal walls, where some radiation may be absorbed and some may be reflected. The total amount of direct radiation which is reflected at internally facing surfaces will be added to the scattered radiation budget for further use later.

The diffuse load originates at participating transmissive boundary surfaces. It is these surfaces that permit diffuse radiation to enter, irrespective of their orientation relative to the direction vector. For each transmissive surface, some of the incoming diffuse load may be immediately absorbed and/or reflected to the outside. The rest is assumed to be transmitted inside and summed from all of these surfaces to give an initial diffuse budget. Onto this budget is added a fraction of the previously computed scattered radiation from the direct load, the fraction used is defined as an input to the model. This provides the total diffuse load. This is then uniformly distributed across all surfaces which are participating in the solar calculation, irrespective of whether they are opaque or semi-transparent. There is no scope to define local absorptivity for this distribution and no biasing with regards proximity to transmissive surfaces. Note that a non-participating boundary zone will allow direct load to enter the model space but will not provide an incoming quantity of diffuse load.

Note that the solar flux which is externally incident on an opaque surface will be completely disregarded, e.g. solar load on an opaque roof of a model whose internals only are modeled will not be included as a heat gain. Instead, this heat gain should be manually calculated and applied as a thermal condition, typically using a fixed heat flux or a radiation/mixed condition.

14.3.10.5. Using the Solar Load Model

When you want to run a steady-state solution with solar load enabled, you simply set up the solar load model ([Setting Up the Solar Load Model \(p. 797\)](#)) and boundary conditions ([Setting Boundary Conditions for Solar Loading \(p. 802\)](#)) for your case, and then run the simulation. The solution data file will contain the solar fluxes that you can use for postprocessing. For a steady-state solution, the solar loads are computed on initialization. If you want to initially solve a case without solar loading (say, for stability) and then add the effects of solar loading afterward, you will need to enable the solar load model through the text user interface (TUI).

Important

Note that you can compute the solar load at any time once you have set up the model by using the `sol-on-demand` text interface command (see [Additional Text Interface Commands \(p. 811\)](#) for details).

When you want to run a transient solar load simulation, the process is the same as for the steady-state case but you will need to specify the additional **Time Steps per Solar Load Update** parameter in the **Radiation Model** dialog box. ANSYS FLUENT will re-compute the sun position and irradiation and update solar loads with this specified frequency.

Important

Note that parallel simulations involving the solar load model are set up and computed using the same steps as in serial.

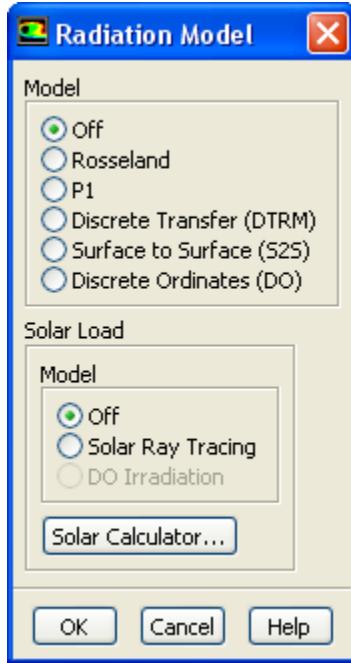

14.3.10.5.1. User-Defined Functions (UDFs) for Solar Load

You can write a user-defined function (UDF) to specify direct and diffuse solar intensity using the `DEFINE_SOLAR_INTENSITY` macro. See [DEFINE_SOLAR_INTENSITY](#) in the UDF Manual for more information. After it is interpreted or compiled, you can hook your intensity UDF for direct or diffuse solar irradiation by selecting `user-defined` in the drop-down lists for these parameters in the **Radiation Model** dialog box. See Step 2 in [Setting Up the Solar Load Model \(p. 797\)](#) for details.

14.3.10.5.2. Setting Up the Solar Load Model

The solar load model is enabled in the **Radiation Model** dialog box ([Figure 14.26 \(p. 798\)](#)).

Models → **Radiation** → **Edit...**

Figure 14.26 The Radiation Model Dialog Box

Important

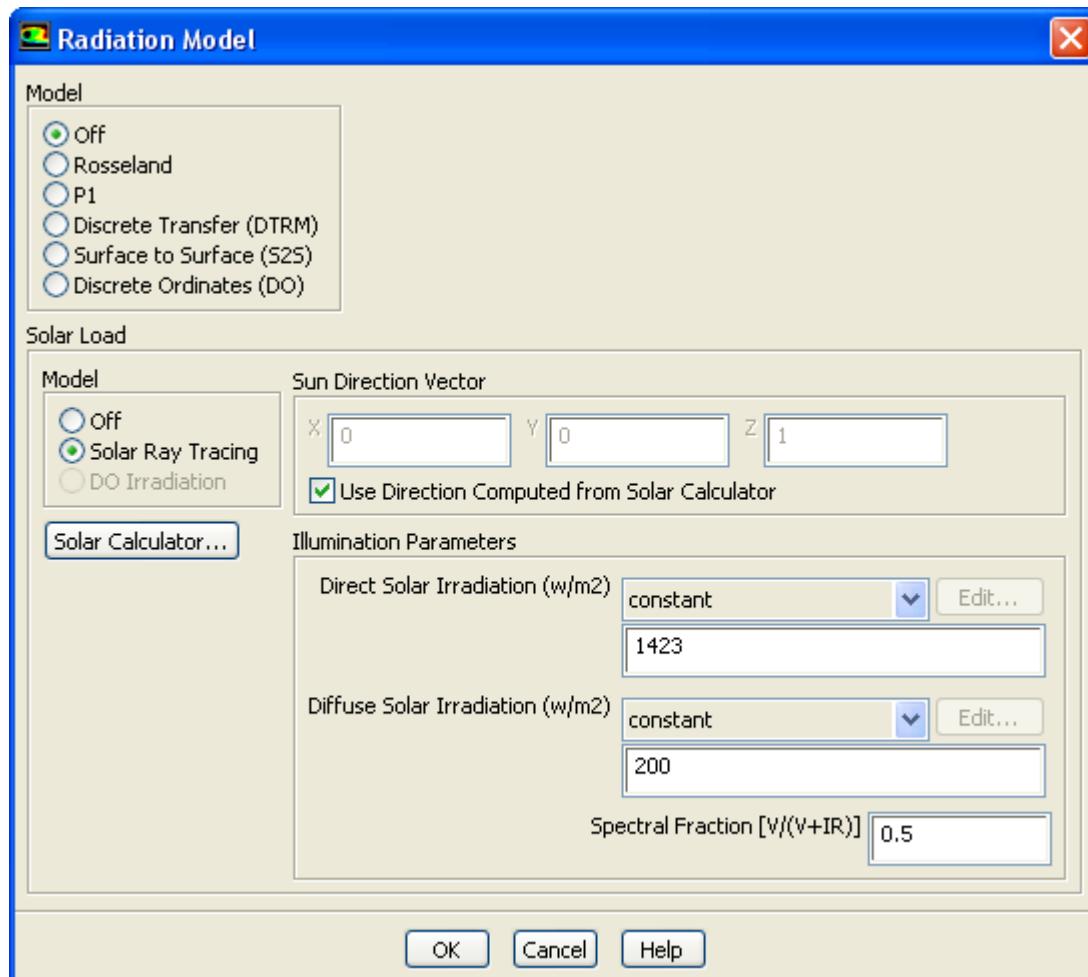

Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

The solar load model has two options: **Solar Ray Tracing** and **DO Irradiation**. **Solar Ray Tracing** can be applied as a standalone solar loading model, or it can be used in conjunction with one of the ANSYS FLUENT radiation models (P1, Rosseland, Discrete Transfer, Surface-to-Surface, Discrete Ordinates). **DO Irradiation** is available only when the **Discrete Ordinates (DO)** radiation model is enabled.

To set up the solar load model, perform the following steps:

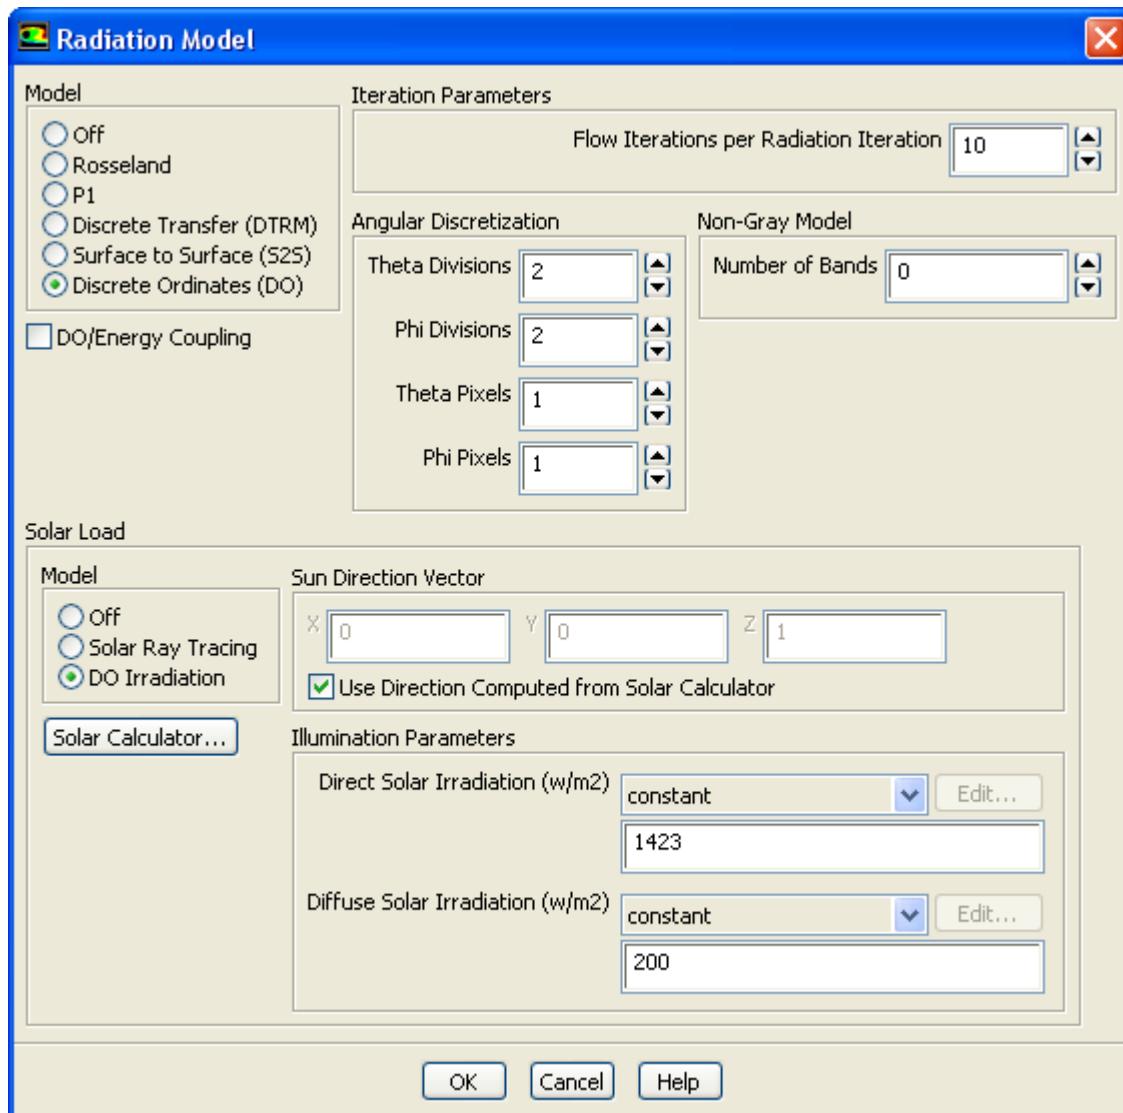

1. Enable the solar load model in the **Radiation Model** Dialog Box.
 - a. To enable the solar ray tracing algorithm, select **Solar Ray Tracing** under **Solar Load** (*Figure 14.27 (p. 799)*).

Figure 14.27 The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option)

- b. To enable the DO irradiation option, first select **Discrete Ordinates** under **Model**, and then select **DO Irradiation** under **Solar Load** ([Figure 14.28 \(p. 800\)](#)).

Figure 14.28 The Radiation Model Dialog Box (with Solar Load Model DO Irradiation Option)

2. Define the solar parameters.

- Enter values for the **X**, **Y**, and **Z** components of the **Sun Direction Vector**. Alternatively, you can choose to have this vector computed from the solar calculator by enabling the **Use Direction Computed from Solar Calculator** option.
- Specify the illumination parameters.
 - Enter a value for **Direct Solar Irradiation** under **Illumination Parameters**. This parameter is the amount of energy per unit area in W/m^2 due to direct solar irradiation. This value may depend on the time of year and the clearness of the sky. Make your selection in the drop-down list next to **Direct Solar Irradiation** and either enter a **constant** value, have the value computed from the **solar calculator**, or specify it using a **user-defined function**. (For more information on writing solar intensity UDFs, see **DEFINE_SOLAR_INTENSITY** in the **UDF Manual**.) For transient simulations, you have the additional option of specifying a time-dependent **piecewise-linear** and **polynomial** profile for direct solar irradiation.
 - Enter a value for **Diffuse Solar Irradiation**, which is the amount of energy per unit area in W/m^2 due to diffuse solar irradiation. This value may depend on the time of year, the

clearness of the sky, and also on ground reflectivity. Make your selection in the drop-down list next to **Diffuse Solar Irradiation** and either enter a **constant** value, have the value computed from the **solar calculator**, or specify it using a **user-defined function**. (For more information on writing solar intensity UDFs, see **DEFINE_SOLAR_INTENSITY** in the UDF Manual.) For transient simulations, you have the additional option of specifying a time-dependent **piecewise-linear** and **polynomial** profile for diffuse solar irradiation.

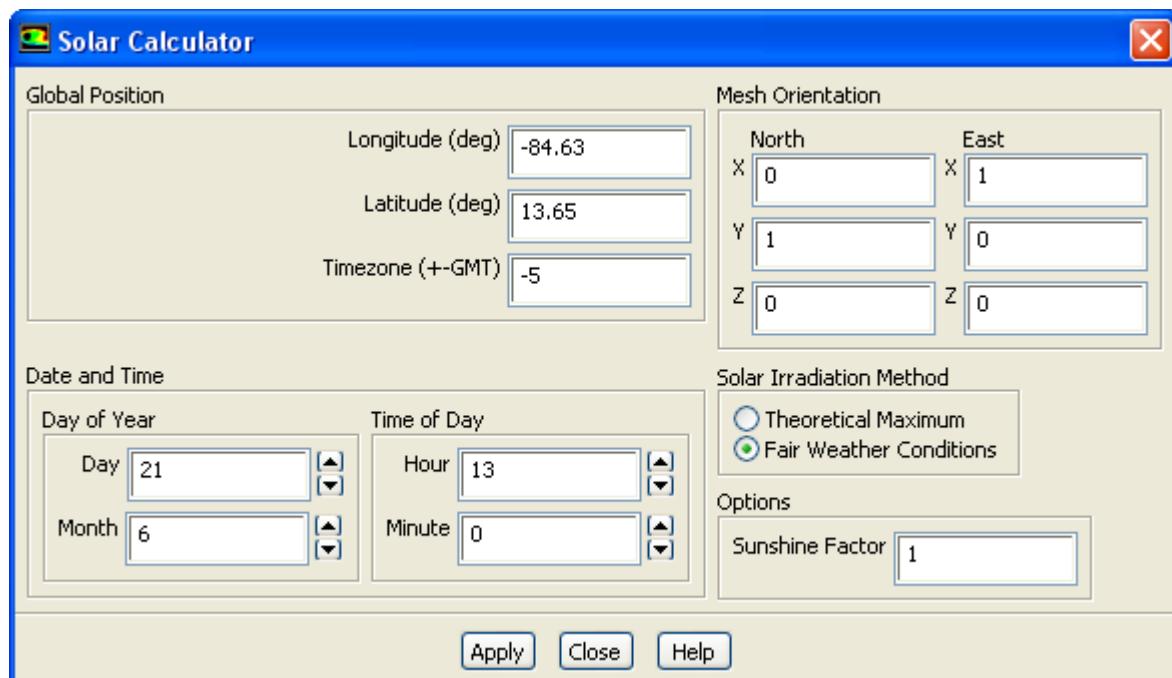

- iii. If you are using the **Solar Ray Tracing** solar load model (*Figure 14.27 (p. 799)*), then you will need to enter a value for **Spectral Fraction**. The spectral fraction is the fraction of incident solar radiation in the visible part of the solar radiation spectrum. The spectral fraction is not used for DO irradiation since the DO implementation is intended only for a single band.

$$\text{Spectral Fraction} = \frac{V}{V + IR} \quad (14-19)$$

where V is the visible incident solar radiation, and $V + IR$ is the total incident solar radiation (visible plus infrared).

3. Use the solar calculator to compute solar beam direction and irradiation.
 - a. Click **Solar Calculator...** in the **Radiation Model** dialog box to open the **Solar Calculator** dialog box (*Figure 14.29 (p. 801)*).

Figure 14.29 The Solar Calculator Dialog Box

- b. In the **Solar Calculator** dialog box, define the **Global Position** by the following parameters:
 - i. Enter a real number in degrees for **Longitude**. Values may range from -180 to 180 where negative values indicate the Western hemisphere and positive values indicate the Eastern hemisphere.
 - ii. Enter a real number for **Latitude** in degrees. Values can range from -90° (the South Pole) to 90° (the North Pole), with 0° defined as the equator.

- iii. Enter an integer for **Timezone** that is the local time zone in hours relative to Greenwich Mean Time (+-GMT). This value can range from + 12 to - 12.
-

Important

Note that you must specify all three **Global Position** parameters for the solar calculator.

- c. Define the local **Date and Time** by the following parameters:
 - i. Enter an integer for **Day** and **Month** under **Day of Year**.
 - ii. Enter an integer for **Hour** that ranges from 0 to 24 under **Time of Day**. Enter an integer or floating point number for **Minute**.

The time of day is based on a 24-hour clock: 0 hours and 0 minutes corresponds to 12:00 a.m. and 23 hours 59 .99 min corresponds to 11:59.99 p.m. For example, if the local time was 12:01:30 a.m., you would enter 0 for **Hour** and 1.5 for **Minute**. If the local time was 4:17 p.m., you would enter 16 for **Hour** and 17 for **Minute**.
- d. Define the **Mesh Orientation** as the vectors for North and East in the CFD mesh system of coordinates.
- e. Select the appropriate **Solar Irradiation Method**. The **Fair Weather Conditions** is the default method.
- f. Enter an integer for **Sunshine Fraction** (default = 1).
- g. Click **Apply**.

The solar calculator output parameters are computed and the results are reported in the console. The default values are shown below:

```
Fair Weather Conditions:  
Sun Direction Vector: X: -0.0785396, Y: 0.170758, Z: 0.982178  
Sunshine Fraction: 1  
Direct Normal Solar Irradiation (at Earth's surface) [W/m^2]:  
881.635  
Diffuse Solar Irradiation - vertical surface: [W/m^2]:  
152.107  
Diffuse Solar Irradiation - horizontal surface: [W/m^2]:  
118.727  
Ground Reflected Solar Irradiation - vertical surface: [W/m^2]:  
96.4649
```

4. For transient simulations, enter the **Time Steps Per Solar Load Update** under **Update Parameters**. The number of time steps that you specify will direct the ANSYS FLUENT solver to update the solar load data for the specified flow-time intervals in the unsteady solution process.

14.3.10.5.3. Setting Boundary Conditions for Solar Loading

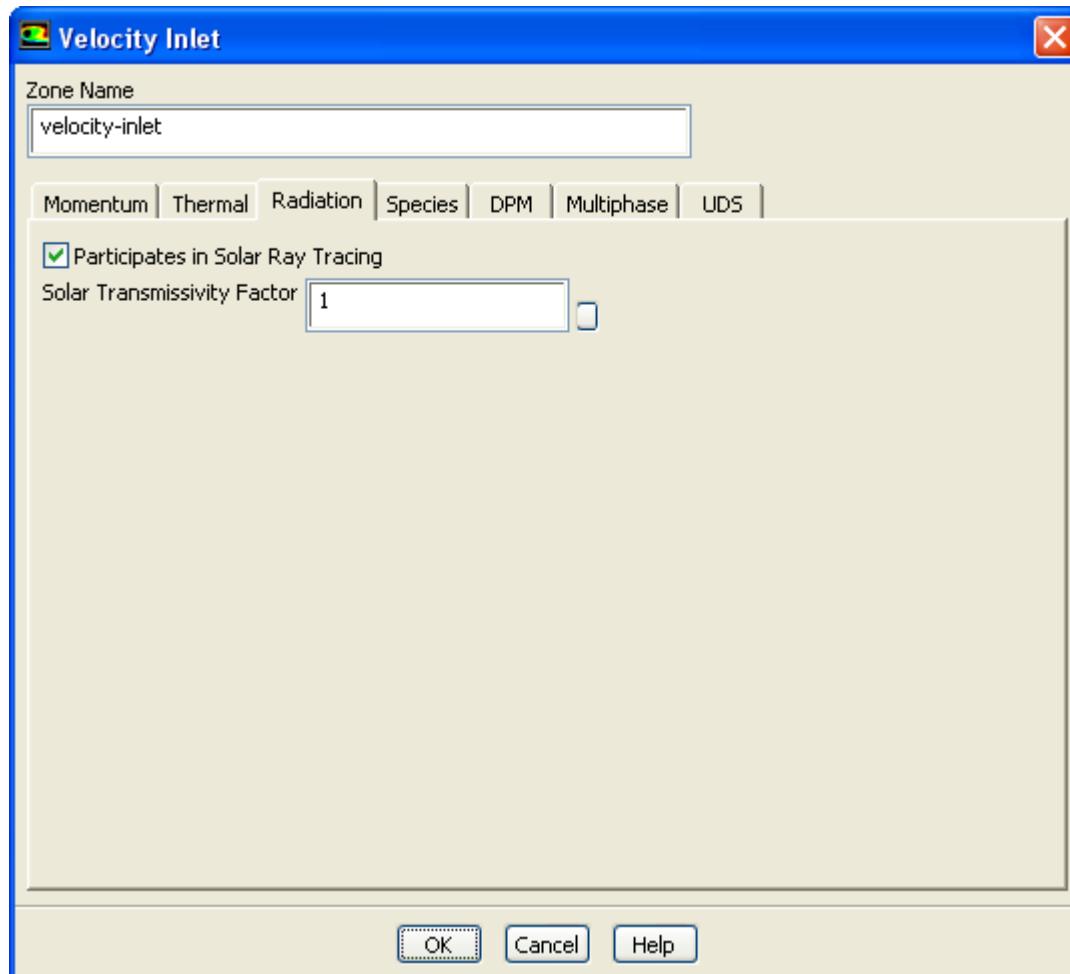

Once you have defined the solar parameters for the solar load model ([Setting Up the Solar Load Model \(p. 797\)](#)), you will need to set up boundary conditions for boundary zones that will participate in solar loading.

Boundary Conditions

14.3.10.5.4. Solar Ray Tracing

1. Set the boundary condition for each inlet and exit boundary zone that you want to include in solar loading.
 - a. Open the inlet or exit boundary condition dialog box (e.g., **Velocity Inlet**) and click the **Radiation** tab (*Figure 14.30 (p. 803)*).

Figure 14.30 The Velocity Inlet Dialog Box

- b. Enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default). If you deactivate solar ray tracing by disabling this option the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.
- c. Enter a value between 0 and 1 for the **Solar Transmissivity Factor**. This will allow you to control the amount of solar irradiation entering the domain. By reducing the solar transmissivity factor from 1 to 0.5, you can effectively cut the total internal energy source entering the domain by half.

Important

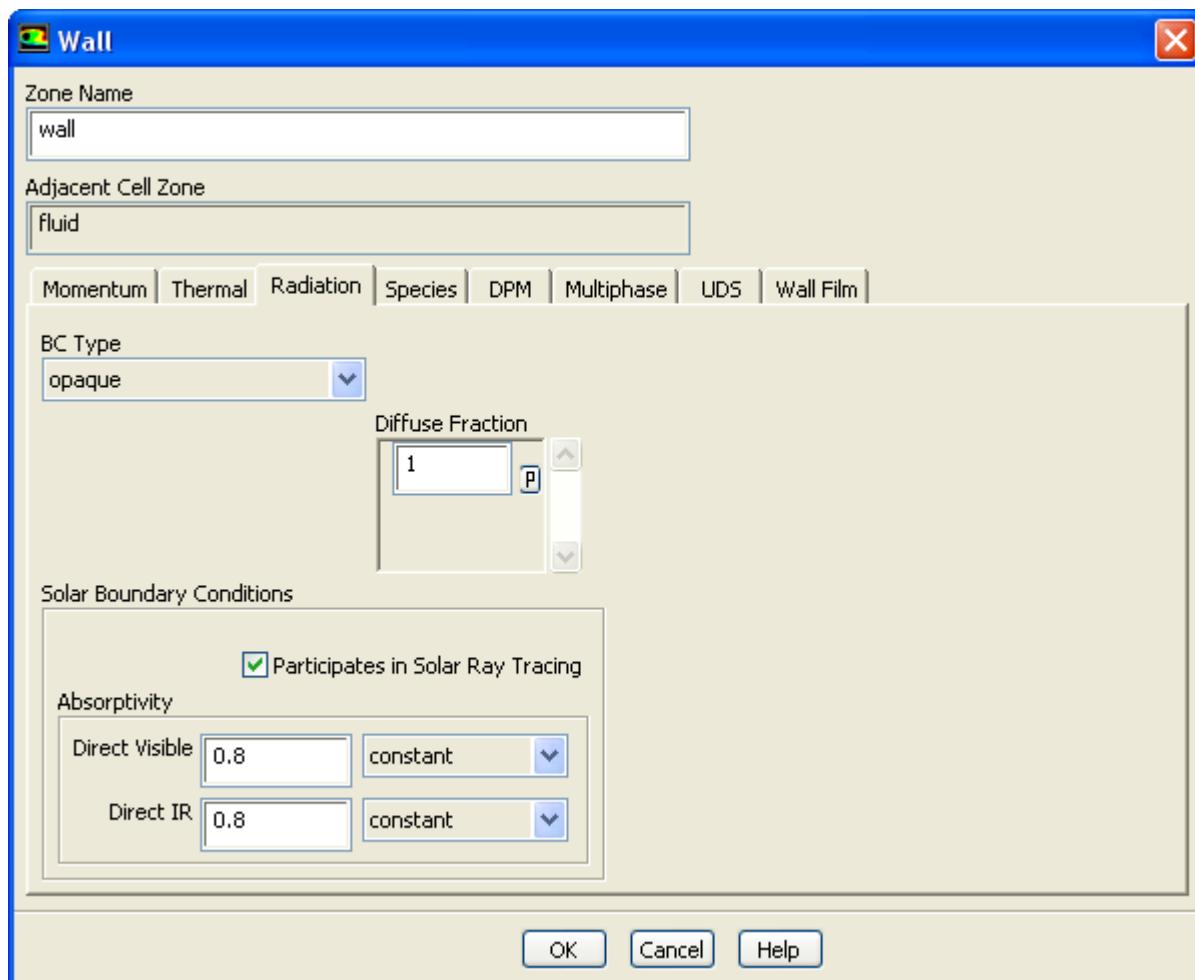

Note that the solar transmissivity factor is applied to both direct and diffuse solar irradiation components.

- d. Click **OK**.
2. Set the boundary condition for each wall boundary zone that you want to include in solar loading.
- Open a **Wall** boundary condition dialog box and click the **Radiation** tab.
 - Define the wall as **opaque** or **semi-transparent**. An opaque wall will not allow any solar radiation to pass through it, while a semi-transparent surface will allow a portion of the solar radiation to pass through it.)
 - For an opaque wall, select **opaque** from the drop-down list for **BC Type** ([Figure 14.31 \(p. 804\)](#)). Then enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the **Solar Boundary Conditions** group box and enter constant values for **Direct Visible** and **Direct IR** absorptivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

Important

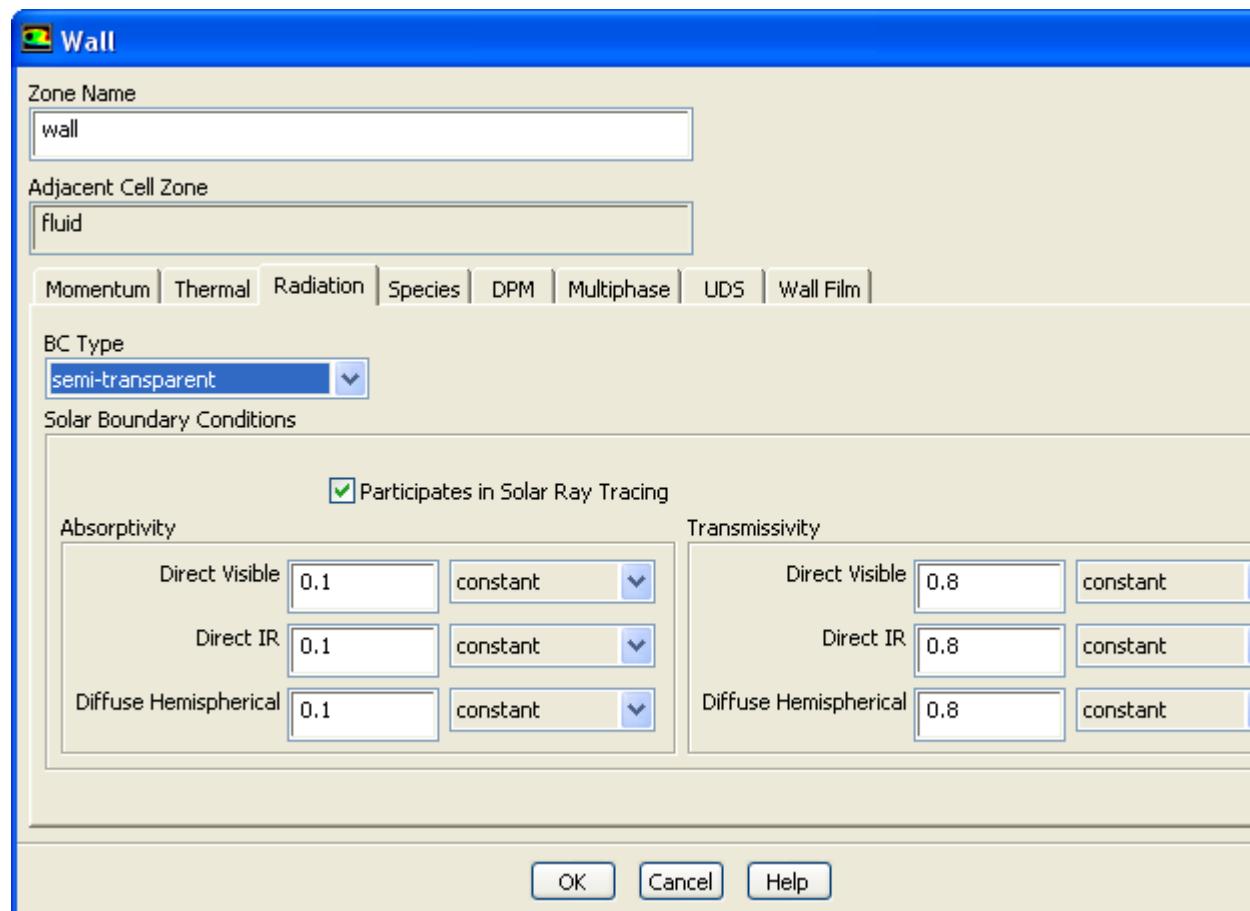

Absorption in the visible and infrared portions of the spectrum define the surface material for the opaque wall.

Figure 14.31 The Wall Dialog Box

- ii. For a semi-transparent wall, select **semi-transparent** from the drop-down list for **BC Type** (Figure 14.32 (p. 805)). Then, enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the **Solar Boundary Conditions** group box and enter constant values for **Direct Visible**, **Direct IR**, and **Diffuse Hemispherical** absorptivity and transmissivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

Figure 14.32 The Wall Dialog Box

Absorption and transmittance in the visible and infrared portions of the spectrum, as well as the "shading" formulation (**Diffuse Hemispherical**), define the surface material for a semi-transparent wall. These parameters are properties of the glazed unit and should be provided by the glazing manufacturer. The direct components are based on normal incident radiation (ANSYS FLUENT adjusts this for the actual angle of incidence). Most manufacturers present this information in a slightly different way so it may be necessary to seek guidance from the supplier. Another useful source of data can be found in the ASHRAE Fundamentals Handbook, chapter on Fenestration.

- iii. Click **OK**.

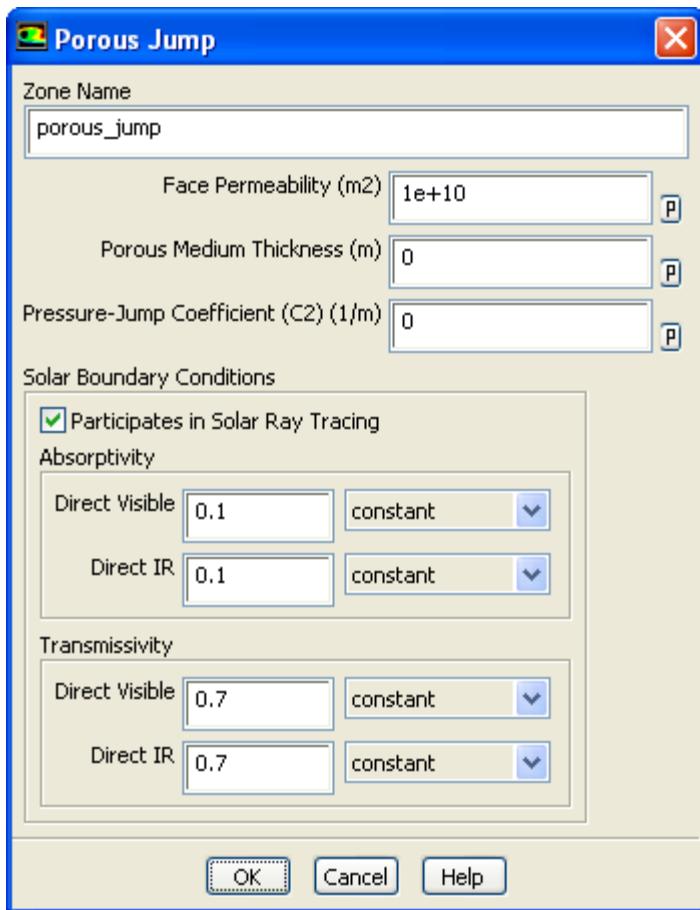

Important

ANSYS FLUENT will calculate the reflectivity as the difference between one and the sum of absorptivity and transmissivity:

$$\text{reflectivity} = 1 - (\text{absorptivity} + \text{transmissivity}) \quad (14-20)$$

3. Set the boundary condition for each porous jump boundary zone that you want to include in solar loading. You can define the boundary such that it acts as a semi-transparent surface that will allow a portion of the solar radiation to pass through it, along with fluid flow. In this way you can represent a partial opening (e.g., a grate, a grill, or a louver) that is a combination of gaps and (typically) opaque surfaces.
 - a. Open the **Porous Jump** boundary condition dialog box ([Figure 14.33 \(p. 806\)](#)).

Figure 14.33 The Porous Jump Dialog Box

- b. Define the **Face Permeability**, **Porous Medium Thickness**, and **Pressure-Jump Coefficient**, as described in [User Inputs for the Porous Jump Model \(p. 353\)](#).
- c. Define the settings in the **Solar Boundary Conditions** group box.
 - i. Enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default). Note that if you deactivate solar ray tracing by disabling the **Particip-**

- ates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.
- ii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Absorptivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the absorption of the porous jump.

Important

One reasonable way to estimate the **Direct Visible** and **Direct IR** absorptivity values for a grill, etc., is to use the product of the obstructed area fraction and the surface absorptivity. For example, if 40% of the grill facial area is obstructed with grill slats, and the slats have a surface absorptivity of 0.7, you could estimate the absorptivity as being 0.28.

- iii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Transmissivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the transmissivity of the porous jump.

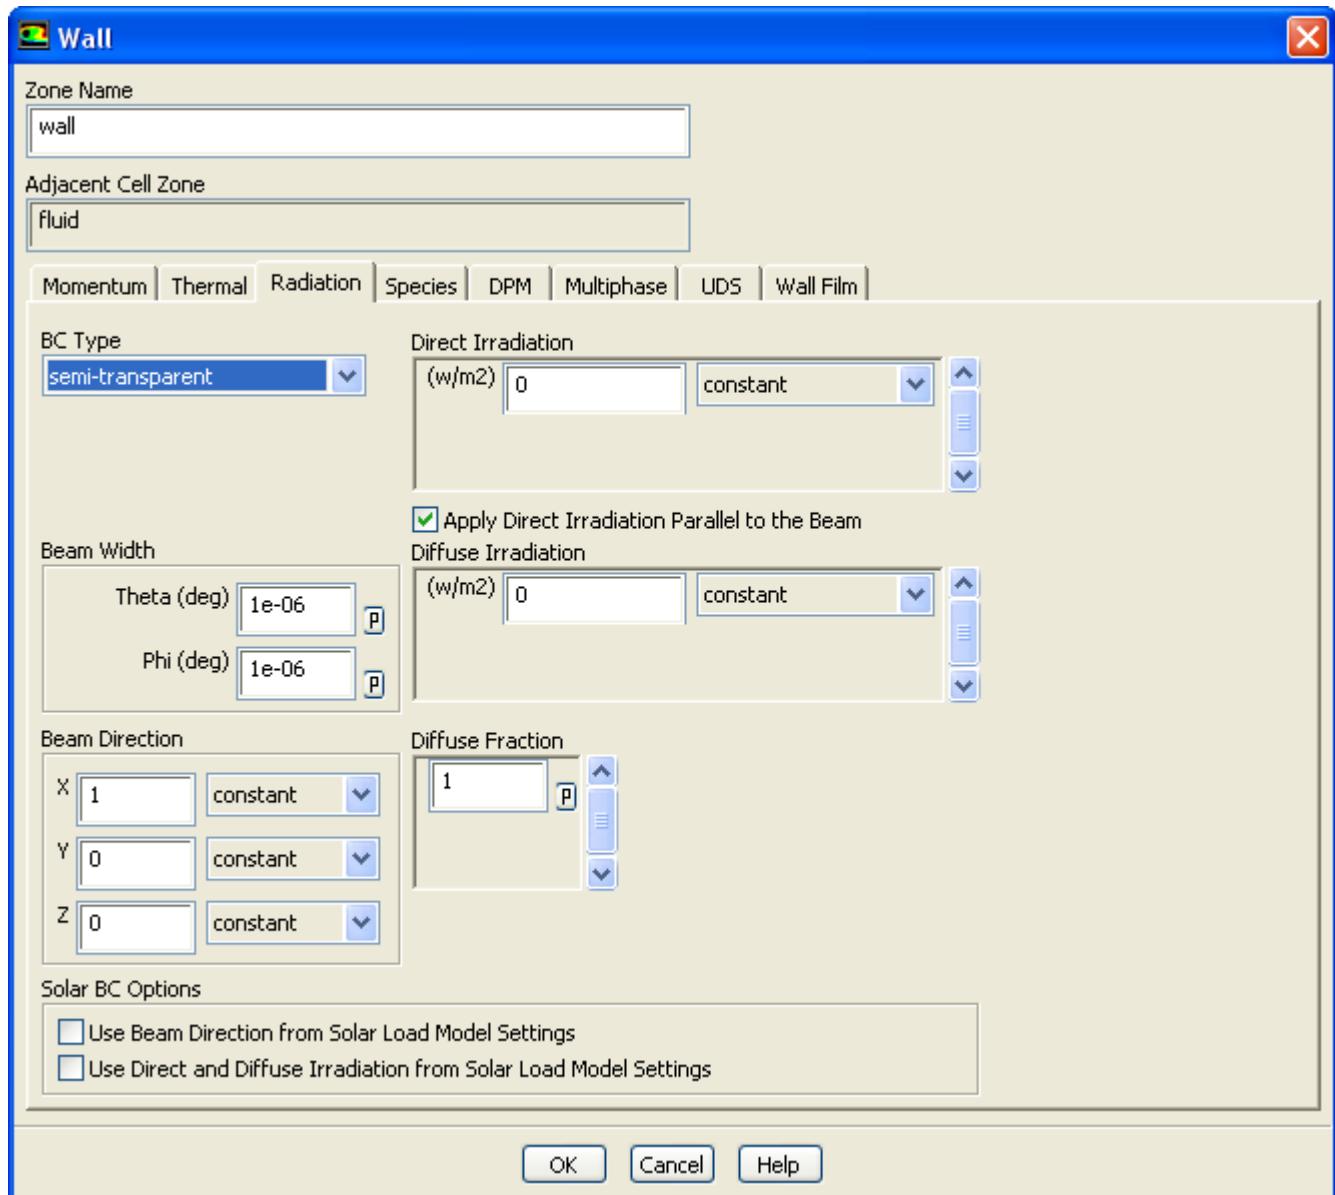

Important

One reasonable way to estimate the **Direct Visible** and **Direct IR** transmissivity values for a grill, etc., is to use the open area fraction. For example, if a grill has openings between the slats that amount to 60% of the area, you could estimate the transmissivity as being 0.6.

- d. Click **OK**.

14.3.10.5.5. DO Irradiation

1. For DO irradiation, all boundary conditions are set up as normal for the DO model, except that now you can select semi-transparent boundary surfaces which will provide a source of solar irradiation.
 - a. Open a **Wall** boundary condition dialog box and click the **Radiation** tab (*Figure 14.34 (p. 808)*).

Figure 14.34 The Wall Dialog Box

- Select **semi-transparent** from the drop-down list for **BC Type**.
- Enable the **Use Beam Direction from Solar Load Model Settings** option, under **Solar BC Options**, to have the values for beam direction applied from the **Solar Load Model** settings in the **Radiation** dialog box.

Important

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (e.g., radiation coming from the sun), while the sun direction vector in the solar load model points to the sun. Incident radiation and sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.

- d. Enable the **Use Direct and Diffuse Irradiation from Solar Load Model Settings** option to have the solar calculator output be applied for direct and diffuse irradiation.
- When **Use Direct and Diffuse Irradiation from Solar Load Model Settings** is enabled, the beam width will automatically be set to 0.53 degrees - the angle subtended by the sun.
- e. Click **OK**.

14.3.10.5.6. Text Interface-Only Commands

ANSYS FLUENT has provided some additional commands for solar load setup that are only available in the text interface. These commands are present in the following sections.

14.3.10.5.6.1. Automatically Saving Solar Ray Tracing Data

It is possible to direct ANSYS FLUENT to automatically save solar load data to a generic file that you can examine or use in an external program. This is done by executing the text command `autosave-solar-data` from the text interface.

```
define → models → radiation → solar-parameters → autosave-solar-data
```

1. Enter the **Solar Data File Frequency** (default= 0).
2. Enter the filename, in quotations.
3. Choose to write file in binary format.

The text interface command for `autosave-solar-data` for a file named `solar` and a frequency of 1 is shown below:

```
/define/models/radiation/solar-parameters> autosave-solar-data
  Autosave Solar Data File Frequency [0] 1
  Enter Filename ["] "solar"
```

14.3.10.5.6.2. Automatically Reading Solar Data

When you are executing a transient simulation in parallel ANSYS FLUENT and you want to take solar loading conditions into consideration, you can use the `autoread-solar-data` text command to automatically read the solar load data file you generated during a serial run into parallel ANSYS FLUENT. This is done by executing the text command `autoread-solar-data` from the text interface.

```
define → models → radiation → solar-parameters → autoread-solar-data
```

1. Enter the **Solar Data File Frequency** (default= 0).
2. Enter the filename, in quotations.

The text interface command for `autoread-solar-data` for a file named `solar` and a frequency of 1 is shown below:

```
/define/models/radiation/solar-parameters> autoread-solar-data
  Autoread Solar Data File Frequency [0] 1
  Enter Filename ["] "solar"
  Use Binary Format for Reading Data Files [yes]
```

14.3.10.5.6.3. Aligning the Camera Direction With the Position of the Sun

When the solar load model is enabled, you can direct ANSYS FLUENT to align the camera direction with the sun position using the text interface command:

```
define → models → radiation → solar-parameters → sol-camera-pos
```

This command is useful when you are executing a transient simulation and you want to capture an image of your model with solar load parameters displayed (such as solar heat flux) as the sun position changes with time in order to create an animation. See *Postprocessing Solar Load Quantities* (p. 811) for details.

14.3.10.5.6.4. Specifying the Scattering Fraction

You can modify the default scattering fraction (l) using the text interface command:

```
define → models → radiation → solar-parameters → scattering-fraction
```

The scattering fraction is the amount of direct radiation that has been reflected from opaque surfaces (after entering through the transparent surfaces) that will be considered to remain within the space and be evenly distributed among all surfaces. The value is between 0 and 1.

The text interface command for specifying a scattering-fraction of 0.5 is shown below:

```
/define/models/radiation/solar-parameters> scattering-fraction  
Scattering Fraction [1] .5
```

14.3.10.5.6.5. Applying the Solar Load on Adjacent Fluid Cells

You can direct ANSYS FLUENT to apply the solar load that is computed from the solar ray tracing algorithm to adjacent fluid cells by issuing the following command at the text interface:

```
define → models → radiation → solar-parameters → sol-adjacent-fluidcells
```

The text interface command is shown below:

```
/define/models/radiation/solar-parameters> sol-adjacent-fluidcells  
Apply Solar Load on adjacent Fluid Cells? [no] y
```

This command allows you to apply solar loads to adjacent fluid cells only, even if solid or shell conduction zones are present. By applying the solar load on adjacent fluid cells, you are overruling the default order of the adjacent cell assignment in ANSYS FLUENT which is shell, solid, fluid.

14.3.10.5.6.6. Specifying Quad Tree Refinement Factor

You can modify the default value (7) for the maximum quad tree refinement factor in the solar ray tracing algorithm using the text command:

```
define → models → radiation → solar-parameters → quad-tree-parameters
```

The text interface command is shown below, when a new maximum refinement value of 10 is specified:

```
/define/models/radiation/solar-parameters> quad-tree-parameters  
Maximum Quad-Tree Refinement [7] 10
```

14.3.10.5.6.7. Specifying Ground Reflectivity

You can modify the default value (0.2) for the ground reflectivity using the text command:

```
define → models → radiation → solar-parameters → ground-reflectivity
```

Ground reflectivity ρ_g ([Equation 14–18 \(p. 796\)](#)) includes the contribution of reflected solar radiation from ground surfaces. It is treated as part of the total diffuse solar irradiation when the solar calculator is used in conjunction with the Diffuse Solar Irradiation illumination parameter. The default value is 0.2.

```
/define/models/radiation/solar-parameters> ground-reflectivity
Ground Reflectivity [0.2] 0.5
```

14.3.10.5.6.8. Additional Text Interface Commands

Some solar load commands that are available in the graphical user interface are also made available in the text interface. For example, you can turn the solar load model on using the text command:

```
define → models → radiation → solar?
```

You can also enter the solar calculator parameters in the text interface by executing the command:

```
define → models → radiation → solar-calculator
```

Once invoked, you will be prompted to enter the solar calculator input parameters.

To set the illumination parameters, select this option from the `solar-parameters` menu:

```
define → models → radiation → solar-parameters → illumination-parameters
```

And finally, you can direct ANSYS FLUENT to compute the solar load on demand, by issuing the text command:

```
define → models → radiation → solar-parameters → sol-on-demand
```

When the command is initiated, the solar data are written to the console.

14.3.10.6. Postprocessing Solar Load Quantities

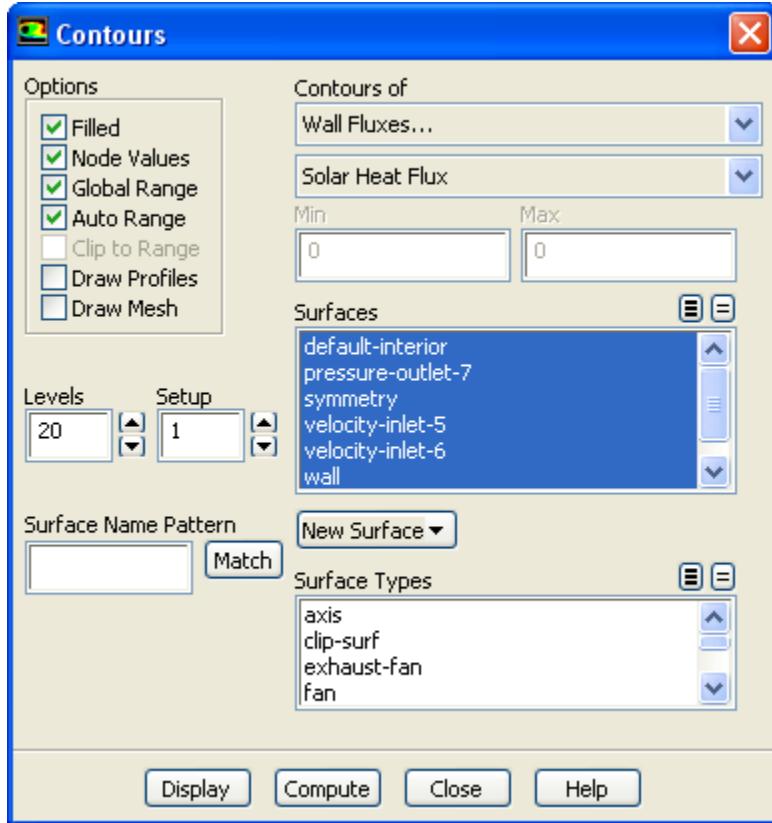

The following solar load quantities can be used to visualize the illuminated areas and shadows created by solar radiation.

- solar heat flux (i.e., sum of visible and IR absorbed solar flux on opaque walls)
- absorbed visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- reflected visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- transmitted visible and IR solar flux (semi-transparent walls and porous jump boundaries only)

These quantities are available for postprocessing of solar loading at wall boundaries and can be displayed as contours of **Wall Fluxes** in the **Contours** dialog box. For steady-state simulations, the solar flux data is computed at solution initialization and is available for postprocessing. You can also compute the solar load at any time during your ANSYS FLUENT session, after you have set up the model and applied boundary conditions. To compute the solar load on demand, you can issue the `sol-on-demand` command in the text interface (see [Additional Text Interface Commands \(p. 811\)](#) for details).

Solar heat flux, for example, can be displayed for surfaces using the **Contours** dialog box. A sample dialog box is shown below ([Figure 14.35 \(p. 812\)](#)).

◆ **Graphics and Animations** →  **Contours** → **Set Up...**

Figure 14.35 The Contours Dialog Box

14.3.10.6.1. Solar Load Animation at Different Sun Positions

The solar camera alignment command is useful when you want to take timed pictures of solar loading effects of your model during transient simulations, and later create animations of the image files using an external program. Follow the procedure below.

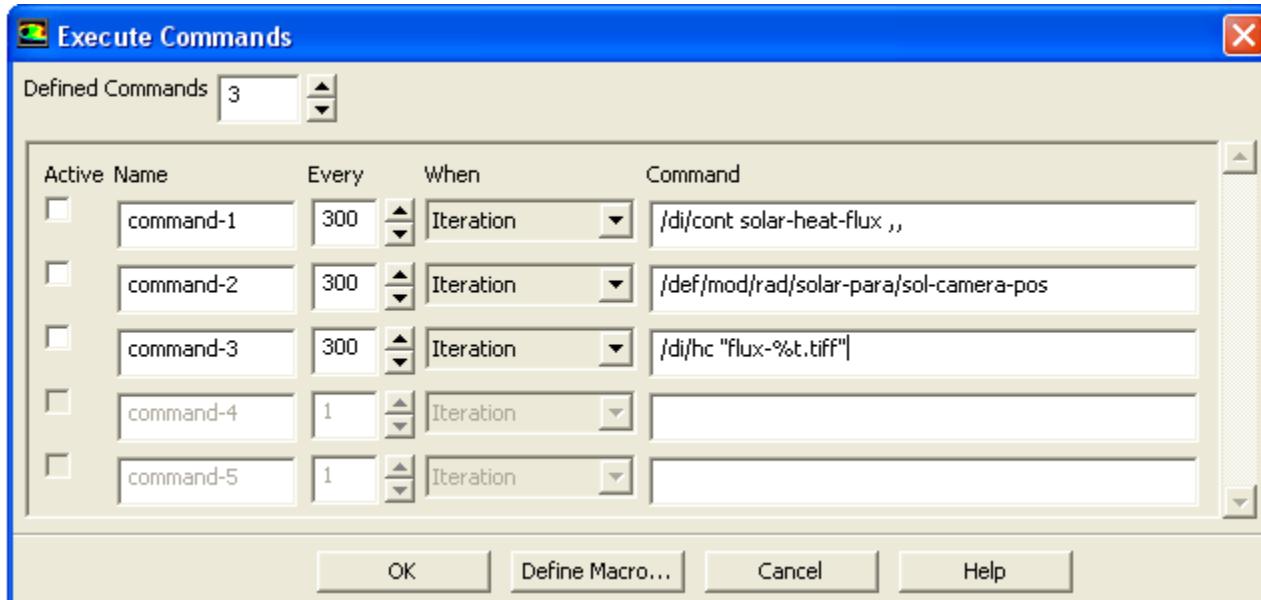

1. Read (or set up) your transient case file in ANSYS FLUENT.
2. Set up the automatic execution of solution commands in the **Execute Commands** dialog box that will: 1) display solar load parameter graphics, 2) re-position the solar camera such that the view is aligned with the instantaneous sun direction, and 3) generate a picture image file (.tiff) during the solution process in the **Execute Commands** dialog box.

Calculation Activities (Execute Commands) → Create/Edit...

3. Initialize and run the solution.
4. Animate the .tiff files using an external animation tool.

The following commands entered in the **Execute Commands** dialog box will direct ANSYS FLUENT to display contours of solar heat flux, align the camera with the current direction of the sun, and then generate a picture image file (.tiff) of the solar heat flux contour every 300 time steps during the unsteady simulation. See *Figure 14.36* (p. 813).

```
/di/cont solar-heat-flux ,,
/def/mod/rad/solar-para/sol-camera-pos
/di/hc "flux-%t.tiff"
```

Figure 14.36 The Execute Commands Dialog Box

14.3.10.6.2. Reporting and Displaying Solar Load Quantities

ANSYS FLUENT provides some additional solar load variables that you can use for postprocessing when your model includes solar ray tracing. You can generate graphical plots or alphanumeric reports of the following variables:

In the **Wall Fluxes...** category:

- **Solar Heat Flux**
- **Transmitted Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Transmitted IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed IR Solar Flux** (semi-transparent walls and porous jump boundaries)

See *Field Function Definitions* (p. 1653) for their definitions.

14.4. Modeling Periodic Heat Transfer

ANSYS FLUENT is able to predict heat transfer in periodically repeating geometries, such as compact heat exchangers, by including only a single periodic module for analysis.

This section discusses streamwise-periodic heat transfer. The treatment of streamwise-periodic flows is discussed in *Periodic Flows* (p. 514), and a description of no-pressure-drop periodic flow is provided in *Periodic Boundary Conditions* (p. 336).

Information about streamwise-periodic heat transfer is presented in the following sections:

[14.4.1. Overview and Limitations](#)

[14.4.2. Theory](#)

- 14.4.3. Using Periodic Heat Transfer
- 14.4.4. Solution Strategies for Periodic Heat Transfer
- 14.4.5. Monitoring Convergence
- 14.4.6. Postprocessing for Periodic Heat Transfer

14.4.1. Overview and Limitations

The following sections contain information about periodic heat transfer:

- 14.4.1.1. Overview
- 14.4.1.2. Constraints for Periodic Heat Transfer Predictions

14.4.1.1. Overview

As discussed in [Overview and Limitations \(p. 514\)](#), streamwise-periodic flow conditions exist when the flow pattern repeats over some length L , with a constant pressure drop across each repeating module along the streamwise direction.

Periodic thermal conditions may be established when the thermal boundary conditions are of the constant wall temperature or wall heat flux type. In such problems, the temperature field (when scaled in an appropriate manner) is periodically fully-developed [\[62\] \(p. 2370\)](#). As for periodic flows, such problems can be analyzed by restricting the numerical model to a single module or periodic length.

14.4.1.2. Constraints for Periodic Heat Transfer Predictions

In addition to the constraints for streamwise-periodic flow discussed in [Limitations for Modeling Streamwise-Periodic Flow \(p. 515\)](#), the following constraints must be met when periodic heat transfer is to be considered:

- The pressure-based solver must be used.
- The thermal boundary conditions must be of the specified heat flux or constant wall temperature type. Furthermore, in a given problem, these thermal boundary types cannot be combined: all boundaries must be either constant temperature or specified heat flux. You can, however, include constant-temperature walls and zero-heat-flux walls in the same problem. For the constant-temperature case, all walls must be at the same temperature (profiles are not allowed) or zero heat flux. For the heat flux case, profiles and/or different values of heat flux may be specified at different walls.
- When constant-temperature wall boundaries are used, you cannot include viscous heating effects or any volumetric heat sources.
- In cases that involve solid regions, the regions cannot straddle the periodic plane.
- The thermodynamic and transport properties of the fluid (heat capacity, thermal conductivity, viscosity, and density) cannot be functions of temperature. (You cannot, therefore, model reacting flows.) Transport properties may, however, vary spatially in a periodic manner, and this allows you to model periodic turbulent flows in which the effective turbulent transport properties (effective conductivity, effective viscosity) vary with the (periodic) turbulence field.

[Theory \(p. 814\)](#) and [Using Periodic Heat Transfer \(p. 816\)](#) provide more detailed descriptions of the input requirements for periodic heat transfer.

14.4.2. Theory

Streamwise-periodic flow with heat transfer from constant-temperature walls is one of two classes of periodic heat transfer that can be modeled by ANSYS FLUENT. A periodic fully-developed temperature

field can also be obtained when heat flux conditions are specified. In such cases, the temperature change between periodic boundaries becomes constant and can be related to the net heat addition from the boundaries as described in this section.

Important

Periodic heat transfer can be modeled only if you are using the pressure-based solver.

14.4.2.1. Definition of the Periodic Temperature for Constant-Temperature Wall Conditions

For the case of constant wall temperature, as the fluid flows through the periodic domain, its temperature approaches that of the wall boundaries. However, the temperature can be scaled in such a way that it behaves in a periodic manner. A suitable scaling of the temperature for periodic flows with constant-temperature walls is [62] (p. 2370)

$$\theta = \frac{T(\vec{r}) - T_{wall}}{T_{bulk,inlet} - T_{wall}} \quad (14-21)$$

The bulk temperature, $T_{bulk,inlet}$, is defined by

$$T_{bulk,inlet} = \frac{\int_T |\rho \vec{v} \cdot d\vec{A}|}{\int_A |\rho \vec{v} \cdot d\vec{A}|} \quad (14-22)$$

where the integral is taken over the inlet periodic boundary (A). It is the scaled temperature, θ , which obeys a periodic condition across the domain of length L .

14.4.2.2. Definition of the Periodic Temperature Change σ for Specified Heat Flux Conditions

When periodic heat transfer with heat flux conditions is considered, the form of the unscaled temperature field becomes analogous to that of the pressure field in a periodic flow:

$$\frac{T(\vec{r} + \vec{L}) - T(\vec{r})}{L} = \frac{T(\vec{r} + 2\vec{L}) - T(\vec{r} + \vec{L})}{L} = \sigma. \quad (14-23)$$

where \vec{L} is the periodic length vector of the domain. This temperature gradient, σ , can be written in terms of the total heat addition within the domain, Q , as

$$\sigma = \frac{Q}{\dot{m}c_p L} = \frac{T_{bulk,exit} - T_{bulk,inlet}}{L} \quad (14-24)$$

where \dot{m} is the specified or calculated mass flow rate.

14.4.3. Using Periodic Heat Transfer

A typical calculation involving both streamwise-periodic flow and periodic heat transfer is performed in two parts. First, the periodic velocity field is calculated (to convergence) without consideration of the temperature field. Next, the velocity field is frozen and the resulting temperature field is calculated. These periodic flow calculations are accomplished using the following procedure:

1. Set up a mesh with translationally periodic boundary conditions.
2. Input constant thermodynamic and molecular transport properties.
3. Specify either the periodic pressure gradient or the net mass flow rate through the periodic boundaries.
4. Compute the periodic flow field, solving momentum, continuity, and (optionally) turbulence equations.
5. Specify the thermal boundary conditions at walls as either heat flux or constant temperature.
6. Define an inlet bulk temperature.
7. Solve the energy equation (only) to predict the periodic temperature field.

In order to model the periodic heat transfer, you will need to set up your periodic model in the manner described in [User Inputs for the Pressure-Based Solver \(p. 516\)](#) for periodic flow models with the pressure-based solver, noting the restrictions discussed in [Limitations for Modeling Streamwise-Periodic Flow \(p. 515\)](#) and [Constraints for Periodic Heat Transfer Predictions \(p. 814\)](#). In addition, you will need to provide the following inputs related to the heat transfer model:

1. Activate solution of the energy equation in the **Energy** dialog box.

2. Define the thermal boundary conditions according to one of the following procedures:

- If you are modeling periodic heat transfer with specified-temperature boundary conditions, set the wall temperature T_{wall} for all wall boundaries in their respective **Wall** dialog box. Note that all wall boundaries must be assigned the same temperature and that the entire domain (except the periodic boundaries) must be “enclosed” by this fixed-temperature condition, or by symmetry or adiabatic ($q=0$) boundaries.
 - If you are modeling periodic heat transfer with specified-heat-flux boundary conditions, set the wall heat flux in the **Wall** dialog box for each wall boundary. You can define different values of heat flux on different wall boundaries, but you should have no other types of thermal boundary conditions active in the domain.
3. Define solid regions, if appropriate, according to one of the following procedures:

- If you are modeling periodic heat transfer with specified-temperature conditions, conducting solid regions can be used within the domain, provided that on the perimeter of the domain they are enclosed by the fixed-temperature condition. Heat generation within the solid regions is not allowed when you are solving periodic heat transfer with fixed-temperature conditions.
- If you are modeling periodic heat transfer with specified-heat-flux conditions, you can define conducting solid regions at any location within the domain, including volumetric heat addition within the solid, if desired.

- Set constant material properties (density, heat capacity, viscosity, thermal conductivity), *not* temperature-dependent properties, using the **Create/Edit Materials** dialog box.

Materials

- Specify the **Upstream Bulk Temperature** in the **Periodic Conditions** dialog box.

Boundary Conditions → Periodic Conditions...

Important

If you are modeling periodic heat transfer with specified-temperature conditions, the bulk temperature should not be equal to the wall temperature, since this will give you the trivial solution of constant temperature everywhere.

- Set the solution parameters as described in *Solution Strategies for Periodic Heat Transfer* (p. 817).
- Run the solution and monitor the convergence as described in *Monitoring Convergence* (p. 818).
- Postprocess the results as described in *Postprocessing for Periodic Heat Transfer* (p. 818).

14.4.4. Solution Strategies for Periodic Heat Transfer

After completing the inputs described in *Using Periodic Heat Transfer* (p. 816), you can solve the flow and heat transfer problem to convergence. The most efficient approach to the solution, however, is a sequential one in which the periodic flow is first solved without heat transfer and then the heat transfer is solved leaving the flow field unaltered. This sequential approach is accomplished as follows:

- Disable solution of the energy equation in the **Equations** dialog box, accessed via the **Solution Controls** task page.

Solution Controls → Equations...

- Solve the remaining equations (continuity, momentum, and, optionally, turbulence parameters) to convergence to obtain the periodic flow field.

Important

When you initialize the flow field before beginning the calculation, use the mean value between the inlet bulk temperature and the wall temperature for the initialization of the temperature field.

- Return to the **Solution Controls** task page and turn off solution of the flow equations and turn on the energy solution.
- Solve the energy equation to convergence to obtain the periodic temperature field of interest.

While you can solve your periodic flow and heat transfer problems by considering both the flow and heat transfer simultaneously, you will find that the procedure outlined above is more efficient.

14.4.5. Monitoring Convergence

If you are modeling periodic heat transfer with specified-temperature conditions, you can monitor the value of the bulk temperature ratio

$$\theta = \frac{T_{wall} - T_{bulk,inlet}}{T_{wall} - T_{bulk,exit}} \quad (14-25)$$

during the calculation using the **Statistic Monitors** dialog box to ensure that you reach a converged solution. Select **per/bulk-temp-ratio** as the variable to be monitored. See *Monitoring Statistics* (p. 1389) for details about using this feature.

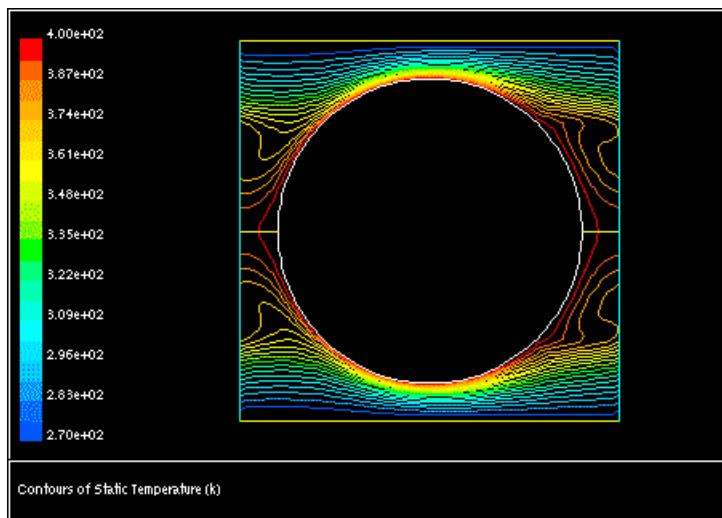

14.4.6. Postprocessing for Periodic Heat Transfer

The actual temperature field predicted by ANSYS FLUENT in periodic models will not be periodic, and viewing the temperature results during postprocessing will display this actual temperature field ($T(\vec{r})$) of *Equation 14-21* (p. 815). The displayed temperature may exhibit values outside the range defined by the inlet bulk temperature and the wall temperature. This is permissible since the actual temperature profile at the inlet periodic face will have temperatures that are higher or lower than the inlet bulk temperature.

Static Temperature is found in the **Temperature...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

Figure 14.37 (p. 818) shows the temperature field in a periodic heat exchanger geometry.

Figure 14.37 Temperature Field in a 2D Heat Exchanger Geometry With Fixed Temperature Boundary Conditions

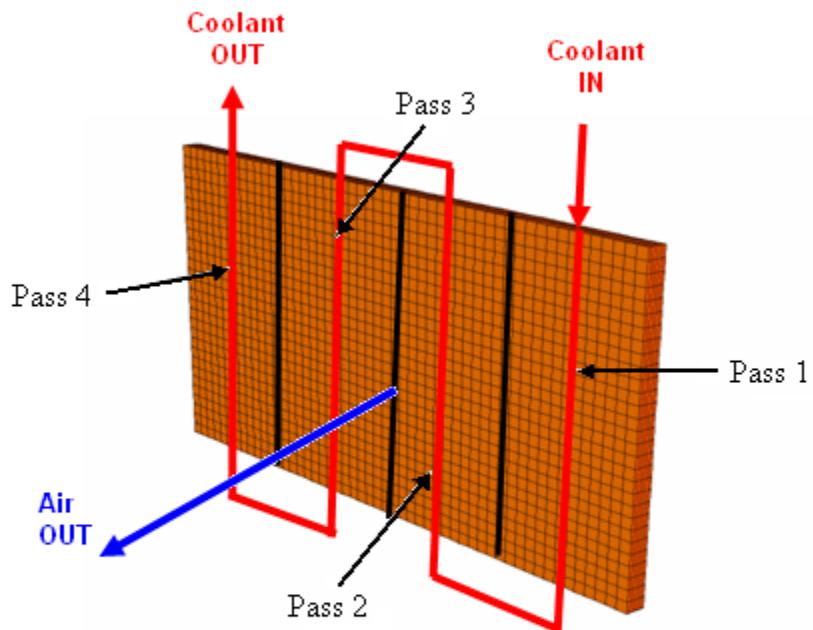

Chapter 15: Modeling Heat Exchangers

Many engineering systems, including power plants, climate control, and engine cooling systems typically contain tubular heat exchangers. However, for most engineering problems, it is impractical to model individual fins and tubes of a heat exchanger core. In principle, heat exchanger cores introduce a pressure drop to the primary fluid stream and transfer heat to a second fluid, a coolant, referred to here as the auxiliary fluid.

ANSYS FLUENT provides two distinct methods of modeling a heat exchanger: the dual cell model and the macro model. These models can be used to compute the auxiliary fluid inlet temperature for a fixed heat rejection or the total heat rejection for a fixed auxiliary fluid inlet temperature. The dual cell model allows the solution of the passes of the auxiliary flow on a separate mesh, i.e., other than the primary fluid mesh (see [Figure 15.1 \(p. 819\)](#)), unlike the macro model, where the auxiliary flow passes are modeled as 1-D flow.

Figure 15.1 An Example of a Four-Pass Heat Exchanger

Important

Note that the heat exchanger models are not appropriate for modeling a cold-only flow; in such a case, you should instead use the porous media model, as described in [Porous Media Conditions \(p. 229\)](#).

For theoretical information about the various heat exchanger models, please refer to "Heat Exchangers" in the [Theory Guide](#).

The following sections contain information about the heat exchanger models:

- [15.1. Choosing a Heat Exchanger Model](#)
- [15.2. The Dual Cell Model](#)
- [15.3. The Macro Heat Exchanger Models](#)
- [15.4. Postprocessing for the Heat Exchanger Model](#)
- [15.5. Useful Reporting TUI Commands](#)

15.1. Choosing a Heat Exchanger Model

ANSYS FLUENT provides various options for modeling heat exchangers, each with their own features and limitations. The following instructions can help you determine which option/combination of options is the most appropriate for your problem.

1. Decide whether you want to use the dual cell model or the macro model.
 - a. The dual cell model provides the greatest flexibility with regard to the shape of the heat exchanger core and the nature of the mesh, and allows the auxiliary fluid to be highly non-uniform as it enters the core (e.g., due to passing through arbitrary shaped inlet tanks). However, the dual cell model may need to be discounted as an option because of the following limitations:
 - If the heat exchanger performance data that you have is in the form of a velocity vs. effectiveness curve, the dual cell model cannot be used.
 - The dual cell model does not allow you to model phase change in the auxiliary fluid.If the previous limitations are not relevant for your problem, you can proceed directly to using the dual cell model, as described in [Using the Dual Cell Heat Exchanger Model \(p. 822\)](#).
 - b. While the macro model has more restrictions than the dual cell model, it is quite suitable for thin rectangular heat exchanger cores, where the pass-to-pass is perpendicular to the primary flow direction, the auxiliary flow is uniform, and the mesh is uniform and structured. To verify that your problem can tolerate the limitations of the macro model, see [Restrictions \(p. 830\)](#).
2. If you chose to use the macro model in the previous step, you must decide whether you want to use the grouped or ungrouped version of this model. If you want to define a single heat exchanger using multiple fluid zones, or if you would like to connect the fluid flow path among multiple heat exchangers, you should use the grouped version, as described in [Using the Grouped Macro Heat Exchanger Model \(p. 841\)](#). Otherwise, you can use the ungrouped version, as described in [Using the Ungrouped Macro Heat Exchanger Model \(p. 831\)](#).
3. If you chose to use the macro model in the step 1., you must decide whether you want to model the heat transfer using the number-of-transfer-units (NTU) method or the simple effectiveness method. This decision largely rests on the kind of experimental data that you have: the NTU method requires that you provide the various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values; the simple effectiveness method requires that you provide the data points for a curve that defines how the effectiveness (i.e., the ratio of actual rate of heat transfer from the hot to cold fluid to the maximum possible rate of heat transfer) varies with the fluid velocity. Additionally,

you should consider the differences between the two heat transfer models outlined in *Table 15.1: NTU Model Vs. Simple Effectiveness Model* (p. 821).

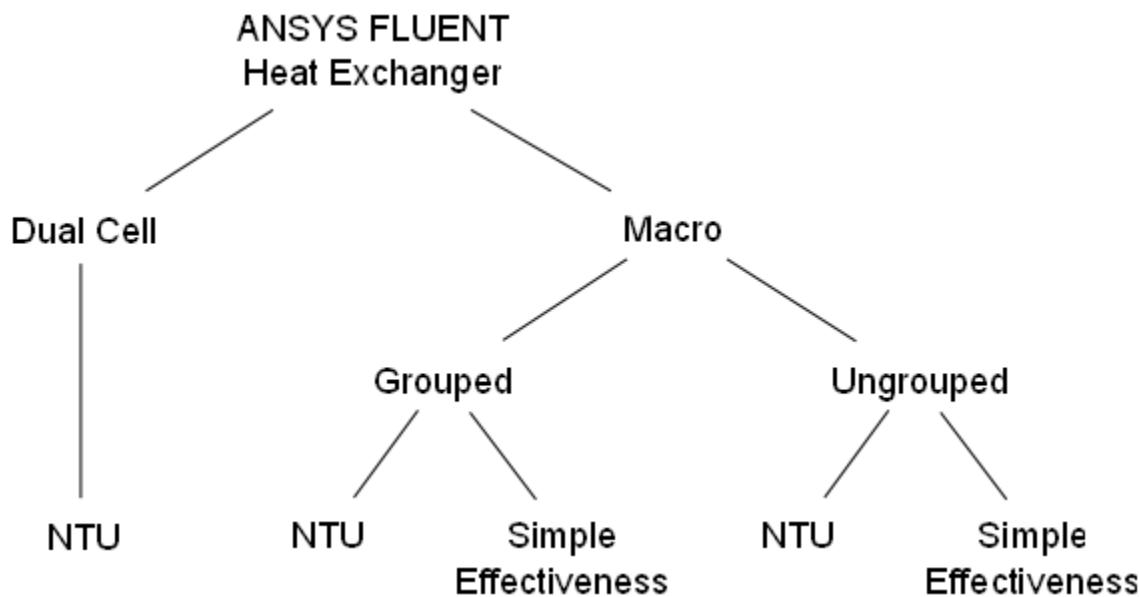

Table 15.1 NTU Model Vs. Simple Effectiveness Model

	NTU Model	Simple Effectiveness Model
How many phases are allowed in the auxiliary flow?	single phase only	single phase and two phase
What is the direction of heat transfer?	To and from the auxiliary fluid	From the auxiliary fluid only
Can you model primary fluid-side reverse flow?	Yes	No
Can the primary fluid have a variable density?	Yes	No
Must the primary fluid capacity be less than the auxiliary fluid capacity?	No	Yes

You will specify whether you want the NTU or simple effectiveness model in the **Model Data** tab of either the **Ungrouped Macro Heat Exchanger** dialog box or the **Heat Exchanger Group** dialog box, depending on whether you opted for the ungrouped or grouped version of the macro model, respectively.

An overview of the options available to you when modeling heat exchangers is shown in *Figure 15.2* (p. 821).

Figure 15.2 Heat Exchanger Modeling Options

15.2. The Dual Cell Model

The dual cell heat exchanger model allows the solution of both the primary and auxiliary flow on separate co-located meshes and couples the two flows only through heat transfer at the heat exchanger core.

For theoretical information about this model, refer to [The Dual Cell Model](#) in the Theory Guide.

15.2.1. Restrictions

The following restrictions exist for the dual cell heat exchanger models:

- Heat transfer calculations are based on the NTU method only, as the simple effectiveness method is not available. See step 3. in [Choosing a Heat Exchanger Model \(p. 820\)](#) for details about the differences between these two models.
- In the case of a heat exchanger in which the primary and auxiliary meshes are not identical, heat transfer may be non-conservative (i.e., the heat lost by the hot fluid may not equal the heat gained by the cold fluid). To minimize the difference in heat transfer, the topology and size of the primary and auxiliary cells should be similar. Note that you can make the meshes identical by copying a zone via the mesh/modify-zones/copy-move-cell-zone text command.

15.2.2. Using the Dual Cell Heat Exchanger Model

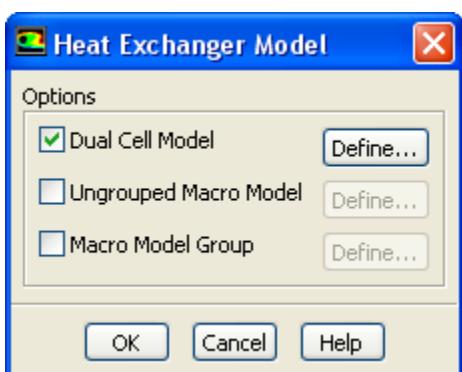

The steps for setting up the dual cell heat exchanger model is as follows:

1. Read the mesh file.
 - a. If the mesh file does not already contain overlapping heat exchanger cores for primary and auxiliary fluids, then you must create a duplicate of the zone that represents the core using the following text command:
`mesh → modify-zones → copy-move-cell-zone`
 See [Copying Cell Zones \(p. 202\)](#) for details on copying meshes.
 - b. Make sure that the auxiliary fluid mesh is divided into separate zones, one for each pass.
Mesh → Separate → Cells...
 See [Separating Cell Zones \(p. 191\)](#) for details on separating meshes.

2. Enable the calculation of energy in the **Energy** dialog box.
Models → Energy → Edit...
3. Enable the **Dual Cell Model** in the **Heat Exchanger Model** dialog box and click **Define...** ([Figure 15.3 \(p. 822\)](#)).

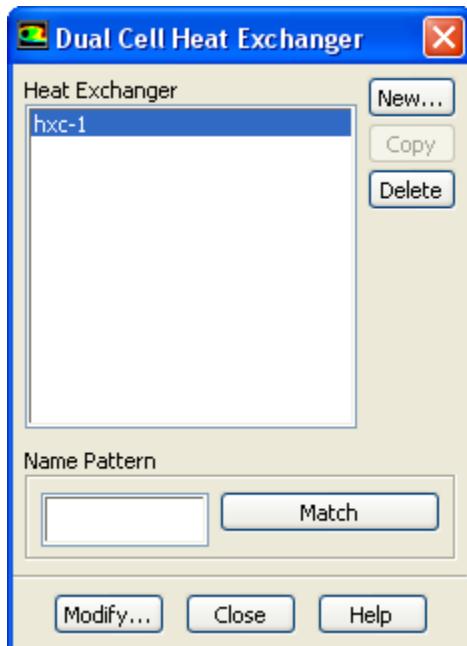

Models → Heat Exchanger → Edit...

Figure 15.3 The Heat Exchanger Model Dialog Box

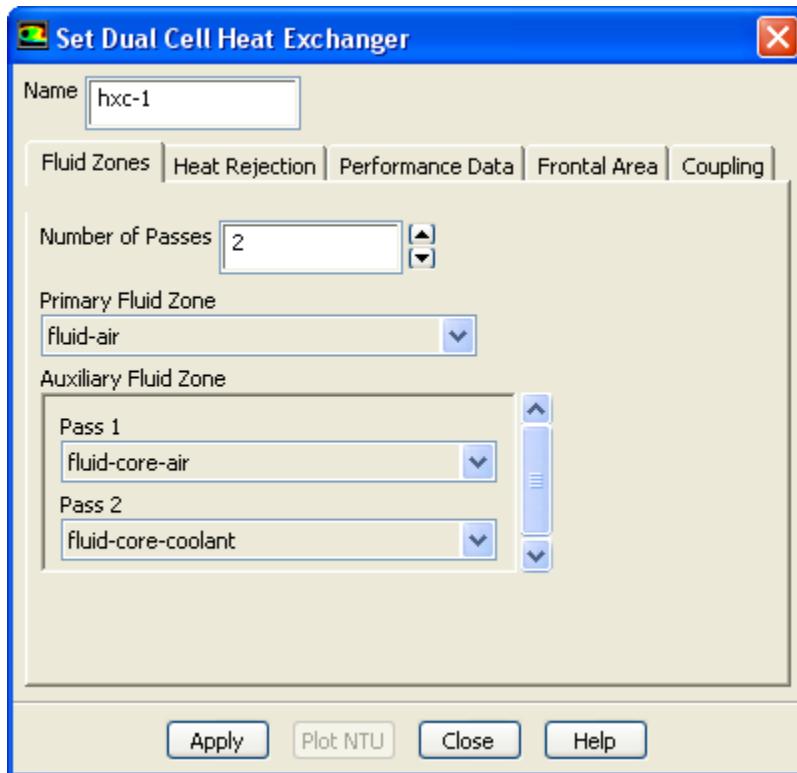

4. Specify the inputs to the dual cell heat exchanger model, using the **Dual Cell Heat Exchanger** dialog box ([Figure 15.4 \(p. 823\)](#)).

Figure 15.4 The Dual Cell Heat Exchanger Dialog Box

5. Click **New...** to define the heat exchanger. The **Set Dual Cell Heat Exchanger** dialog box will appear ([Figure 15.5 \(p. 823\)](#)), where you will define the heat exchanger parameters.

Figure 15.5 The Set Dual Cell Heat Exchanger Dialog Box

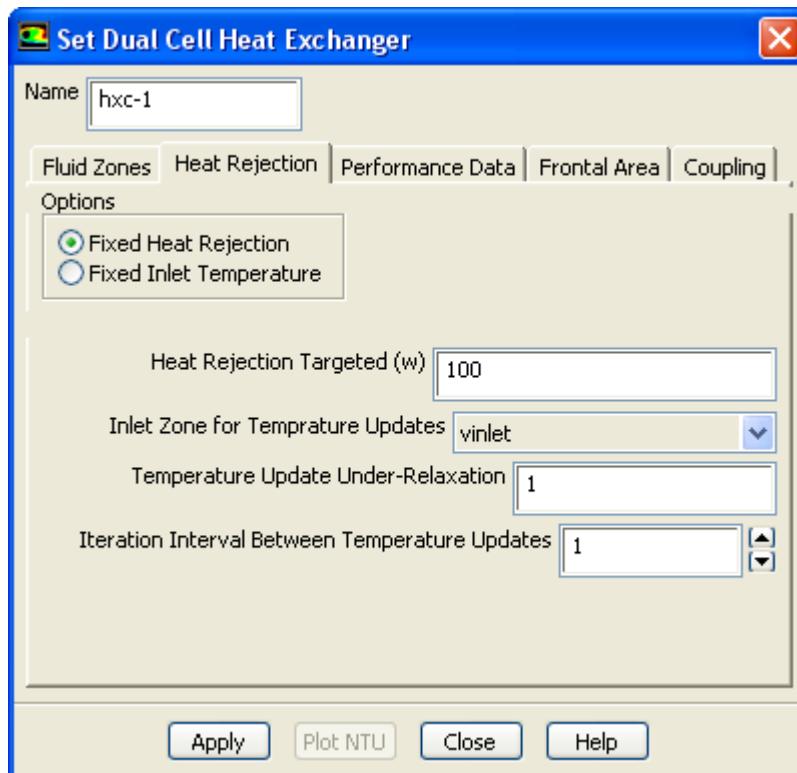

- a. Enter the heat exchanger **Name** or keep the default name. The suffix -1 is incremented automatically on defining more than one heat exchanger.
- b. In the **Fluid Zones** tab (*Figure 15.5 (p. 823)*)
 - i. Specify the **Number of Passes** of your heat exchanger.
 - ii. Select the appropriate **Primary** and **Auxiliary Fluid Zone**, representing the heat exchanger core.

Important

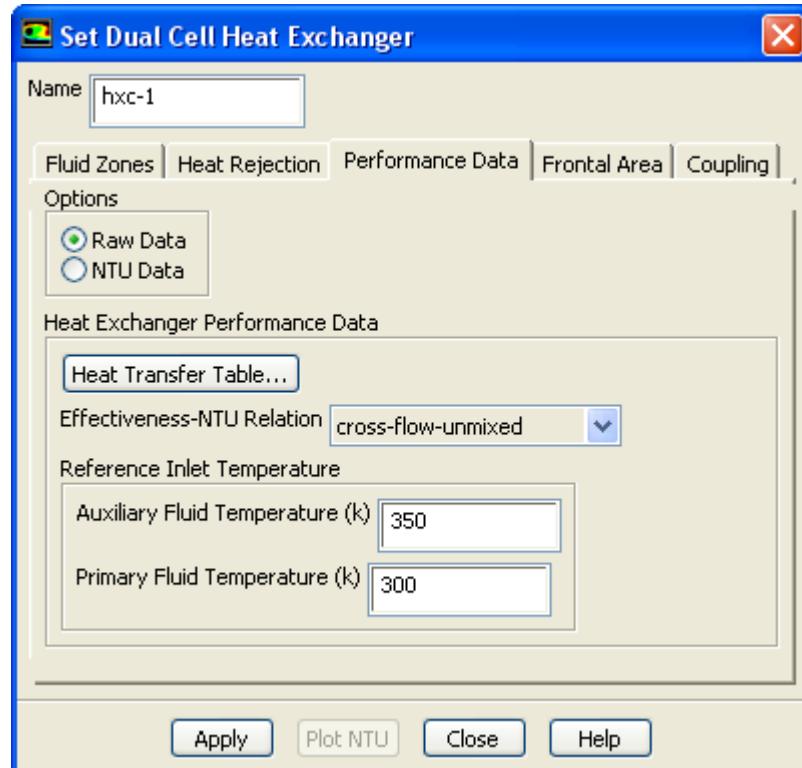

The selected zones must be overlapping in physical space.

- c. Click the **Heat Rejection** tab (*Figure 15.6 (p. 824)*).

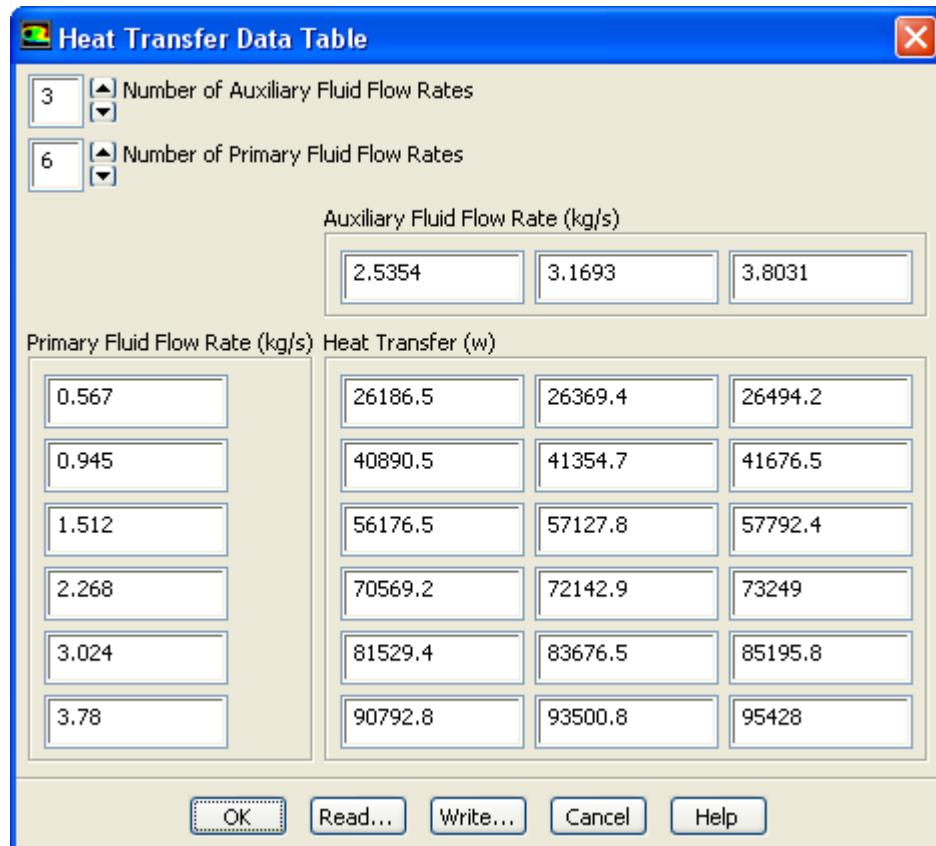

Figure 15.6 The Heat Rejection Tab

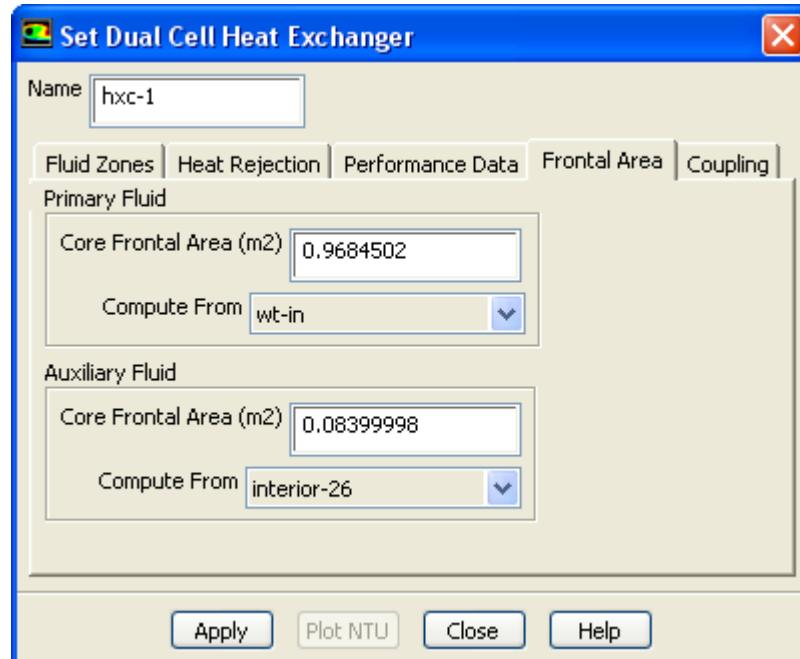

- i. If you select **Fixed Heat Rejection**, set the inputs for the following:
 - **Heat Rejection Targeted** which is the heat rejection desired from the heat exchanger.
 - **Inlet Zone for Temperature Updates** allows ANSYS FLUENT to change the temperature of the specified inlet zone in order to match the targeted heat rejection.
 - **Temperature Update Under-Relaxation** is a factor which controls convergence.
 - **Iteration Interval Between Temperature Updates** is used to control divergence.
- ii. Select **Fixed Inlet Temperature** if the output desired is total heat rejection.
- d. Click the **Performance Data** tab (*Figure 15.7 (p. 825)*).

Figure 15.7 The Performance Data Tab

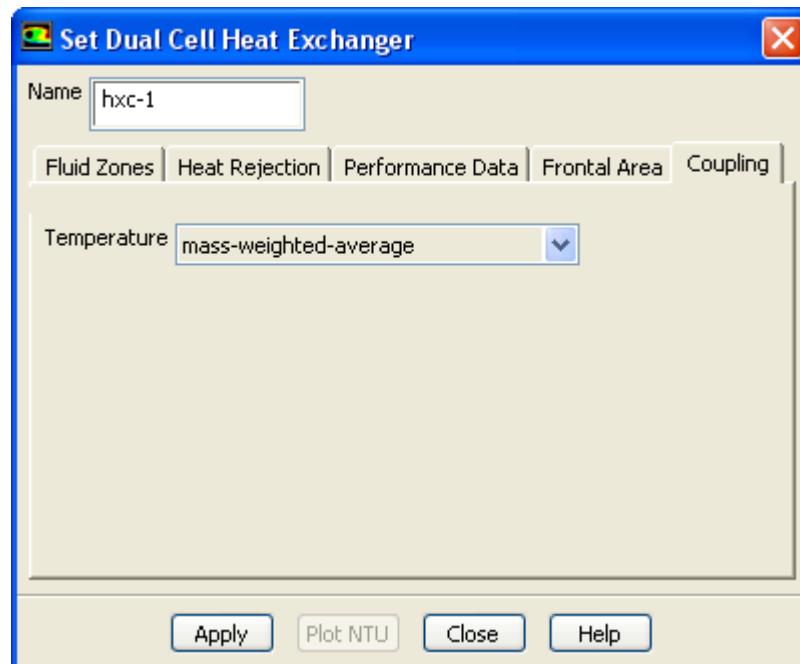

- i. If you select the **Raw Data** option, then specify the following:
 - **Heat Transfer Data...** opens the *Heat Transfer Data Table Dialog Box* (p. 1803), where you will input experimental data that defines how heat transfer values relate to the fluid flow rates (*Figure 15.8* (p. 826)). See *Specifying Heat Exchanger Performance Data* (p. 836) more details.

Figure 15.8 The Heat Transfer Data Table Dialog Box

- **Effectiveness-NTU Relation** computes the NTU values from the heat transfer data. Choose **cross-flow-unmixed**, **parallel-flow**, or **counter-flow**, all of which are described in [NTU Relations](#).
 - **Auxiliary Fluid Temperature** is the inlet reference temperature for the auxiliary fluid.
 - **Primary Fluid Temperature** is the inlet reference temperature for the primary fluid.
- ii. If you select the **NTU Data** option, click **NTU Table...** to access the **NTU Table** dialog box. Populate this table in the same manner as described previously for the [Heat Transfer Data Table Dialog Box \(p. 1803\)](#). More information is available in [Specifying Heat Exchanger Performance Data \(p. 836\)](#).
- e. Click the **Frontal Area** tab. You have the option to input the **Primary** and **Auxiliary Fluid Core Frontal Area** directly, or compute the area from a surface zone, as shown in [Figure 15.9 \(p. 827\)](#).

Figure 15.9 The Frontal Area Tab

- f. Click the **Coupling** tab if you want to couple the heat exchanger passes (Figure 15.10 (p. 827)).

Figure 15.10 The Coupling Tab

Consider the following example illustrating the coupling of a four-pass heat exchanger.

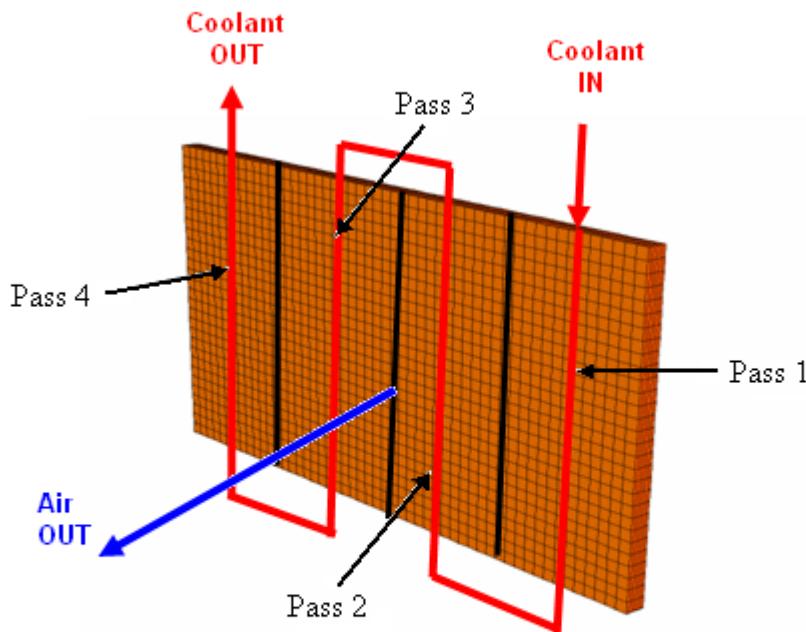

Figure 15.11 An Example of a Four-Pass Heat Exchanger

Figure 15.11 (p. 828) shows a four-pass heat exchanger with air as the primary fluid and the coolant as the auxiliary fluid. The coolant flows through the tubes in a serpentine manner and air flows normal to the tubes, forming a cross flow pattern. To model this type of flow using the dual cell heat exchanger model, you must first generate the mesh. The mesh should contain the following:

- i. A single primary cell zone.
- ii. Four adjacent auxiliary cell zones, one for each pass. Each auxiliary zone should be separated from the other by a coupled or uncoupled wall. Each pass will have its own inlet and outlet zones.
- iii. The primary and four auxiliary zones should overlap in physical space.

In the **Coupling** tab, **mass-weighted-average** is selected by default for the **Temperature** of the outlet of Pass 1 to the inlet of Pass 2. Similarly, the mass-weighted-average temperature of the outlet of Pass 2 will be applied at the inlet zone of Pass 3, and so on. Alternatively, you can couple the passes by using **Profiles...** in the **Boundary Conditions** task page. If you do so, make sure you select **none** from the **Temperature** drop-down list in the **Coupling** tab.

Important

Make sure to specify the auxiliary zones in the correct order (i.e. the zone for Pass 1 should be selected first, then Pass 2, and so on) in the **Fluid Zones** tab of the **Set Dual Cell Heat Exchanger** dialog box.

- g. Click **Apply** to save the heat exchanger inputs.
6. To view the plot of NTU vs. primary mass flow rate for each auxiliary mass flow rate, click **Plot NTU**.

The **Plot NTU** button will plot the performance data curve for the selected heat exchanger. The performance data is supplied through the **Performance Data** tab.

When you close the **Set Dual Cell Heat Exchanger** dialog box, you will return to the **Dual Cell Heat Exchanger** dialog box, where you should now see the heat exchanger name in the **Heat Exchanger** list.

You can

- Modify the settings of heat exchanger by selecting it from the list and clicking **Modify....**
 - Copy the data of one heat exchanger to another using the **Copy** button, assuming you have more than one heat exchanger.
 - Delete any unwanted heat exchangers by selecting the heat exchanger from the list and clicking **Delete**.
-

Important

All the inputs are copied except for the name, primary fluid zone and auxiliary fluid zone.

15.3. The Macro Heat Exchanger Models

To use the macro heat exchanger model, you must define one or more fluid zone(s) to represent the heat exchanger core. Typically, the fluid zone is sized to the dimension of the core itself. As part of the setup procedure, you will define the auxiliary fluid path, the number of macros, and the physical properties and operating conditions of the core (pressure drop parameters, heat exchanger effectiveness, auxiliary fluid flow rate, etc.).

Additional information about macro heat exchangers can be found in [Overview of the Macro Heat Exchanger Models](#) in the [Theory Guide](#). For the theory behind these models, refer to [Macro Heat Exchanger Model Theory](#) in the [Theory Guide](#).

ANSYS FLUENT provides two heat transfer models: the default NTU model and the simple effectiveness model. The simple effectiveness model interpolates the effectiveness from the velocity vs. effectiveness curve that you provide. For the NTU model, ANSYS FLUENT calculates the effectiveness, ε , from the NTU value that is calculated by ANSYS FLUENT from the heat transfer data provided by the user in tabular format. ANSYS FLUENT will automatically convert this heat transfer data to a primary fluid mass flow rate vs. NTU curve (this curve will be piecewise linear). This curve will be used by ANSYS FLUENT to calculate the NTU for macros based on their size and primary fluid flow rate.

The NTU model provides the following features:

- The model can be used to check heat capacity for both the primary and the auxiliary fluid and takes the lesser of the two for the calculation of heat transfer.
- The model can be used to model heat transfer to the primary fluid from the auxiliary fluid and vice versa.
- The model can be used to model primary fluid-side reverse flow.
- The model can be used with variable density of the primary fluid.
- The model can be used in either the serial or parallel ANSYS FLUENT solvers.
- The model can be used to make a network of heat exchangers using a heat exchanger group (*Using the Grouped Macro Heat Exchanger Model* (p. 841)).
- Transient profiles can be used for the coolant inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

The simple effectiveness model provides the following features:

- The model can be used to model heat transfer from the auxiliary fluid to the fluid.
- The auxiliary fluid properties can be a function of pressure and temperature, thus allowing phase change of the auxiliary fluid.
- The model can be used by serial as well as parallel solvers.
- The model can be used to make a network of heat exchangers using a heat exchanger group (*Using the Grouped Macro Heat Exchanger Model* (p. 841)).
- Transient profiles can be used for the coolant inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

For additional information, please see the following sections:

15.3.1. Restrictions

15.3.2. Using the Ungrouped Macro Heat Exchanger Model

15.3.3. Using the Grouped Macro Heat Exchanger Model

15.3.1. Restrictions

The following restrictions exist for the macro heat exchanger models:

- The core must be approximately rectangular in shape.
- The primary fluid streamwise direction (see [Equation 6–1](#) in the [Theory Guide](#)) must be aligned with one of the three orthogonal axes defined by the rectangular core.
- It is highly recommended that the free-form **Tet** mesh is not used in the macro heat exchanger model. Instead, evenly distributed **Hex/Wedge** cells should be used for improved accuracy and a more robust solution process.
- Flow acceleration effects are neglected in calculating the pressure loss coefficient.
- For the simple effectiveness model, the primary fluid capacity rate must be less than the auxiliary fluid capacity rate.
- Auxiliary fluid phase change cannot be modeled using the NTU model.
- The macro-based method requires that an equal number of cells reside in each macro of equal size and shape.
- Coolant flow is assumed to be 1-D.

- The pass width has to be uniform.
- Accuracy is not guaranteed when the mesh is not structured or layered.
- Accuracy is not guaranteed when there is upstream diffusion of temperature at the inlet/outlet of the core.
- Non-conformal meshes cannot be attached to the inlet/outlet of the core. An extra layer has to be created to avoid it.

15.3.2. Using the Ungrouped Macro Heat Exchanger Model

The heat exchanger model settings may be written into and read from the boundary conditions file ([Reading and Writing Boundary Conditions \(p. 74\)](#)) using the text commands, `file/write-settings` and `file/read-settings`, respectively. Otherwise, the steps for setting up the ungrouped macro heat exchanger model is as follows:

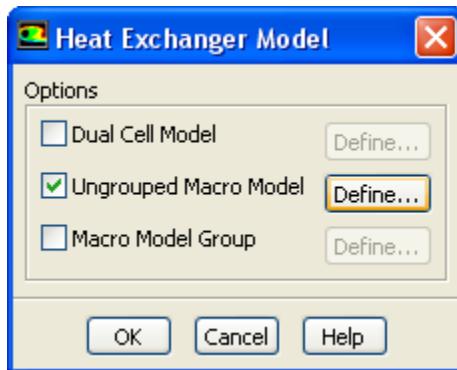

1. Enable the calculation of energy in the [Energy Dialog Box \(p. 1778\)](#).

◆ **Models** → ◆ **Energy** → **Edit...**

2. Enable the **Ungrouped Macro Model** option and click the **Define...** button in the [Heat Exchanger Model Dialog Box \(p. 1799\)](#) ([Figure 15.12 \(p. 831\)](#)) to access the **Ungrouped Macro Heat Exchanger** dialog box.

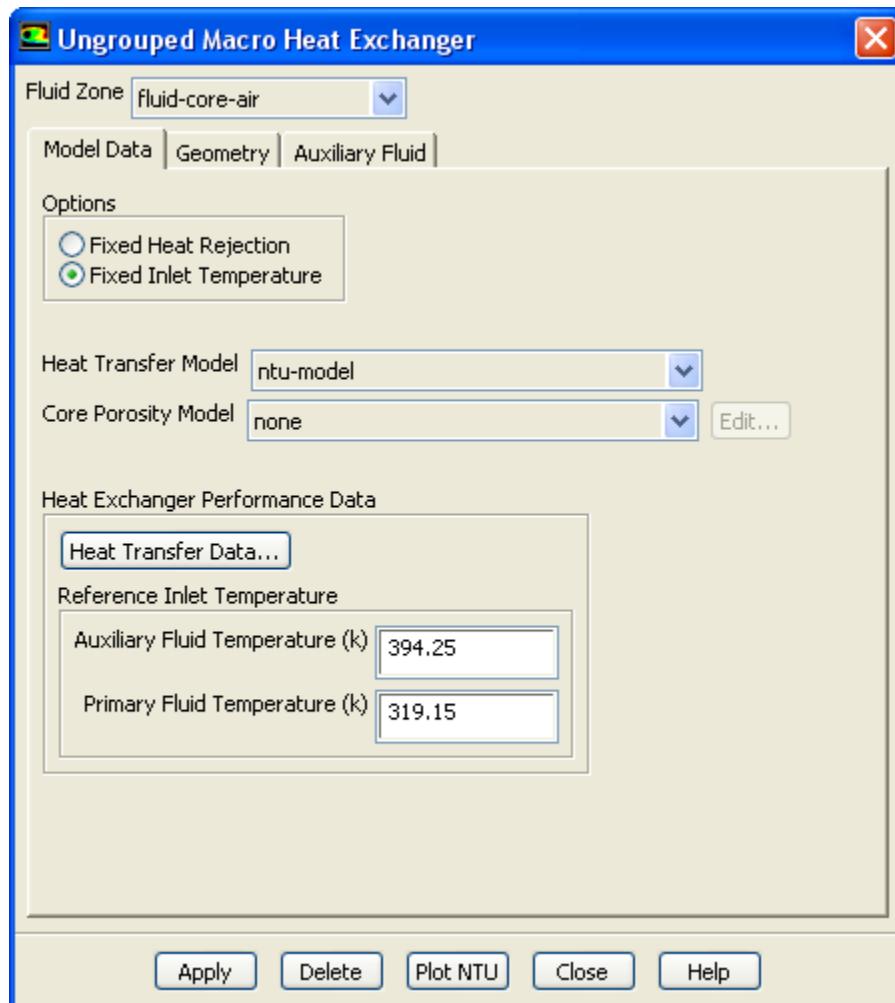

◆ **Models** → ◆ **Heat Exchanger** → **Edit...**

Figure 15.12 The Heat Exchanger Model Dialog Box

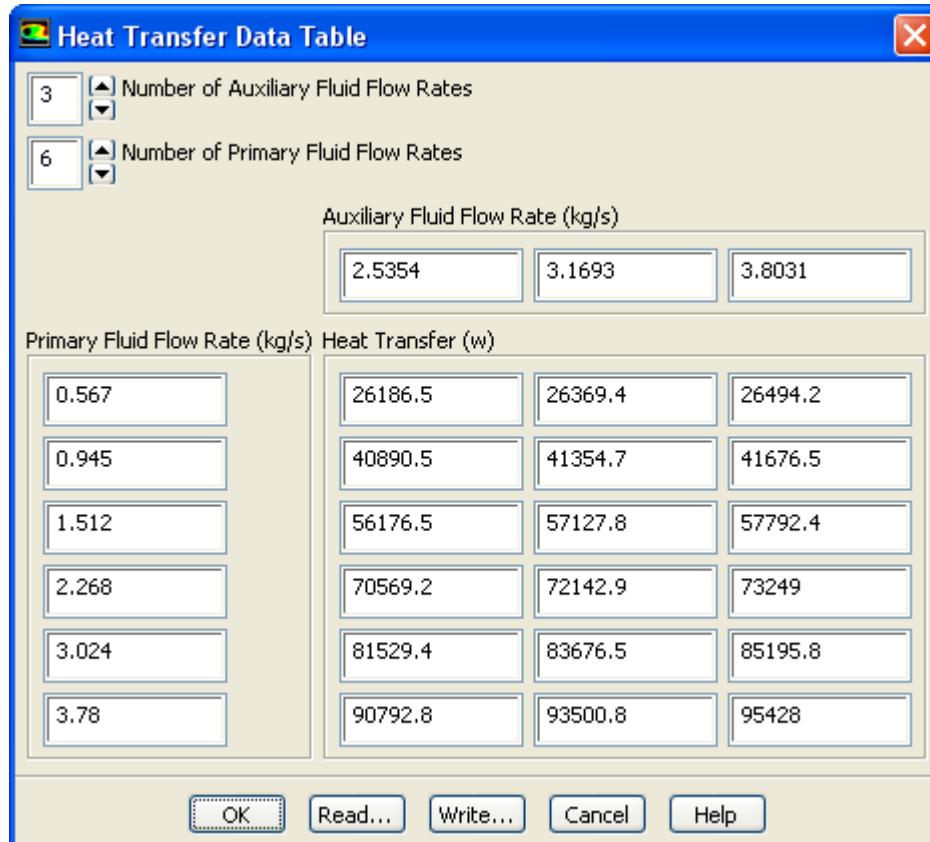

3. Specify the heat exchanger inputs in the **Ungrouped Macro Heat Exchanger** dialog box.

Figure 15.13 The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab

- In the **Fluid Zone** drop-down list, select the fluid zone representing the heat exchanger core.
- Under the **Model Data** tab, choose **Fixed Heat Rejection** or **Fixed Inlet Temperature**, as required (Figure 15.13 (p. 832)).
- Specify the **Heat Transfer Model** as either the default **ntu-model** or the **simple-effectiveness-model**. See step 3. in *Choosing a Heat Exchanger Model* (p. 820) for details about the differences between these two models.
- Specify the **Core Porosity Model** if you want ANSYS FLUENT to use the pressure loss coefficient function to automatically compute (and update) the porous media coefficients in the cell zones condition dialog box, as described in *Streamwise Pressure Drop* in the *Theory Guide*. More information is available in *Setting the Pressure-Drop Parameters and Effectiveness* (p. 839).
- If the **ntu-model** is chosen, a **Heat Transfer Data...** button will appear under **Heat Exchanger Performance Data**. Clicking the **Heat Transfer Data...** button will open the *Heat Transfer Data Table Dialog Box* (p. 1803), where you will input experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 15.8 (p. 826)). See *Specifying Heat Exchanger Performance Data* (p. 836) more details.

Figure 15.14 The Heat Transfer Data Table Dialog Box for the NTU Model

- f. Enter the **Auxiliary Fluid Temperature** and the **Primary Fluid Temperature** for the **ntu-model**. These are the fixed inlet temperatures at which the test was performed to obtain the heat transfer data.
- g. If the **simple-effectiveness-model** is chosen, then clicking the **Velocity Effectiveness Curve...** button, under the **Heat Exchanger Performance Data**, allows you to set the velocity and corresponding effectiveness for each point. More information is available in *Specifying Heat Exchanger Performance Data (p. 836)*.
- h. In the **Geometry** tab, define the macro mesh using the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass** fields. The **Number of Rows/Pass** is along the auxiliary flow direction (height) and the **Number of Columns/Pass** is defined in the pass-to-pass (width) direction. Also, enter the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction**. You may want to snap the plane tool to either the inlet or outlet of the heat exchanger using the **Update from Plane Tool**. Note that the plane tool must be attached exactly and oriented so that its green arrow points in the auxiliary flow direction, and its blue arrow points in the pass-to-pass direction.

Important

To attach the plane tool exactly, exact coordinates (printed in the console by probing) of the three corner nodes must be entered in the plane tool (x_0, x_1, x_2) in a specific order. Also, note that x_0 to x_1 is the auxiliary flow direction and x_1 to x_2 is the pass-to-pass direction.

More information is available in [Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions \(p. 837\)](#) and [Defining the Macros \(p. 837\)](#).

Figure 15.15 The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Geometry Tab

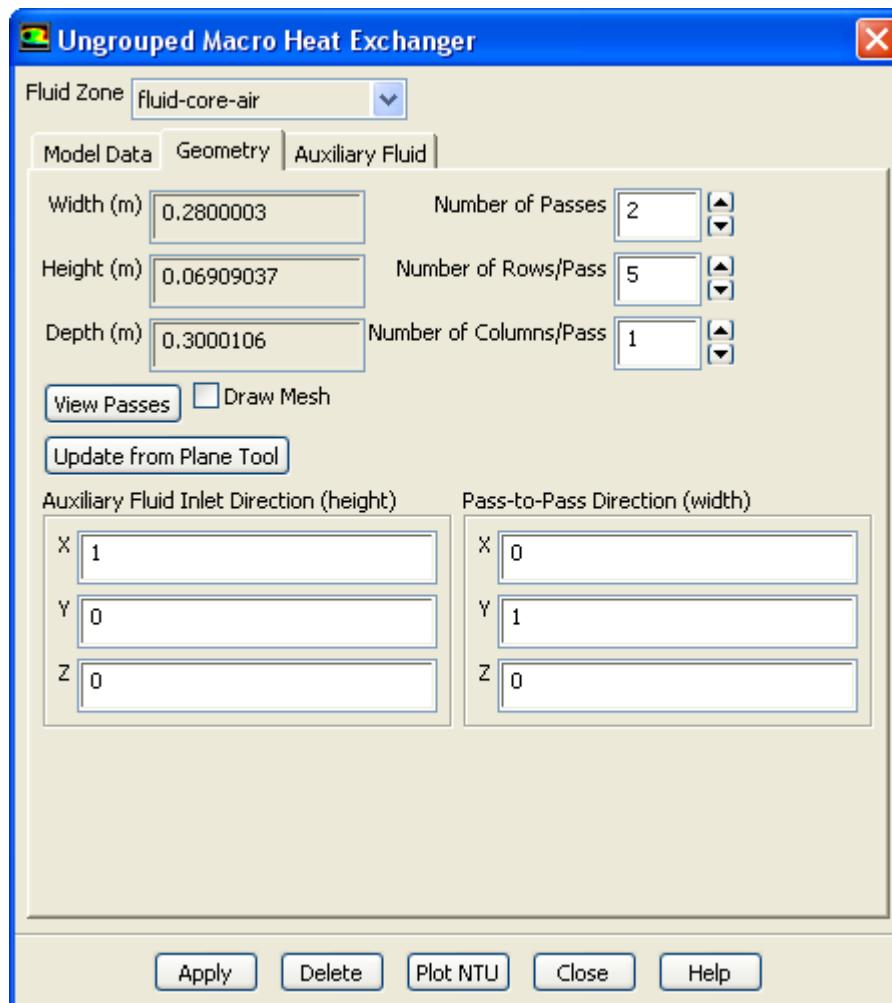

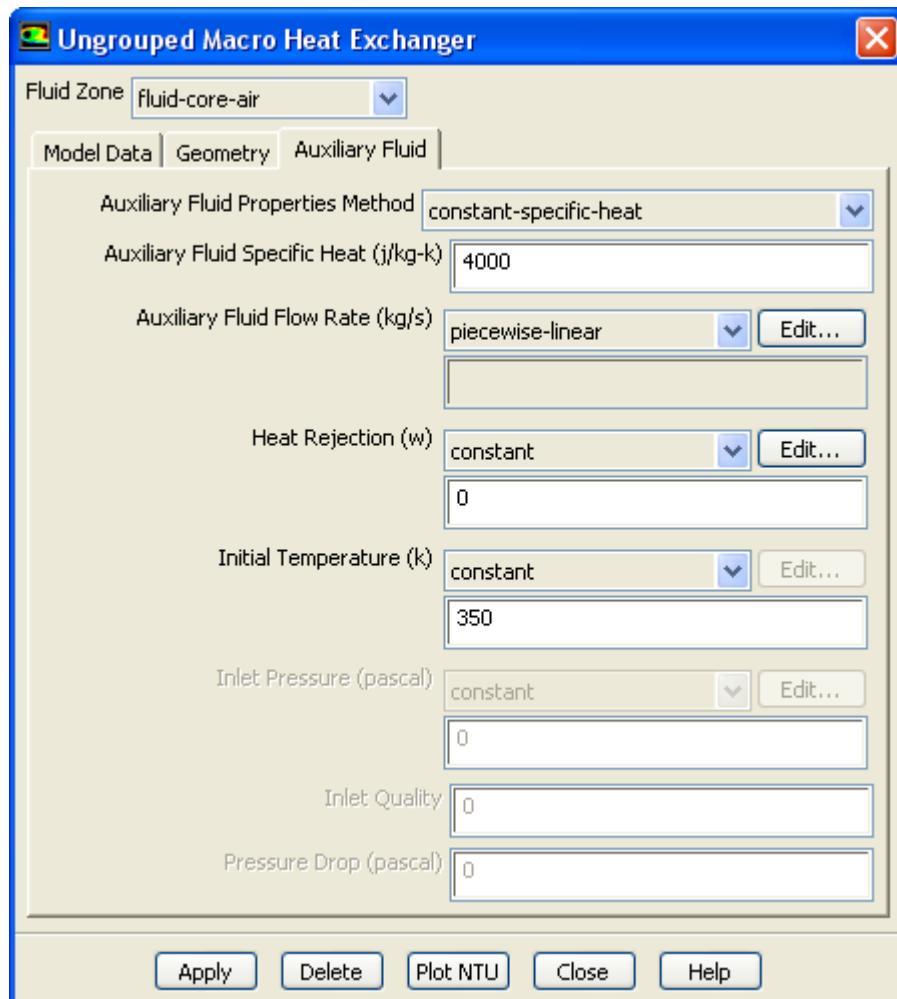

Figure 15.16 The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Auxiliary Fluid Tab

- i. In the **Auxiliary Fluid** tab, specify the **Auxiliary Fluid Properties Method**, either as a **constant-specific-heat** or as a **user-defined-enthalpy**.
- j. **Auxiliary Fluid Flow Rate**, **Heat Rejection**, **Inlet Temperature**, and **Inlet Pressure** can be provided as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time. If **user-defined-enthalpy** is selected as the **Auxiliary Fluid Properties Method**, you will need to specify the **Inlet Quality** and the **Pressure Drop**. More information is available in *Specifying the Auxiliary Fluid Properties and Conditions (p. 838)*.
- k. Click **Apply** in the **Ungrouped Macro Heat Exchanger** dialog box to save all the settings. Once you click the **Apply** button, the NTU matrix will be computed from the raw data. Therefore, make sure you click **Apply** at the very end of your setup.

Important

When you click **Apply**, look for any error or warning message in the ANSYS FLUENT console. Some of the common errors you may see displayed are due to the NTU computations not converging. In such cases, check that

- you have entered the data correctly
- the values of the data are reasonable
- the operating condition for the auxiliary fluid flow rate is not too far from the range of the heat transfer data

Other error messages you may encounter may be due to macros not getting any cells assigned to it. In such cases, make sure that

- the heat exchanger core is rectangular
- the directions are correct
- you are using uniformly spaced cells in both directions
- the mesh is either a hexahedra or wedge and is structured

I. Repeat steps (a)–(k) for any other heat exchanger fluid zones.

To use multiple fluid zones to define a single heat exchanger, or to connect the auxiliary fluid flow path among multiple heat exchangers, see [Using the Grouped Macro Heat Exchanger Model \(p. 841\)](#).

For additional information, please see the following sections:

- [15.3.2.1. Selecting the Zone for the Heat Exchanger](#)
- [15.3.2.2. Specifying Heat Exchanger Performance Data](#)
- [15.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions](#)
- [15.3.2.4. Defining the Macros](#)
- [15.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions](#)
- [15.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness](#)

15.3.2.1. Selecting the Zone for the Heat Exchanger

Choose the fluid zone for which you want to define a heat exchanger in the **Fluid Zone** drop-down list.

15.3.2.2. Specifying Heat Exchanger Performance Data

Based on the heat transfer model you choose in the **Model Data** tab, some performance data must be entered for the heat exchanger.

- **ntu-model:** For the **ntu-model** you will provide the heat transfer for different primary and auxiliary fluid flow rates. Click the **Heat Transfer Data...** button to open up a tabular dialog box. Set the number of auxiliary flow rates and primary fluid flow rates. The dialog box will resize itself accordingly. You will need to provide various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values. You may write this data to a file that can be read later.
- **simple-effectiveness-model:** For this model, you will need to provide velocity versus effectiveness data. To provide this you can click the **Velocity Effectiveness Curve...** button. This will open up a tabular dialog box. In this dialog box, you can set the number of points in the curve, then you can provide velocities and corresponding effectiveness values. This data can be written to a file and read back.

15.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions

To define the auxiliary fluid direction and flow path, you will specify direction vectors for the **Auxiliary Fluid Inlet Direction** and the **Pass-to-Pass Direction** in the **Geometry** tab. *Figure 15.17* (p. 837) shows these directions relative to the macros.

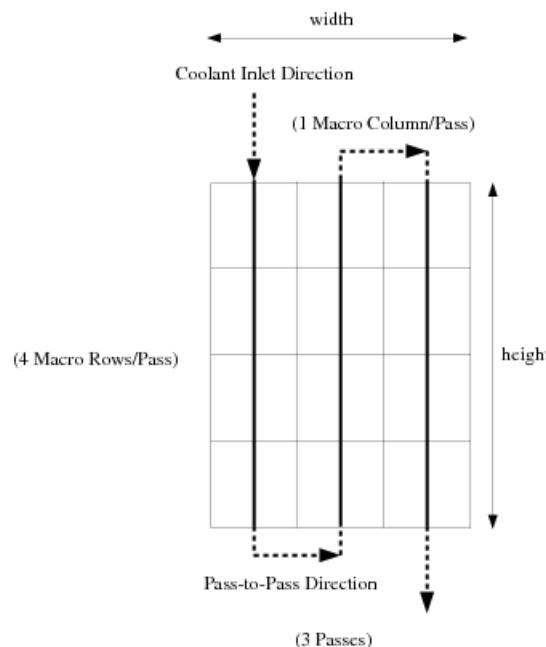

For some problems in which the principal axes of the heat exchanger core are not aligned with the coordinate axes of the domain, you may not know the auxiliary fluid inlet and pass-to-pass direction vectors a priori. In such cases, you can use the plane tool as follows to help you to determine these direction vectors.

1. "Snap" the plane tool onto the boundary of the heat exchanger core. (Follow the instructions in *Initializing the Plane Tool* (p. 1485) for initializing the tool to a position on an existing surface.)
2. Translate and rotate the axes of the tool appropriately until they are aligned with the principal directions of the heat exchanger core. The depth direction is determined by the red axis, the height direction by the green axis, and the width direction by the blue axis.
3. Once the axes are aligned, click the **Update from Plane Tool** button in the **Ungrouped Macro Heat Exchanger** dialog box. The directional vectors will be set automatically. (Note that the **Update from Plane Tool** button will also set the height, width, and depth of the heat exchanger core.)

15.3.2.4. Defining the Macros

As discussed in *The Macro Heat Exchanger Models* (p. 829), the fluid zone representing the heat exchanger core is split into macros. Macros are constructed based on the specified number of passes, the number of macro rows per pass, the number of macro columns per pass, and the corresponding auxiliary fluid inlet and pass-to-pass directions (see *Figure 15.17* (p. 837)). Macros are numbered from 0 to $(n - 1)$ in the direction of auxiliary fluid flow, where n is the number of macros.

Figure 15.17 1x4x3 Macros

In the **Ungrouped Macro Heat Exchanger** dialog box, in the **Geometry** tab, specify the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass**. The model will automatically extrude the macros to the depth of the heat exchanger core. For each pass, the **Number of Rows/Pass**

are defined in the direction of the auxiliary flow inlet direction and the **Number of Columns/Pass** are defined in the direction of the pass-to-pass direction.

Important

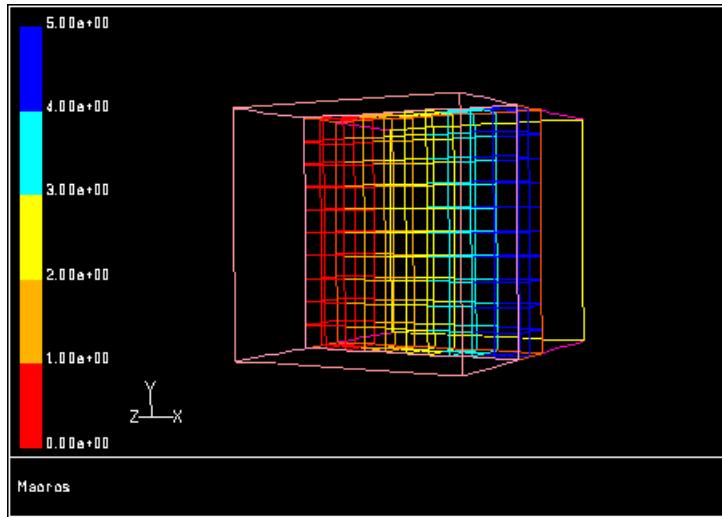

The **Number of Rows/Pass**, as well as the **Number of Columns/Pass** must be divisible by the number of cells in their respective directions. For example, if you have 50 cells in the auxiliary flow direction, you can use 25 for the **Number of Rows/Pass**, but you should not use 26 or 24. If you have 51 cells in that direction, you can only use 51 for the **Number of Rows/Pass**. The same holds true for the other direction.

15.3.2.4.1. Viewing the Macros

You can view the auxiliary fluid path by displaying the macros. To view the macros for your specified **Number of Passes**, **Number of Rows/Pass**, and **Number of Columns/Pass**, click the **Apply** button at the bottom of the dialog box, then click the **View Passes** button to display it. The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n - 1$ is blue.

For some problems, especially complex geometries, you may want to include portions of the computational-domain mesh in your macros plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the macros. This is accomplished by enabling the **Draw Mesh** option. The [Mesh Display Dialog Box \(p. 1767\)](#) will appear automatically when you enable the **Draw Mesh** option, where you can set the mesh display parameters. When you click the **View Passes** button in the **Ungrouped Macro Heat Exchanger** dialog box, the mesh display, as defined in the **Mesh Display** dialog box, will be included in the macros plot (see [Figure 15.18 \(p. 838\)](#)).

Figure 15.18 Mesh Display With Macros

15.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions

To define the auxiliary fluid properties and conditions, you will specify the **Auxiliary Fluid Flow Rate** (m) in the **Auxiliary Fluid** tab. The properties of the auxiliary fluid can be specified using the **Auxiliary Fluid Properties Method** drop-down list. You can choose a **constant-specific-heat** (c_p) and set the value in the **Auxiliary Fluid Specific Heat** field below, or as a user-defined function for the enthalpy using the **user-defined-enthalpy** option and selecting the corresponding UDF from the **Auxiliary Fluid Enthalpy UDF** drop-down list.

The function should return a single value depending on the index:

- Enthalpy for given values of temperature, pressure, and quality.
- Temperature for given values of enthalpy and pressure
- Specific heat for given values of temperature and pressure

The user-defined function should be of type

```
DEFINE_SOURCE(udf_name, cell_t c, Thread *t, real d[n], int index).
```

where n in the expression $d[n]$ would be 0 for temperature, 1 for pressure, or 2 for quality. The variable index is 0 for enthalpy, 1 for temperature, or 2 for specific heat. This user-defined function should return

```
real value; /* (temperature or enthalpy or Cp depending on index). */
```

- If you want ANSYS FLUENT to compute the auxiliary fluid inlet temperature for a specified heat rejection, follow the steps below:
 1. Enable the **Fixed Heat Rejection** option in the **Model Data** tab.
 2. Specify the **Heat Rejection** (q_{total} in [Equation 6–15](#) in the [Theory Guide](#)) in the **Auxiliary Fluid** tab.
 3. Specify the **Initial Temperature**, which will be used by ANSYS FLUENT as an initial guess for the inlet temperature (T_{in} in [Equation 6–11](#) in the [Theory Guide](#) and [Equation 6–16](#) in the [Theory Guide](#)).
- If you want ANSYS FLUENT to compute the total heat rejection of the core for a given inlet auxiliary fluid temperature, follow the steps below:
 1. Enable the **Fixed Inlet Temperature** option in the **Model Data** tab.
 2. Specify the **Inlet Temperature** (T_{in} in [Equation 6–11](#) in the [Theory Guide](#) and [Equation 6–16](#) in the [Theory Guide](#)) in the **Auxiliary Fluid** tab.
- If you enable the **User Defined Enthalpy** option under the **Auxiliary Fluid Properties Method**, you must also specify the **Inlet Pressure** (p_{in} in [Equation 6–21](#) in the [Theory Guide](#)) and **Inlet Quality** (x in [Equation 6–20](#) in the [Theory Guide](#)).

15.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness

The pressure drop parameters and effectiveness define the **Core Porosity Model**. If you would like ANSYS FLUENT to set the porosity of this a heat exchanger zone using a particular core model, you can select the appropriate model. This will automatically set the porous media inputs. There are three ways to specify the **Core Porosity Model** parameters:

- Use the values in ANSYS FLUENT's default model.
- Define a new core porosity model with your own values.
- Read a core porosity model from an external file.

If you do not choose a core porosity model, you will need to set the porosity parameters in the cell zone conditions dialog box for the heat exchanger zone(s). To do this, follow the procedures described in [User Inputs for Porous Media](#) (p. 235).

The models you define will be saved in the case file.

15.3.2.6.1. Using the Default Core Porosity Model

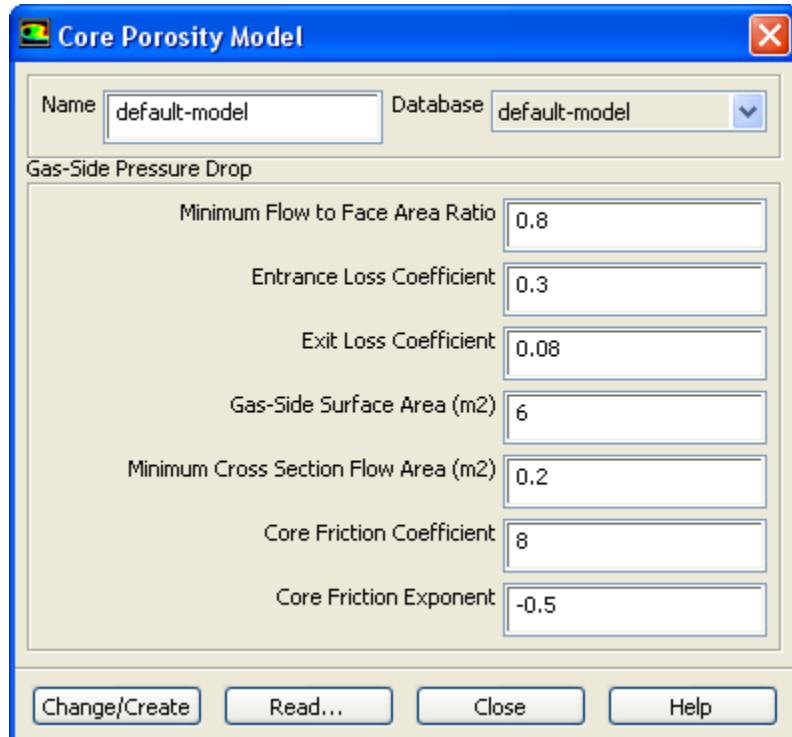

ANSYS FLUENT provides a default model for a typical heat exchanger core. The **default-model** core porosity model is a list of constant values from the **Ungrouped Macro Heat Exchanger** dialog box. These constants are used for setting the porous media parameters. To use these values, simply retain the selection of **default-model** in the **Core Porosity Model** drop-down list in the **Ungrouped Macro Heat Exchanger** dialog box. (You can view the default parameters as described below.)

15.3.2.6.2. Defining a New Core Porosity Model

If you want to define pressure-drop and effectiveness parameters that are different from those in the default core porosity model, you can create a new model. The steps for creating a new model are as follows:

1. Click the **Edit...** button to the right of the **Core Porosity Model** drop-down list, for which **default-model** should have been selected. This will open the *Core Porosity Model Dialog Box (p. 1809)* (*Figure 15.19 (p. 840)*).

Figure 15.19 The Core Porosity Model Dialog Box

2. Enter the name of your new model in the **Name** box at the top of the dialog box.
3. Under **Gas-Side Pressure Drop**, specify the following parameters used in *Equation 6–2* in the Theory Guide:
 - **Minimum Flow to Face Area Ratio** (σ)
 - **Entrance Loss Coefficient** (K_c)
 - **Exit Loss Coefficient** (K_e)
 - **Gas-Side Surface Area** (A)
 - **Minimum Cross Section Flow Area** (A_c)

and the **Core Friction Coefficient** and **Core Friction Exponent** (a and b , respectively, in [Equation 6-3](#) in the Theory Guide).

4. Click the **Change/Create** button. This will add your new model to the database.

15.3.2.6.3. Reading Heat Exchanger Parameters from an External File

You can read parameters for your **Core Porosity Model** from an external file. A sample file is shown below:

```
( "modelname"
  ( 0.73 0.43 0.053 5.2 0.33 9.1 0.66 ))
```

The first entry in the file is the name of the model (e.g., `modelname`). The second set of numbers contains the gas-side (primary-side) pressure drop parameters:

$$(\sigma K_c K_e A A_c a b)$$

To read an external heat exchanger file, you will follow these steps:

1. In the **Core Porosity Model** dialog box, click the **Read...** button.
2. In the resulting **Select File** dialog box, specify the **HXC Parameters File** name and click **OK**. ANSYS FLUENT will read the core porosity model parameters, and add the new model to the database.

15.3.2.6.4. Viewing the Parameters for an Existing Core Model

To view the parameters associated with a core porosity model that you have already defined, select the model name in the **Database** drop-down list (in the **Core Porosity Model** dialog box). The values for that model from the database will be displayed in the **Core Porosity Model** dialog box.

15.3.3. Using the Grouped Macro Heat Exchanger Model

To define a single heat exchanger that uses multiple fluid zones, or to connect the auxiliary fluid flow path among multiple heat exchangers, you can use heat exchanger groups. To use heat exchanger groups, perform the following steps:

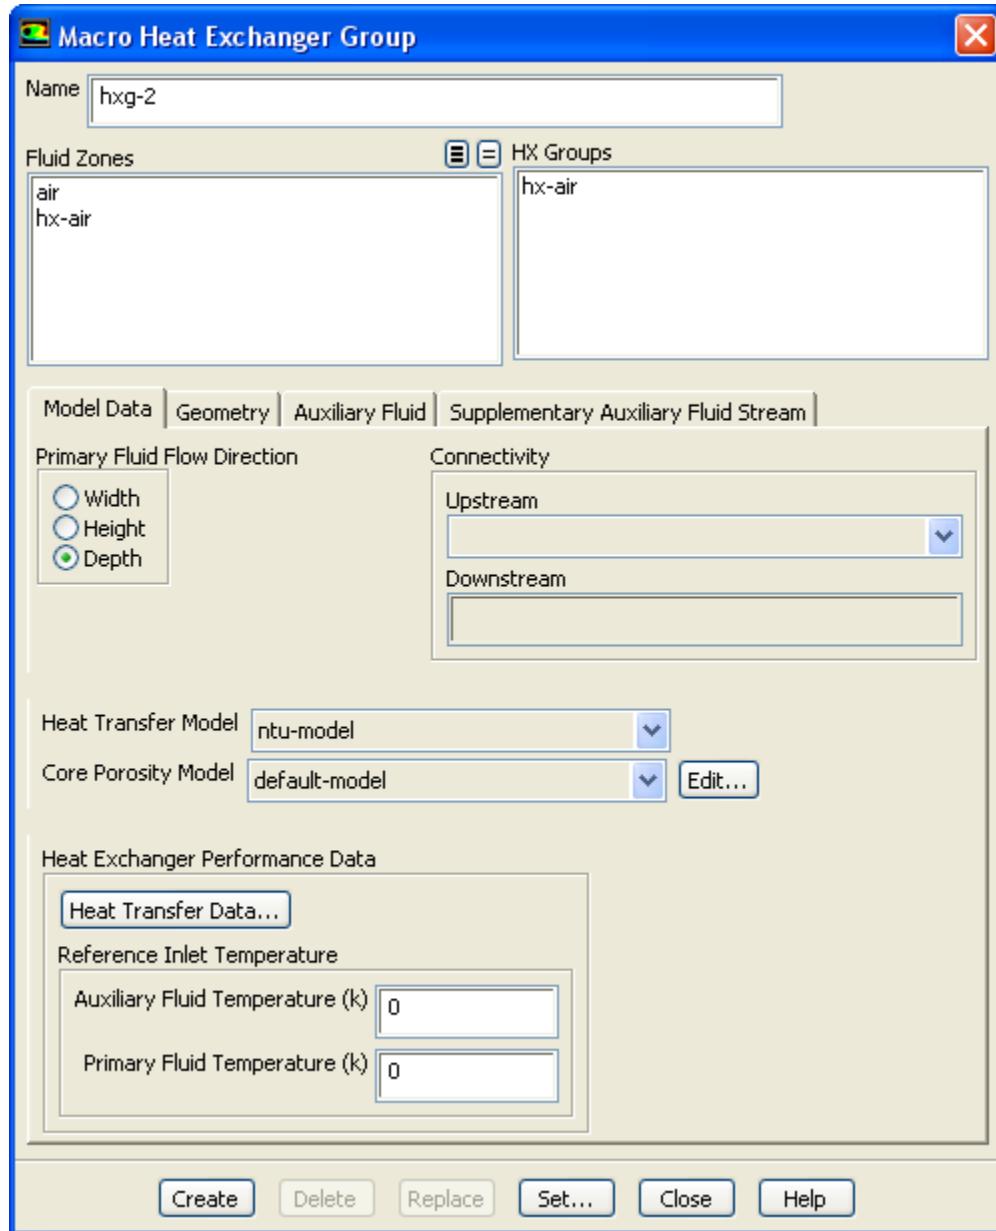

1. Enable the calculation of energy in the [Energy Dialog Box \(p. 1778\)](#).

Models → **Energy** → **Edit...**

2. Enable the **Macro Model Group** option and click the **Define...** button in the [Heat Exchanger Model Dialog Box \(p. 1799\)](#) to access the **Macro Heat Exchanger Group** dialog box.

Models → **Heat Exchanger** → **Edit...**

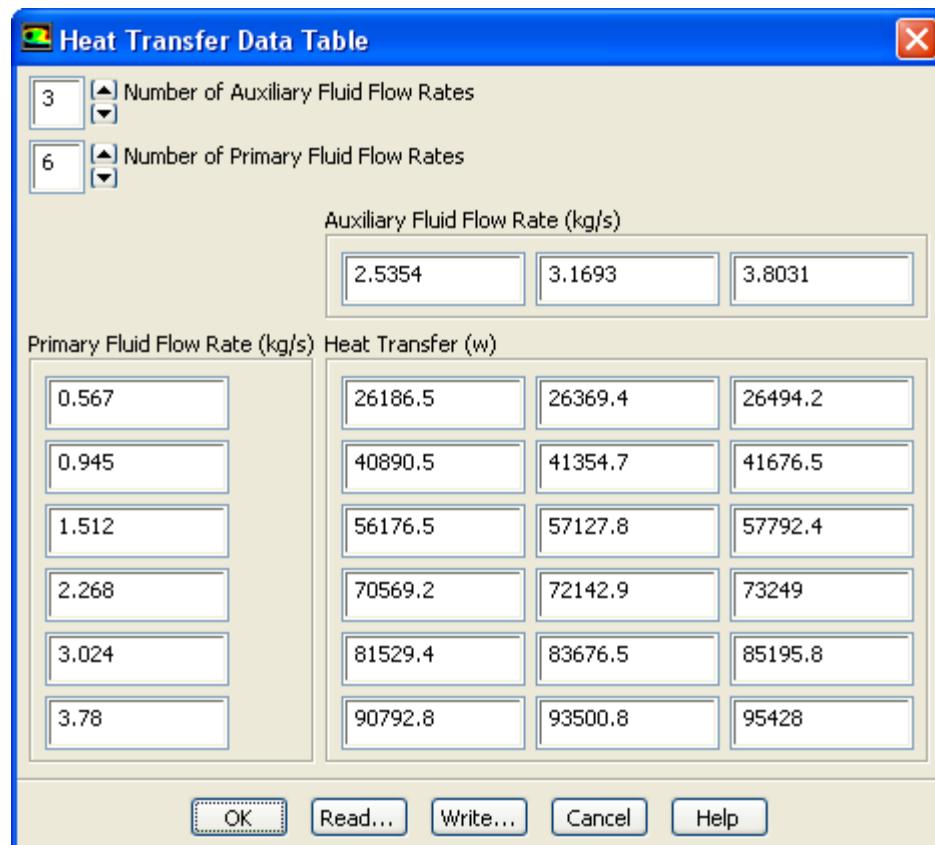

3. Specify the inputs to the heat exchanger group in the **Macro Heat Exchanger Group** dialog box ([Figure 15.20 \(p. 842\)](#)).

Figure 15.20 The Macro Heat Exchanger Group Dialog Box

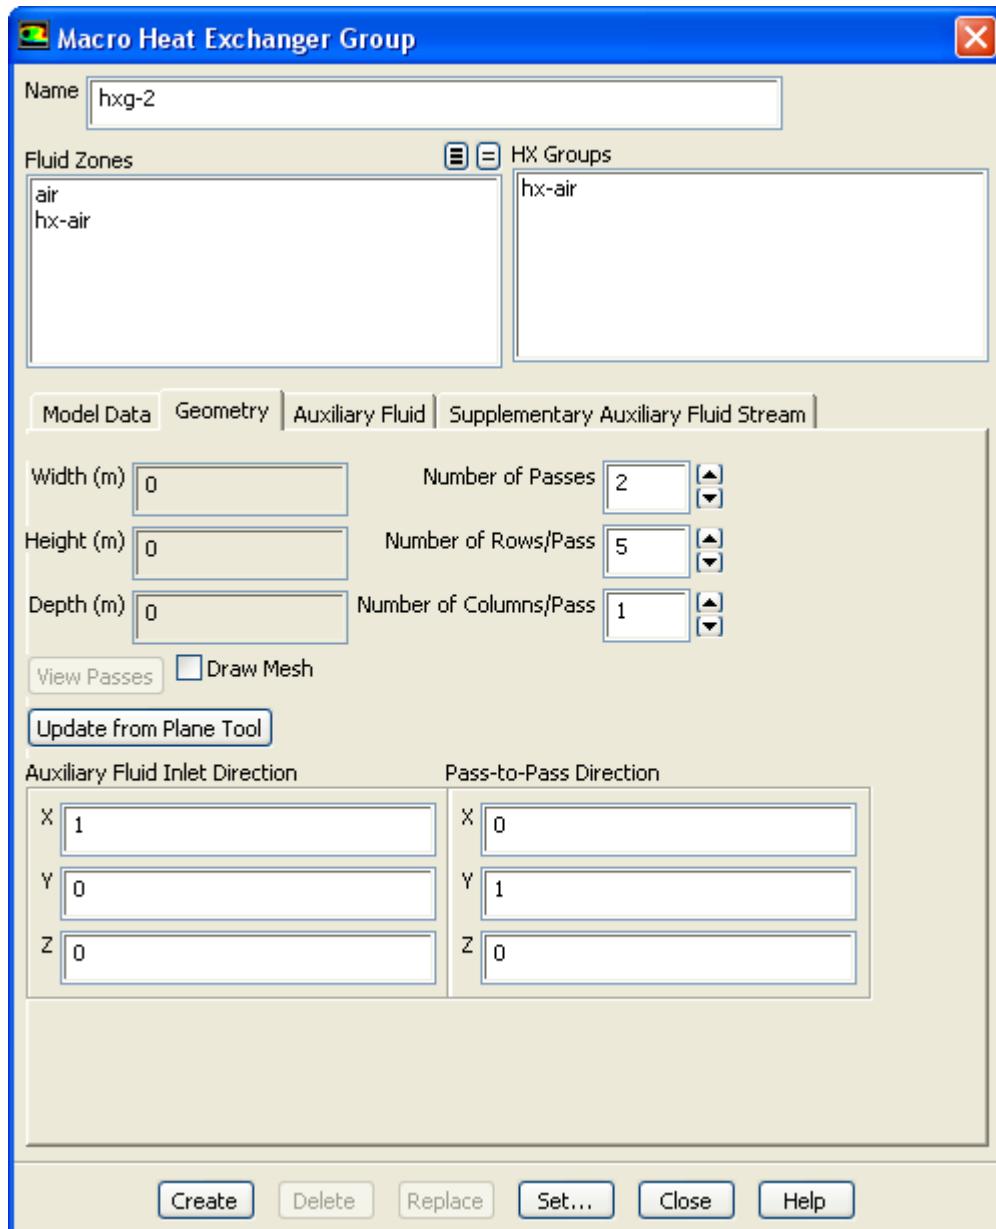

- Enter the **Name** of the heat exchanger group.
- Under **Fluid Zones**, select the fluid zones that you want to define in the heat exchanger group (*Selecting the Fluid Zones for the Heat Exchanger Group (p. 847)*).
- Click the **Model Data** tab.
 - Under **Primary Fluid Flow Direction**, specify the primary fluid flow direction as either **Width**, **Height**, or **Depth**.
 - Under **Connectivity**, select the **Upstream** heat exchanger group if such a connection exists (see *Selecting the Upstream Heat Exchanger Group (p. 847)*).
 - In the **Heat Transfer Model** drop-down list, choose either the **ntu-model** or the **simple-effectiveness-model**. See step 3. in *Choosing a Heat Exchanger Model (p. 820)* for details about the differences between these two models.

- iv. From the **Core Porosity Model** drop-down list, specify the core model that should be used to calculate the porous media parameters for the zones in the group. More information is available in [Setting the Pressure-Drop Parameters and Effectiveness \(p. 839\)](#).
- v. If the **ntu-model** is chosen, a **Heat Transfer Data...** button will appear under **Heat Exchanger Performance Data**. Clicking the **Heat Transfer Data...** button will open the [Heat Transfer Data Table Dialog Box \(p. 1803\)](#), where you will input experimental data that defines how heat transfer values relate to the fluid flow rates ([Figure 15.8 \(p. 826\)](#)). See [Specifying Heat Exchanger Performance Data \(p. 836\)](#) more details.

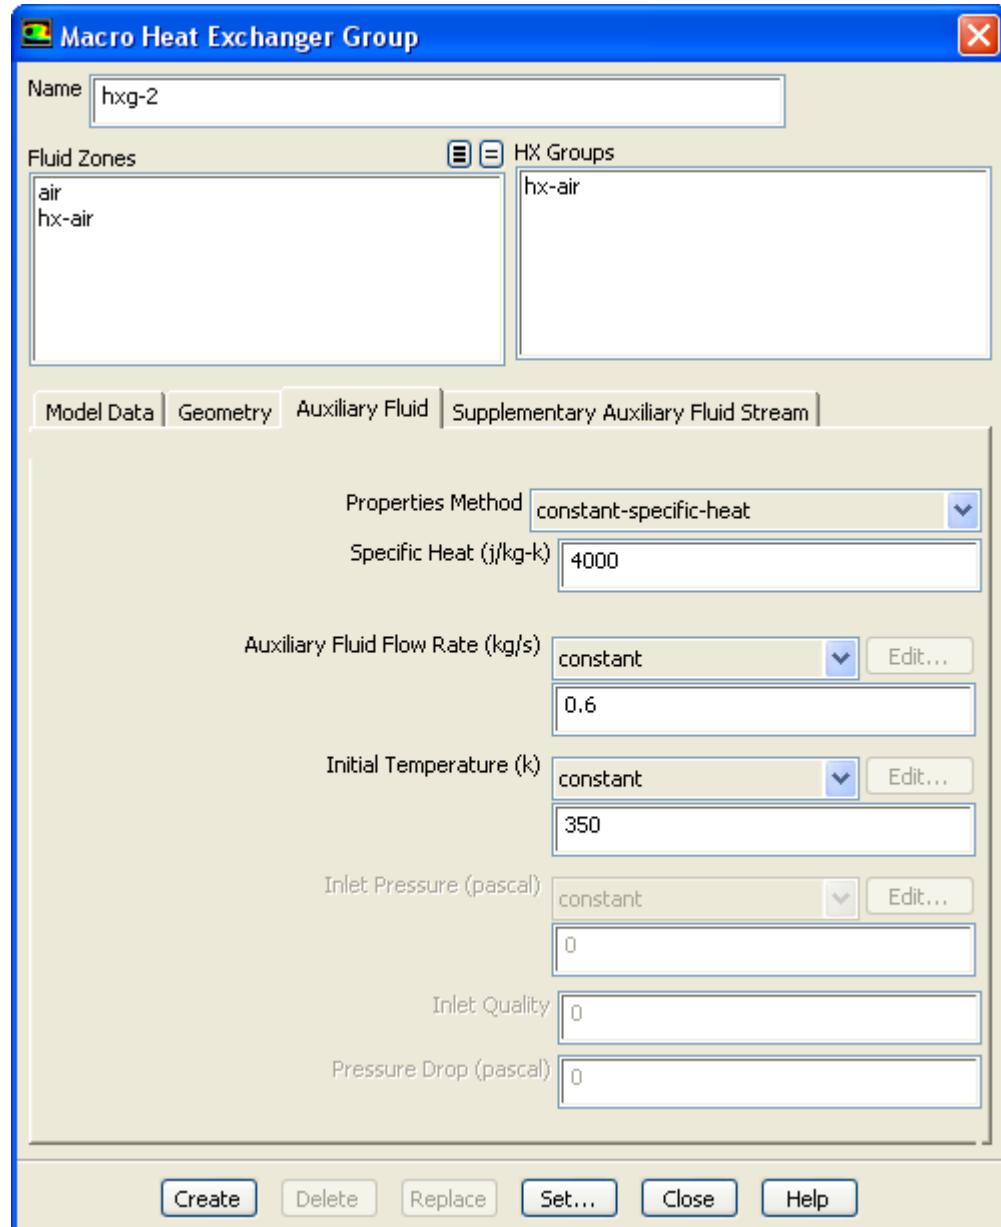

Figure 15.21 The Heat Transfer Data Table Dialog Box for the NTU Model

- vi. Enter the **Auxiliary Fluid Temperature** and the **Primary Fluid Temperature** for the **ntu-model**. These are the fixed inlet temperatures at which the test was performed to obtain the heat transfer data.
- vii. If the **simple-effectiveness-model** is chosen, then clicking the **Velocity Effectiveness Curve...** button, under the **Heat Exchanger Performance Data**, allows you to set the velocity and corresponding effectiveness for each point. More information is available in [Specifying Heat Exchanger Performance Data \(p. 836\)](#).
- d. Click the **Geometry** tab ([Figure 15.22 \(p. 844\)](#)).

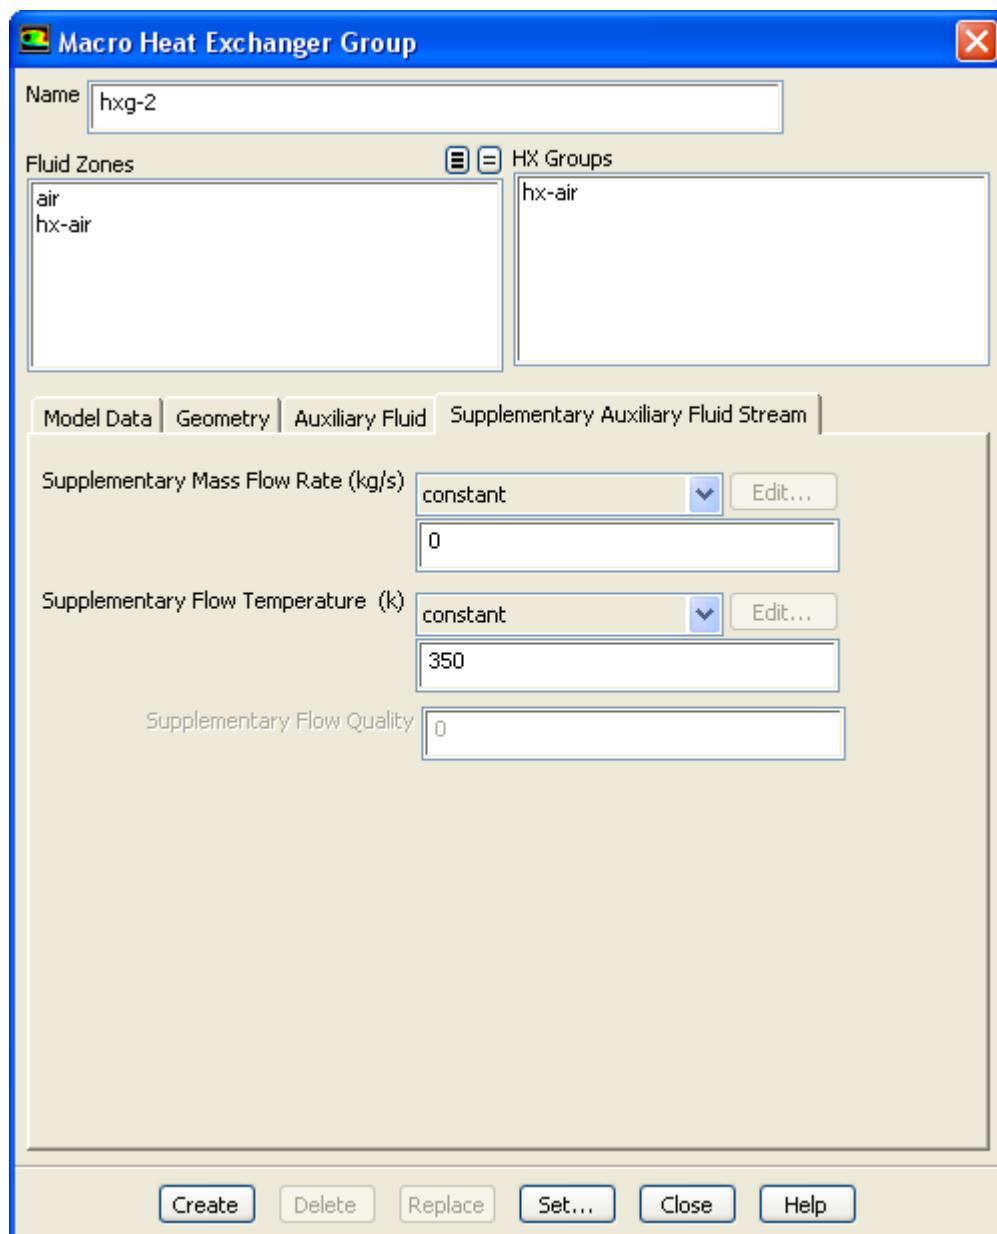

Figure 15.22 The Macro Heat Exchanger Group Dialog Box - Geometry Tab

- i. Define the macro mesh by specifying the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass**. More information is available in *Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 837)* and *Defining the Macros (p. 837)*.
- ii. Specify the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** (see *Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 847)*).
- e. Click the **Auxiliary Fluid** tab (*Figure 15.23 (p. 845)*) to specify the auxiliary fluid operating conditions.

Figure 15.23 The Macro Heat Exchanger Group Dialog Box - Auxiliary Fluid Tab

- i. Specify the **Specific Heat** as either a **constant-specific-heat** or as a **user-defined-enthalpy**.
- ii. **Auxiliary Fluid Flow Rate**, **Initial Temperature**, and **Inlet Pressure** can be provided as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time (see *Specifying the Auxiliary Fluid Properties and Conditions (p. 838)*).
- f. If a supplementary auxiliary stream is to be modeled, click the **Supplementary Auxiliary Fluid Stream** tab.

Figure 15.24 The Macro Heat Exchanger Group Dialog Box - Supplementary Auxiliary Fluid Stream Tab

- i. You can specify the **Supplementary Mass Flow Rate** as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time.
 - ii. You can specify the **Supplementary Flow Temperature** as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time.
- g. Click **Create** or **Replace** in the **Macro Heat Exchanger Group** dialog box to save all the settings. **Replace** changes the parameters of the already existing group that is selected in the **HX Groups** list.

Important

Creating or replacing any heat exchanger group initializes any previously calculated values for temperature and enthalpy for all macros.

4. If a heat exchanger group comprises multiple fluid zones and you wish to override any of the inputs defined in the previous steps, click the **Set...** button to open the **Ungrouped Macro Heat Exchanger** dialog box (*Figure 15.13 (p. 832)*). Select the particular fluid zone as usual. Notice that the individual heat exchanger inherits the properties of the group by default. You may override any of the following:

- **Number of Passes, Number of Rows/Pass, and Number of Columns/Pass**
- **Auxiliary Fluid Inlet Direction** and the **Pass-to-Pass Direction**
- **Core Porosity Model**

For additional information, please see the following sections:

- 15.3.3.1. Selecting the Fluid Zones for the Heat Exchanger Group
- 15.3.3.2. Selecting the Upstream Heat Exchanger Group
- 15.3.3.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions
- 15.3.3.4. Specifying the Auxiliary Fluid Properties
- 15.3.3.5. Specifying Supplementary Auxiliary Fluid Streams
- 15.3.3.6. Initializing the Auxiliary Fluid Temperature

15.3.3.1. Selecting the Fluid Zones for the Heat Exchanger Group

Select the fluid zones that you want to define in the heat exchanger group in the **Fluid Zones** drop-down list. The auxiliary fluid flow in all these zones will be in parallel. Note that one zone cannot be included in more than one heat exchanger group.

15.3.3.2. Selecting the Upstream Heat Exchanger Group

If you want to connect the current group in series with another group, choose the upstream heat exchanger group. Note that any group can have at most one upstream and one downstream group. Also, a group cannot be connected to itself. Select a heat exchanger group from the **Upstream** drop-down list under **Connectivity** in the **Model Data** tab of the **Macro Heat Exchanger Group** dialog box.

Important

Connecting to an upstream heat exchanger group can be done only while creating a heat exchanger group. The connection will persist even if the connection is later changed and the **Replace** button is clicked. To change a connection to an upstream heat exchanger group, you need to delete the connecting group and create a new heat exchanger group with the proper connection.

15.3.3.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions

The **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction**, in the **Geometry** tab can be specified as directed in *Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 837)* in the **Ungrouped Macro Heat Exchanger** dialog box. Note that the **Update from Plane Tool** will set the height, width, and depth as the average of the fluid zones selected in the **Fluid Zones**.

15.3.3.4. Specifying the Auxiliary Fluid Properties

The auxiliary fluid can be specified as having a **constant-specific-heat**, or a user-defined function can be written to calculate the enthalpy, as described in *Specifying the Auxiliary Fluid Properties and Conditions (p. 838)*.

15.3.3.5. Specifying Supplementary Auxiliary Fluid Streams

The addition or removal of a supplementary auxiliary fluid is allowed in any of the heat exchanger groups. Note that auxiliary streams are not allowed for individual zones. You will input the mass flow rate, temperature, and quality of the supplementary auxiliary fluid. You will also need to specify the heat transfer for various flow rates of primary and auxiliary flows. The auxiliary stream has the following assumptions:

- The magnitude of a negative auxiliary stream must be less than the primary auxiliary fluid inlet flow rate of the heat exchanger group.
- Added streams will be assumed to have the same fluid properties as the primary inlet auxiliary fluid.

15.3.3.6. Initializing the Auxiliary Fluid Temperature

When the heat exchanger group is connected to an upstream heat exchanger group, ANSYS FLUENT will automatically set the initial guess for the auxiliary fluid inlet temperature, T_{in} , to be equal to the T_{in} of the upstream heat exchanger group. Thus the boundary condition T_{in} for the first heat exchanger group in a connected series will automatically propagate as an initial guess for every other heat exchanger group in the series. However, when it is necessary to further improve convergence properties, you will be allowed to override T_{in} for any connected heat exchanger group by providing a value in the **Initial Temperature** field. Whenever such an override is supplied, ANSYS FLUENT will automatically propagate the new T_{in} to any heat exchanger groups further downstream in the series. Similarly, every time the T_{in} boundary condition for the first heat exchanger group is modified, ANSYS FLUENT will correspondingly update every downstream heat exchanger group.

If you want to impose a non-uniform initialization on the auxiliary fluid temperature field, first connect the heat exchanger groups and then set T_{in} for each heat exchanger group in streamwise order.

All heat exchangers included in a group must use the fixed T_{in} option. All heat exchangers within a heat exchanger group must have the same T_{in} . In other words, no local override of this setting is possible through the **Ungrouped Macro Heat Exchanger** dialog box.

15.4. Postprocessing for the Heat Exchanger Model

Postprocessing for the heat exchanger models involves computing the total heat rejection rate by setting up volume monitors and reporting of variables such as computed heat rejection, inlet or outlet temperature, specific heat, and mass flow rate.

Note that when postprocessing dual cell heat exchanger models using dialog boxes other than the **Heat Exchanger Report** dialog box (which requires you to explicitly specify whether you want reports on either the **Primary** or the **Auxiliary** fluid), attention must be paid to the fact that there are overlapping cell zones in the heat exchanger region. For example:

- When creating an isosurface and making selections from the **From Zones** selection list of the **Iso-Surface** dialog box, you should never select both the primary and the auxiliary fluid zones at the same time. Note that if no selections are made in this list, then all the cell zones are selected.
- When making selections from the **Surfaces** list of the **Contours** dialog box, you should not select a surface that is associated with the primary fluid zone and a surface associated with the auxiliary fluid zone at the same time, if those surfaces are spatially coincident.

For additional information, please see the following sections:

- 15.4.1. Heat Exchanger Reporting
- 15.4.2. Total Heat Rejection Rate

15.4.1. Heat Exchanger Reporting

Reporting the results for the heat exchanger models is done using the **Heat Exchanger Report** dialog box.

Reports →  Heat Exchanger → Set Up...

The following variable options are available for reporting:

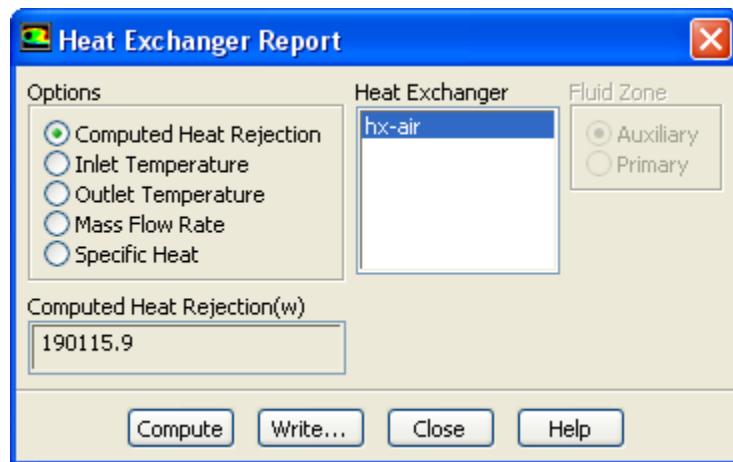

- **Computed Heat Rejection**
- **Inlet Temperature**
- **Outlet Temperature**
- **Mass Flow Rate**
- **Specific Heat**

15.4.1.1. Computed Heat Rejection

To display the **Computed Heat Rejection**

1. Select **Computed Heat Rejection** from the **Options** list.
2. Select the **Heat Exchanger** from the selection list.
3. Click **Compute**.

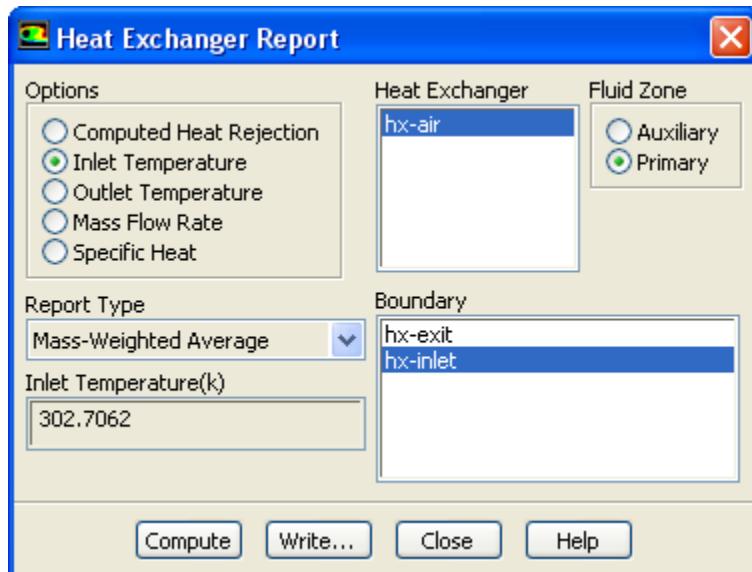

Figure 15.25 The Heat Exchanger Report Dialog Box for Reporting Computed Heat Rejection

You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

15.4.1.2. Inlet/Outlet Temperature

Inlet/Outlet Temperature can be reported for both primary and auxiliary fluid in the **Heat Exchanger Report** dialog box.

Figure 15.26 The Heat Exchanger Report Dialog Box for Reporting the Inlet Temperature

1. Select **Inlet Temperature** or **Outlet Temperature** from the **Options** list.
2. Select the heat exchanger from the **Heat Exchanger** selection list.
3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.
4. Select the appropriate boundary zone and report type from the **Boundary** and **Report Type** lists, respectively.

Important

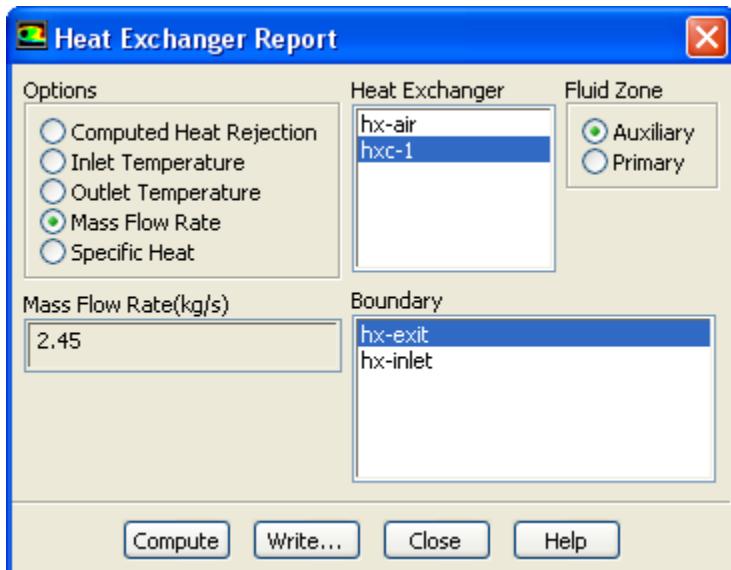

Note that the macro heat exchangers (unlike the dual cell heat exchanger) do not contain an auxiliary cell zone. Hence, the **Boundary** and **Report Type** fields will not appear in the dialog box if you are reporting an auxiliary inlet/outlet temperature.

5. Click **Compute**.

You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

15.4.1.3. Mass Flow Rate

Mass Flow Rate can be reported for both the primary and auxiliary fluid in the **Heat Exchanger Report** dialog box.

Figure 15.27 The Heat Exchanger Report Dialog Box for Reporting Mass Flow Rate

1. Select **Mass Flow Rate** from the **Options** group box.
2. Select the heat exchanger from the **Heat Exchanger** selection list.
3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.
4. Select the appropriate boundary zone and report type from the **Boundary** and **Report Type** lists, respectively.
5. Click **Compute**.

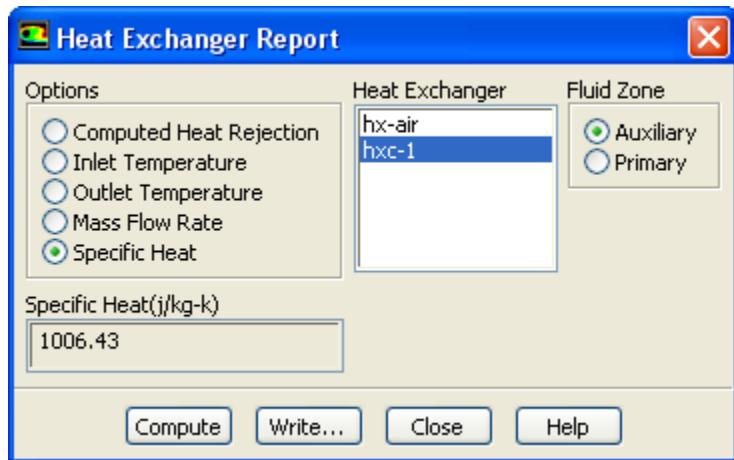

Important

Note that the macro heat exchangers (unlike the dual cell heat exchanger) do not contain an auxiliary cell zone. Hence, the **Boundary** field will not appear in the dialog box if you are reporting an auxiliary fluid mass flow rate.

You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

15.4.1.4. Specific Heat

Specific Heat for the primary or auxiliary fluid can be reported through the **Heat Exchanger Report** dialog box. If specific heat is defined as a function of temperature, the specific heat reported will be a cell volume averaged value.

Figure 15.28 The Heat Exchanger Report Dialog Box for Reporting Specific Heat

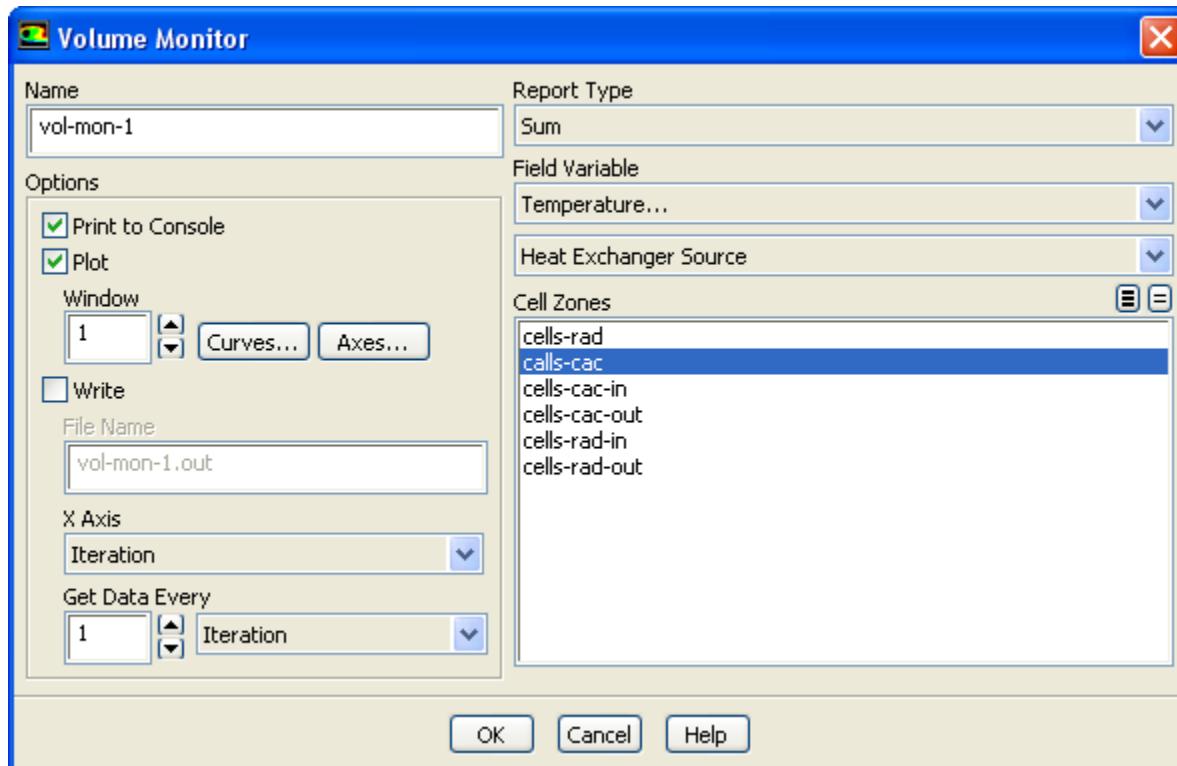

1. Select **Specific Heat** from the **Options** group box.
2. Select the heat exchanger from the **Heat Exchanger** selection list.
3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.
4. Click **Compute**.

15.4.2. Total Heat Rejection Rate

To postprocess the total heat rejection rate, you can set up a volume monitor to monitor convergence and view the computed values.

Monitors (Volume Monitors) → Create...

1. Select **Sum** from the **Report Type** drop-down list.
2. Select **Temperature** and **Heat Exchanger Source** from the **Field Variables** drop-down lists.
3. Select the appropriate **Cell Zones** and click **OK** to close the **Volume Monitor** dialog box.

Figure 15.29 The Volume Monitor Dialog Box

Important

Note that the macro heat exchangers contain only the primary fluid as the cell zone, but in case of the dual cell model, you can select either the primary or auxiliary fluid.

15.5. Useful Reporting TUI Commands

To report the results for the macro heat exchangers, you can use the following text command:

```
define → models → heat-exchanger → macro-model → heat-exchanger-macro-report
```

Specify the fluid zone *id/name* for which you want to obtain information.

To view the connectivity of the heat exchanger groups, use the text command:

```
(report-connectivity)
```

Chapter 16: Modeling Species Transport and Finite-Rate Chemistry

ANSYS FLUENT can model the mixing and transport of chemical species by solving conservation equations describing convection, diffusion, and reaction sources for each component species. Multiple simultaneous chemical reactions can be modeled, with reactions occurring in the bulk phase (volumetric reactions) and/or on wall or particle surfaces, and in the porous region. Species transport modeling capabilities, both with and without reactions, and the inputs you provide when using the model are described in this chapter. For theoretical information about species transport, see "Species Transport and Finite-Rate Chemistry" in the [Theory Guide](#).

Note that you may also want to consider modeling your turbulent reacting flame using the mixture fraction approach (for non-premixed systems, described in [Modeling Non-Premixed Combustion \(p. 901\)](#)), the reaction progress variable approach (for premixed systems, described in [Modeling Premixed Combustion \(p. 957\)](#)), the partially premixed approach (described in [Modeling Partially Premixed Combustion \(p. 969\)](#)), or the composition PDF Transport approach (described in [Modeling a Composition PDF Transport Problem \(p. 975\)](#)). Modeling multiphase species transport and finite-rate chemistry can be found in [Modeling Multiphase Flows \(p. 1173\)](#).

Information is divided into the following sections:

- 16.1. Volumetric Reactions
- 16.2. Wall Surface Reactions and Chemical Vapor Deposition
- 16.3. Particle Surface Reactions
- 16.4. Species Transport Without Reactions
- 16.5. Reacting Channel Model

16.1. Volumetric Reactions

Information about using species transport and finite-rate chemistry as related to volumetric reactions is presented in the following subsections. For more information about the theoretical background of volumetric reactions, see [Volumetric Reactions](#) in the [Theory Guide](#).

- 16.1.1. Overview of User Inputs for Modeling Species Transport and Reactions
- 16.1.2. Enabling Species Transport and Reactions and Choosing the Mixture Material
- 16.1.3. Defining Properties for the Mixture and Its Constituent Species
- 16.1.4. Setting up Coal Simulations with the Coal Calculator Dialog Box
- 16.1.5. Defining Cell Zone and Boundary Conditions for Species
- 16.1.6. Defining Other Sources of Chemical Species
- 16.1.7. Solution Procedures for Chemical Mixing and Finite-Rate Chemistry
- 16.1.8. Postprocessing for Species Calculations
- 16.1.9. Importing a Volumetric Kinetic Mechanism in CHEMKIN Format

16.1.1. Overview of User Inputs for Modeling Species Transport and Reactions

The basic steps for setting up a problem involving species transport and reactions are listed below, and the details about performing each step are presented in [Enabling Species Transport and Reactions and Choosing the Mixture Material \(p. 857\)](#) – [Defining Cell Zone and Boundary Conditions for Species \(p. 878\)](#). Additional information about setting up and solving the problem is provided in [Defining Other Sources of Chemical Species \(p. 878\)](#) – [Postprocessing for Species Calculations \(p. 882\)](#).

1. Enable species transport and volumetric reactions, and specify the mixture material. See [Enabling Species Transport and Reactions and Choosing the Mixture Material \(p. 857\)](#). The mixture material concept is explained in [Mixture Materials \(p. 856\)](#).
2. If you are also modeling wall or particle surface reactions, enable wall surface and/or particle surface reactions. See [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#) [Particle Surface Reactions \(p. 892\)](#) for details.
3. Check and/or define the properties of the mixture. See [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#). Mixture properties include the following:
 - species in the mixture
 - reactions
 - other physical properties (e.g., viscosity, specific heat)
4. Check and/or set the properties of the individual species in the mixture. See [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#).
5. Set species cell zone and boundary conditions. See [Defining Cell Zone and Boundary Conditions for Species \(p. 878\)](#).

In many cases, you will not need to modify any physical properties because the solver gets species properties, reactions, etc. from the materials database when you choose the mixture material. Some properties, however, may not be defined in the database. You will be warned when you choose your material if any required properties need to be set, and you can then assign appropriate values for these properties. You may also want to check the database values of other properties to be sure that they are correct for your particular application. For details about modifying an existing mixture material or creating a new one from scratch, see [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#). Modifications to the mixture material can include the following:

- Addition or removal of species
- Changing the chemical reactions
- Modifying other material properties for the mixture
- Modifying material properties for the mixture's constituent species

If you are solving a reacting flow, you will usually want to define the mixture's specific heat as a function of composition, and the specific heat of each species as a function of temperature. You may want to do the same for other properties as well. By default, most species specific heats in the database are piecewise-polynomial functions of temperature, but you may choose to specify a different temperature-dependent function if you know of one that is more suitable for your problem.

16.1.1.1. Mixture Materials

The concept of mixture materials has been implemented in ANSYS FLUENT to facilitate the setup of species transport and reacting flow. A mixture material may be thought of as a set of species and a list of rules governing their interaction. The mixture material carries with it the following information:

- A list of the constituent species, referred to as "fluid" materials
- A list of mixing laws dictating how mixture properties (density, viscosity, specific heat, etc.) are to be derived from the properties of individual species if composition-dependent properties are desired
- A direct specification of mixture properties if composition-independent properties are desired
- Diffusion coefficients for individual species in the mixture

- Other material properties (e.g., absorption and scattering coefficients) that are not associated with individual species
- A set of reactions, including a reaction type (finite-rate, eddy-dissipation, etc.) and stoichiometry and rate constants

Both mixture materials are stored in the ANSYS FLUENT materials database. Many common mixture materials are included (e.g., methane-air, propane-air). Generally, one/two-step reaction mechanisms and many physical properties of the mixture and its constituent species are defined in the database. When you indicate which mixture material you want to use, the appropriate mixture material, fluid materials, and properties are loaded into the solver. If any necessary information about the selected material (or the constituent fluid materials) is missing, the solver will inform you that you need to specify it. In addition, you may choose to modify any of the predefined properties. See [Using the Materials Task Page \(p. 405\)](#) for information about the sources of ANSYS FLUENT's database property data.

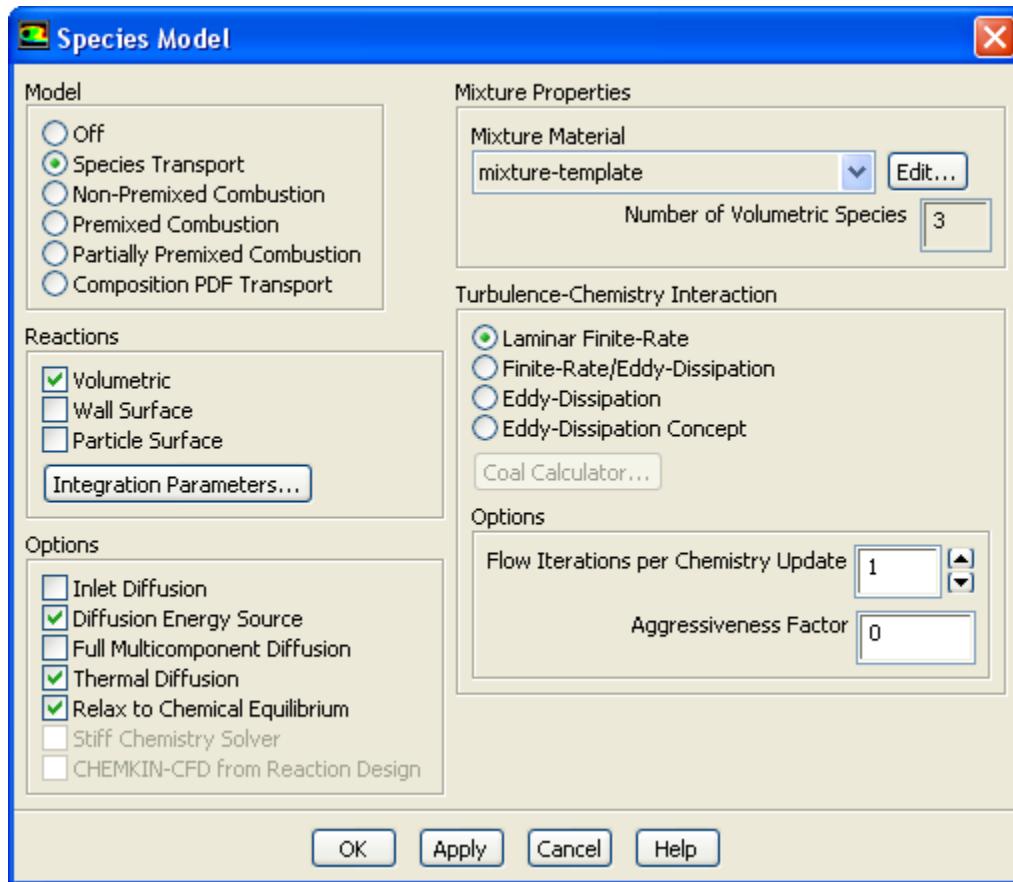

For example, if you plan to model combustion of a methane-air mixture, you do not need to explicitly specify the species involved in the reaction or the reaction itself. You will simply select **methane-air** as the mixture material to be used, and the relevant species (CH_4 , O_2 , CO_2 , H_2O , and N_2) and reaction data will be loaded into the solver from the database. You can then check the species, reactions, and other properties and define any properties that are missing and/or modify any properties for which you wish to use different values or functions. You will generally want to define a composition- and temperature-dependent specific heat, and you may want to define additional properties as functions of temperature and/or composition.

The use of mixture materials is performed in the [Create/Edit Materials Dialog Box \(p. 1882\)](#), as described in [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#).

16.1.2. Enabling Species Transport and Reactions and Choosing the Mixture Material

The problem setup for species transport and volumetric reactions begins in the **Species Model** dialog box ([Figure 16.1 \(p. 858\)](#)). For cases which involve multiphase species transport and reactions, refer to [Modeling Species Transport in Multiphase Flows](#) in the Theory Guide.

Models → **Species** → **Edit...**

Figure 16.1 The Species Model Dialog Box

- Under **Model**, select **Species Transport**.
- Under **Reactions**, enable **Volumetric**.
- In the **Mixture Material** drop-down list under **Mixture Properties**, choose which mixture material you want to use in your problem. The drop-down list will include all of the mixtures that are currently defined in the database. To check the properties of a mixture material, select it and click the **Edit...** button. If the mixture you want to use is not in the list, choose the **mixture-template** material, and see *Defining Properties for the Mixture and Its Constituent Species* (p. 861) for details on setting your mixture's properties. If there is a mixture material listed that is similar to your desired mixture, you may choose that material and see *Defining Properties for the Mixture and Its Constituent Species* (p. 861) for details on modifying properties of an existing material.

When you choose the **Mixture Material**, the **Number of Volumetric Species** in the mixture will be displayed in the dialog box for your information.

Important

Note that if you re-open the **Species Model** dialog box after species transport has already been enabled, only the mixture materials available in your case will appear in the list. You can add more mixture materials to your case by copying them from the database, as described in *Copying Materials from the ANSYS FLUENT Database* (p. 407), or by creating a new mixture, as described in *Creating a New Material* (p. 408) and *Defining Properties for the Mixture and Its Constituent Species* (p. 861).

As mentioned in [Mixture Materials](#) (p. 856), modeling parameters for the species transport and (if relevant) reactions will automatically be loaded from the database. If any information is missing, you will be informed of this after you click **OK** in the **Species Model** dialog box. If you want to check or modify any properties of the mixture material, you will use the [Create/Edit Materials Dialog Box](#) (p. 1882), as described in [Defining Properties for the Mixture and Its Constituent Species](#) (p. 861).

4. Choose the **Turbulence-Chemistry Interaction** model. Four models are available:

Laminar Finite-Rate

computes only the Arrhenius rate (see [Equation 7–8](#) in the [Theory Guide](#)) and neglects turbulence-chemistry interaction. You can specify the following inputs:

Flow Iterations per Chemistry Update

Increasing the number reduces the computational expense of the chemistry calculations. By default, ANSYS FLUENT will update the chemistry once per 10 flow iterations. This option is available when either the **Relax to Chemical Equilibrium** or the **Stiff Chemistry Solver** option is enabled.

Aggressiveness Factor

This is a numerical factor which controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 (the default) is the most robust, but results in the slowest convergence. This option is available when either the **Relax to Chemical Equilibrium** or the **Stiff Chemistry Solver** option is enabled.

Finite-Rate/Eddy-Dissipation

(for turbulent flows only) computes both the Arrhenius rate and the mixing rate and uses the smaller of the two. You can specify the **Flow Iterations per Chemistry Update** and **Aggressiveness Factor** if you have the **Relax to Chemical Equilibrium** option enabled.

Eddy-Dissipation

(for turbulent flows only) computes only the mixing rate (see [Equation 7–25](#) and [Equation 7–26](#) in the [Theory Guide](#)). You can specify the **Flow Iterations per Chemistry Update** and **Aggressiveness Factor** if you have the **Relax to Chemical Equilibrium** option enabled.

Eddy-Dissipation Concept

(for turbulent flows only) models turbulence-chemistry interaction with detailed chemical mechanisms (see [Equation 7–8](#) [Equation 7–30](#) in the [Theory Guide](#)). When using this model, you can modify the following:

Flow Iterations per Chemistry Update

Increasing the number reduces the computational expense of the chemistry calculations. By default, ANSYS FLUENT will update the chemistry once per 10 flow iterations.

Aggressiveness Factor

This is a numerical factor which controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 (the default) is the most robust, but results in the slowest convergence.

Volume Fraction Constant

and the **Time Scale Constant** (C_ζ in [Equation 7–28](#) and C_t in [Equation 7–29](#) in the [Theory Guide](#)), although the default values are recommended.

5. You can set the integration parameters for the **Laminar Finite-Rate** and **Eddy-Dissipation Concept** models by clicking the **Integration Parameters...** button under **Reactions**. When using ISAT for chemistry tabulation, it is important to set appropriate maximum table size and error tolerance. For details about this option, see [Steps for Using the Composition PDF Transport Model](#) (p. 975).

6. (optional) If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, enable the **Full Multicomponent Diffusion** or **Thermal Diffusion** option.
See [Full Multicomponent Diffusion \(p. 459\)](#) for details.
 7. (optional) If you want to model Relaxation to Chemical Equilibrium or include the stiff chemistry solver, enable the **Relax to Chemical Equilibrium** or **Stiff Chemistry Solver** option. For information about the Relaxation to Chemical Equilibrium model, please refer to [The Relaxation to Chemical Equilibrium Model](#) in the Theory Guide.
-

Important

The **Relax to Chemical Equilibrium** model requires thermodynamic data of all the species to calculate chemical equilibrium. This thermodynamic data is contained (by default) in the file `.../fluentx.x/cpropep/data/thermo.db`. If you define your own species in ANSYS FLUENT, as determined by the **Chemical Formula** in the **Create/Edit Materials** dialog box, and this species name is not in the `thermo.db` file, ANSYS FLUENT will report an error. To overcome this error, you must manually enter all the unknown species in the `thermo` file.

8. Enabling **CHEMKIN-CFD from Reaction Design** for laminar reactions, will allow you to use the proprietary reaction-rate utilities and solution algorithms from Reaction Design, which is based on and compatible with their CHEMKIN technology [\[41\] \(p. 2369\)](#). For **Eddy-Dissipation Concept, Turbulence-Chemistry Interaction** and the **Composition PDF Transport** model, enabling the **CHEMKIN-CFD from Reaction Design** option will allow you to use reaction rates from Reaction Design's KINetics module, instead of the default ANSYS FLUENT reaction rates. ANSYS FLUENT's ISAT algorithm is employed to integrate these rates.

Refer to the KINetics for Fluent manual [\[2\] \(p. 2367\)](#) from Reaction Design for details on the chemistry formulation options. For more information, or to obtain a license to the Fluent/KINetics module, please contact Reaction Design at info@reactiondesign.com info or +1 858-550-1920, or go to www.reactiondesign.com.

9. Enable the **Thickened Flame Model** to model laminar flames, or more typically as an LES combustion model for turbulent premixed and partially-premixed flame. Specify the **Number of Grid Points in Flame**, which by default are 8 grid points. Consequently, in the **Create/Edit Materials** dialog box, you will specify the **Laminar Flame Speed**, for which you have a choice of **constant**, **user-defined**, or **metghalchi-keck-law**, and the **Laminar Flame Thickness**, for which you have a choice of **constant**, **user-defined**, or **diffusivity-over-flame-speed**.
-

Note

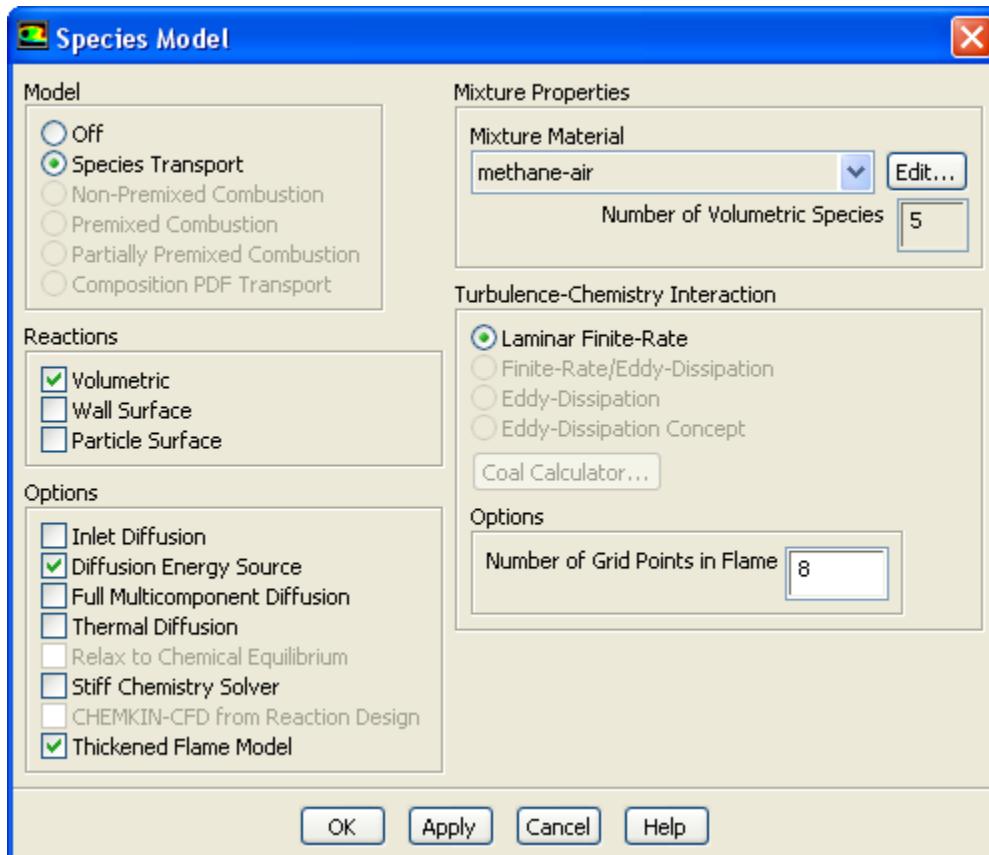

When the **Thickened Flame Model** is enabled ([Figure 16.2 \(p. 861\)](#)), you have the option to hook a UDF in the **User-Defined Function Hooks** dialog box to customize the **Thickened Flame Model** parameters. Refer to [DEFINE_THICKENED_FLAME_MODEL](#) in the UDF manual for details.

Important

The **Thickened Flame Model** is available only for unsteady laminar or turbulent (LES/DES/SAS) flows, with **Species Transport** and **Volumetric Reactions** enabled.

For information about the theory behind the **Thickened Flame Model**, refer to [The Thickened Flame Model](#) in the Theory Guide.

Figure 16.2 The Species Model Dialog Box Displaying the Thickened Flame Model

16.1.3. Defining Properties for the Mixture and Its Constituent Species

As discussed in [Overview of User Inputs for Modeling Species Transport and Reactions](#) (p. 855), if you use a mixture material from the database, most mixture and species properties will already be defined. You may follow the procedures in this section to check the current properties, modify some of the properties, or set all properties for a brand-new mixture material that you are defining from scratch.

Remember that you will need to define properties for the mixture material and also for its constituent species. It is important that you define the mixture properties before setting any properties for the constituent species, since the species property inputs may depend on the methods you use to define the properties of the mixture. The recommended sequence for property inputs is as follows:

1. Define the mixture species, and reaction(s), and define physical properties for the mixture. Remember to click the **Change/Create** button when you are done setting properties for the mixture material.
2. Define physical properties for the species in the mixture. Remember to click the **Change/Create** button after defining the properties for each species.

These steps, all of which are performed in the [Create/Edit Materials Dialog Box](#) (p. 1882), are described in detail in this section.

Materials

16.1.3.1. Defining the Species in the Mixture

If you are using a mixture material from the database, the species in the mixture will already be defined for you. If you are creating your own material or modifying the species in an existing material, you will need to define them yourself.

In the **Create/Edit Materials** dialog box (*Figure 16.3 (p. 862)*), check that the **Material Type** is set to **mixture** and your mixture is selected in the **FLUENT Mixture Materials** list. Click the **Edit...** button to the right of **Mixture Species** to open the *Species Dialog Box* (p. 1909) (*Figure 16.4 (p. 863)*).

Figure 16.3 The Create/Edit Materials Dialog Box (Showing a Mixture Material)

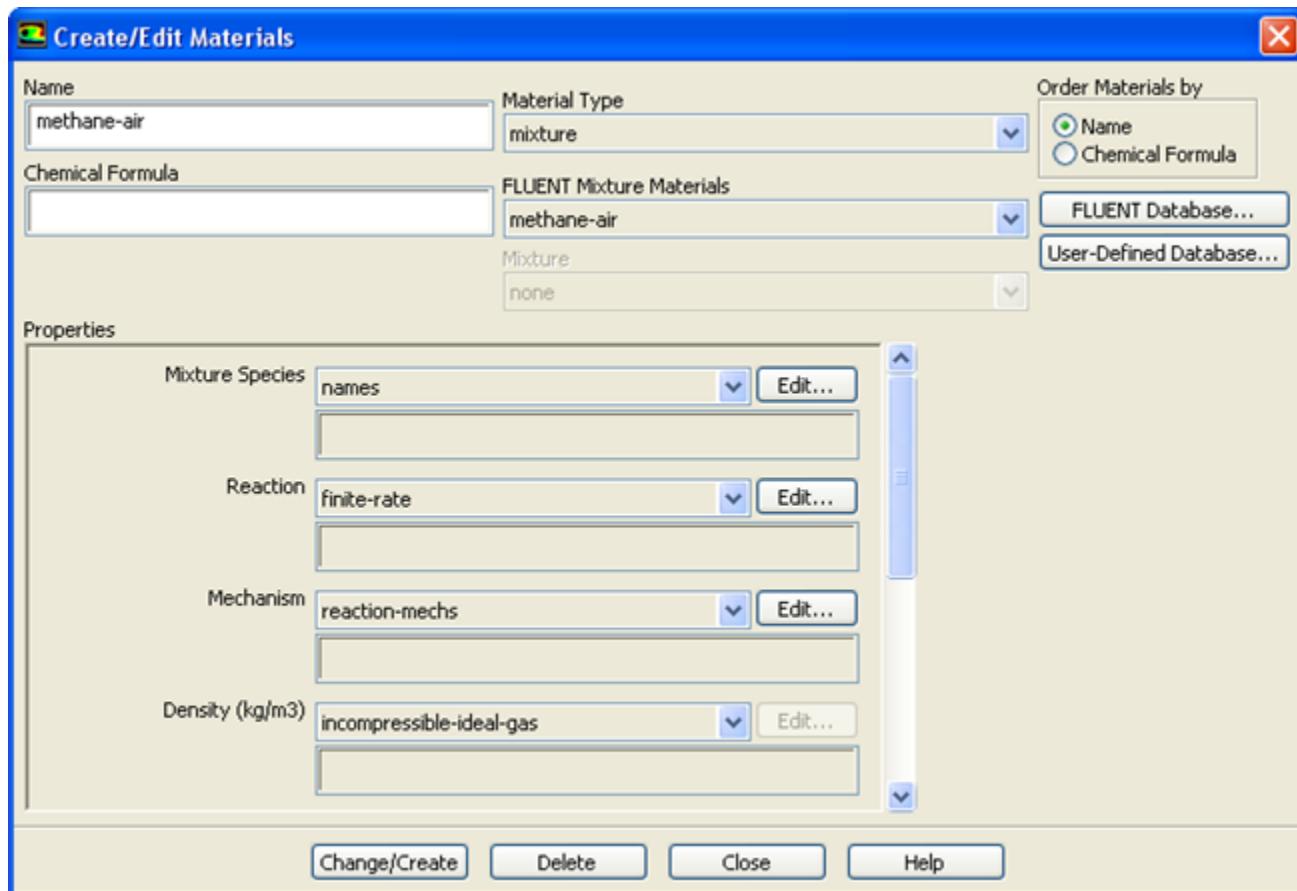

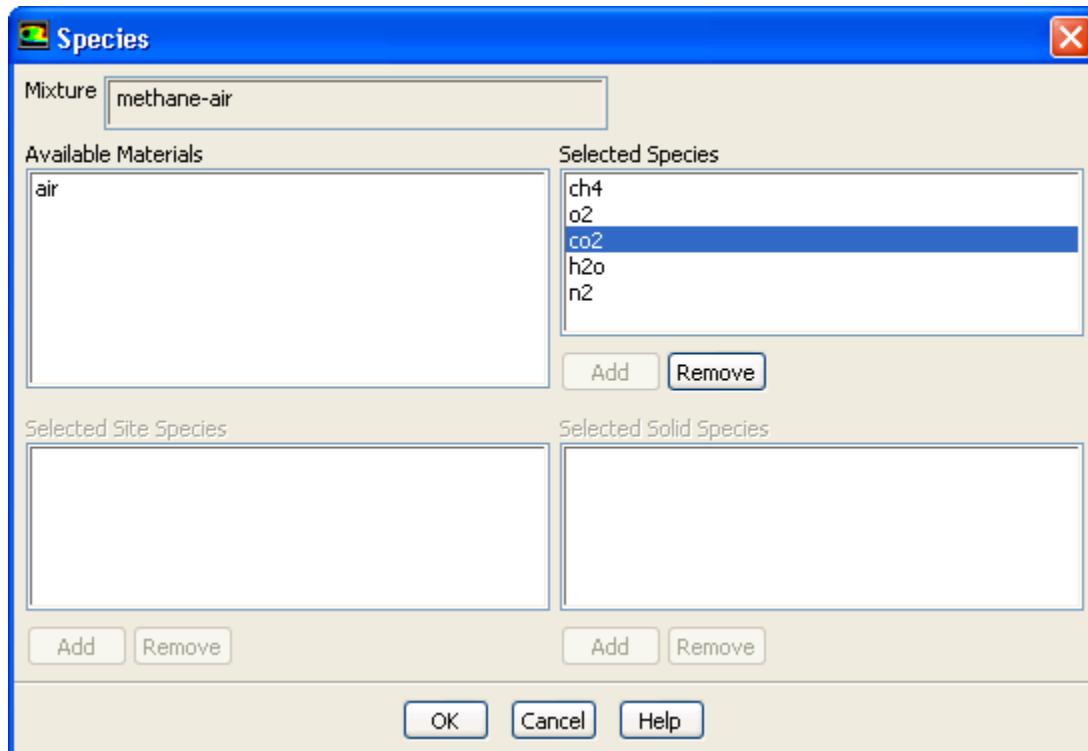

Figure 16.4 The Species Dialog Box

16.1.3.1.1. Overview of the Species Dialog Box

In the **Species** dialog box, the **Selected Species** list shows all of the fluid-phase species in the mixture. If you are modeling wall or particle surface reactions, the **Selected Solid Species** list will show all of the bulk solid species in the mixture. Solid species are species that are deposit to, or etch from, wall boundaries or discrete-phase particles (e.g., Si(s)) and do not exist as fluid-phase species. If you are modeling wall surface reactions with site balancing, where species adsorb onto the wall surface, react, and then desorb off the surface, the **Selected Site Species** list will show all of the site species in the mixture.

The use of solid and site species with wall surface reactions is described in *Wall Surface Reactions and Chemical Vapor Deposition* (p. 886). See *Particle Surface Reactions* (p. 892) for information about particle surface reactions.

Important

The order of the species in the **Selected Species** list is very important. ANSYS FLUENT considers the last species in the list to be the bulk species. You should therefore be careful to retain the most abundant species (by mass) as the last species when you add species to or delete species from a mixture material.

The **Available Materials** list shows materials that are available but not in the mixture. Generally, you will see air in this list, since air is always available by default.

16.1.3.1.2. Adding Species to the Mixture

If you are creating a mixture from scratch or starting from an existing mixture and adding some missing species, you will first need to load the desired species from the database (or create them, if they are

not present in the database) so that they will be available to the solver. You will need to close the **Species** dialog box before you begin, since it is a “modal” dialog box that will not allow you to do anything else when it is open. The procedure for adding species is as follows:

1. In the **Create/Edit Materials** dialog box, click the **Fluent Database...** button to open the **Fluent Database Materials** dialog box and copy the desired species, as described in [Copying Materials from the ANSYS FLUENT Database \(p. 407\)](#). Remember that the constituent species of the mixture are fluid materials, so you should select **fluid** as the **Material Type** in the **Fluent Database Materials** dialog box to see the correct list of choices. Note that available solid and site species (for surface reactions) are also contained in the **fluid** list.

Important

If you do not see the species you are looking for in the database, you can create a new fluid material for that species, following the instructions in [Creating a New Material \(p. 408\)](#), and then continue with step 2, below.

2. Re-open the **Species** dialog box. You will see that the fluid materials you copied from the database (or created) are listed in the **Available Materials** list.
3. To add a species to the mixture, select it in the **Available Materials** list and click the **Add** button below the **Selected Species** list (or below the **Selected Site Species** or **Selected Solid Species** list, to define a site or solid species). The species will be added to the end of the relevant list and removed from the **Available Materials** list.
4. Repeat the previous step for all the desired species. When you are finished, click the **OK** button.

Important

Adding a species to the list will alter the order of the species. You should be sure that the last species in the list is the bulk species, and you should check all cell and boundary zone conditions, under-relaxation factors, and other solution parameters that you have set, as described in detail in the following sections.

16.1.3.1.3. Removing Species from the Mixture

To remove a species from the mixture, simply select it in the **Selected Species** list (or the **Selected Site Species** or **Selected Solid Species** list) and click the **Remove** button below the list. The species will be removed from the list and added to the **Available Materials** list.

Important

Removing a species from the list will alter the order of the species. You should be sure that the last species in the list is the bulk species, and you should check any cell zone or boundary conditions, under-relaxation factors, or other solution parameters that you have set, as described in detail in the following sections.

16.1.3.1.4. Reordering Species

If you find that the last species in the **Selected Species** list is not the most abundant species (as it should be), you will need to rearrange the species to obtain the proper order.

1. Remove the bulk species from the **Selected Species** list. It will now appear in the **Available Species** list.
2. Add the species back in again. It will automatically be placed at the end of the list.

16.1.3.1.5. The Naming and Ordering of Species

As discussed previously, you should retain the most abundant species as the last one in the **Selected Species** list when you add or remove species. Additional considerations you should be aware of when adding and deleting species are presented here.

There are three characteristics of a species that identify it to the solver: name, chemical formula, and position in the list of species in the **Species** dialog box. Changing these characteristics will have the following effects:

- You can change the **Name** of a species (using the *Create/Edit Materials Dialog Box* (p. 1882), as described in *Renaming an Existing Material* (p. 406)) without any consequences.
- You should *never* change the given **Chemical Formula** of a species.
- You will change the order of the species list if you add or remove any species. When this occurs, all cell zone or boundary conditions, solver parameters, and solution data for species will be reset to the default values. (Solution data, cell zone or boundary conditions, and solver parameters for other flow variables will not be affected.) Thus, if you add or remove species you should take care to redefine species cell zone and boundary conditions and solution parameters for the newly defined problem. In addition, you should recognize that patched species concentrations or concentrations stored in any data file that was based on the original species ordering will be incompatible with the newly defined problem. You can use the data file as a starting guess, but you should be aware that the species concentrations in the data file may provide a poor initial guess for the newly defined model.

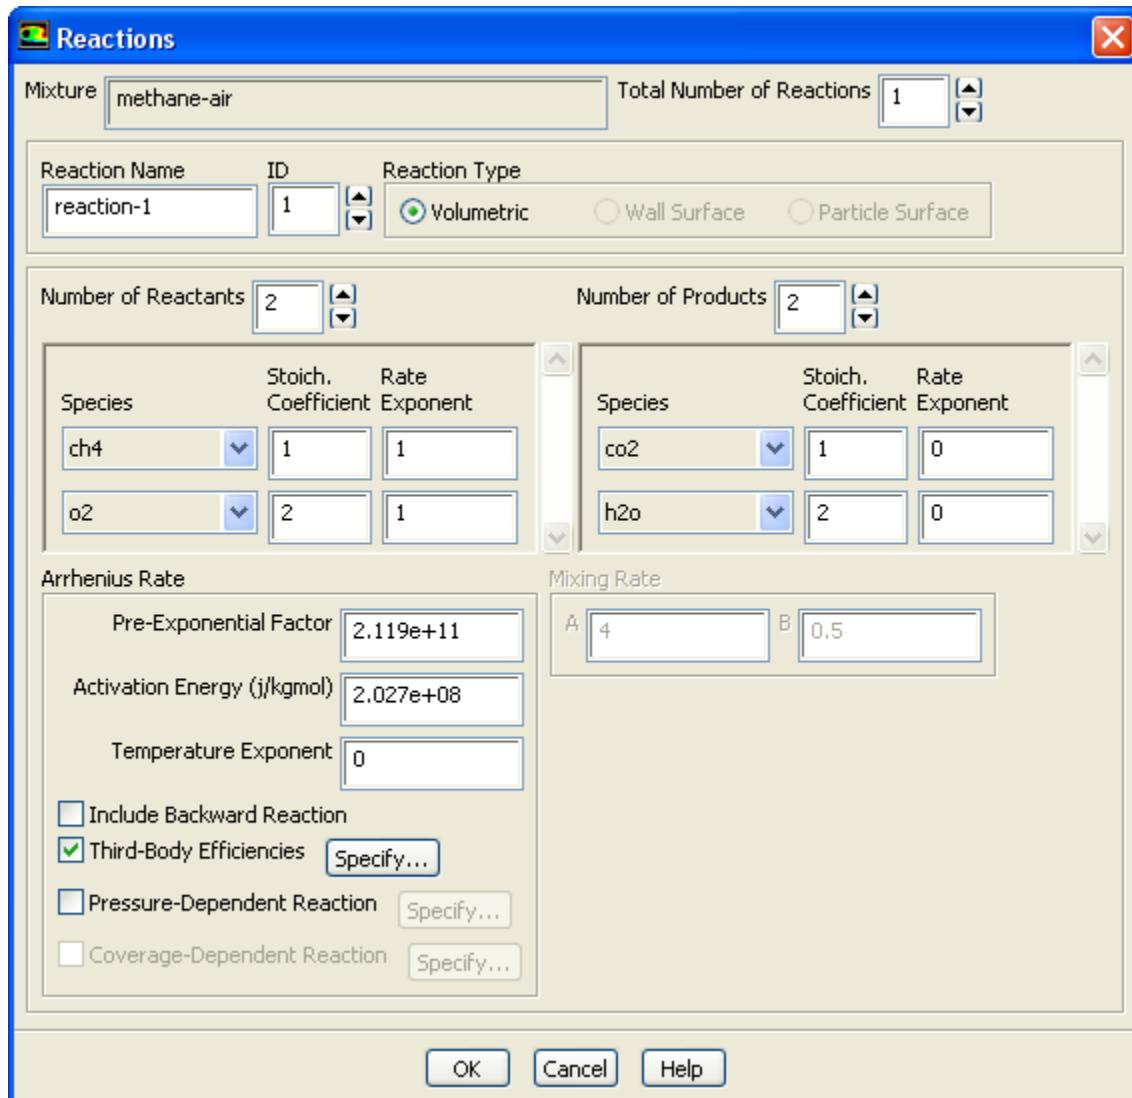

16.1.3.2. Defining Reactions

If your ANSYS FLUENT model involves chemical reactions, you can define the reactions in which the defined species participate. This will be necessary only if you are creating a mixture material from scratch, you have modified the species, or you want to redefine the reactions for some other reason.

Depending on which turbulence-chemistry interaction model you selected in the **Species Model** dialog box (see *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857)), the appropriate reaction model will be displayed in the **Reaction** drop-down list in the **Edit Material** dialog box. If you are using the **Laminar Finite-Rate** or **Eddy-Dissipation Concept** model, the reaction model will be **finite-rate**; if you are using the **Eddy-Dissipation** model, the reaction model will be **eddy-dissipation**; if you are using the **Finite-Rate/Eddy-Dissipation** model, the reaction model will be **finite-rate/eddy-dissipation**.

16.1.3.2.1. Inputs for Reaction Definition

To define the reactions, click the **Edit...** button to the right of **Reaction**. The **Reactions** dialog box (*Figure 16.5* (p. 866)) will open.

Figure 16.5 The Reactions Dialog Box

The steps for defining reactions are as follows:

1. Set the total number of reactions (volumetric reactions, wall surface reactions, and particle surface reactions) in the **Total Number of Reactions** field. Use the arrows to change the value, or type in the value and press **Enter**.

Note that if your model includes discrete-phase combusting particles, you should include the particulate surface reaction(s) (e.g., char burnout, multiple char oxidation) in the number of reactions *only* if you plan to use the multiple surface reactions model for surface combustion.

2. Specify the **Reaction Name** of the reaction you want to define.
3. Set the **ID** of the reaction you want to define. Again, if you type in the value be sure to press **Enter**.
4. If this is a fluid-phase reaction, keep the default selection of **Volumetric** as the **Reaction Type**. If this is a wall surface reaction (described in [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#)) or a particle surface reaction (described in [Particle Surface Reactions \(p. 892\)](#)), select **Wall Surface** or **Particle Surface** as the **Reaction Type**. See [User Inputs for Particle Surface Reactions \(p. 892\)](#) for further information about defining particle surface reactions.

5. Specify how many reactants and products are involved in the reaction by increasing the value of the **Number of Reactants** and the **Number of Products**. Select each reactant or product in the **Species** drop-down list and then set its stoichiometric coefficient and rate exponent in the appropriate **Stoich. Coefficient** and **Rate Exponent** fields. The stoichiometric coefficient is the constant $v'_{i,r}$ or $v''_{i,r}$ in [Equation 7–6](#) in the [Theory Guide](#) and the rate exponent is the exponent on the reactant or product concentration, $\eta'_{j,r}$ or $\eta''_{j,r}$ in [Equation 7–8](#) in the [Theory Guide](#).

There are two general classes of reactions that can be handled by the **Reactions** dialog box, so it is important that the parameters for each reaction are entered correctly. The classes of reactions are as follows:

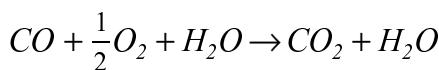

- Global forward reaction (no reverse reaction): Product species generally do not affect the forward rate, so the rate exponent for all products ($\eta''_{j,r}$) should be 0. For reactant species, set the rate exponent ($\eta'_{j,r}$) to the desired value. If such a reaction is not an elementary reaction, the rate exponent will generally not be equal to the stoichiometric coefficient ($v'_{i,r}$) for that species. An example of a global forward reaction is the combustion of methane:

where $v'_{CH_4} = 1$, $\eta'_{CH_4} = 0.2$, $v'_{O_2} = 2$, $\eta'_{O_2} = 1.3$, $v''_{CO_2} = 1$, $\eta''_{CO_2} = 0$, $v''_{H_2O} = 2$, and $\eta''_{H_2O} = 0$.

[Figure 16.5 \(p. 866\)](#) shows the coefficient inputs for the combustion of methane. See also the **methane-air** mixture material in the [FLUENT Database Materials Dialog Box \(p. 1890\)](#).

Note that, in certain cases, you may wish to model a reaction where product species affect the forward rate. For such cases, set the product rate exponent ($\eta''_{j,r}$) to the desired value. An example of such a reaction is the gas-shift reaction (see the **carbon-monoxide-air** mixture material in the [FLUENT Database Materials Dialog Box \(p. 1890\)](#)), in which the presence of water has an effect on the reaction rate:

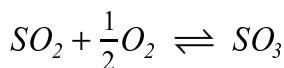

In the gas-shift reaction, the rate expression may be defined as:

$$k [CO] [O_2]^{1/4} [H_2O]^{1/2} \quad (16-2)$$

where $v'_{CO} = 1$, $\eta'_{CO} = 1$, $v'_{O_2} = 0.5$, $\eta'_{O_2} = 0.25$, $v''_{CO_2} = 1$, $\eta''_{CO_2} = 0$, $v''_{H_2O} = 0$, and $\eta''_{H_2O} = 0.5$.

- Reversible reaction: An elementary chemical reaction that assumes the rate exponent for each species is equivalent to the stoichiometric coefficient for that species. An example of an elementary reaction is the oxidation of SO_2 to SO_3 :

where $v'_{SO_2} = 1$, $\eta'_{SO_2} = 1$, $v'_{O_2} = 0.5$, $\eta'_{O_2} = 0.5$, $v''_{SO_3} = 1$, and $\eta''_{SO_3} = 1$.

See step 6 below for information about how to enable reversible reactions.

6. If you are using the laminar finite-rate, finite-rate/eddy-dissipation, Eddy-Dissipation Concept or PDF Transport model for the turbulence-chemistry interaction, enter the following parameters for the Arrhenius rate in the **Arrhenius Rate** group box:

Pre-Exponential Factor

(the constant A_r in [Equation 7–10](#) in the [Theory Guide](#)). The units of A_r must be specified such that the units of the molar reaction rate, $\hat{R}_{i,r}$ in [Equation 7–5](#) in the [Theory Guide](#), are moles/volume-time (e.g., kmol/m³·s) and the units of the volumetric reaction rate, R_i in [Equation 7–5](#) in the [Theory Guide](#), are mass/volume-time (e.g., kg/m³·s).

Important

It is important to note that if you have selected the British units system, the Arrhenius factor should still be input in SI units. This is because ANSYS FLUENT applies no conversion factor to your input of A_r (the conversion factor is 1.0) when you work in British units, as the correct conversion factor depends on your inputs for $v'_{i,r}$, β_r , etc.

Activation Energy

(the constant E_r in the forward rate constant expression, [Equation 7–10](#) in the [Theory Guide](#)).

Temperature Exponent

(the value for the constant β_r in [Equation 7–10](#) in the [Theory Guide](#)).

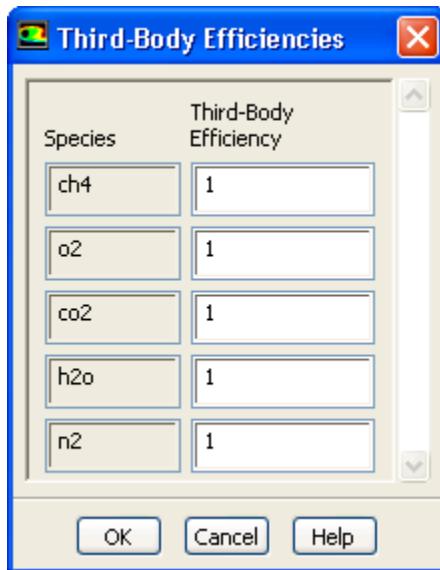

Third-Body Efficiencies

(the values for $\gamma_{j,r}$ in [Equation 7–9](#) in the [Theory Guide](#)). If you have accurate data for the efficiencies and want to include this effect on the reaction rate (i.e., include Γ in [Equation 7–8](#) in the [Theory Guide](#)), enable the **Third Body Efficiencies** option and click the **Specify...** button to open the *Third-Body Efficiencies Dialog Box* (p. 1914) ([Figure 16.6](#) (p. 869)).

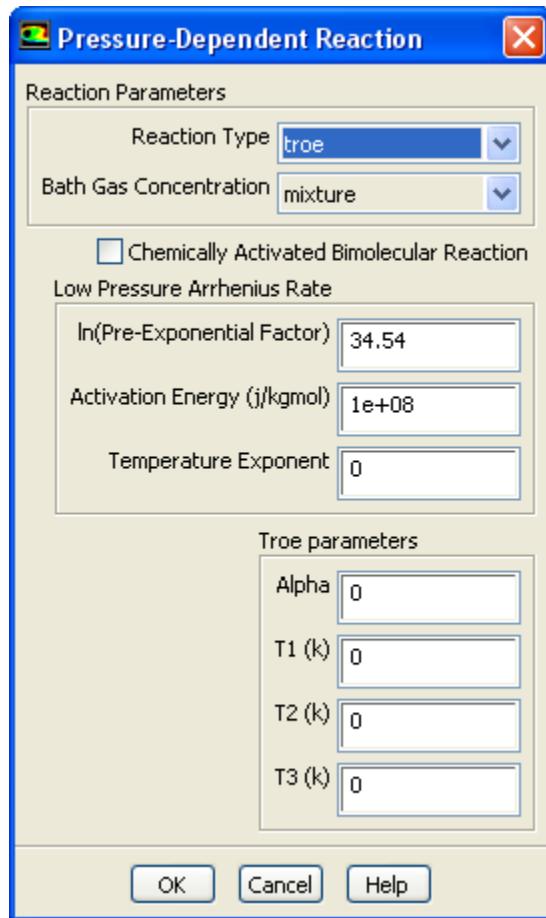

For each **Species** in the dialog box, specify the **Third-Body Efficiency**.

Important

It is not necessary to include the third-body efficiencies. You should not enable the **Third-Body Efficiencies** option unless you have accurate data for these parameters.

Figure 16.6 The Third-Body Efficiencies Dialog Box**Pressure-Dependent Reaction**

(if relevant) If you are using the laminar finite-rate or Eddy-Dissipation Concept model for turbulence-chemistry interaction, or have enabled the composition PDF transport model (see [Modeling a Composition PDF Transport Problem \(p. 975\)](#)), and the reaction is a pressure fall-off reaction (see [Pressure-Dependent Reactions](#) in the [Theory Guide](#)), enable the **Pressure-Dependent Reaction** option for the **Arrhenius Rate** and click the **Specify...** button to open the **Pressure-Dependent Reaction** dialog box ([Figure 16.7 \(p. 870\)](#)).

Figure 16.7 The Pressure-Dependent Reaction Dialog Box

Under **Reaction Parameters**, select the appropriate **Reaction Type** (**lindemann**, **troe**, or **sri**). See [Pressure-Dependent Reactions](#) in the [Theory Guide](#) for details about the three methods.

Next, specify if the **Bath Gas Concentration** ($[M]$) in [Equation 7-18](#) in the [Theory Guide](#)) is to be defined as the concentration of the **mixture**, or as the concentration of one of the mixture's constituent species, by selecting the appropriate item in the drop-down list.

Enabling the **Chemically Activated Bimolecular Reaction** option results in a net rate constant at any pressure being defined as [Equation 7-24](#) in the [Theory Guide](#).

The parameters you specified under **Arrhenius Rate** in the **Reactions** dialog box represent the high-pressure Arrhenius parameters. You can, however, specify values for the following parameters under **Low Pressure Arrhenius Rate**:

In(Pre-Exponential Factor)

(A_{low} in [Equation 7-16](#) in the [Theory Guide](#)) The pre-exponential factor A_{low} is often an extremely large number, so you will input the natural logarithm of this term.

Activation Energy

(E_{low} in [Equation 7-16](#) in the [Theory Guide](#))

Temperature Exponent

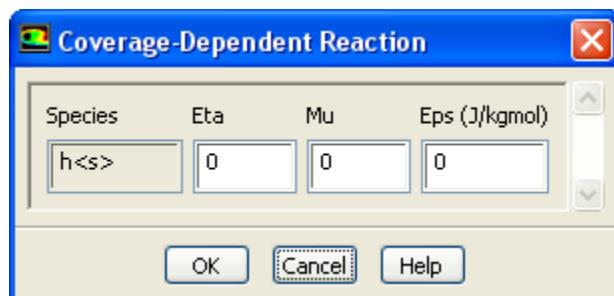

(β_{low} in [Equation 7-16](#) in the [Theory Guide](#))

If you selected **troe** for the **Reaction Type**, you can specify values for **Alpha**, **T1**, **T2**, and **T3** (α , T_1 , T_2 , and T_3 in [Equation 7–21](#) in the [Theory Guide](#)) under **Troe parameters**. If you selected **sri** for the **Reaction Type**, you can specify values for **a**, **b**, **c**, **d**, and **e** (a , b , c , d , and e in [Equation 7–22](#) in the [Theory Guide](#)) under **SRI parameters**.

Coverage Dependent Reaction

If you are modeling **Wall Surface** reactions with site-balancing and you have reaction rates that depend on site coverages, you can enable the **Coverage Dependent Reaction** option. Click **Specify...** to open the **Coverage Dependent Reaction** dialog box ([Figure 16.8 \(p. 871\)](#)) and input the coverage parameters.

Figure 16.8 The Coverage Dependent Reaction Dialog Box

In the **Coverage Dependent Reaction** dialog box, all the site species of the reaction will be present with a default value of 0 for all the parameters, corresponding to no surface coverage modification. Enter the relevant values of the parameters μ , ε , and η (as defined in [Equation 7–48](#) in the [Theory Guide](#)) for all the species for which the reaction has coverage dependence.

7. If you are using the laminar finite-rate, Eddy-Dissipation Concept or PDF Transport model for turbulence-chemistry interaction, and the reaction is reversible, enable the **Include Backward Reaction** option for the **Arrhenius Rate**. When this option is enabled, you will not be able to edit the **Rate Exponent** for the product species, which instead will be set to be equivalent to the corresponding product **Stoich. Coefficient**. If you do not wish to use ANSYS FLUENT's default values, or if you are defining your own reaction, you will also need to specify the standard-state enthalpy and standard-state entropy, to be used in the calculation of the backward reaction rate constant ([Equation 7–11](#) in the [Theory Guide](#)). Note that the reversible reaction option is not available for either the eddy-dissipation or the finite-rate/eddy-dissipation turbulence-chemistry interaction model.
8. If you are using the eddy-dissipation or finite-rate/eddy-dissipation model for turbulence-chemistry interaction, you can enter values for **A** and **B** under the **Mixing Rate** heading. These values should not be changed unless you have reliable data. In most cases you will use the default values.

A is the constant A in the turbulent mixing rate ([Equation 7–25](#) and [Equation 7–26](#) in the [Theory Guide](#)) when it is applied to a species that appears as a reactant in this reaction. The default setting of 4.0 is based on the empirically derived values given by Magnussen et al. [49] (p. 2369).

B is the constant B in the turbulent mixing rate ([Equation 7–26](#) in the [Theory Guide](#)) when it is applied to a species that appears as a product in this reaction. The default setting of 0.5 is based on the empirically derived values given by Magnussen et al. [49] (p. 2369).

9. Repeat steps 2–8 for each reaction you need to define. After defining all reactions, click **OK**.

16.1.3.2.2. Defining Species and Reactions for Fuel Mixtures

Quite often, combustion systems will include fuel that is not easily described as a pure species (such as CH₄ or C₂H₆). Complex hydrocarbons, including fuel oil or even wood chips, may be difficult to define in terms of such pure species. However, if you have available the heating value and the ultimate analysis (elemental composition) of the fuel, you can define an equivalent fuel species and an equivalent heat of formation for this fuel. Consider, for example, a fuel known to contain 50% C, 6% H, and 44% O by weight. Dividing by atomic weights, you can arrive at a “fuel” species with the molecular formula C_{4.17}H₆O_{2.75}. You can start from a similar, existing species or create a species from scratch, and assign it a molecular weight of 100.04 kg/kmol (4.17 × 12 + 6 × 1 + 2.75 × 16). The chemical reaction would be considered to be

You will need to set the appropriate stoichiometric coefficients for this reaction.

The heat of formation (or standard-state enthalpy) for the fuel species can be calculated from the known heating value ΔH since

$$\Delta H = \sum_{i=1}^N h_i^0 (v''_{i,r} - v'_{i,r}) \quad (16-4)$$

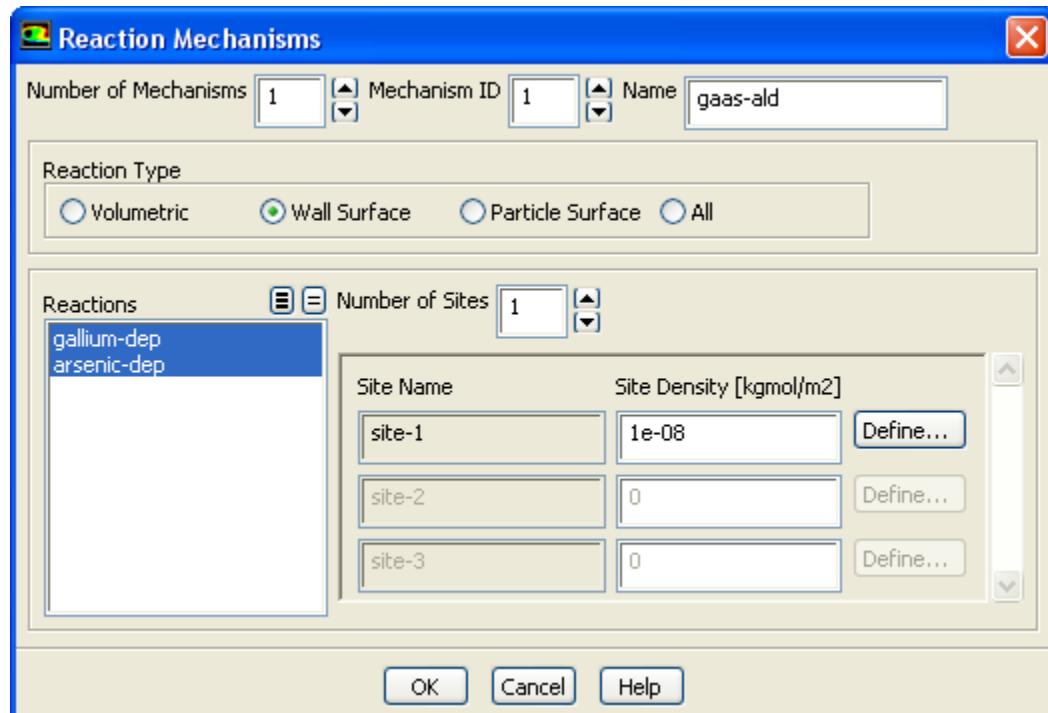

where h_i^0 is the standard-state enthalpy on a molar basis. Note the sign convention in [Equation 16-4 \(p. 872\)](#) : ΔH is negative when the reaction is exothermic.

16.1.3.3. Defining Zone-Based Reaction Mechanisms

If your ANSYS FLUENT model involves reactions that are confined to a specific area of the domain, you can define “reaction mechanisms” to enable different reactions selectively in different geometrical zones. You can create reaction mechanisms by selecting reactions from those defined in the **Reactions** dialog box and grouping them. You can then assign a particular mechanism to a particular zone.

16.1.3.3.1. Inputs for Reaction Mechanism Definition

To define a reaction mechanism, click the **Edit...** button to the right of **Mechanism**. The [Reaction Mechanisms Dialog Box \(p. 1917\)](#) ([Figure 16.9 \(p. 873\)](#)) will open.

Figure 16.9 The Reaction Mechanisms Dialog Box

The steps for defining a reaction mechanism are as follows:

1. Set the total number of mechanisms in the **Number of Mechanisms** field. Use the arrows to change the value, or type the value and press **Enter**.
2. Set the **Mechanism ID** of the mechanism you want to define. Again, if you type in the value, be sure to press **Enter**.
3. Specify the **Name** of the mechanism.
4. Select the type of reaction to add to the mechanism under **Reaction Type**. If you select **Volumetric**, the **Reactions** list will display all available fluid-phase reactions. If you select **Wall Surface** or **Particle Surface**, the **Reactions** list will display all available wall surface reactions (described in [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#)) or particle surface reactions (described in [Particle Surface Reactions \(p. 892\)](#)). If you select **All**, the **Reactions** list will display all available reactions. This option is meant for backward compatibility with ANSYS FLUENT 6.0 or earlier cases.
5. Select the reactions to be included in the mechanism.
 - For **Volumetric** or **Particle Surface** reactions, select available reactions for the mechanism in the **Reactions** list.
 - For **Wall Surface** reactions, use the following procedure:
 - a. Select available wall surface reactions for the mechanism in the **Reactions** list.
 - b. If any site species appear in the selected reaction(s), set the number of sites in the **Number of Sites** field. Use the arrows to change the value, or type the value and press **Enter**. See [Reaction-Diffusion Balance for Surface Chemistry](#) in the Theory Guide for details about site species in wall surface reactions.
 - c. If you specify a **Number of Sites** that is greater than zero, specify the properties of the site.

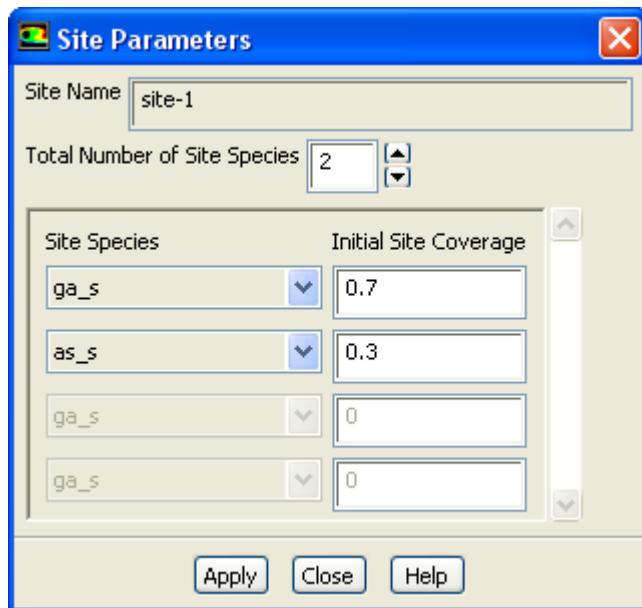

Site Name
(optional)

Site Density

(in kmol/m²) This value is typically in the range of 10^{-8} to 10^{-6} .

Click the **Define...** button. This will open the *Site Parameters Dialog Box* (p. 1918) (*Figure 16.10* (p. 874)), where you will define the parameters of the site species.

Figure 16.10 The Site Parameters Dialog Box

**Site Name**

is the optional name of the site that was specified in the **Reaction Mechanisms** dialog box.

Total Number of Site Species

is the number of adsorbed species that are to be modeled at the site. (Use the arrows to change the value, or type the value and press **Enter**.)

Under **Site Species**, select the appropriate species from the drop-down list(s) and specify the fractional **Initial Site Coverage** for each species. For steady-state calculations, it is recommended (though not strictly required) that the initial values of **Initial Site Coverage** sum to unity. For transient calculations, it is required that these values sum to unity.

Click **Apply** in the **Site Parameters** dialog box to store the new values.

- Repeat steps 2–5 for each reaction mechanism you need to define. When you are finished defining all reaction mechanisms, click **OK**.

16.1.3.4. Defining Physical Properties for the Mixture

When your ANSYS FLUENT model includes chemical species, the following physical properties must be defined, either by you or by the database, for the mixture material:

- density, which you can define using the gas law or as a volume-weighted function of composition
- viscosity, which you can define as a function of composition

- thermal conductivity and specific heat (in problems involving solution of the energy equation), which you can define as functions of composition
- mass diffusion coefficients and Schmidt number, which govern the mass diffusion fluxes ([Equation 7–2](#) and [Equation 7–3](#) in the [Theory Guide](#))

Detailed descriptions of these property inputs are provided in [Physical Properties](#) (p. 403).

Important

Remember to click the **Change/Create** button when you are done setting the properties of the mixture material. The properties that appear for each of the constituent species will depend on your settings for the properties of the mixture material. If, for example, you specify a composition-dependent viscosity for the mixture, you will need to define viscosity for each species.

16.1.3.5. Defining Physical Properties for the Species in the Mixture

For each of the fluid materials in the mixture, you (or the database) must define the following physical properties:

- molecular weight, which is used in the gas law and/or in the calculation of reaction rates and mole-fraction inputs or outputs
- standard-state (formation) enthalpy and reference temperature (in problems involving solution of the energy equation)
- viscosity, if you defined the viscosity of the mixture material as a function of composition
- thermal conductivity and specific heat (in problems involving solution of the energy equation), if you defined these properties of the mixture material as functions of composition
- standard-state entropy, if you are modeling reversible reactions
- thermal and momentum accommodation coefficients, if you have enabled the low-pressure boundary slip model.

Detailed descriptions of these property inputs are provided in [Physical Properties](#) (p. 403).

Important

Global reaction mechanisms with one or two steps inevitably neglect the intermediate species. In high-temperature flames, neglecting these dissociated species may cause the temperature to be overpredicted. A more realistic temperature field can be obtained by increasing the specific heat capacity for each species. Rose and Cooper [\[70\]](#) (p. 2370) have created a set of specific heat polynomials as a function of temperature.

The specific heat capacity for each species is calculated as

$$c_p(T) = \sum_{k=0}^m a_k T^k \quad (16-5)$$

The modified c_p polynomial coefficients (J/kg-K) from [64] (p. 2370) are provided in *Table 16.1: Modified Specific Heat Capacity (Cp) Polynomial Coefficients (J/kg-K)* (p. 876) and *Table 16.2: Modified Specific Heat Capacity (Cp) Polynomial Coefficients* (p. 876).

Table 16.1 Modified Specific Heat Capacity (Cp) Polynomial Coefficients (J/kg-K)

	N ₂	CH ₄	CO	H ₂
a_0	1.02705e+03	2.00500e+03	1.04669e+03	1.4147e+04

16.1.4. Setting up Coal Simulations with the Coal Calculator Dialog Box

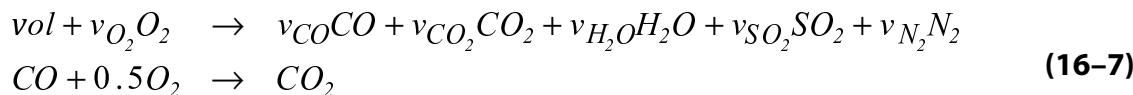

The **Coal Calculator** dialog box automates calculation and setting of the relevant input parameters for the Species, Discrete-Phase (DPM) and Pollutant models associated with coal combustion. It is available in the **Species** dialog box for the **Species Transport** model when the **Eddy-Dissipation** or **Finite-Rate/Eddy-Dissipation** turbulence-chemistry option is selected.

The inputs to the **Coal Calculator** dialog box are:

1. Coal **Proximate Analysis**, which is the mass fraction of **Volatile, Fixed Carbon, Ash** and **Moisture** in the coal. ANSYS FLUENT will normalize the mass fractions so that they sum to unity.
2. Coal **Ultimate Analysis**, which is the mass fraction of atomic **C, H, O, N** and optionally **S**, in the Dry-Ash-Free (DAF) coal. ANSYS FLUENT will normalize the mass fractions so that they sum to unity.
3. A choice of **One-step** or **Two-step** chemical mechanism. The one-step mechanism is,

The two-step mechanism involves oxidation of volatiles to CO in the first reaction and oxidation of CO to CO_2 in the second reaction:

The stoichiometric co-efficients in [Equation 16-6 \(p. 877\)](#) and [Equation 16-7 \(p. 877\)](#) are calculated from the ultimate and proximate analyses.

4. An option to **Include SO₂**. When this is enabled, an input for the atomic mass fraction of sulphur, **S**, appears in the ultimate analysis frame.
5. **Wet Combustion**, which will enable the DPM Wet Combustion option by default in all injections created after the **OK** button is clicked in the Coal Calculator dialog box.
6. The **Coal Particle Material Name**. A DPM combusting-particle material will be created with this name. The default name is *coal-particle*.
7. The **Coal As-Received HCV**, where HCV denotes the Higher Calorific Value.
8. **Volatile Molecular Weight** is the molecular weight of pure volatiles.
9. The **CO/CO₂ Split in Reaction 1 Products** can be used to specify the molar fraction of CO to CO_2 in the first reaction of [Equation 16-7 \(p. 877\)](#). The default value of 1 implies that all carbon is reacted to CO , with no CO_2 produced.
10. The **High Temperature Volatile Yield**. Enhanced devolatilization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction. To model this, the actual volatile fraction used is calculated as that specified in the **Proximate Analysis** input multiplied by the **High Temperature Volatile Yield**. The actual fixed carbon fraction is then calculated as one minus the sum of the actual volatile, ash and moisture fractions.
11. **Fraction of N in Char (DAF)**. This input is used in calculating the split of atomic nitrogen for the Fuel NOx model.
12. **Coal Dry Density** is used to calculate the volume fraction of liquid-water for the **Wet Combustion** option in the **Injections** dialog box.

When **OK** is clicked, ANSYS FLUENT makes the following changes:

1. A Mixture material is created, named *coal-volatiles-air*, with a one or two step reaction mechanism as specified in the **Mechanism** option. If the Fluid material species (O_2 , CO , CO_2 etc.) do not exist, they are created. A Fluid material called *coal-volatiles*, is also created with a standard state enthalpy calculated from the ultimate and proximate analyses, as-received HCV and volatile molecular weight.
2. A combusting-particle material is created with **Volatile Component Fraction** and **Combustible Fraction** calculated from the ultimate and proximate analyses. The discrete phase model (DPM) is enabled.
3. For the fuel NOx model, the default fuel species is set to *vol*, the char N conversion is set to *NO*, and the fuel NOx **Volatile** and **Char** mass fractions are set according to the ultimate and proximate compositions. Note that even though some of the default fuel NOx parameters are changed, the fuel NOx model itself is not enabled.

4. If **Wet Combustion** is selected, all subsequent injections that are created will have wet combustion enabled. The evaporation material will be set to *water-liquid*, and the volume fraction of water will be calculated from the **Moisture** mass fraction specified in the proximate analysis, and the **Coal Dry Density**. The **Density** for the combusting-particle in the **Create/Edit Materials** dialog box will also be set to **Coal Dry Density**.

16.1.5. Defining Cell Zone and Boundary Conditions for Species

You will need to specify the inlet mass fraction for all species in your simulation. In addition, for pressure outlets you will set species mass fractions to be used in case of backflow. At walls, ANSYS FLUENT will apply a zero-gradient (zero-flux) boundary condition for all species by default, although you can change each species boundary condition to a specified value. If you have surface reactions defined (see [Wall Surface Reactions and Chemical Vapor Deposition \(p. 886\)](#)), you can choose to enable wall-surface reactions and select the chemical mechanism. For fluid zones, you also have the option of specifying a reaction mechanism. Input of cell zone and boundary conditions is described in [Cell Zone and Boundary Conditions \(p. 211\)](#).

Important

- Non-reflecting boundary conditions (NRBCs) are not compatible with species transport models. They are mainly used to solve ideal-gas single species flow. For information about NRBCs, see [Non-Reflecting Boundary Conditions \(p. 355\)](#).
- Note that you will explicitly set mass fractions only for the first $N - 1$ species. The solver will compute the mass fraction of the last species by subtracting the total of the specified mass fractions from 1. If you want to explicitly specify the mass fraction of the last species, you must reorder the species in the list (in the [Create/Edit Materials Dialog Box \(p. 1882\)](#)), as described in [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#).

16.1.5.1. Diffusion at Inlets with the Pressure-Based Solver

For the pressure-based solver in ANSYS FLUENT, the net transport of species at inlets consists of both convection and diffusion components. The convection component is fixed by the specified inlet species mass or mole fraction, whereas the diffusion component depends on the gradient of the computed species concentration field (which is not known a priori). At very small convective inlet velocities, for example when modeling perforated combustion liners with an inlet, substantial mass can be gained or lost through the inlet due to diffusion. For this reason, inlet diffusion is disabled by default, but can be enabled with the **Inlet Diffusion** option in the **Species Model** dialog box.

Models → Species → Edit...

16.1.6. Defining Other Sources of Chemical Species

You can define a source or sink of a chemical species within the computational domain by defining a source term in the **Fluid** dialog box. You may choose this approach when species sources exist in your problem but you do not want to model them through the mechanism of chemical reactions. [Defining Mass, Momentum, Energy, and Other Sources \(p. 257\)](#) describes the procedures you would follow to define species sources in your ANSYS FLUENT model. If the source is not a constant, you can use a user-defined function. See the [UDF Manual](#) for details about user-defined functions.

16.1.7. Solution Procedures for Chemical Mixing and Finite-Rate Chemistry

While many simulations involving chemical species may require no special procedures during the solution process, you may find that one or more of the solution techniques noted in this section helps to accelerate the convergence or improve the stability of more complex simulations. The techniques outlined below may be of particular importance if your problem involves many species and/or chemical reactions, especially when modeling combusting flows.

16.1.7.1. Stability and Convergence in Reacting Flows

Obtaining a converged solution in a reacting flow can be difficult for a number of reasons. First, the impact of the chemical reaction on the basic flow pattern may be strong, leading to a model in which there is strong coupling between the mass/momentum balances and the species transport equations. This is especially true in combustion, where the reactions lead to a large heat release and subsequent density changes and large accelerations in the flow. All reacting systems have some degree of coupling, however, when the flow properties depend on the species concentrations. These coupling issues are best addressed by the use of a two-step solution process, as described below, and by the use of under-relaxation as described in [Setting Under-Relaxation Factors \(p. 1323\)](#).

A second convergence issue in reacting flows involves the magnitude of the reaction source term. When the ANSYS FLUENT model involves very rapid reaction rates (reaction time scales are much faster than convection and diffusion time scales), the solution of the species transport equations becomes numerically difficult. Such systems are termed “stiff” systems. Stiff systems with laminar chemistry can be solved using either the pressure-based solver with the **Stiff Chemistry Solver** option enabled, or the density-based solver (see [Solution of Stiff Laminar Chemistry Systems \(p. 880\)](#)). The laminar chemistry model may also be used for turbulent flames, where turbulence-chemistry interactions are neglected. However, for such flames, the Eddy-Dissipation Concept or PDF Transport models, which account for turbulence-chemistry interactions, may be a better choice.

16.1.7.2. Two-Step Solution Procedure (Cold Flow Simulation)

Solving a reacting flow as a two-step process can be a practical method for reaching a stable converged solution to your ANSYS FLUENT problem. In this process, you begin by solving the flow, energy, and species equations with reactions disabled (the “cold-flow”, or unreacting flow). When the basic flow pattern has thus been established, you can re-enable the reactions and continue the calculation. The cold-flow solution provides a good starting solution for the calculation of the combusting system. This two-step approach to combustion modeling can be accomplished using the following procedure:

1. Set up the problem including all species and reactions of interest.
2. Temporarily disable reaction calculations by turning off **Volumetric** in the [Species Model Dialog Box \(p. 1814\)](#).

 **Models** →  **Species** → **Edit...**

3. Disable calculation of the product species in the [Equations Dialog Box \(p. 2054\)](#).

 **Solution Controls** → **Equations...**

4. Calculate an initial (cold-flow) solution. (Note that it is generally not productive to obtain a fully converged cold-flow solution unless the non-reacting solution is also of interest to you.)
5. Enable the reaction calculations by turning on **Volumetric** again in the [Species Model Dialog Box \(p. 1814\)](#).

6. Enable all equations in the Equations dialog box. If you are using the laminar finite-rate, finite-rate/eddy-dissipation, Eddy-Dissipation Concept or PDF Transport model for turbulence-chemistry interaction, you may need to patch an ignition source (as described in *Ignition in Combustion Simulations* (p. 880)).

16.1.7.3. Density Under-Relaxation

One of the main reasons a combustion calculation can have difficulty converging is that large changes in temperature cause large changes in density, which can, in turn, cause instabilities in the flow solution. When you use the pressure-based solver, ANSYS FLUENT allows you to under-relax the change in density to alleviate this difficulty. The default value for density under-relaxation is 1, but if you encounter convergence trouble you may wish to reduce this to a value between 0.5 and 1 (in the **Solution Controls** task page).

16.1.7.4. Ignition in Combustion Simulations

If you introduce fuel to an oxidant, spontaneous ignition does not occur unless the temperature of the mixture exceeds the activation energy threshold required to maintain combustion. This physical issue manifests itself in an ANSYS FLUENT simulation as well. If you are using the laminar finite-rate, finite-rate/eddy-dissipation, Eddy-Dissipation Concept or PDF Transport model for turbulence-chemistry interaction, you have to supply an ignition source to initiate combustion. This ignition source may be a heated surface or inlet mass flow that heats the gas mixture above the required ignition temperature. Often, however, it is the equivalent of a spark: an initial solution state that causes combustion to proceed. You can supply this initial spark by patching a hot temperature into a region of the ANSYS FLUENT model that contains a sufficient fuel/air mixture for ignition to occur.

Solution Initialization → Patch...

Depending on the model, you may need to patch both the temperature and the fuel/ oxidant/product concentrations to produce ignition in your model. The initial patch has no impact on the final steady-state solution—no more than the location of a match determines the final flow pattern of the torch that it lights. See *Patching Values in Selected Cells* (p. 1351) for details about patching initial values.

16.1.7.5. Solution of Stiff Laminar Chemistry Systems

When modeling stiff laminar flames with the laminar finite-rate model, you can either use the pressure-based solver with the **Stiff Chemistry Solver** option enabled as seen in the *Species Model Dialog Box* (p. 1814) (*Figure 16.1* (p. 858)), or the density-based solver.

When using the pressure-based solver for unsteady simulations, the **Stiff Chemistry Solver** option applies a fractional step algorithm. In the first fractional step, the chemistry in each cell is reacted at constant pressure for the flow time-step, using the ISAT integrator. In the second fractional step, the convection and diffusion terms are treated just as in a non-reacting simulation.

For steady simulations using the pressure-based solver, the **Stiff Chemistry Solver** option approximates the reaction rate R_i in the species transport equation (see *Equation 7–5* in the *Theory Guide*) as,

$$R_i^* = \frac{1}{\tau} \int_0^\tau R_i dt \quad (16-8)$$

where τ is an appropriate time-step. Note that as τ tends to zero the approximation becomes exact but the stiff numerics will cause the pressure-based solver to diverge. On the other hand, as τ tends to infinity the approximation becomes increasingly inaccurate.

finity, the approximated reaction rate R_i^* tends to zero and, while the numerical stiffness is alleviated, there is no reaction. In ANSYS FLUENT, the default value for τ is set to one-tenth of the minimum convective or diffusive time-scale in the cell. This value was found to be sufficiently accurate and robust, although it can be modified using the solve/set/stiff-chemistry text command. ISAT is employed to integrate the stiff chemistry in [Equation 16–8 \(p. 880\)](#).

Details about the ISAT algorithm may be found in [Particle Reaction](#) in the Theory Guide and [Using ISAT Efficiently \(p. 989\)](#). For efficient and accurate use of ISAT, a review of this section is highly recommended.

Choosing the density-based implicit solver can provide further solution stability by enabling the **Stiff Chemistry Solver** option. This option allows a larger stable Courant (CFL) number specification, although additional calculations are required to calculate the eigenvalues of the chemical Jacobian [99] (p. 2372). When enabling the stiff-chemistry solver, the following must be specified:

- **Temperature Positivity Rate Limit:** limits new temperature changes by this factor multiplied by the old temperature. Its default value is 0.2.
- **Temperature Time Step Reduction:** limits the local CFL number when the temperature is changing too rapidly. Its default value is 0.25.
- **Max. Chemical Time Step Ratio:** limits the local CFL number when the chemical time scales (eigenvalues of the chemical Jacobian) become too large to maintain a well-conditioned matrix. Its default value is 0.9.

If the density-based implicit solver is used, then the stiff-chemistry solver can be enabled by using the text command:

```
solve → set → stiff-chemistry
```

You will be prompted to specify the following:

- Positivity Rate Limit (for temperature): limits new temperature changes by this factor multiplied by the old temperature. Its default value is 0.2.
- Temperature time-step reduction factor: limits the local CFL number when the temperature is changing too rapidly. Its default value is 0.25.
- Maximum allowable time-step/chemical-time-scale ratio: limits the local CFL number when the chemical time scales (eigenvalues of the chemical Jacobian) become too large to maintain a well-conditioned matrix. Its default value is 0.9.

The default values of these parameters are applicable in most cases.

16.1.7.6. Eddy-Dissipation Concept Model Solution Procedure

Due to the high computational expense of the Eddy-Dissipation Concept model, it is recommended that you use the following procedure to obtain a solution using the pressure-based solver:

1. Calculate an initial solution using the equilibrium Non-premixed or Partially-premixed model (see [Modeling Non-Premixed Combustion \(p. 901\)](#) and [Modeling Partially Premixed Combustion \(p. 969\)](#)).
2. Import a CHEMKIN format reaction mechanism (see [Importing a Volumetric Kinetic Mechanism in CHEMKIN Format \(p. 883\)](#)).
3. Enable the reaction calculations by turning on **Volumetric Reactions** in the **Species Model** dialog box and selecting **Eddy-Dissipation Concept** under **Turbulence-Chemistry Interaction**. Select the mechanism that you just imported as the **Mixture Material**.

4. Set the species boundary conditions.

 **Boundary Conditions**

5. Disable the flow and turbulence and solve for the species and temperature only.
6. Enable all equations and iterate to convergence. Note that the default numerical parameters for the solution of the Eddy-Dissipation Concept equations are set to provide maximum robustness with slowest convergence. The convergence rate can be increased by setting the Acceleration Factor in the **Species** dialog box or with the text command:

```
define → models → species → set-turb-chem-interaction
```

The Acceleration Factor can be set from 0 (slow but stable) to 1 (fast but least stable).

16.1.8. Postprocessing for Species Calculations

ANSYS FLUENT can report chemical species as mass fractions, mole fractions, and molar concentrations. You can also display laminar and effective mass diffusion coefficients. The following variables are available for postprocessing of species transport and reaction simulations:

- **Mass fraction of species-n**
- **Mole fraction of species-n**
- **Molar Concentration of species-n**
- **Lam Diff Coef of species-n**
- **Eff Diff Coef of species-n**
- **Thermal Diff Coef of species-n**
- **Enthalpy of species-n** (pressure-based solver calculations only)
- **species-n Source Term** (density-based solver calculations only)
- **Relative Humidity**
- **TFM Thickening Factor** (Thickened Flame Model only)
- **TFM Omega** (Thickened Flame Model only)
- **TFM Thickening Factor** (turbulent cases (LES/DES/SAS) with Thickened Flame Model only)
- **Laminar Flame Speed** (Thickened Flame Model only)
- **Laminar Flame Thickness** (Thickened Flame Model only)
- **Cell Time Scale** (Eddy-Dissipation Concept and Laminar finite-rate stiff-chemistry only)
- **Fine Scale Mass fraction of species-n** (Eddy-Dissipation Concept model only)
- **EDC Cell Volume Fraction** (Eddy-Dissipation Concept model only)
- **Fine Scale Temperature** (Eddy-Dissipation Concept model only)
- **Net Rate of species-n** (Eddy-Dissipation Concept and Laminar finite-rate stiff-chemistry only)
- **Kinetic Rate of Reaction-n**
- **Turbulent Rate of Reaction-n**
- **Liquid species mass fraction of species-n** (solidification and melting model only)

- **Heat of Reaction**

These variables are contained in the **Species...**, **Temperature...**, and **Reactions...** categories of the variable selection drop-down list that appears in postprocessing dialog boxes. See [Field Function Definitions \(p. 1653\)](#) for a complete list of flow variables, field functions, and their definitions. [Displaying Graphics \(p. 1499\)](#) and [Reporting Alphanumeric Data \(p. 1633\)](#) explain how to generate graphics displays and reports of data.

16.1.8.1. Averaged Species Concentrations

Averaged species concentrations at inlets and exits, and across selected planes (i.e., surfaces that you have created using the **Surface** menu items) within your model can be obtained using the [Surface Integrals Dialog Box \(p. 2188\)](#), as described in [Surface Integration \(p. 1644\)](#).

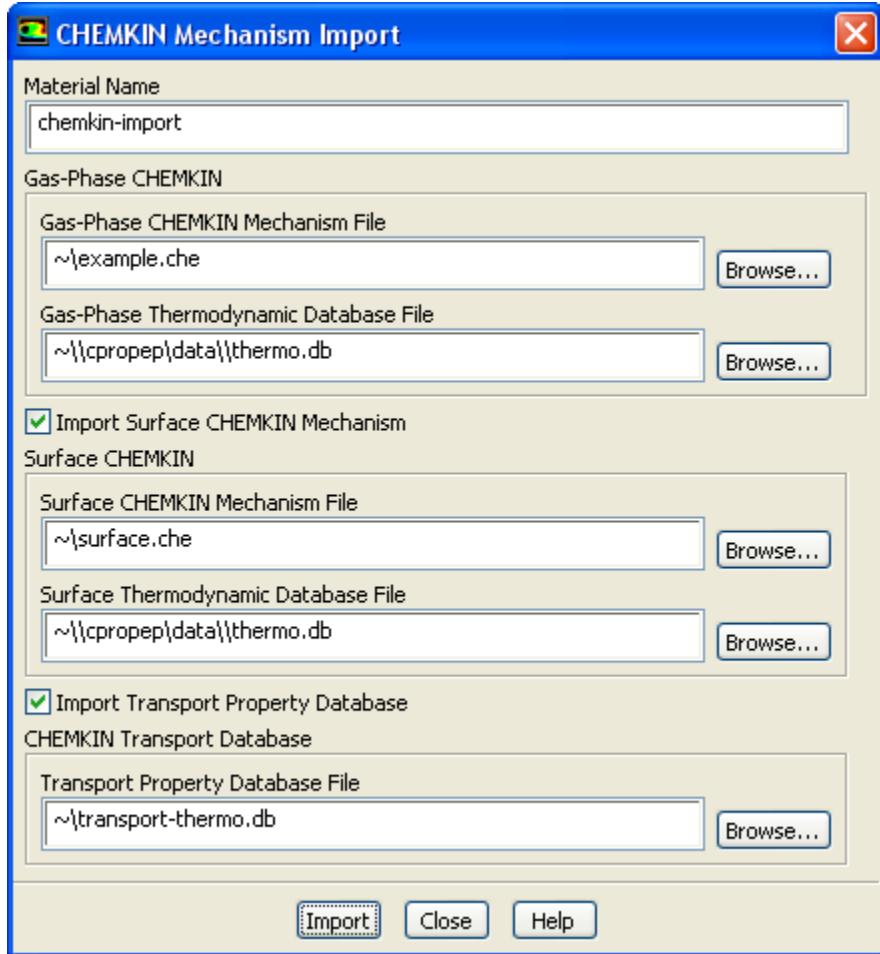

◆ Reports →  Surface Integrals → Set Up...

Select the **Molar Concentration of species-n** for the appropriate species in the **Field Variable** drop-down list.

16.1.9. Importing a Volumetric Kinetic Mechanism in CHEMKIN Format

If you have a gas-phase chemical mechanism in CHEMKIN format, you can import the mechanism file into ANSYS FLUENT using the **CHEMKIN Mechanism Import** dialog box ([Figure 16.11 \(p. 884\)](#)).

File → Import → **CHEMKIN Mechanism...**

Figure 16.11 The CHEMKIN Mechanism Import Dialog Box for Volumetric Kinetics

In the **CHEMKIN Mechanism Import** dialog box

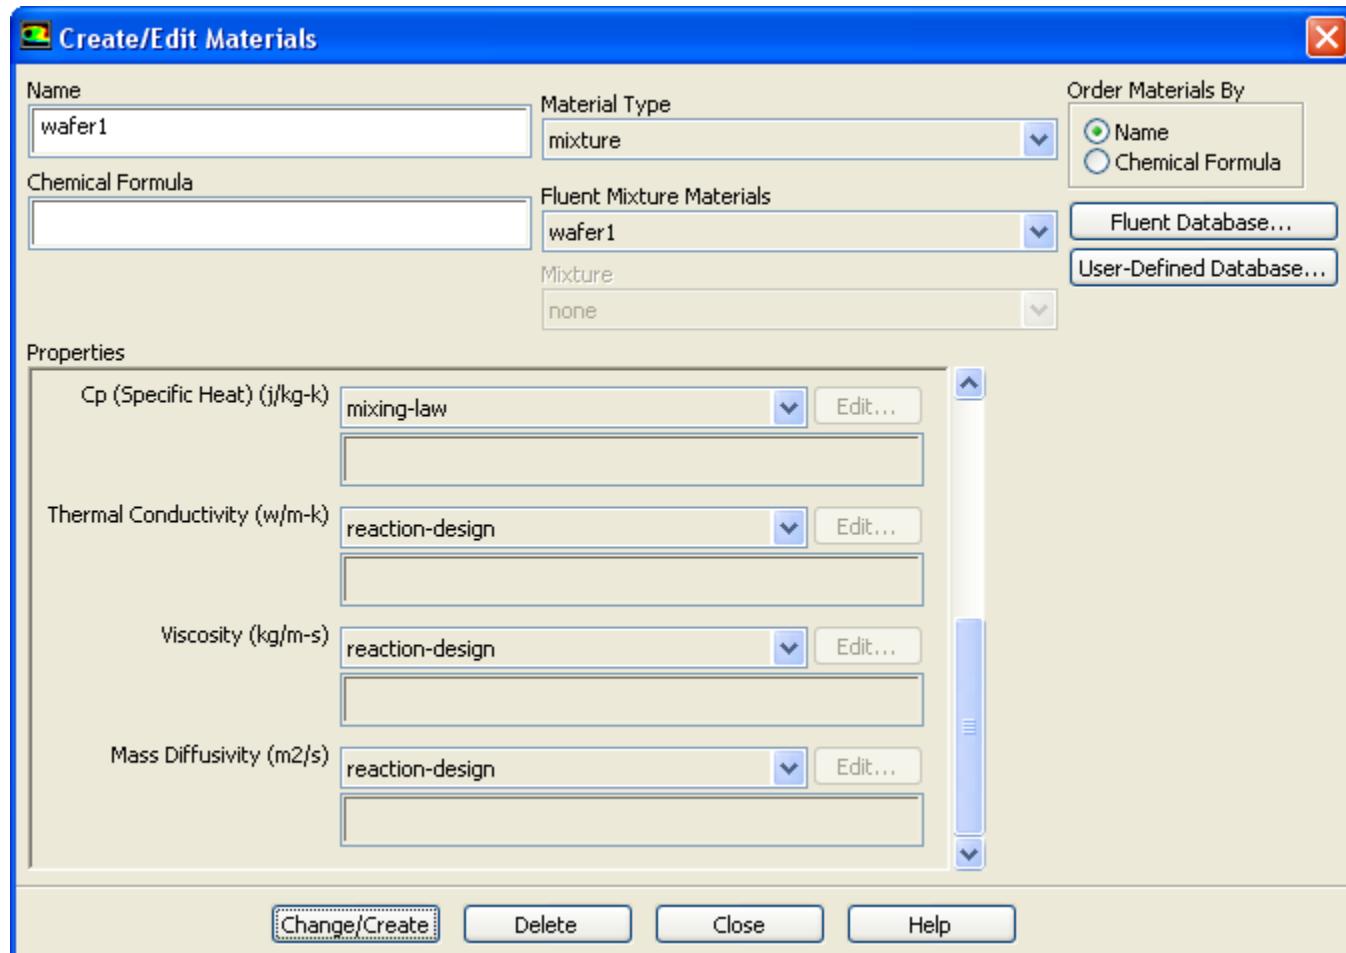

1. Enter a name for the chemical mechanism under **Material Name**.
2. Enter the path to the CHEMKIN file (e.g., *path/ file.che*) under **Gas-Phase CHEMKIN Mechanism File**.
3. Specify the location of the **Gas-Phase Thermodynamic Database File** if the default thermodynamic database file, (thermo .db), does not contain all the gas-phase species in the CHEMKIN mechanism. The format for thermo .db is detailed in the CHEMKIN manual [41] (p. 2369).
4. (Optional). Import transport properties by enabling the **Import Transport Property Database** and entering the path to the CHEMKIN transport file. ANSYS FLUENT will enable mixture-averaged multi-component diffusion and set the Lennard-Jones kinetic theory parameters for all the species in the imported CHEMKIN mechanism. If you would like to use Stefan-Maxwell diffusion, enable the **Full Multicomponent Diffusion** in the **Species** dialog box.

If you want to use KINetics transport properties, you must first enable the **CHEMKIN-CFD from Reaction Design** option in the **Species** dialog box (Figure 16.1 (p. 858)). Once a file with KINetics transport properties is read, ANSYS FLUENT will create a material with the specified name, which will contain the data for the species and reactions, and add it to the list of available **Mixture Materials** in the *Create/Edit Materials Dialog Box* (p. 1882). For material properties such as **Specific Heat, Viscosity, Thermal Conductivity, Mass Diffusivity**, and **Thermal Diffusion**, listed in the *Create/Edit Materials* dialog box, the option **reaction-design** will appear in the drop-down list of

each of the properties (*Figure 16.12 (p. 885)*), allowing you to use material property values computed by KINetics.

Note that when **Full Multicomponent Diffusion** is enabled in the **Species** dialog box, KINetics returns full multicomponent diffusivities. If **Full Multicomponent Diffusion** is disabled, KINetics returns mixture averaged mass diffusivities for each species.

Figure 16.12 The Material Dialog Box When Importing CHEMKIN Transport Properties

Note that since ANSYS FLUENT does not solve for the last species, you should ensure that the last species in the CHEMKIN mechanism species list is the bulk species. If not, edit the CHEMKIN mechanism file before importing it into ANSYS FLUENT, and move the bulk species (i.e. the species in your system with the largest total mass) to the end of the species list.

5. Click the **Import** button.

Important

Note that the CHEMKIN import facility does not provide full compatibility with all CHEMKIN rate formulations and that to access more complete functionality, you should consider the KINetics module option described in *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857).

For information on importing a surface kinetic mechanism in CHEMKIN format, see [Importing a Surface Kinetic Mechanism in CHEMKIN Format \(p. 889\)](#).

16.2. Wall Surface Reactions and Chemical Vapor Deposition

For gas-phase reactions, the reaction rate is defined on a volumetric basis and the rate of creation and destruction of chemical species becomes a source term in the species conservation equations. Heterogeneous surface reactions create sources (and sinks) of chemical species in the gas-phase as well, but also alter surface coverages for surface site reactions, and may deposit or etch species for bulk (solid) reactions.

For more information about the theoretical background of wall surface reactions and chemical vapor depositions, see [Wall Surface Reactions and Chemical Vapor Deposition](#) in the [Theory Guide](#). Information about using wall surface reactions is presented in the following subsections:

- 16.2.1. Overview of Surface Species and Wall Surface Reactions
- 16.2.2. User Inputs for Wall Surface Reactions
- 16.2.3. Including Mass Transfer To Surfaces in Continuity
- 16.2.4. Wall Surface Mass Transfer Effects in the Energy Equation
- 16.2.5. Modeling the Heat Release Due to Wall Surface Reactions
- 16.2.6. Solution Procedures for Wall Surface Reactions
- 16.2.7. Postprocessing for Surface Reactions
- 16.2.8. Importing a Surface Kinetic Mechanism in CHEMKIN Format

16.2.1. Overview of Surface Species and Wall Surface Reactions

ANSYS FLUENT treats chemical species adsorbed and desorbed, as well as those deposited into or etched from the bulk solid surfaces as distinct from the same chemical species in the gas. Similarly, surface reactions are defined distinctly and treated differently than gas-phase reactions involving the same chemical species.

Surface reactions can be limited so that they occur on only some of the wall boundaries (while the other wall boundaries remain free of surface reaction). The surface reaction rate is defined and computed per unit surface area, in contrast to the fluid-phase reactions, which are based on unit volume.

16.2.2. User Inputs for Wall Surface Reactions

The basic steps for setting up a problem involving wall surface reactions are the same as those presented in [Overview of User Inputs for Modeling Species Transport and Reactions \(p. 855\)](#) for setting up a problem with only fluid-phase reactions, with a few additions:

1. In the [Species Model Dialog Box \(p. 1814\)](#):

 **Models** →  **Species** → **Edit...**

- a. Enable **Species Transport**, select **Volumetric** and **Wall Surface** under **Reactions**, and specify the **Mixture Material**. See [Enabling Species Transport and Reactions and Choosing the Mixture Material \(p. 857\)](#) for details about this procedure, and [Mixture Materials \(p. 856\)](#) for an explanation of the mixture material concept.
- b. (optional) If you want to model the heat release due to wall surface reactions, enable the **Heat of Surface Reactions** option.
- c. (optional) If you want to include the effect of surface mass transfer in the continuity equation, enable the **Mass Deposition Source** option.

- d. To control the robustness and the convergence speed, enter a value between 0 and 1 for the **Aggressiveness Factor**. A value of 0 (the default) is the most robust, but results in the slowest convergence.
 - e. (optional) If you are using the pressure-based solver and you want to include species diffusion effects in the energy equation, enable the **Diffusion Energy Source** option. See [Wall Surface Mass Transfer Effects in the Energy Equation \(p. 888\)](#) for details.
 - f. (optional, but recommended for CVD) If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, enable the **Full Multicomponent Diffusion** or **Thermal Diffusion** option. See [Full Multicomponent Diffusion \(p. 459\)](#) for details.
2. Check and/or define the properties of the mixture. See [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#).

Materials

Mixture properties include the following:

- species in the mixture
- reactions
- other physical properties (e.g., viscosity, specific heat)

Important

- You will find all species (including the solid/bulk and site species) in the list of **Fluent Fluid Materials**. For a deposited species such as Si, you will need both Si(g) and Si(s) in the materials list for the **fluid** material type.
 - Note that the *final* gas-phase species named in the **Selected Species** list should be the carrier gas. This is because ANSYS FLUENT will not solve the transport equation for the final species. Note also that any reordering, adding or deleting of species should be handled with caution, as described in [Reordering Species \(p. 864\)](#).
3. Check and/or set the properties of the individual species in the mixture. (See [Defining Properties for the Mixture and Its Constituent Species \(p. 861\)](#).) Note that if you are modeling the heat of surface reactions, you should be sure to check (or define) the formation enthalpy for each species.
4. Set species boundary conditions.

Boundary Conditions

In addition to the boundary conditions described in [Defining Cell Zone and Boundary Conditions for Species \(p. 878\)](#), you will first need to indicate whether or not surface reactions are in effect on each wall. If so, you will then need to assign a reaction mechanism to the wall. To enable the effect of surface reaction on a wall, enable the **Reaction** option in the **Species** section of the **Wall** dialog box.

Important

If you have enabled the global **Low-Pressure Boundary Slip** option in the [Viscous Model Dialog Box](#) (p. 1778), the **Shear Condition** for each wall will be reset to **No Slip** even though the slip model will be in effect. Note that the **Low-Pressure Boundary Slip** option is available only when the **Laminar** model is selected in the [Viscous Model](#) dialog box.

See [Inputs at Wall Boundaries](#) (p. 313) for details about boundary condition inputs for walls. See [User Inputs for Porous Media](#) (p. 235) for details about boundary condition inputs for porous media.

16.2.3. Including Mass Transfer To Surfaces in Continuity

In the surface reaction boundary condition described above, the effects of the wall normal velocity or bulk mass transfer to the wall are not included in the computation of species transport. The momentum of the net surface mass flux from the surface is also ignored because the momentum flux through the surface is usually small in comparison with the momentum of the flow in the cells adjacent to the surface. However, you can include the effect of surface mass transfer in the continuity equation by activating the **Mass Deposition Source** option in the [Species Model Dialog Box](#) (p. 1814).

16.2.4. Wall Surface Mass Transfer Effects in the Energy Equation

Species diffusion effects in the energy equation due to wall surface reactions are included in the normal species diffusion term described in [Treatment of Species Transport in the Energy Equation](#) in the [Theory Guide](#).

If you are using the pressure-based solver, you can neglect this term by disabling the **Diffusion Energy Source** option in the [Species Model Dialog Box](#) (p. 1814). For the density-based solvers, this term is always included; you cannot disable it. Neglecting the species diffusion term implies that errors may be introduced to the prediction of temperature in problems involving mixing of species with significantly different heat capacities, especially for components with a Lewis number far from unity. While the effect of species diffusion should go to zero at $Le = 1$, you may see subtle effects due to differences in the numerical integration in the species and energy equations.

16.2.5. Modeling the Heat Release Due to Wall Surface Reactions

The heat release due to a wall surface reaction is, by default, ignored by ANSYS FLUENT. You can, however, choose to include the heat of surface reaction by activating the **Heat of Surface Reactions** option in the [Species Model Dialog Box](#) (p. 1814) and setting appropriate formation enthalpies in the [Edit Material Dialog Box](#) (p. 1928).

16.2.6. Solution Procedures for Wall Surface Reactions

As in all CFD simulations, your surface reaction modeling effort may be more successful if you start with a simple problem description, adding complexity as the solution proceeds. For wall surface reactions, you can follow the same guidelines presented for fluid-phase reactions in [Solution Procedures for Chemical Mixing and Finite-Rate Chemistry](#) (p. 879).

In addition, if you are modeling the heat release due to surface reactions and you are having convergence trouble, you should try temporarily turning off the **Heat of Surface Reactions** and **Mass Deposition Source** options in the [Species Model Dialog Box](#) (p. 1814).

If you are modeling surface site species, good estimates of the **Initial Site Coverage** will aid convergence.

16.2.7. Postprocessing for Surface Reactions

In addition to the gas-phase variables listed in *Postprocessing for Species Calculations* (p. 882), for surface reactions you can display/report the surface coverage as well as the deposition rate of the solid species deposited on a surface. Select **Surface Coverage of species-n** or **Surface Deposition Rate of species-n** in the **Species...** category of the variable selection drop-down list.

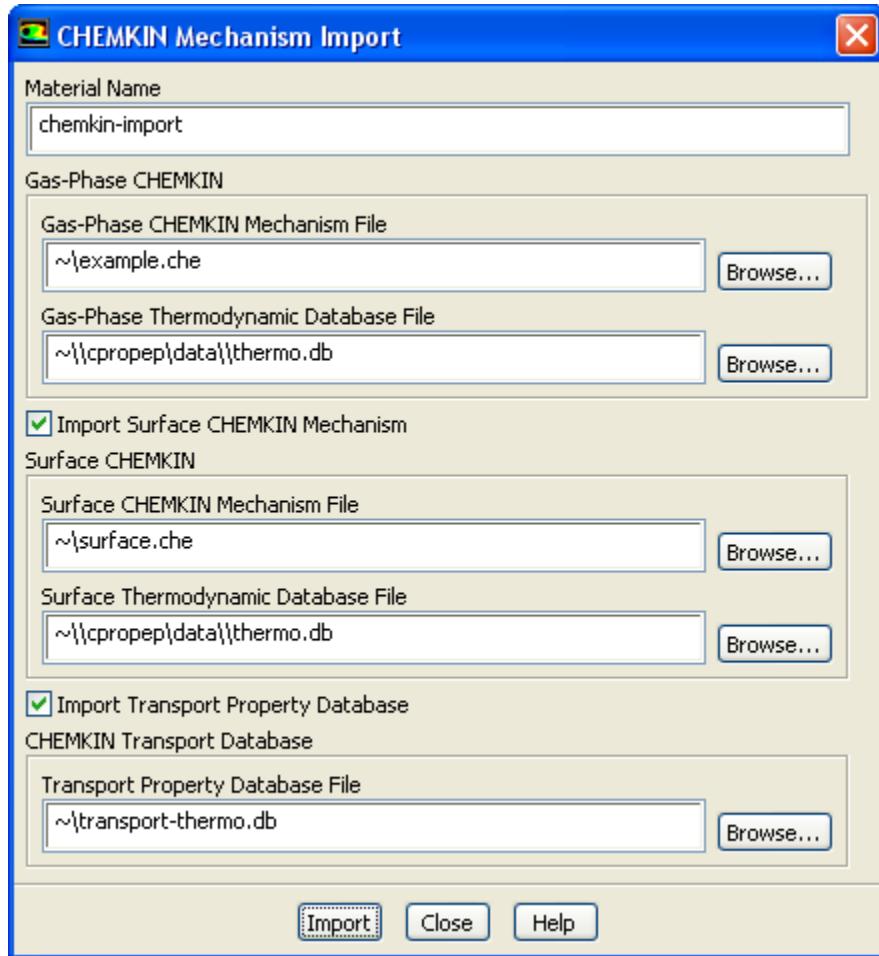

Important

For surface reactions involving porous media, you can display/report the surface reaction rates using the **Kinetic Rate of Reaction-n(Porous)** in the **Reactions...** category of the variable selection drop-down list.

16.2.8. Importing a Surface Kinetic Mechanism in CHEMKIN Format

Importing surface kinetic mechanisms in CHEMKIN format (*Importing a Volumetric Kinetic Mechanism in CHEMKIN Format* (p. 883)) requires that the gas-phase mechanism file accompany the surface mechanism file for full compatibility with CHEMKIN. If the gas-phase mechanism file is not available, then you will need to create one that you will import along with the surface mechanism file. The mechanism files are imported into ANSYS FLUENT using the **CHEMKIN Mechanism Import** dialog box (*Figure 16.13* (p. 890)).

File → Import → CHEMKIN Mechanism...

Figure 16.13 The CHEMKIN Mechanism Import Dialog Box for Surface Kinetics

In the **CHEMKIN Mechanism Import** dialog box

1. Enter a name for the chemical mechanism under **Material Name**.
2. Enable **Import Surface CHEMKIN Mechanism**.
3. Enter the path to the **Gas-Phase CHEMKIN Mechanism File** (e.g., *path/gas-file.che*) and the **Surface CHEMKIN Mechanism File** (e.g., *path/surface-file.che*).
4. Specify the location of the **Gas-Phase** and **Surface Thermodynamic Database File**. The thermodynamic database format is detailed in the CHEMKIN User's Guide [41] (p. 2369). The default thermo.db file supplied with ANSYS FLUENT has only gas-phase species available. You will need to supply a surface thermo.db file for your surface species if this thermo information is not in the mechanism file.

Important

Note that ANSYS FLUENT will initially search for the thermodynamic data in the **Surface CHEMKIN Mechanism File**. If the data does not exist in the mechanism file, then ANSYS FLUENT will search for the thermodynamic data in the specified **Surface Thermodynamic Database File**.

5. (Optional). Import transport properties by enabling the **Import Transport Property Database** and entering the path to that file.

To read in KINetics transport properties, go to [Importing a Volumetric Kinetic Mechanism in CHEMKIN Format \(p. 883\)](#) for detailed information.

6. Click the **Import** button.

ANSYS FLUENT will create a material with the specified name, which will contain the CHEMKIN data for the species and reactions, and add it to the list of **Fluent Mixture Materials**. You can view all of the reactions by clicking the **Edit...** button to the right of **Mechanism**, under **Properties** in the [Create/Edit Materials Dialog Box \(p. 1882\)](#).

Note that for surface reaction mechanisms, the surface reaction rate constant can be expressed in terms of a sticking coefficient. ANSYS FLUENT will convert this sticking coefficient form to the Arrhenius rate expression [40] (p. 2369).

Important

The CHEMKIN import facility does not provide full compatibility with all CHEMKIN rate formulations. To access more complete functionality, you should consider the KINetics module option described in [Enabling Species Transport and Reactions and Choosing the Mixture Material \(p. 857\)](#).

16.2.8.1. Compatibility and Limitations for Gas Phase Reactions

ANSYS FLUENT will allow for the following reaction types:

- Arrhenius reactions with arbitrary reaction order, third-body efficiencies and non-integer stoichiometric coefficients.
- Pressure-dependent reactions (Lindemann, Troe and SRI forms)
- Arbitrary reaction units
- Duplicate reactions (keyword DUP)

ANSYS FLUENT will not allow for the following reaction types:

- Landau-Teller reactions (keyword LT)
- Reverse Landau-Teller reactions (keyword RLT)
- Janev reactions (keyword JAN)
- Exponential modified power series reactions (keyword FIT1)
- Radiation reactions (keyword HV)
- Energy loss reactions (keyword EXCI)
- Multi-fluid temperature dependence reactions (keyword TDEP)
- Electron momentum transfer collision frequency (keyword MOME)
- Arbitrary reverse reaction (keyword REV)

Important

Note that the reaction types that ANSYS FLUENT will not allow are mostly applicable to plasmas.

16.2.8.2. Compatibility and Limitations for Surface Reactions

ANSYS FLUENT will allow for the following reaction types:

- Arrhenius reactions with arbitrary reaction order, third-body efficiencies and non-integer stoichiometric coefficients.
- Sticking coefficients (keyword STICK). Fluent converts these to an equivalent Arrhenius expression.
- Arbitrary reaction units
- Duplicate reactions (keyword DUP)
- Surface coverage modification (keyword COV)

ANSYS FLUENT will not allow for the following reaction types:

- Ion-Energy Dependent reaction (keyword ENRGDEP)
- Bohm rate expressions (keyword BOHM)
- Ion-Enhanced reaction
- Motz-Wise correction (keywords MWON and MWOFF)

Important

ANSYS FLUENT will warn you of any incompatibilities.

For a detailed description of the keywords, see [40] (p. 2369).

16.3. Particle Surface Reactions

As described in [The Multiple Surface Reactions Model](#) in the [Theory Guide](#), it is possible to define multiple particle surface reactions to model the surface combustion of a combusting discrete-phase particle. For more information about the theoretical background of particle surface reactions, see [Particle Surface Reactions](#) in the [Theory Guide](#). Information about using particle surface reactions is provided in the following subsections:

- [16.3.1. User Inputs for Particle Surface Reactions](#)
- [16.3.2. Modeling Gaseous Solid Catalyzed Reactions](#)
- [16.3.3. Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion](#)

16.3.1. User Inputs for Particle Surface Reactions

The setup procedure for particle surface reactions requires only a few inputs in addition to the procedure for volumetric reactions described in [Overview of User Inputs for Modeling Species Transport and Reactions](#) (p. 855) – [Defining Other Sources of Chemical Species](#) (p. 878). These additional inputs are as follows:

- In the **Species Model** dialog box, enable the **Particle Surface** option under **Reactions**.
 Models → **Species** → **Edit...**
- When you specify the species involved in the particle surface reaction, be sure to identify the surface species, as described in [Defining Properties for the Mixture and Its Constituent Species](#) (p. 861).

Important

You will find all species (including the surface species) in the list of **Fluent Fluid Materials**. If, for example, you are modeling coal gasification, you will find solid carbon, C(s), in the materials list for the **fluid** material type.

- For each particle surface reaction, select **Particle Surface** as the **Reaction Type** in the **Reactions** dialog box, and specify the following parameters (in addition to those described in [Defining Reactions \(p. 865\)](#)):

Diffusion-Limited Species

When there is more than one gaseous reactant taking part in the particle surface reaction, the diffusion-limited species is the species for which the concentration gradient between the bulk and the particle surface is the largest. See [Figure 7.1: "A Reacting Particle in the Multiple Surface Reactions Model"](#) in the [Theory Guide](#) for an illustration of this concept. In most cases, there is a single gas-phase reactant and the diffusion-limited species does not need to be defined.

Catalyst Species

This option is available only when there are no solid species defined in the stoichiometry of the particle surface reaction. In such a case, you will need to specify the solid species that acts as a catalyst for the reaction. The reaction will proceed only on the particles that contain this solid species. See [Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion \(p. 893\)](#) for details on defining the particle surface species mass fractions.

Diffusion Rate Constant

($C_{1,r}$ in [Equation 7-71](#) in the [Theory Guide](#))

Effectiveness Factor

(η_r , in [Equation 7-69](#) in the [Theory Guide](#))

16.3.2. Modeling Gaseous Solid Catalyzed Reactions

The catalytic particle surface reaction option is enabled in ANSYS FLUENT when **Particle Surface** is selected as the **Reaction Type** in the [Reactions Dialog Box \(p. 1911\)](#) and there are no solid species in the reaction stoichiometry. The solid species acting as a catalyst for the reaction is defined in the **Reactions** dialog box. The catalytic particle surface reaction will proceed only on those particles containing the catalyst species.

16.3.3. Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion

When you use the multiple surface reactions model, the procedure for setting up a problem involving a discrete phase is slightly different from that outlined in [Steps for Using the Discrete Phase Models \(p. 1077\)](#). The revised procedure is as follows:

- Enable any of the discrete phase modeling options, if relevant, as described in [Physical Models for the Discrete Phase Model \(p. 1083\)](#).
- Specify the initial conditions, as described in [Setting Initial Conditions for the Discrete Phase \(p. 1096\)](#).
- Define the boundary conditions, as described in [Setting Boundary Conditions for the Discrete Phase \(p. 1124\)](#).
- Define the material properties, as described in [Setting Material Properties for the Discrete Phase \(p. 1128\)](#).

Important

You must select **multiple-surface-reactions** in the **Combustion Model** drop-down list in the **Create/Edit Materials** dialog box before you can proceed to the next step.

5. If you have defined more than one particle surface species, for example, carbon (C_{ss}) and sulfur (S_{ss}), you will need to return to the **Set Injection Properties** dialog box (or **Set Multiple Injection Properties** dialog box) to specify the mass fraction of each particle surface species in the combustible particle. Click the **Multiple Reactions** tab, and enter the **Species Mass Fractions**. These mass fractions refer to the combustible fraction of the combustible particle, and should sum to 1. If there is only one surface species in the mixture material, the mass fraction of that species will be set to 1, and you will not specify anything under **Multiple Surface Reactions**.
 6. Set the solution parameters and solve the problem, as described in *Solution Strategies for the Discrete Phase* (p. 1138).
 7. Examine the results, as described in *Postprocessing for the Discrete Phase* (p. 1142).
-

Important

Solid deposition reactions on the particle are not allowed together with custom laws.

16.4. Species Transport Without Reactions

In addition to the volumetric and surface reactions described in the previous sections, you can also use ANSYS FLUENT to solve a species mixing problem without reactions. The species transport equations that ANSYS FLUENT will solve are described in **Volumetric Reactions** in the **Theory Guide**, and the procedure you will follow to set up the non-reacting species transport problem is the same as that described in *Overview of User Inputs for Modeling Species Transport and Reactions* (p. 855) – *Defining Other Sources of Chemical Species* (p. 878), with some simplifications.

The basic steps are listed below:

1. Enable **Species Transport** in the **Species Model** dialog box and select the appropriate **Mixture Material**.

See *Overview of User Inputs for Modeling Species Transport and Reactions* (p. 855) for information about the mixture material concept, and *Enabling Species Transport and Reactions and Choosing the Mixture Material* (p. 857) for more details about using the **Species Model** dialog box.

2. (optional) If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, enable the **Full Multicomponent Diffusion** or **Thermal Diffusion** option.
3. Check and/or define the properties of the mixture and its constituent species.

Mixture properties include the following:

- species in the mixture
- other physical properties (e.g., viscosity, specific heat)

See [Defining Properties for the Mixture and Its Constituent Species](#) (p. 861) for details.

4. Set species boundary conditions, as described in [Defining Cell Zone and Boundary Conditions for Species](#) (p. 878).

No special solution procedures are usually required for a non-reacting species transport calculation. Upon completion of the calculation, you can display or report the following quantities:

- **Mass fraction of species-n**
- **Mole fraction of species-n**
- **Concentration of species-n**
- **Lam Diff Coef of species-n**
- **Eff Diff Coef of species-n**
- **Enthalpy of species-n** (pressure-based solver calculations only)
- **Relative Humidity**
- **Mean Molecular Weight**
- **Liquid species mass fraction of species-n** (solidification and melting model only)

These variables are contained in the **Species...** and **Properties...** categories of the variable selection drop-down list that appears in postprocessing dialog boxes. See [Field Function Definitions](#) (p. 1653) for a complete list of flow variables, field functions, and their definitions. [Displaying Graphics](#) (p. 1499) and [Reporting Alphanumeric Data](#) (p. 1633) explain how to generate graphics displays and reports of data.

16.5. Reacting Channel Model

Information about using the reacting channel model is presented in the following subsections. For more information about the theoretical background, see [Reacting Channel Model](#) in the [Theory Guide](#).

- 16.5.1. Overview and Limitations of the Reacting Channel Model
- 16.5.2. Enabling the Reacting Channel Model
- 16.5.3. Boundary Conditions for Channel Walls
- 16.5.4. Postprocessing for Reacting Channel Model Calculations

16.5.1. Overview and Limitations of the Reacting Channel Model

The reacting channel model in ANSYS FLUENT offers an efficient solution methodology for solving reacting flow in shell and tube heat exchangers with long and thin channels. The volume inside the reacting channels is not meshed and solved with the outer flow. Instead, a plug flow approximation is used for the reacting channels, which is coupled to the outer flow through heat transfer across the channel walls.

The reacting channel model is available only for steady state 3D problems.

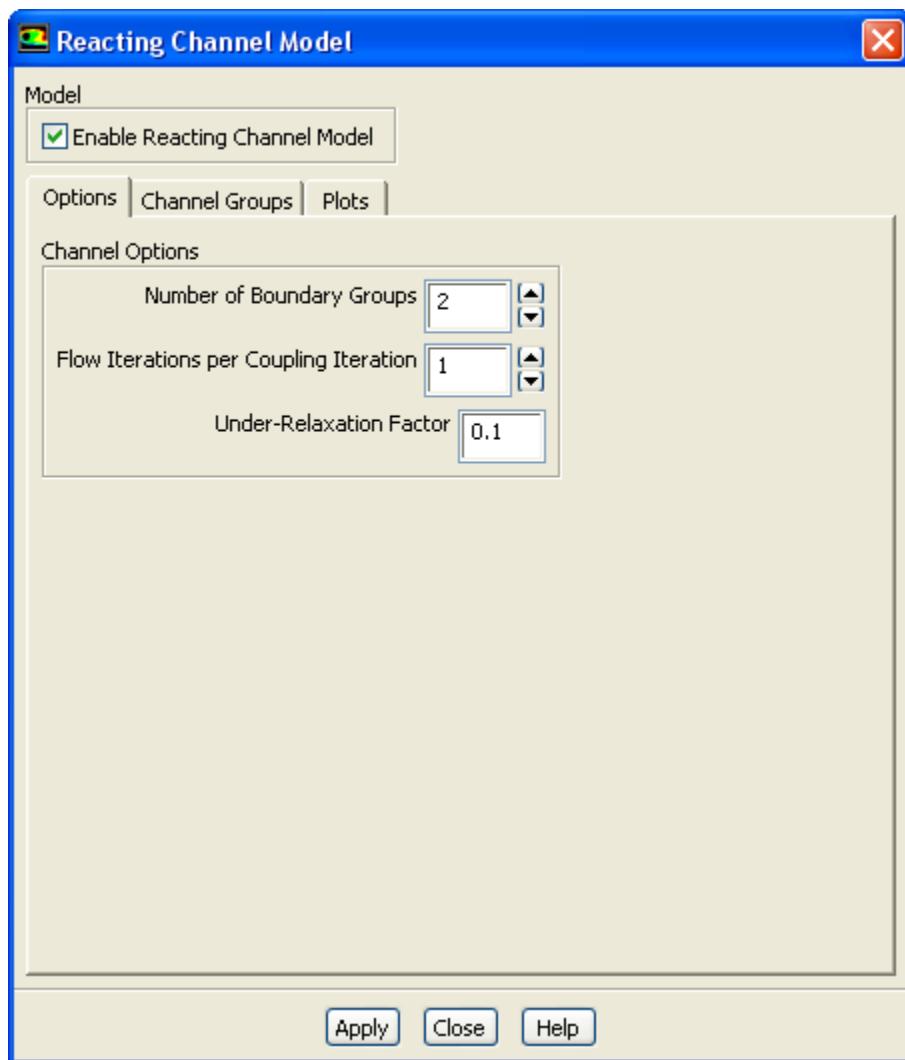

16.5.2. Enabling the Reacting Channel Model

The steps and procedure to setup a reacting channel model are outlined below. In this section, the steps pertinent to the reacting channel model only are explained. The setting of other models used in conjunction with reacting channel models are explained in other sections of the User's Guide.

To enable the reacting channel model, select **Reacting Channel Model** from the **Models** list in the **Models** task page.

Models → Reacting Channel Model → Edit...

Figure 16.14 The Reacting Channel Model Dialog Box

When you activate the **Enable Reacting Channel Model** option, the dialog box will expand to show the relevant inputs.

1. Under the **Options** tab, specify the **Channel Options** ([Figure 16.14 \(p. 896\)](#)).
- a. Specify the **Number of Boundary Groups**. If you have multiple channels, you can group together channels with common flow direction, mixture materials, inlet compositions, temperature, pressure, and mass flow rate.

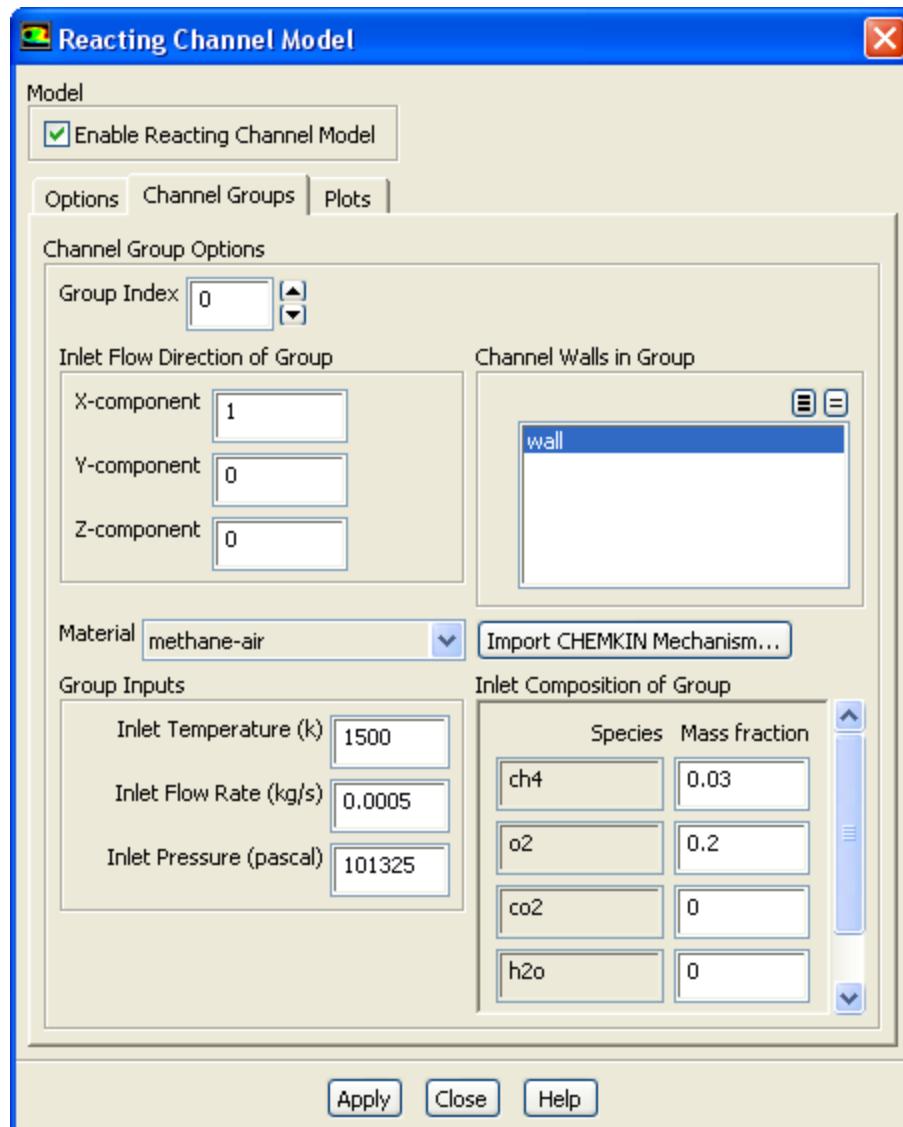

Note

If you have multiple tubes, you will need to define each tube as a different wall and set up the model by grouping the walls together if they have the same boundary conditions.

- b. Enter the number of **Flow Iterations Per Coupling Iteration**. This is the number of outer flow iterations for each channel flow iteration.

- c. Enter an **Under-Relaxation Factor**. The value you enter is used to update the heat flux from the reacting channel. See [Equation 7-85](#) in the [Theory Guide](#).
2. Under the **Channel Groups** tab, specify the **Channel Group Options** ([Figure 16.15 \(p. 897\)](#)).

Figure 16.15 Channel Groups

- a. Set the **Group Index**. If more than one boundary group has been specified, the inputs for each group will be required. Select the **Group Index** of the group and enter the group data.
- b. Specify the **X-, Y-, and Z-component** of the flow at the inlets of the channels in the current group under **Inlet Flow Direction of Group**.

Note
